Abstract: MUM – a Multi-Universe MOO - is an innovative implementation of object-oriented MUDs, which are becoming popular as a basis of network-based collaborative work, education, and socialization. The paper starts with a brief review of MUD/MOO history, explains the reasons for our interest in MOOs, describes our experience with Jersey - a predecessor of MUM - presents the main features of MUM, explains selected aspects of its design, and outlines our plans for the future.

1. Introduction - history

A MOO is an object-oriented implementation of MUD, which, in turn, is an acronym for Multi-User Dungeons or Multi-User Dialogs. MUDs first appeared about 20 years ago as an Internet-based version of a popular role-playing fantasy game called Dungeons and Dragons. The essence of a MUD is a text-based networked environment representing an emulated world (universe) in which participants can move around (navigate), communicate with one another, create, destroy, pick up and drop simulated objects, use them, and carry them around. From their gaming origins, MUDs evolved into environments supporting socialization and, eventually, education and work [Diversity University, Fitzpatrick, 1996, Harrison, 1996, Journal of MUD Research, Lindstaedt, 1997, Lingua MOO, Mansfield, 1997, Mateas, 1996, O'Day, 1998, Poltrock, 1997, Roseman, 1996, Spellmann, 1997, Steed, 1998, TeamWave].

Currently most popular implementations of MUDs for 'serious mudding' are based on MOOs (MUD Object-Oriented), in particular the LambdaMOO [LambdaMOO] developed by Pavel Curtis and described in [Haynes, 1998]. LambdaMOO includes a special-purpose object-oriented programming language and run-time environment that allows its users to set up a MOO server and create a universe of places and objects with the usual MOO functionality, define a group of users with the authority to modify and extend the universe, and authorize others to use the universe in more or less restrictive ways. Since MOOs can be programmed, they are arbitrarily extendible in two ways: Users can instantiate existing objects and create new classes of objects and functionality.

2. Motivation - the growing interest in MOOs for 'serious mudding'

Our interest in MOOs was stimulated by problems faced by geographically dispersed work teams and the hypothesis that emulated co-location of team members in a virtual space might alleviate this problem. Our initial investigation used Jersey [Tomek, 1998a, Tomek, 1998b], a MOO based on the commercial programming language Smalltalk [Hopkins 1998] rather than Lambda MOO.

Jersey MOO consisted of a Smalltalk server and a web user interface implemented with Java applets. The main window (Figure 1) provided an area for user input, an output area displaying personal communication among the occupants of the user's current location, mouse-click-based access to information about all users and objects in this location, on-line help, and specialized windows for viewing the properties of selected objects and locations, and for interaction with them. The server resided on a remote machine, and network communication between the client and the server was in terms of ASCII text. Client commands to the server had the form of Smalltalk messages. Further details about Jersey are available in [Tomek, Giles 1999].

Figure 1: Jersey's main user interface.

After some experimentation with Jersey, we concluded that its design makes it difficult to implement certain features that we considered essential for collaborative work and education. We thus decided to implement a new MOO from scratch and the result is MUM – a Multi-Universe MOO. In the following section, we summarize the main features of MUM and the rest of the paper details selected aspects of its design and outlines the work that still remains to be done.

3. MUM – a Multi-Universe MOO

On the basis of our Jersey experience, we decided that we need an environment that provides high quality customisable and extendible user interfaces in which the client does as much work as possible to alleviate the load on the server and the network. The environment must also allow easy (preferably automatic) code updating, allow users to register their interest in events occurring in the emulated universe and obtain automatic notification when these events occur, and provide maximum flexibility. Support for features needed for collaborative work and a framework for software agents was considered essential. We also wanted to address the problem expressed in the following statement of Pavel Curtis [Haynes 1998]:

“What would “something better” look like? On the top of my personal list is a vastly more equitable distribution of both power and economics. If online “virtual” communities are to have the same robustness as the more physically oriented ones, they must become pliant and mutable under the same forces that

BEST COPY AVAILABLE

cause real-life communities to grow and change. It must be possible for incompatible subcommunities to separate and grow apart, thereby relieving the kinds of stresses that constantly tear at LambdaMOO.”

As a result of the above considerations, MUM was designed with a number of unique features including the following:

- A MUM is a combination of a server and a client. Each user can access not only universes running under servers on remote machines, but also create a local universe and allow others to access it.
- The potential multitude of universes is registered in a metaserver. When a user connected to Internet launches MUM, MUM connects to the metaserver, retrieves information about all universes currently connected to it, and allows the user to connect to any one of them (Figure 2).
- MUM is fully event-driven. This means that each object in a MUM universe acts on the basis of events sent to it by other objects, and interaction between MUM objects is restricted to exchanging events.
- All events are 'subscribable'.
- Users can control objects via commands displayed in the user interface.
- Objects only evaluate events from objects that are authorized to send that event to this object.
- Specialized tools and user interfaces are stored in 'tool manuals', objects residing in the universe. A user can download a tool via MUM's main interface. When communication with an object requires a new tool, the tool is automatically downloaded.
- When a user connects to a universe, the server automatically updates his or her code if the user's version is out of date.

MUM is implemented in Smalltalk, allowing very easy modification even at run time.

Figure 2: The metaserver provides access to all currently connected universes.

4. MUM Design

In this section, we will explain the principles of selected design features of MUM including MUM objects, events, event handling, and tools.

4.1. Objects, Events, and their Handlers

As mentioned above, all objects in a MUM universe are driven by events. Their classes are subclasses of class EDO (EventDrivenObject), which defines properties shared by all objects such as name, description, location, and owner. Each EDO has its own event handler, its event queue, and a dictionary of events that it understands. Each event has a group of users who are authorized to execute it. Events are instances of an event class, a specialised subclass of MUMEvent.

When an EDO's event queue receives an event, its event handler's process is placed into the queue of active processes and when it gets control, it executes an event in its EDO's event queue. In executing the

event, the handler first checks whether the sender is authorised to evaluate this event. If it is, it notifies all registered subscribers, and evaluates the event, typically producing new events and sending them to other EDOs. The details of this process are explained next.

A typical event requires the execution of several steps, each of them calculating a new event and sending it to one or more EDOs. In many cases, an event dispatched to another EDO requests an operation whose execution must be confirmed by the receiver. The eventual confirmation will contain information including the result of the request. Upon dispatching a 'request event', the handler suspends execution of the event in expectation of a confirmation, to resume only after the confirmation is received. In the meantime, the handler passes control to another event handler with waiting events.

For better insight into events and their execution, consider the following example. Assume that a user wants his or her agent (proxy EDO) to move from one room to another. To do this, the agent sends the event 'I want to enter' to the destination room's EDO, requesting a permission to enter. If the room responds with an event granting the permission, the agent may enter and its handler proceeds to execute a certain sequence of states. If the permission is denied, the agent cannot enter and its handler executes a different sequence of actions.

This example shows that whereas the dispatch of some events allows uninterrupted transition to another state, other events require suspension of the event being executed, and its eventual resumption, followed by a selection of one of several possible continuations. As a consequence, the handler must distinguish several kinds of events including request events, confirmation events, and broadcast events. According to this analysis, the object describing the execution of an event – its event descriptor – must allow for branching of state sequences. MUM implements this by describing event execution by a finite state automaton (FSA) whose states describe event-producing blocks of actions, and whose transitions define sequences of states branching at confirmation states.

4. 2. User Interfaces, Tools, and Tool Manuals

If users had to trigger MUM events by typing messages, the environment would not be too attractive. Tools such as the UniTool in Figure 3 are MUM's way to resolve the gap between internal event-based operation and the need for friendly user interfaces. Tools give the user easy to use, extendible, customizable, and downloadable interfaces that hide the internal complexity of event generation and dispatching, and translate events into meaningful information. Using a tool, users send events by operating widgets in the tool's interface.

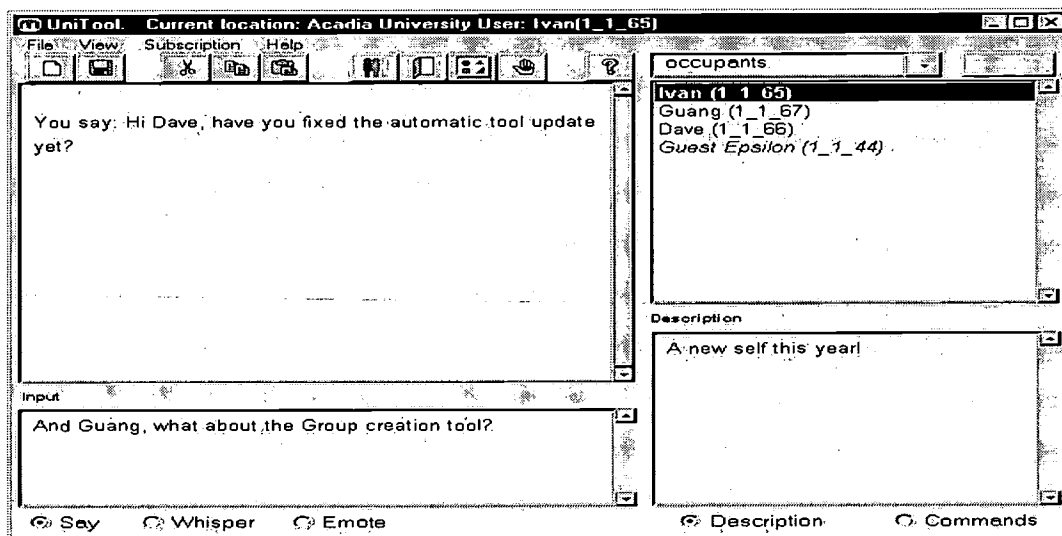

Figure 3: Unitool – MUM's universal communication and navigation interface.

Every MUM tool has two parts – a base and the tool UI. The tool UI defines the user interface, responds to user input, and displays output, typically resulting from events coming from the universe. Its interface to the universe works with events and is the base object that accepts messages from the tool, converts them to events, and sends them to the universe on one side, and accepts events from the universe and converts them to tool messages on the other (Figure 4).

Figure 4: A MUM tool consists of a base and a UI object.

Tool definitions reside in the universe in the form of 'tool manuals'. A tool manual is an EDO containing the definition of the tool interface and its base, the name of the tool, and other information. It includes a vocabulary that can be used to 'catch' the agent EDO to understand messages coming from the universe on the server side to the tool on the client side in one direction, and messages going from the tool to the universe in the opposite direction.

As mentioned earlier, a tool can be loaded dynamically when the user needs it. This is made possible by the tool manual. Although several essential tools are automatically loaded when the user connects to the Universe, others are not loaded until they are needed to interact with a specified EDO, or requested by the user. When a tool is requested, the updating of the client and the agent and the installation of the tool are automatic.

5. Conclusions and Future Work

We described an alternative type of an event-based virtual environment based on the MOO concept and outlined some features of its design. Its main innovative features include a shift of processing from the server to the client to minimize the load on the network and the server processor, a much greater emphasis on comfortable and customizable user interfaces, simple downloading of tools from the sever, automatic downloading of software updates, full reliance on subscribable events and automatic event notification, possibility of multiple servers and universes hosted by the same machine that hosts the client, and management of multiple universes by a metaserver. We discussed at some length selected aspects of MUM's design, focusing on the implementation of events and their handling. We explained why a finite state automaton is used as a model of flexible execution of the required variety of events.

At the time of writing, MUM consists of a working framework and essential functionality but the number of available MUM objects and tools is still limited. Our future goals are to test the performance and stability of MUM with a larger number of users, add or extend CSCW features such as groups, roles, and policies, add numerous MUM objects and tools for general use and for the support of MUM developers, design and implement a framework for software agents, improve support for inter-universe navigation, implement security features, and provide interoperability with external tools. We plan to add CSCW features at a later date.

The task of developing a large library of object types is enormous, and to accomplish it, we will share the software with the general public as soon as it reaches the required level of completion and performance.

Indexing and Metatag Schemes for Web-based Information Retrieval

Dr. Andrew G. Torok

Northern Illinois University, Department of Educational Technology, Research and Assessment

Tel: (815) 753-3406, Fax: (815) 753-9388, E-mail: atorok@niu.edu

Abstract: Web-based searches typically result in lower precision than with other document retrieval systems. A major contributor to low precision is limited technology for generating detailed document and content descriptions such as those associated with bibliographic databases. The result is ineffective indexing of Web pages. This paper reviews indexing theory and suggests that authors can contribute significantly to improving retrieval by applying basic indexing criteria. The Dublin Core Meta Data set and XML are seen as a means for implementing indexing theory for web-based documents. A project using the Dublin Core in support of a university class is presented.

1. Introduction

Ideally, when searching for information, one should have access to the world's information resources. Traditional indexing and classification systems have done a reasonably good job of providing access to the bibliographic universe. In today's world, convenience dictates use of information retrieval tools. As a result, traditional retrieval systems are often overlooked in preference for the World Wide Web. Estimates indicate that over 95 percent of all published materials are not accessible through the Web. In addition to not having access to the bibliographic universe, Web searches result in significantly lower Precision and Recall. [Torok & West, 1999] Precision is a standard measure that provides a percentage estimate of the number of relevant items retrieved out of all items retrieved. Recall is the percentage estimate of all relevant items retrieved out of all relevant items in a database. These measures reflect the relevance judgments associated with document retrieval. Although a number of factors contribute to low Web-based retrieval performance, the most significant ones are those resulting from inadequate indexing. The literature tends to focus on the limitations of search engine indexing. Search engines can do little more than index what publishers make available. Retrieval problems stem from authors' lack of indexing knowledge and limitations in HTML for describing document format. For example, many Web page authors do not utilize meta tags or utilize them inappropriately. Web document descriptions are limited to the URL, title field, hyperlinks and broad attributes such as graphics. These makes content and field indexing difficult. Essentially, few Web-based devices exist for maximizing Precision and Recall. Hyperlinks are one of the few such devices available, but these are generally sporadically assigned. Web publishers should have the responsibility of preparing publications in a way that facilitates retrieval. Understanding basic indexing principles can help. Following this line of argument, let us briefly examine basic indexing principles.

2. Indexing Theory

Essentially, indexing and searching are all about finding the right words. In retrieving an item, something about it should indicate how it relates to the query. The idea is to match the words in a user's mind with those used in a document. Unfortunately, the words don't always mean the same thing. Vocabulary control or the lack of it, creates one of the biggest problems in finding desired documents, or avoiding the retrieval of unwanted documents. This can range from simply not knowing which words to use, to variant meanings associated with a word. The concept-mapping feature of search engines is sufficient to cluster related documents, but do not allow for vocabulary control. The responsibility of providing the "right" words rests with both the searcher and the document author. Indexes provide a critical link between the information need and relevant documents.

When searching for information, users are directed to the index. Most indexes are inverted, meaning that the index displays a term and provides a reference which point back to the source document or documents, which contain that word. Indexes can also contain a variety of syntactic and semantic devices that identify the role of a word in context, or link a subject to other relevant concepts. The purpose of a good index is to retrieve relevant items from a set of related items, and to minimize the retrieval of unimportant items.

3. Indexing Practice

Indexing practices and tools are designed to maximize Precision and Recall. For example, the traditional "see" cross-reference is a Recall device. Link and role indicators are Recall and Precision devices respectively. Other devices include various types of cross-references, scope notes, parenthetical expressions, term weighting and authority control. Thesauri are the principal tools for authority control. Indexes must be constructed to truly reflect content, and to accommodate the mind frame of a wide range of information seekers. The document producer must also share in the responsibility of providing appropriate terms. A document should accurately convey the intended meaning, and provide searchable field tags to discriminate between document components.

There are three main types of indexes. These are:

- Pre-coordinate indexes (classification schemes, such as Library of Congress)
- Post-coordinate indexes (standard computer retrieval)
- Some variant flavor of both (faceted classification, human indexer selection)

Classification schemes reflect the relevance judgment of subject experts in assigning documents to major subject categories. Most classification schemes are hierarchical arrangements, with more specific classes falling under broader ones. Yahoo, Alta Vista and numerous other search engine providers, use this system. The problem with pre-coordinate schemes is that it is difficult to ascertain in advance what prompts a relevance judgment from a user. Thus, the danger in pre-coordinate schemes is that relevant information may not be classified to suit individual needs. Also, coverage of the knowledge universe is limited drastically by the number of human indexers. The obvious answer is to provide an *ad hoc* classification, determined by an individual's information need. This is the basis of post-coordinate schemes. Essentially, if a user's query can be thought of as a classification, all documents meeting the query parameters fall into that class for that given search. Computer searching provides a post-coordinate type of classification. It is made possible by search engines, which index every word in a Web site. Some search engines utilize stop word lists as an attempt at vocabulary control. Most Web search providers use a combination of pre and post coordinate indexing. For the most part, search engine indexing devices favor increasing Recall, but at the expense of lowering Precision. In order to achieve a balance, indexers need to consider basic design criteria.

4. Design Features of Indexes

Four major design criteria govern a good index:

- A accuracy
- C consistency
- E exhaustively, and
- S specificity

Good indexes are accurate. They contain no errors, such as typos, blind cross-references or ambiguities. At the very least, it should be easy to ascertain that a subject or concept is present. Accuracy may also reflect the ability to show relationships across word variants, automatically up posting to spelling variations, being mindful of case sensitivity, and being able to distinguish between proper and common terms. Accuracy may also have to do with keeping an index up-to-date.

Consistency refers to the consistent application of indexing rules. In human indexing we talk about inter and intra indexing consistency. That is, does a given indexer always index the same across documents, or would all indexers index a given document the same. In machine indexing, intra-indexing consistency is usually not a

problem although a searcher may have difficulty ascertaining how the indexing actually occurs. Inter indexing across search engines is a real problem, particularly between directory and keyword search engines.

Exhaustivity refers to how completely a document is actually indexed. Some search engines index only portions of a document. Simple frequency counts of term occurrence are not sufficient to justify indexing. The more index terms posted to a document, the higher the Recall. However, exhaustive indexing can lower Precision. Document type and other elements are needed to be truly exhaustive. Exhaustivity also relates to the extent that documents are retrieved from a universe.

Specificity involves the level at which an index entry describes document content. If a document deals with cocker spaniels, it should not be indexed under dogs. If the document is also indexed under the subject heading of dogs and related synonyms, links should indicate that the document deals with a particular breed of dog. Semantic differences should be preserved. Essentially, documents should be indexed at the level they present a subject, but should reflect synonymous relationships. Concept indexing practices need to pay more attention to this criterion. Let us turn our attention to things an author can do that facilitate retrieval.

5. Web-based Indexing

To facilitate derivative indexing, document producers should use great care in selecting appropriate terminology to reflect meaning. Documents should begin with informative titles, the use of headings and sub-headings, and structured paragraphs. Documentation should include things like author, date of publication, source, and last revision. These fields are not always searchable in a document, nor is the content amiable to retrieval from different disciplines. Multimedia formats are especially difficult to index. In addition to tagging "free" text document fields, externally derived terms may be added to facilitate retrieval. In modern parlance, this is called "meta data" or meta information".

Meta tags provide a convenient way for document indexing. One author describes meta tags "as attaching a label to an object, such as a can of peas or a package of light bulbs. The label provides information about the contents of the container without actually having to open the container. [<http://www.imsproject.org/metaddata>] Meta tags are organized into categories, or fields. Each field represents some characteristic of the document or the contents. Meta tags go in the HEAD section of the HTML document, generally after the TITLE tags. They are sometimes the first section to be indexed by a search engine. The two most important Meta tags are those describing the document, and words, which have, clear contextual meaning, such as descriptors derived from a controlled vocabulary. Good indexing tools also guard against malpractice designed to retrieve pages with little relevance to the index terms. Meta tagging lacks the sophistication of well-established knowledge classification schemes. Current schemes tend to reflect practice within a particular industry.

6. XML

Two meta tag schemes currently in use are XML and the Dublin Core. Extensible markup Language (XML) was officially adopted as a standard by the World Wide Web Consortium (W3C) in February of 1998. The W3C calls XML a common syntax for expressing structure in data, or structured authoring. Structured data refers to data that is tagged for its content, meaning, or use. [<http://builder.cnet.com/Authoring/Xml20/ss01.html>] For example, an XML tag could explicitly identify the type of information <BYLINE>, author of a document <AUTHOR>, cost in an inventory list <PRICE>, all the way down to any level of detail <DOGFOODBRAND>.

XML is a web-based scripting language that promises to provide more efficient applications, and increase both Precision and Recall. XML can specifically categorize data within Web pages, word processing documents, e-mail messages and so on using defined dictionaries of specialized grammar called Document Type Definitions (DTD). Specific DTDs are being developed for various applications. For example, the Microsoft Channel Definition Format (CDF) which describes active channel content, and push vendor Marimba's Open Software Description (OSD) which describes software components. XML can act as a Dewey Decimal System for the Internet. XML overcomes the limitations of HTML by explicitly describing document formats and contents. Essentially, XML

allows Web publishers to insert meta tags into their pages. Browsers can read the field codes but would not display them. XML meta tags can also permit browsers to manipulate data without going back and forth to the server. By separating structure and content from presentation, XML will especially benefit people who produce documents intended to appear across multiple media. Another potential application will be the rebirth of Push. Push refers to developing individualized profiles and sending relevant information to the desktop when it appears on the Web.

7. Dublin Core Background

Until XML matures, one of the few formalized definitions for the use of meta tags is the Dublin Core Metadata Element Set. [<http://purl.org/dc>] Essentially, the Dublin Core consists of core meta tags that provides information about document and document-like objects. Document elements, that is the meta tags, are represented by descriptive names intended to convey a common semantic understanding of the element. A tremendous advantage is that the Dublin Core can be implemented in HTML for a wide variety of documents. Thus in formulating a search, the query could contain a reference to the element and the searcher could more accurately determine document specific information. The Dublin Core is an approximation of what libraries have been doing with bibliographic description, such as MARC. Element descriptions have been developed for 15 categories, including: title, author, subject or keywords, description, publisher, other contributors, date, resource type, format, resource identifier, source, language, relation, coverage, and rights. An example of a meta tag for author might look like:

```
<META NAME="DC.author" CONTENT+"Andrew Torok">
```

The Dublin Core provides for the concept of links and roles mentioned earlier. Roles can be described using SCHEME qualifiers. In the event there are existing schemes for coding the elements, these are also indicated in the meta tags. An example might be recommended syntax for representing proper names. Schemes would refer to major standards and conventions, such as those emanating from the American National Standards Institute (ANSI). The schemes are referred to by using links to a source such as a URL. The Dublin Core also provides other qualifiers for data description. For example, the SCHEME may refer only to an existing coding system. For specific local information, a TYPE qualifier could be used. A variety of organizations are working on the syntax for the elements, but have not been widely accepted. For example, Educom has created meta tags for educational documents and on-line training courses. [http://www.ott.navy.mil/1_4/adl/educum.htm]

Most current Web authoring tools have no provision for automatically coding for Dublin Core. Thus the meta tags must be keyed in directly. Also, not all search engines recognize the Dublin Core syntax. On the other hand, there are commercial Web page developers who consider the Dublin Core meta tags an integral component of their publications.

8. NIU Dublin Core

The College of Education at Northern Illinois University is experimenting with the Dublin Core set for Web support of a basic education class. The class is a survey of educational practice and pedagogy. Various ASCII and binary coded documents are indexed according to the Dublin core. Publications come from locally generated documents, documents downloaded from the Web, and links to relevant Web sites. Copyright issues notwithstanding, locally generated documents may consist of original material as provided by teachers and students, or various print and electronic publications. A macro using Visual Basic converts Microsoft Word documents and prompts for the Dublin Core Metatags. Publications are made available on the university Web site, and can be accessed from a course Web page.

An ASCII index card is created for binary coded documents. The reflective activities are CGI scripted so students can complete the forms and send them back to the teachers. Access to the documents is made available through a free Sun Microsystems search engine, called SWISH-E, that can recognize the Dublin Core data elements. [<HTTP://SUNSITE.BERKELEY.EDU/swish-e/>] Actually, SWISH-E can be configured to search various document fields. If desired terms are not found in the meta data, it automatically continues on to find the words in the document body. Index terms are selected from various thesauri and vocabulary lists. Identifiers are also generated

BEST COPY AVAILABLE

1097

from various existing standards. Graduate assistants are typing in the 15 fields

The population served at any given time consists of several hundred students, across several sections. One advantage of using the Dublin core is to set some uniformity across the various sections of the course. This helps the different instructors present information consistently, provides equitable access to resources, and is advantageous for distance education. The general objective is to provide students access to a core set of publications which reflect course objectives and support collaboration. Despite various instructors contributing numerous print and electronic publications, Precision is quite good. The uniform document and content descriptions afforded by the Dublin meta data permit pinpoint Boolean searching.

One of the biggest problems is that the programming and indexing take time. As the document collection grows, another problem will be that documents reflecting a rather narrow subject area may appear redundant. However, the problem should not be as severe as relying totally on broad Web searches. Non-text publications pose a particularly difficult problem as items are scanned in, downloaded from the Web, or input from a digital camera. At this time, the indexing and retrieval seem to work quite well. As external indexing in the form of XML becomes standard, students may well be able to locate relevant publications from the Web. This will allow for greater collaboration with other colleges. This will also lessen the need for faculty-generated selection and acquisition, and more fully support a constructivist environment. As XML document indexing and retrieval mature, the use of Push technology may become a feasible method for maintaining a specialized Web site. A Push model to support college curricula has been described in the literature. [Torok, 1997]

9. Conclusions

In conclusion, there appears to be continued improvements in Web document indexing and the ability of search engines to reflect user vagaries. Ultimately, the goal should be to maintain the freedom of expression characteristically associated with the Internet and the World Wide Web. There should be equal room for scholarly publications, cloaked in their social and political mantras, and figments of the imagination uninhibited by editorial constraints. The objective language of disciplines should not remain a mystery, nor should it give way to meta language purely to suit the needs of those unwilling to pay the price of formal learning. There does not need to be a watering down of academic disciplines and their curricula. If publishers are held to accurately describing the nature of their publications, users will have greater success in identifying relevant publications, or avoiding undesirable ones. Adhering to good indexing practices, and utilizing new technologies such as XML will help.

Knowledge Objects and Knowledge Navigation

Steven Tripp

University of Aizu, CLR, Aizu-Wakamatsu 965-8580, JAPAN

Abstract: The production of multimedia computer-based educational materials is time-consuming and expensive. There is a growing need for methodologies which facilitate the efficient production of courseware. One possible approach is to define standards for the representation of knowledge. This paper investigates the design of re-usable educational knowledge objects.

1. Introduction

The creation of more efficient instructional methodologies is always a priority for instructional designers. At the present time the creation of computer-based instructional materials is both time-consuming and costly. In general, each instructional design project is a unique event involving the inextricable linking of content and methods. Since content cannot be separated from methods it cannot be reused or recycled with a new delivery system. Neither can the delivery system easily accommodate new content. Recently there has been interest in AI circles in the production of ontologies, or reusable databases [Gruber, n.d.]. Little has been reported in educational technology on the subject, perhaps because of the lack of a convenient authoring system for true object-oriented applications. However, without some standards concerning the representation of knowledge objects, instructional agents will not be able to manipulate them. In this paper we expand upon this problem.

2. Ontologies and Knowledge Objects

Among AI researchers, an ontology is a specification of a conceptualization [Gruber, n.d.]. The purpose of an ontology is to enable knowledge sharing and reuse. In practical terms this requires that a vocabulary be defined that is consistent (but not complete) with respect to a body of knowledge that allows the exchange of queries and assertions between agents. [Gruber, 1993] describes some principles for the design of knowledge sharing ontologies. He says that an ontology should exhibit the following qualities: clarity, coherence, extendibility, minimal encoding bias, and minimal ontological commitments. Clarity means that a should communicate the meanings of its defined terms. Coherence means that it should allow logical inferences based upon its axioms. Its shared vocabulary should allow the extension of definitions without re-definition of terms. Encoding bias refers to decisions which are made solely because of limitations of the representation system. Finally, minimal ontological commitment means that the system should make as few claims about the world as possible (i.e., should be the weakest possible theory). Because designing an ontology is engineering and not science or philosophy there will inevitably be trade-offs and compromises in its development. The recent announcement of XML, the extensible markup language, may provide a convenient syntax for the creation of exchangeable knowledge objects.

The idea of instructional knowledge objects is not new. This idea has been exploited in the design of the Electronic Trainer developed by David Merrill's group at Utah State University. In the Electronic Trainer, a set of object categories contains information. For example one type of category is an entity and its parts. A procedure is another type of category. Because there are certain standard ways of teaching and testing an entity and its parts or a procedure, the instructional strategies can be built into the authoring system and applied to the

BEST COPY AVAILABLE

1099

knowledge objects without any additional authoring. Also different instructional strategies can be applied to the same knowledge objects. For example, a student may learn about the parts of a machine by having them explained one by one. Alternatively, the student can learn by exploring the parts of the machine in an arbitrary order and be taught the name by clicking on the parts. Essentially, Merrill's design follows the traditional computer science strategy of dividing program and data. It acknowledges that there is a limited set of instructional strategies for any kind of knowledge objects and that if the object is described in a sufficiently rigorous way, an appropriate strategy can be applied to the object, and a lesson can be generated automatically.

The advantages of this approach should be obvious. It allows multiple, and perhaps yet unthought of, instructional strategies to be applied to the same objects over and over again. Secondly, the same strategies can be applied to new, yet undescribed, content without any further authoring. In the very inefficient world of computer-based education, Merrill's approach represents significant progress.

3. Logical Databases

Merrill's approach is a good first step, but it has some weaknesses. First, from a programmer's point view it is unfortunate that the knowledge objects do not have a logical status. In other words, inferences (other than those explicitly described and anticipated) cannot be performed. Another problem is that the knowledge objects are not represented hierarchically. Objects cannot contain objects. In the real world, processes may contain procedures which contain concepts which contain entities which have parts and all of these may have relationships to other processes which are themselves the result of procedures. This kind of logical embedding of multiple objects is not possible in Merrill's programs. However, with XML such embedding is specifically anticipated.

4. Design Parameters for Knowledge Objects

What is needed for the design of instructional knowledge objects is a set of concepts in relationships that can be combined in certain regular ways to describe a set of knowledge sufficiently rigorously that an instructional discourse engine can act upon it, in other words, commit to it. In a sense, what we need is a grammar of knowledge that can represent any and all objects and relations that we might want to teach. Such objects could be shared and reused by instructional designers throughout the world and could be acted upon by an instructional browser provided that the objects were tagged according to a standard markup language. At the current time such a markup grammar does not exist but it is the purpose of this paper to describe what kinds of objects should be represented and how those objects should be joined in hierarchical structures.

First we need to define some of the primitives which would be structured by our grammar. As a simple example we can imagine that the most basic instructional objects would be concepts, procedures, processes, entities, relationships, and histories. Each of these objects would have, at the very least, a name, representation, and links to objects are both, below, and parallel to it. Representation could be text or pictures or movies or audio or any other media representation. Of course multiple representations are possible. If the object is a concept, it would of course need to be defined by its features. Also there would be examples and non-examples. These would be represented by links to other objects. For example, an example a mammal is a dog, which itself is a concept. In fact, a dog is a kind of mammal and therefore kinds of mammals would also have to be represented. If the object is a procedure we might need to represent an actor, the actor's purposes, the steps in the procedure, the order of the steps, the actions needed to perform a step, and results of each step, and the main result of the procedure itself.

Naturally, for processes we would need to represent the phases in the process, the order of the phases, the actions that take place in each phase, the results of each action, and the initial state and the final state of the process. If the object is an entity we would need to represent its parts. Each part would have a name and a representation. Entities might also have structures, quantities, and magnitudes or sizes.

If we're going to represent relationships we might distinguish between unary or binary relationships or symmetrical and asymmetrical relationships or many others. In fact, one problem with relationships is that there doesn't seem to be any small finite set which can be conveniently listed. It may be that this defining of relationships will have to be left to the author.

Another possible attribute of an object is its history. An object may belong to a particular historical period, or be the result of a historical process, or have ancestors or descendants. Naturally, an object will have its own history of when it was created and by whom and where.

This list of objects and attributes is not intended to be complete but is offered as a suggestion of the kinds of objects and attributes it would need to be represented in order to be processed by an instructional agent.

5. Representing Knowledge Objects for Instructional Purposes

Following Merrill, in instructional design it is usual to speak of entities, concepts, processes, and procedures. I have followed this pattern in the design of might knowledge objects, while adding a fifth object, relationships.

5.1 An Ontological Grammar

My ontology is represented as a phrase structure grammar which allows recursive embedding of knowledge objects.

The basic rules of the grammar are as follows. First it consists of the fundamental "parts of speech" of the grammar, i.e., the knowledge objects:

O = Object
 R = Relationship Object
 C = Concept Object
 E = Entity Object
 Ps = Process Object
 Pd = Procedure Object

Then the grammar defines a combinatorial algebra for the objects:

$O \Rightarrow O R O$

In a grammar such as this, the arrow (\Rightarrow) may be read as "may be rewritten as."

$O \Rightarrow \left\{ \begin{array}{l} C \\ E \\ Ps \\ Pd \end{array} \right\}$ -- Curly brackets are used to indicate a choice.

$C \Rightarrow N + Rep + K + F + D + Sub-B + Ex + Non-Ex$
 $E \Rightarrow N + Rep + P + Q + U + Mq + Mu + Syn + Part-Sub$
 $Ps \Rightarrow N + Rep + Ph + Sub-El + Purp$
 $Pd \Rightarrow N + Rep + Steps + Sub-El + Goal$
 $R \Rightarrow N + One2One? + Concept$

Each object represented in the grammar is a complex combination of variables and behaviors (executables).

N ⇒ (Name (text variable))
 Rep ⇒ (Representation: text, picture, movie, audio, or scene(s))
 K ⇒ (Kinds: list variable)
 F ⇒ (Features: list variable)
 D ⇒ (Definition: text variable)
 Sub-B ⇒ (Sub-behaviors. Concept behaviors related to the kinds)
 Ex ⇒ (Examples: Entity behaviors)
 Non-Ex ⇒ (Non-examples: Entity Behaviors)
 P ⇒ (Parts: A list variable)
 Q ⇒ (Quantity: A floating point variable)
 U ⇒ (Units: A text variable)
 Mq ⇒ (Magnitude-quantity: quantity in standard measure)
 Mu ⇒ (Magnitude units: standard units)
 Syn ⇒ (Synonyms: A text list)
 Part-sub ⇒ (Parts of the Entity: behaviors corresponding to the parts list)
 Ph ⇒ (Phases: A text list)
 Sub-EI ⇒ (Sub elements of the Process. Each is a concept)
 Purp ⇒ (Purpose of the process: A Concept behavior)
 Steps ⇒ (Steps of the procedure: A text list.)
 Sub-EI ⇒ (Sub-elements corresponding to the Steps list: Each is a concept)
 Goal ⇒ (Goal of the procedure: A concept behavior)
 One2One ⇒ (One to one: An integer range variable which defines whether the relation is one to one or one to many)

6. Combining Objects into Logical Structures

As defined by the above grammar, any object can be transformed into an object-relation-object structure. Needless to say, relations are also objects but they are defined in a special way in this grammar. A relationship can only be the child of another object in cannot stand alone.

As this relationship object illustrates any object can be the child of any other object. In other words a process can be the child of a concept or an entity can be the child of a procedure. In this way an infinite set of knowledge object trees can be structured from a finite set of objects and relations, so a large body of knowledge can be constructed from a set of relatively small objects. Given such a description, it can be seen that several tools will be necessary both on the authoring side an on the client side. On the authoring side we would program which allows us to create knowledge objects without worrying too much about syntax. Once the objects are created they can be made available by a normal Web server. This side of the equation seems readily doable.

However, on student or client side is not clear that any current or foreseeable browser would be sufficient. Although typical browsers could navigate the links in the knowledge objects they would not incorporate instructional strategies and thus would not constitute an instructional engine. Also, it seems that simple instructional strategies are not sufficient in an instructional situation. A human tutor does not simply present information questions to a student and react blindly to the students responses. It is here that some kind of instructional discourse engine would be necessary.

In this context, Grice's conversational maxims may be helpful. According to [Grice, 1974], cooperative behavior in conversation can be described in terms of four conversational maxims:

1. The maxim of quantity: where one tries to be as informative as one possibly can, and gives as much information as is needed and no more

2. The maxim of quality: where one tries to be truthful, and does not give information that is false or that is not supported by evidence
3. The maxim of relation: where one tries to be relevant, and says things that are pertinent to the discussion
4. The maxim of manner: where one tries to be as clear, as brief, and is orderly as one can in what one says, and where one avoids obscurity and ambiguity.

While there is some controversy about the appropriateness of using these maxims to describe all conversations that need not bother us here. Grice's maxims offer us a good guideline as to the types of operations which instructional discourse engine should be able to perform. For example, the student should be able to ask for more or less information in accordance with the maxim of quantity. In this way the student should be able to control the number of examples and the degree of detail provided for a particular knowledge object. In addition, this control should make predictions about the amount of information needed by the student in order to understand related ideas.

Secondly, the maxim of quality can be invoked, not when the student doubts the truth of a particular proposition, but when a student cannot see the reason why a particular proposition may be true. Thus, the instructional discourse engine should be able to supply additional evidence in support of a particular proposition. It can do that by navigating the knowledge tree either by going lower and gathering more details or by going higher and presenting an overriding principle which the student may have missed or forgotten for some reason.

When a student cannot see why something is relevant, he should be able to invoke the maxim of relation and ask the instructional discourse engine to show why the current knowledge object is relevant to the educational purpose at hand. Since the engine can extract the relationship between the current object and its parent object or sibling objects it should be able to construct an argument based upon that relationship.

Finally, since the instructional discourse engine can see the knowledge tree it should be able to construct an instructional trajectory which is as brief as possible, in accordance with the maxim of manner. Again, if the student feels that the engine is being ambiguous or obscure, he should be able to request that the engine justify its path.

Although this is purely personal and anecdotal, it seems to me that whenever I am frustrated with computer-based instruction, the source of the frustration can be traced to a violation of one of Grice's four maxims. Building such an instructional discourse engine may not be easy but at the very least it requires networks of knowledge objects which are linked into trees which can be logically navigated. Thus, the first step in this project is to work towards an acceptable description language for instructional knowledge objects.

7. Summary

These suggestions only sketch an early stage in the design of an instructional ontology. The actual structure of the description language will need to conform to the results of empirical experience. However, it is plain that some sort of progress along this path will be necessary for the development of efficient and effective instructional design.

Abstract: Our research concerns the applicability of the existent Student Models in the area of distance education. In the current study a number of Student Models are reviewed. A short description of the models, their bibliographic reference in addition with a short discussion on their applicability in the area of distance education is going to follow.

Student Model a short definition

In general terms, student modelling involves the construction of a qualitative representation that accounts for student behavior in terms of existing background knowledge about a domain and about students learning the domain. Such a representation, called a student model, can assist an intelligent tutoring system, an intelligent learning environment, or an intelligent collaborative learner in adapting to specific aspects of student behavior [McCalla, 1992 a].

Types of Student Models.

According Anderson, Corbett and Koedinger there are actually two types of Student modelling, which called knowledge tracing and model tracing [Anderson et al., 1995, p. 167-207]. These are their names for the particular techniques they use, but the distinction is perfectly general. Knowledge tracing refers to the problem of determining what students know, including both correct domain knowledge and robust misconceptions.

Model tracing refers to tracking a student's problem solving as s/he works on a problem. Model tracing is useful for systems that attempt to answer requests for help or to give unsolicited hints and feedback in the middle of problem solving. In fact, to do an adequate job of helping, hinting and critiquing an on-going solution attempt a system must at minimum understand what line of reasoning the student is attempting to pursue. On the other hand, knowledge tracing is useful for making longer range pedagogical decisions, such as what problem to assign next or what evaluation grade to assign to the student. All the existing attempts to apply probabilistic reasoning to student modelling have been directed toward performing knowledge tracing only. [Conati and VanLehn, 1996]

Giangrandi Paolo and Carlo Tasso who have criticized the concept of a static and of a temporal student model have provided an additional differentiation on the concept of student modelling. According to their definition a model which describes the student's knowledge without considering the possible evolution in time is called static while a description of the temporal history of the student's knowledge that includes all the information about the student and makes it possible to explain the student's behaviour for both the past and the current interaction is called temporal.[Giangrandi & Tasso, 1996, p. 184-190; Giangrandi & Tasso, 1997, p. 415-426].

MaCalla introduces two other types of student model the explicit and the implicit student model and makes a useful distinction between them [McCalla, 1992 b, p. 107-131]. An explicit student model is a representation of the learner in the learning system that is used to derive instructional decisions. An implicit student model is reflected in design decisions that have been derived from the system designer's view of the learner.

Examples of Student Models.

In the first part of this section a number of domain independent Student Models are going to be illustrated while in the second part a short description of domain dependent Student Models is going to be provided.

Section 1: Domain independent Student Models

Jim Greer and Gordon McCalla, in their book "Student Modelling: The Key to Individualized Knowledge-Based Instruction" [Greer & McCalla, 1994] make a reference to a number of domain independent Student Models introduced by Kass [Kass, 1989, p. 386-410].

Overlay Student Model

According to this model the learner's knowledge at any point is considered as a subset of an expert's knowledge. The objective of instruction is to establish the closest possible correspondence between the two sets. In such approach it is assumed that all differences between the learner's behavior and that of the expert model can be explained as the learner's lack of skill [Fig. 1]

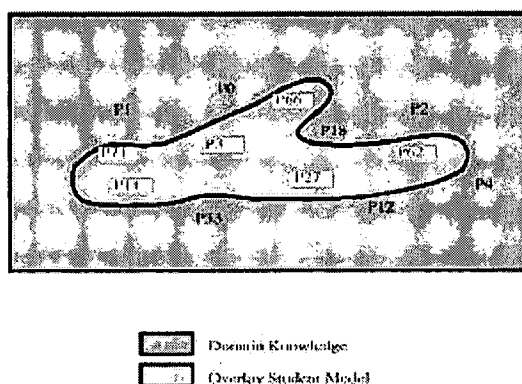

Figure 1: Overlay Student Model

The Overlay Student Model works well for systems where the goal is to strictly impart the knowledge of the expert to the learner. On the other hand the main problem with this model is that the model assumes that a learner's knowledge can be merely a subset of an expert which may not be the case [Greer and McCalla, 1994, p. 7]

Differential Student Model

Figure 2: Differential Student Model

According the Differential student model-which is a modification of the overlay student model - learner's knowledge is divided in two categories: knowledge that the learner should know and knowledge that the learner could not be expected to know [Fig. 2].

BEST COPY AVAILABLE

So in contrast with the overlay student model this model does not assume that all gaps in the student model are equally undesirable. Furthermore the differential student model acknowledges and tries to explicitly represent both learner knowledge and learner-expert differences.

Perturbation Model and Bug Models

While the overlay model represents the learner only in terms of "correct" knowledge, a perturbation model normally combines the standard overlay model with a representation of faulty knowledge [Greer & McCalla, 1994, p. 8]. Furthermore in the perturbation model the learner is not considered as a mere subset of the expert but the learner will possess knowledge potentially different in quantity and in quality from the expert knowledge.

The perturbation model maintains a close link between the learner and the expert models but can also represent the learner's knowledge and beliefs beyond the range of the expert knowledge [Fig 3]

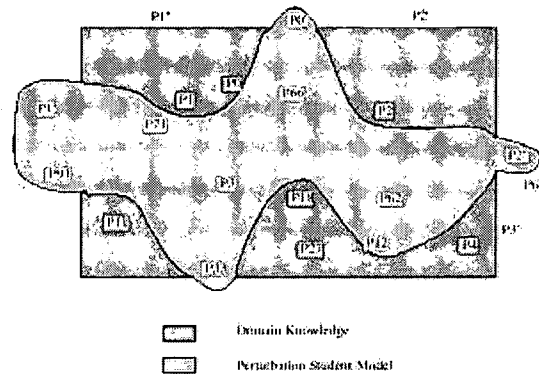

Figure 3: Perturbation model

This model utilizes a bug library which is a fixed collection of bugs and of student's misconceptions. As bug is defined a structural flaw in the procedure that manifests itself in faulty behavior. The inclusion of the bugs in the perturbation model allows more sophisticated understanding of the learner than can be accomplished with a simple overlay on the expert model.

Constrained based Student Model

A constraint based student model represents the learner as the constraints upon the correct knowledge representation. This extends the standard overlay model approach by permitting much more sophisticated reasoning about domain concepts beyond whether they are known or not. A violation of those constraints by the learner indicates that the model needs to be updated. This model is computationally simple and does not prescribe a particular tutorial strategy and it is further unclear how this approach will generalize across domains and tutorial strategies.

Fuzzy Student Model

The fuzzy student model was initially introduced by Hawkes and Derry [Derry & Hawkes, 1992] and was further developed by Katz and Lesgold in the SHERLOCK system [Katz & Lesgold, 1992, p. 205-230]. In such model statistical procedures are used to propagate changes from observable actions to local variables to more global variables. The presence or absence of the knowledge variables are represented by a probability distribution on five levels of the knowledge variable ranging from no knowledge to fully developed knowledge.

PairSM Student Model

PairSM is a domain-independent system introduced by Susan Bull and Smith Matt aimed at helping pairs of students to organize their revision for an approaching test [Bull & Matt, 1997, p. 339-341]. PairSM contains two individual student models which are compared by the system to enable it to suggest ways in which two students may work together effectively. It can recommend collaborative learning, peer tutoring or individual learning, depending on the comparative contents of the models. The aim is to encourage students to experience the benefits of peer interaction.

The two student models of PairSM are initially based on the results of a multiple choice pre-test entered by the tutor. The models are updated by subsequent tests. PairSM contains heuristics for recommending the kind of preparation which may be useful for the learners, by comparing the contents of the two student models, and the manner in which the learners have acquired further knowledge. An overview of the student models is given in Figure 4.

Figure 4: The two student models of pairSM.

SM 1 represents the concepts known by Student 1, and SM 2, those known by Student 2. The intersection of SM 1 and SM 2 represents shared knowledge. SM S1&S2 represents knowledge that the two students can display when working together, but that they cannot produce individually. SM-S1S2 represents knowledge that the pair can display when working together, resulting from one or both knowing the concepts individually, or from interaction between the two learners. SM-S1S2 is the union of SM 1, SM 2 and SM S1&S2 [Bull and Smith 1997, p. 339-341]. Simplified descriptions of the possible situations for each of the individual students are:

no intervention	suggest collaboration
suggest S1 learn individually	suggest peer tutoring S1 -> S2
suggest S2 learn individually	suggest peer tutoring S2 -> S1

For a given topic PairSM may recommend one or more of the above.

See Yourself Write Student Model

The See Yourself Write - introduced by Susan Bull - is a system comprising two parts: a template through which the teacher gives students feedback on each writing assignment they complete, and an individual student model which is automatically created from the feedback provided by the teacher, and which is built up over time [Bull, 1997, p. 315-326]. The student model of See Yourself Write is inspectable, to promote learner reflection and to encourage learners to use the feedback received from their tutors in their future assignments. The domain is writing in a foreign language. See Yourself Write differs from other computational writing environments containing a learner model because the aims differ.

The aim of the See Yourself Write student model differs from that of more conventional learner models in that it is not intended as a source of information for a computational educational system, but rather as a source of information for the student. It reflects to students feedback on their own work, and information about how they are progressing and about their overall performance. Information in the student model is both qualitative and quantitative. Its main purpose is to promote learner reflection on completed assignments in such a way as to lead students to use this feedback to improve subsequent work.

The student model includes both quantitative and qualitative information on student's progress information which can be viewed easily by the student. In addition, the quantitative information (teacher's feedback) is evaluated by the system to provide a more general overview student model to be used by the student in conjunction with feedback on individual assignments.

Section 2: Student Models with domain dependency.

OLAE and POLA Student Model.

OLAE is an off-line probabilistic assessment tool that collects data from students solving problems in introductory college physics. It provides an interface that presents problems and allows the student to solve them by entering algebraic equations. OLAE uses the student's actions to assess the probability that the student knows the physics rules encoded in its model of physics knowledge. The assessment is performed off-line by propagating the evidence provided by the student's actions into a Bayesian network built upon an AND/OR graph representation of the problem solution. The problem solutions are generated forward chaining by the problem solver starting from the problem givens and firing rules as soon as they become applicable. Three kinds of nodes are present in the AND/OR graph. 1) Rule nodes (rectangles in Fig. 5) that represent rules and problem givens. 2) Application nodes (ellipses in Figure 6) that explicitly represent rules firing. 3) Fact nodes (diamonds in Fig 5), that represent conclusions derived during problem solving.

Application nodes are the AND nodes in the graph, while fact nodes are OR nodes modelling the fact that some conclusions can be derived in multiple ways. Each application node is connected to the fact node representing the derived conclusion. OLAE assesses the student knowledge of physics rules from the student's solution of a problem

using a Bayesian net-work consisting of the AND/OR graph for that problem integrated with nodes that represent the equations entered by the student, called action nodes. Each node in the Bayesian network has values TRUE/FALSE, which represent [a] for a rule node, whether the student knows the corresponding rule. [b] For an application node, whether the student actually used a rule during the problem solution. [c] For a fact node, whether the student knows the associated fact about the given problem. [d] For an action node, whether the student has performed the action.

Figure 5: OLAE Student Model

As it is referred by Conati and VanLehn propagation through this network caused incorrect assignment of probabilities [Conati and VanLehn, 1996]. For that reason the further enhance OLAE student model by developing POLA. POLA is a student modelling framework that performs probabilistic assessment of students' performance while they solve problems in introductory Physics. POLA turn OLAE- system that performs probabilistic knowledge tracing-into a system that applies probabilistic reasoning to perform both knowledge and model tracing. POLA generates probabilistic predictions about the student's line of reasoning without using heuristics, even when the problem's solution space is large. Similarly to OLAE a Bayesian network is constructed incrementally from the AND/OR graph and from the student's actions generates predictions about the solution that the student is following. At the end of the problem solving session the network provides an assessment of student's level of mastery of the physics knowledge involved in the problem's solution. POLA builds the Bayesian network incrementally from the AND/OR graph as the student enters actions, but keeps the two structures separately. For each new action that the student types, POLA determines which rules and which givens have been used to derive it. If there is more than one way to derive the student's action the analysis returns the set of possible derivations, each of which is a distinct but possibly overlapping set of rule applications and givens. Derivations are represented explicitly in the Bayesian network by what we call derivation nodes. After each new equation entered by the student the Bayesian network is extended with an action node that represents the equation and with a derivation node for each derivation producing the equation. The derivation nodes are linked to the action node through a leaky-XOR link matrix. Additionally in case where a certain problem has different solution sets a new type of nodes are inserted in the network called solution nodes. Once a solution sets have been identified, POLA starts creating the Bayesian network adding a solution node for each solution set. POLA represents a new approach to applying Bayesian networks to student modelling, since the other existing efforts to use probabilistic reasoning in student modelling have been focused on knowledge tracing only [Conati & VanLehn, 1996].

Discussion

The development of new technologies has promoted an astounding growth in distance education, both in the number of students enrolling and in the number of universities adding education at a distance to their curriculum. A great number of students of different ages participate in courses available via distance. Teaching and learning at a distance requires special attention to the possibilities and limitations of the technologies involved. Even many simple activities, which we take for, granted as part of the instructional process must be reconsidered and adapted to new circumstances. Pedagogy of distance education can be broken in issues which concern the instructor, and issues which concern student. We believe that the study of student models can

positively affect the area of distance education assisting towards better teaching and learning activities to be achieved.

Our research interest focuses on the utilization of domain independent student models in the area of distance education according to the age of the potential student. Having in mind that the human knowledge space increases according to human's age, the Overlay Student Model can be applied with accuracy in cases where of the potential student is not an adult. It is considered that the knowledge space of such student -due to the age factor- is in most of the times a subset of tutor's knowledge space. On the other hand the Differential and the Perturbation Student Model can be applied in cases where the potential student is an adult as these models assumes that all gaps in the student model are equally undesirable, nor the learner knowledge is considered as a mere subset of the expert (tutor). On the contrary the learner is assumed that possess knowledge potentially different in quantity and in quality from the expert knowledge. It is worth to noticed that the utilization of bug library in order students faulty behavior to be highlighted is applicable to potential students regardless of their age. Applicability of a student model regardless of the age of the potential student is also valid for the Fuzzy Student Model, while the Constrained based Student Model can be applied in cases where the taught domain is deterministic.

Pair SM Student Model is of exceptional interest as it s not only applicable regardless of the age of the potential student but it can also be used to monitor collaborative learning, which is a critical issue in the area of distance education. Furthermore the See Yourself Write Student Model although it is implemented to improve writing skills in a foreign language can be used as a domain independent student model which aiming to improve student's performance by utilizing the tutor's feedback.

The Multi-Site Course: Using Technology to Enable Global Course Offerings

Makoto J. Tsuchitani
Stanford Overseas Studies, Stanford University, Stanford, CA 94305-3089
mako@leland.stanford.edu

Abstract: The Stanford Overseas Studies Program has offered students at Stanford University the opportunity to study abroad for the past forty years. In the 1998-1999 academic year, the program took its first step towards utilizing technology to offer its students multi-site courses -- courses taught by a single faculty member with students participating from several overseas centers. This paper presents the issues encountered in offering globally distributed courses and makes recommendations for others interested in offering similar courses.

Introduction

Many universities are involved with expanding the scope of their course offerings via distance education. Last year, for example, the School of Engineering at Stanford University began to offer a Master's degree which could be earned solely via distance education. The Stanford Overseas Studies Program has also been interested in exploring ways to utilize technology to benefit its students. The development of the multi-site course format is a result of recent explorations.

The Stanford Overseas Studies Program is one of the first overseas studies programs at a major university to offer courses where students in a particular course are distributed in centers throughout the world. One of the primary reasons for exploring this multi-site course format was to enrich students' experience in the course through interactions, discussions, and collaborations with others studying and living in different cultures. Every effort was given to guarantee that these courses equaled, if not surpassed, other course offerings in meeting students needs.

This paper will focus on case studies presenting an analysis of the implementation of the multi-site courses during the 1998-1999 academic year. Included in the case studies will be background information on the Stanford Overseas Studies Program and its use of technology; a description of the courses; an analysis of the courses, including a description of the course structure and technology. This paper shall conclude with recommendations for those interested in conducting a multi-site course of their own.

Background

The Stanford University Overseas Studies Program has offered students at the university the opportunity to study abroad for the past forty years. Stanford has overseas centers located in Oxford, England; Paris, France; Florence, Italy; Berlin, Germany; Kyoto, Japan; Moscow, Russia; Santiago, Chile; and Puebla, Mexico. Courses offered at the centers are taught by local instructors as well as visiting Stanford faculty.

While administrators of some overseas studies programs have been fearful of the use of technology in their programs, Stanford Overseas Studies has been supportive of the use of technology in its overseas centers for the past ten years. Those who oppose the use of technology in overseas programs believe it encourages students to stay too connected with their home campus and country, thus interfering with their overseas experience. Although the use of technology at Stanford's overseas centers has generally been limited to students using the computers for word processing, accessing email, and "surfing" the web, Stanford Overseas Studies has been very interested in expanding the use of technology to enrich its overseas course offerings. The use of technology offers the means to expand course offerings by making courses available at multiple sites, as well as making better use of local overseas experts, having them appear as guest lecturers in courses at the Stanford home campus.

Stanford Overseas Studies' first step towards greater use of technology has been the collaboration on various technology based projects with different groups on the Stanford campus. Last spring quarter, together with Stanford Online, for example, engineering students in the Berlin and Kyoto centers were offered the opportunity to take courses via Stanford Online's web based format which utilized a streaming video technology, vXtreme, to present lecture material.

It was not until this past year, however, that Stanford Overseas Studies was able to hire an additional staff member, the Academic Technology Manager, who enabled them to move forward with their agenda to more fully utilize technology in their courses. Stanford Overseas Studies submitted a proposal and was selected to participate in the Academic Technology Specialist Program which is managed by Research and Instructional Technologies Support of the Stanford University Library/Academic Information Services. Academic Technology Specialists provide to faculty on-site, intradepartmental consulting and support in information and instructional technology for academic purposes to foster their awareness and use of technological resources, both within and outside of the university. In the case of Stanford Overseas Studies, their Academic Technology Manager would play a vital role in overseeing the management of the multi-site courses.

Course Descriptions

Stanford Overseas Studies' first multi-site course was a Religious Studies course, "Religion in Culture," which was offered in the fall quarter of 1998. Students in this course studied the different ways in which religion forms and is formed by culture. After an examination of different theoretical approaches to that subject, students worked on projects that drew on the resources of their local sites. Examples of such projects included understandings of the relation of religion (e.g., the church) to the state, depictions of specific sacred themes in art and architecture, the character of distinctive religious activities such as pilgrimage, and the significance of holy people, living and dead, for some believers.

This Religious Studies course involved participants from five different locations. It was taught by a Stanford faculty member who was based at the Florence center. The teaching assistants for the course were located at the Stanford campus in Palo Alto, CA. While the course was open to students at any of the overseas centers, a total of nineteen students from the Florence, Paris, Berlin, and Oxford centers enrolled.

The second multi-site course was a Comparative Literature course, "Literary Institutions," which was offered in the winter quarter of 1999. In this course students examined institutional structures and contexts for literature in different studies. However, rather than focusing on the close readings and interpretation of particular works, students explored how literature is presented to its public at various levels. Some of the questions raised in the course included: What sorts of literature are discussed in the press, and what are the issues raised by such literary criticism? How is literature presented in schools? Is it primarily the "local" national literature or is "world literature" read? Do students read "minority authors"? What texts are taught at universities, and what plays performed in theaters?

The Comparative Literature course involved participants from six different sites. While the faculty member and teaching assistant were located at the Stanford campus in CA, the twenty-four students in the course participated from overseas centers in Oxford, Paris, Berlin, Florence, and Santiago.

Course Structure

Traditional modes for delivering distance education courses have been correspondence courses, courses on audio and video tapes, and satellite/cable broadcast courses. These formats have been most successful at delivering educational programs based on the "traditional" delivery of knowledge model of learning, which treats learners as passive recipients of information. The active learning model, however is based on the notion that more effective learning is achieved when the learner is actively engaged in the creation of knowledge rather than the passive recipient of information. More specifically, learning is achieved within an environment that fosters interactions between learners and instructors, between learners and content experts, and amongst learners themselves.

In order to ensure that the multi-site courses were not just email or web based correspondence courses, an active learning, or learner centered, model was adopted for the multi-site course format. The faculty structured the courses to be project based and emphasized collaborative work amongst students, encouraging students from different centers to work together. This structure required students to complete a significant amount of field research in their local environment. The technology used in the course not only allowed students to communicate with the faculty member, but also enabled them to share their research and experiences from their host countries with one and other. The multi-site courses also employed the use of local mentors at each of the overseas centers. The local mentors were content and/or language experts of the native country. Their primary role was to assist students in accessing local resources when conducting their research. Since students did not have face to face contact with the

faculty member teaching the course, it was important that the local mentors were not perceived as "local" instructors for the course. Otherwise, if the students perceived the local mentors as local, or "surrogate," instructors, they could have begun to rely on the local mentors as "the instructor" and their online participation would have suffered. The course could have become fragmented and "mini courses" might have developed at each center.

Technology

A course web site was constructed for each of the multi-site courses. These web sites included course related information such as the syllabus, assignments, a calendar, and a web based discussion software. The discussion software was utilized as the primary means for interaction between the faculty member, teaching assistants and the students.

Students utilized the computer clusters, available at each of the overseas centers, to access the course web sites. The clusters consisted of Macintosh computers and a laser printer. A flat bed scanner and Sony Mavica digital camera were also available to allow students to capture images and upload them along with their postings. Sony digital cameras were selected because the use of regular floppy disks as the recording media, a familiar technology, made it easier for students to transfer their images and upload them with their postings. Students utilized the cameras to include photographs of literary institutions they visited in their local communities.

The Academic Technology Manager acted as the technical liaison coordinating the campus computing resources for the faculty member, teaching assistants, students, and overseas center staff. Because these courses were somewhat experimental in nature, the Manager's role was crucial in ensuring that the proper technologies were in place in order for the courses to be conducted. In addition, the Manager acted as the system administrator for both courses.

Web Crossing, by Lundeen Associates, was the threaded discussion software utilized to support the Religious Studies course. Web Crossing provided the capability to setup folders to organize course discussion according to topic, assignments, or group project. The faculty member and teaching assistants determined the structure of the folders for the course discussions prior to the beginning of the course.

The Comparative Literature course utilized the Forum, a web based discussion software developed by the Stanford Learning Lab, to support course discussions. The Forum was selected because it provided additional functionality over Web Crossing, and its interface provided a more efficient method for navigating discussion threads. In order to combat the connectivity problems that were experienced in the previous multi-site course, the Stanford Learning Lab was able to provide use of a dedicated line to Sweden that one of its other project partners was utilizing. Use of this line meant that the course web server could reside on the Stanford campus, but appear to be located in Sweden since it was assigned a Swedish IP address. Students at the European centers utilized the Swedish server address in order to route their traffic to Stanford via the Swedish dedicated connection, thus bypassing any bottlenecks on the east coast of the United States. Students from the Santiago Center successfully accessed the course server utilizing the Stanford server address.

A Comparative Analysis

Since course participants in the Religious Studies course were distributed in five different countries it was decided that Web Crossing, a web based discussion application, would be an appropriate technology for providing a rich "classroom environment."

While Web Crossing has the capability to include images along with postings, as well as a chat component, neither of these functions were used, however, in the Religious Studies course because of connectivity problems. Both the Web Crossing server, as well as the web server for the course web site, were located on the Stanford University campus. Access to these servers from the European centers was very slow and unreliable during most of the day (8 am - 11 pm). Connection speeds were so poor that students generally surfed the web with images turned off. Given that conducting telnet sessions was difficult at best, it was decided that synchronous communication was not feasible given the current connectivity between the centers and Stanford campus.

While the course was ultimately successful, a number of other difficulties were encountered. The overseas centers lacked the on-site support staff necessary to adequately support students who had difficulty using the technology. In addition, the faculty member and teaching assistants had limited experience using "advanced" technology prior to teaching this course. They were previously primarily familiar with word processing and email.

While they were ultimately able to learn and effectively utilize the discussion software, it was at times a struggle and a stressful process. Lastly the normal course "house keeping" issues became much more difficult and time consuming to manage with the course being distributed amongst several locations. Registering a distributed group of students into the system and issuing logins and passwords took a significant amount of time and effort.

The faculty member and teaching assistants felt that the course succeeded on many different levels. While it took some time for the students to adapt to the different learning environment, once they felt more comfortable and adjusted to the connectivity problems, they were motivated to participate in the online discussions. In fact the volume of the number of postings surprised the faculty member and teaching assistants. They were especially surprised by the frankness in which the students shared personal information, such as their religious background, which would never had occurred in a "conventional" classroom.

A course web site which incorporated the use of the Forum, a web based threaded discussion software developed by the Stanford Learning Lab, was utilized as the primary vehicle for (asynchronous) communication in the Comparative Literature course. The Forum provided the faculty member the capability of creating folders to organize the course discussions and assignments.

Because the Comparative Literature course had the benefit of utilizing the direct line to Sweden, it was determined that there was sufficient connectivity to support a synchronous communication component in the course. A simple chat client was integrated into the course web site. Weekly chat sessions were conducted as a follow up to weekly assignments, to discuss and share research findings, as well as build a sense of community for the students in the course.

Weekly assignments were posted on the course web site. Students would then post completed assignments into the appropriate folder within the Forum. In order to ensure that students participated in online discussions, students were required to post a minimum of five initial responses to a topic question and respond to at least one topic thread each week. There was less instructor participation in discussions as the quarter progressed in order to allow students to take full ownership of the discussions. In addition, students easily incorporated digital images or other documents (e.g., Microsoft Word, etc.) as attachments to their postings.

In addition to posting assignments to the Forum, the students were involved in a real time chat session (synchronous communication) with the faculty member once a week. The chat sessions were conducted after the weekly assignments had been posted to the Forum. These sessions gave the faculty member and students an opportunity to further discuss assignments in real-time. These sessions also served as a vehicle for building a sense a community for the students in the course.

While Web Crossing displayed the contents of a single discussion folder per screen, the Forum software utilized a three paned window to display a listing of folders, a listing of messages in a folder, and the contents of a specific message. In general its interface was more flexible and took less time to load in a browser. In addition the Forum provided a means for the faculty member to make general course announcements and easily include attachments (i.e. images, Word documents, etc.) with their postings. Another very beneficial feature was the email copy feature available when posting messages. The Forum provided users with the ability to send, via email, a copy of any posting to a specified group of users (i.e., the faculty member, faculty member and teaching assistants, all students in the course, students from a specific center, etc.).

The faculty member played a key role in the success of the Comparative Literature course. His use of a learner centered approach in structuring the course was a major factor in its ultimate success. Because he was a more experienced user of technology, he had an easier time learning to effectively use the technology to manage his course. At the beginning of the course, he spent a significant amount of time and effort online in creating the feel of a community for the course, responding to every student posting in the Forum. In these postings, he would repeatedly emphasize to students that they should look to one and other as resources, encouraging them to seek out other students, especially those at other centers, to collaborate with on their projects.

Conclusion

Stanford Overseas Studies found that the development of the multi-site course format gave us the opportunity to create exciting globally distributed learning communities in which students became active learners, local researchers, and collaborators engaged in real and personal learning activities. The inclusion of students from centers in different countries added an additional dimension of incorporating multiple perspectives on important topics, issues, events.

This shift from the passive to active model of learning required a shift in the roles of both faculty member and students. The cooperation of the faculty member in modifying their teaching style was very important to the

success of the multi-site courses. The faculty member no longer played the familiar role of "disseminator of the knowledge." His/her role became one of facilitator instead. Rather than requiring a major term paper, students were encouraged to work collaboratively in completing a group project. The formation of groups was facilitated by the faculty member. S/he encouraged students with like interests to work together; especially students from different centers.

In developing the multi-site course format, every effort was given to guarantee that these courses equaled, if not surpassed, other course offerings in meeting students needs. That is, the multi-site course was not the repackaging of a course delivered via distance technologies. Special care was given to ensure that the technology used in the course did not become the focus, or interfere with the content, of the course. A major restructuring of the course, including a shift to a learner centered methodology, was thus necessary to utilize the technology in a way to maximally benefit the students in the course. In other words, having the faculty, students, and technology staff embrace a learner centered methodology was a key to the success of the multi-site course format.

The following is a list of issues to consider for those who may be contemplating offering their own multi-site courses:

- Under a learner centered model, students need to assume a far greater responsibility for their learning. Besides choosing what and when to learn, they must become active questioners and investigators. Whatever the environment, it is important that students feel comfortable conducting an intellectual discussion or doing work.
- It is important to encourage participation and/or structure activities to get students involved in online discussion. Students need a clear understanding of what is expected of them and the objectives and outcomes of each assignment/activity. These needs are heightened in courses which are taught via a distance where nonverbal means of communicating is not possible.
- Faculty members need to remember they need to allow students to take ownership of class discussion and assume the role of the facilitator, not necessarily the "instructor."
- Planning and designing an effective distance course requires a significant amount of time and resources. For instance, faculty must develop meaningful projects/research opportunities for students in the local communities. In addition, funding for stipends needs to be secured for bringing "local experts/mentors" into the course.
- Lastly, institutionalization of the appropriate technology is imperative for the success of multi-site courses. Local centers need to have the technology (i.e., software, hardware, and connectivity), along with the local technical support, to participate in this type of course.

Stanford Overseas Studies views these first couple of courses as the first phase of its venture into the multi-site course format. Future plans involve the refining and possibly redefining the use of synchronous communication technology. There are also plans to branch out and offer more media rich courses, such as a photography course, in the multi-site course format.

In conclusion, new technologies for distance education have the potential to provide learning environments that can support active learning only if combined with shifts in teaching styles, content delivery, and learning activities. Curriculum design and technology integration are also essential. Curricula needs to be designed to take full advantage of the technology and go beyond the traditional delivery of knowledge model. Without these changes, Internet based courses are nothing more than correspondence courses conducted by email.

Reconstructing the Social Learning Theory: Social Presence Theory in Online Learning

Chih-Hsiung Tu
Educational Media & Computers
Arizona State University
chih@asu.edu

Abstract: Social presence is one of the most significant factors to examine in distance education. The impact of social presence on learning must be examined because of the prevalence of CMC in education. Many of the studies dealing with social presence on CMC have been done in standard educational settings and organizational settings. None of them have redefined social presence for CMC. This theory must be operationally understood and clearly defined before knowledgeable studies occur. The relationship between social presence and the social learning theory is also examined in this paper. Social interaction is fundamental to the explanation of this relationship. Social learning requires cognitive and environmental determinants, social presence is required to enhance and foster online social interaction, which is the major vehicle of social learning.

Introduction

Learning is a social process (Bandura, 1977; Tapscott, 1998). Primarily, knowledge is constructed through social conversation and dialogue; therefore, learners arrive at their own understanding of social experiences. Traditional media and face-to-face learning environments differ from an online community in the selections of delivery channels. Many educators have adopted the social learning theory (Bandura, 1977) and have applied it to the online learning environment. The existence of teachers' and students' social presence of has been taken for granted because of the characteristics of traditional media and face-to-face environments. Social presence in an online community requires more than computer-mediated communication (CMC) technologies. For instance, there is no presence at all if a person in an online community just observes and doesn't communicate. When one applies the social learning theory to an online learning environment, the level of social presence must be scrutinized. This discussion provides a new paradigm for the application of online social learning.

Scope of Social Presence

Social presence is defined as the degree of salience of another person in an interaction and the consequent salience of an interpersonal relationship [Short et al. 76; Rice 93; Walther 92]. Biocca [97] argued that social presence should be more complicated than just awareness. He defines, "the minimum level of social presence occurs when users feel that a form, behavior, or sensory experience indicates the presence of another intelligence. The amount of social presence is the degree to which a user feels access to the intelligence, intentions, and sensory impressions of another." Factors that contribute to an appreciable degree of social presence are facial expression, direction of gaze, posture, dress, non-verbal, and vocal cues. Social presence was first hypothesized as an attribute of the medium itself [Short et al. 76], or technological social presence; however, this definition is not strictly accurate because several studies [Gunawardena 95b; Gunawardena & Zittle 97; Perse et al. 92] have shown that perception of the degree of social presence will vary among users. Social presence should be viewed as a subjective quality of the medium [Short et al. 76], although it depends upon the medium's objective quality (Technological Social Presence).

Social Presence Concepts in Social Psychology

Two concepts in social psychology are related to social presence: intimacy [Argyle & Dean 65] and immediacy [Wiener & Mehrabian 68].

Intimacy is a function of eye contact, proximity, topic of conversation; etc. changes in one will produce compensatory changes in the others [Short et al. 76]. A communication with maintained eye contact, close proximity, body leaning forward, and smiling conveys greater intimacy. Equilibrium theory [Short et al. 76] was an assumption to explain how humans balance the degree of intimacy. In a face-to-face setting, people tend to avoid maintained eye contact and increase physical separation if personal topics or topics with which a person is uncomfortable are to be discussed. People try to maintain an optimum level of intimacy. That is, when an uncomfortable degree of intimacy is encountered, the participants of the conversation will attempt to alter their behavior to maintain the degree of intimacy at an optimal level of comfort. The interaction is unpleasant if behavior cannot be altered to allow an optimal degree of intimacy. Short et al. [76] determined that very intimate tasks, those that are embarrassing, contain extremely personal content or areas of conflict, the medium lowest in social presence, the telephone, would receive a more favorable evaluation than face-to-face encounters or closed-circuit television. It can be concluded that the social presence of the communications medium should be included in the list of other factors contributing to intimacy, eye-contact, smiling, and personal topics of conversation [Argyle & Dean 65]. The levels of intimacy that people adopt are derived from cultural norms [Argyle & Cook 76] and from a need for affiliation [Walther 92]. Argyle and Cook [76] argued that the discussion topic might contribute to the level of intimacy. If someone is more familiar with the discussion topic, they feel more affiliated, or a greater intimacy.

The second psychological concept involved in social presence is immediacy. This is a measure of the psychological distance a communicator puts between himself or herself and the recipient of the communication. There are two forms of immediacy: technological immediacy is achieved when the maximum amount of information is transmitted [Heilbronn & Libby, 73]; and social immediacy, which is conveyed through speech and associated verbal and non-verbal, cues [Short et al. 76]. The user may alter social immediacy, while technological immediacy is an inherent characteristic. One can generate immediacy or non-immediacy nonverbally [physical proximity, formality of dress, and facial expression] and verbally [Gorham 88]. CMC users normally will use paralinguistic or emoticons to substitute for the missing cues, such as "I agree" for head nodding, and ":-)" for smiling, etc. because non-verbal cues cannot be delivered on CMC. Rice and Love [87] found that socio-emotional contents constitute one third of the total messages on a bulletin board. Gunawardena [95] argues that immediacy enhances social presence; therefore, the degree of social presence is not only an attribute of the medium. Increasing the intensity of immediacy can enhance social presence.

Degree Of Social Presence

Degree of social presence is based upon the characteristics of the medium and the user's perception. That is, the social presence factor is a dynamic variable. Different people discern different amounts of social presence in different media. People, in fact, anthropomorphize computers and treat them as "social actors" [Reeves & Nass 96]. Hence, social presence is the internal image the perceiver evokes of a moving, expressive body. This concept is similar to Goffman's [59] "self-presentation." Normally, the users are asked to measure the degree of social presence [Perse et al. 92]. Short et al. [76] measured social presence through the semantic differential technique with a series of seven-point, bipolar scales, such as sociable/unsociable, personal/impersonal, sensitive/insensitive, and warm/cold.

Social presence may actually be taught or cultured [Johansen et al. 88]. Users have substantial opportunities to modify social presence by varying message qualities [Short et al. 76]. Social presence can be cultured by teleconference leaders or encouraged by initial learning sessions [Johansen et al. 88]. Gunawardena's study [95b] suggested that it is an instructor's interaction skills and techniques that will impact the student's perception of social presence. Consequently, instructors, or moderators, should develop interaction skills that create a sense of social presence.

Three Dimensions of Social Presence

Social presence has three dimensions: social context, online communication, and interactivity. Each dimension is discussed below:

Social context contributes to the degree of social presence, such as task orientation [Steinfeld, 86], privacy [Steinfeld, 86], topics [Walther 92], recipients/social relationships [Williams & Rice, 83], and social process [Walther, 92] etc. Walther [92] proposed that different social processes, settings, and purposes are components of social context and affect social presence.

Task types influence the degree of social presence, and communication processes. Four different task types were proposed [Hollingshead & McGrath, 95]: (a) group generation of ideas or plans, (b) selecting among answers or solutions, (c) negotiation of conflicting views or conflicting interests, and (d) execute performances in competition with opponents or external standards. Steinfeld [86] studied the organizational use of e-mail in different settings. He found that task complexity, task interdependence, environmental uncertainty, and the need for communication across distant locations were positively associated with increasing task orientation in CMC messaging. In fact, Walther's three variables, social process, purpose, and setting, form the "Social Context" dimension of the three dimensions of social presence [social context, communication, and interactivity] discussed earlier in this paper. Walther [92] argued that social relationships would stimulate changes in interactions. CMC systems tend to have less relational communication initially. However, as time passes, CMC users are driven to develop social relationships by forming impressions of others through the information conveyed by text-based CMC. It was concluded that participants became more social toward the latter part of a CMC conference than during the initial stages and exchanged more personal messages [Gunawardena & Zittle 97]. Relational history also has an impact on social relationships.

Perception of privacy, one component of social context, affects the degree of social presence. A less private setting results in a decreased perception of social presence by users. In an experimental study, Champness [72] reported that users felt more public in a videoconference and perceived less social presence. Videoconferencing created a psychological sense of intrusion rather than a feeling of security. Generally speaking, a camera in operation may be seen as intrusive, or attitudes toward the use of TV in public broadcasting may carry over into the laboratory, concerns of electronic eavesdropping exist and produce consequent negative reactions [Ryan, 76]. Steinfeld [86] examined the social presence of e-mail in organizational settings. He reported that users were reluctant to employ e-mail for confidential matters, so this perception of privacy may not have affected their use of e-mail. The privacy characteristics of other CMC systems, 'one to one' CMC may be seen as more private, while 'one to many' CMC (listserv and bulletin board) may be viewed as more public. Therefore, the user's perception of privacy on different CMC systems deserves further investigation.

Online communication is the exchange of thoughts, messages, or information that occurs online. Because of the technology and its text-based format, computer-mediated communication requires that users possess some level of computer communication literacy such as typing, reading and writing. People who are unable read or write well [or who believe they cannot] or have limited typing skills will become the computerized society's new "handicapped" group [Phillips 83]. People in this situation develop communication anxiety [Gunawardena 91] when text-based communication is required. Therefore, it is suggested that text-based communications should be initiated with some light or casual topics, like introductions. Training students to use the medium and making them comfortable using it is crucial to the success of collaborative learning. Garramone et al. [86] and Perse et al. [92] examined students' perceptions of social presence and concluded that the degree of social presence on computer bulletin boards was perceived as higher for users who were more interactive than for those who were not. Perse et al. [92] found a positive relationship between social presence and the student's perception of their own computer expertise.

Interactivity, defined as the ability to convey a two-way exchange and the potential of an immediate response, contributes to social presence [Williams & Rice 83]. The potential for feedback from the other also contributes to the degree of salience of the other person in the interaction. Immediate response is another component of interactivity. In asynchronous CMC response occurs at a different time, so it takes longer to obtain a response from the other party. When an immediate response is expected and is not received a feeling of low interactivity is created, thus decreasing the level of social presence. However, Garramone et al. [86] found that interactivity, allowing for feedback, contributes to the social presence of an electronic bulletin board. Gunawardena [95b] differentiates interactivity and social presence, arguing that social presence requires user's to add one more step to awareness of interactivity; in short, when users notice it, there is social presence.

Social Learning Theory

Bandura's [77] social learning theory states that neither inner forces [person] nor environmental stimuli [environment] drive people as isolated influences. Behavior and complex learning must be "explained in terms of a continuous reciprocal interaction of personal environmental determinants...virtually all learning phenomena resulting from direct experience occurs on a vicarious basis by observing other people's behavior and its consequences for them" [p. 11, 12]. From this point of view, it can be concluded that human behaviors are affected by observation and by direct experience.

The social learning theory emphasizes that behaviors result from the social interaction of people and their environments, rather than from either factor alone [Bowers 73]. That is, personal and environmental factors do not function as independent determinants, rather they determine each other, and the influences are bi-directional. Consequently, the social learning theory approaches the explanation of human behavior in terms of a continuous reciprocal interaction between cognitive, behavioral, and environmental determinants.

The social learning theory views interaction as a process of reciprocal determinism; behavior, other personal factors, and environmental factors all operate as interlocking determinants of each other. Generally, there will be no initiation of social learning at all if the model is unable to be perceived as socially present by the learners. Also, social interaction between learners and teachers/role models is required for social learning to occur. No interaction, no learning [Gunawardena 95a]. Social interaction on CMC is affected by some degree of social presence. Learners must acknowledge and value the other person's social presence; otherwise, social interaction is absent and social learning will not occur. Therefore, behavior, personal factors, and ideal social learning environment can be created and promote learning on CMC with an appropriate degree of social presence. If the degree of social presence is low, social interaction, which is the foundation of social learning, does not occur.

Processes of Observational Learning

Four processes of observational learning are proposed to explain the social learning model [Bandura 77]: (a) observation of the relevant activities, (b) coding of the modeled events for memory representation, (c) retention of what was learned, and (d) generating sufficient incentive to learn. The importance of social presence in observational learning emerges, particularly in an environment without context cues. Social learning behaviors, when social presence is not appreciated, can be very different from what is expected. Learning is avoided by not observing the relevant activities; inadequately coding modeled events for memory representation, failing to retain what was learned, or experiencing insufficient incentives.

Observational learning requires that learners notice the significant features of the model's behavior [Bandura 77]. This particular attention to models occurs in the interpersonal attraction/relation, which is primarily influenced by the degree of social presence in the CMC setting [Walther 97]. The learner must be presented with an optimized social presence. Learners in some face-to-face circumstances are unable to build interpersonal attraction with the models because of unequal participation, cultural and personal reasons. Murfin [94] found that female and minority students responded with less anxiety and better interpersonal relationships to learning science subjects with scientists as models on CMC. This occurred because the students perceived a higher degree of social presence.

Information retention and information recall are required in observational learning to produce symbolic representation (imitation) [Bandura 77]. Instantaneous imitation doesn't require much cognitive functioning; but delayed modeling requires the learner to possess better cognitive functioning and information recall. This is particularly true in asynchronous CMC environments because of the time-delayed nature. Social presence with a prevalent degree of immediacy has a very positive influence upon cognitive learning [Gorham 88]. Kelley and Gorham [88] examining teacher immediacy, a psychological component of social presence, found that teacher immediacy produced positive results on information recall. That is, higher teacher immediacy, higher social presence will support the retentional process of social learning. Social presence appears to enhance delayed modeling.

1119

The third process requires transforming information from symbolic representation to appropriate actions. Cognitive organization, an essential element in this process, will help the learner to integrate the skills learned through observation, if absent the reproduction behavior will be "faulty" [Bandura 77]. Therefore, this process also requires a higher degree of social presence to increase the learner's cognitive learning and information recall and allow production of the expected modeling behavior. Learners of social behaviors only reproduce those behaviors they value. The incentives, delivered verbally or non-verbally, are critical to motivating the learner. These incentives are delivered with difficulty in the CMC setting if the person is unfamiliar with using emoticons or paralanguage to enhance social presence.

Vygotsky's Social Development Theory

Vygotsky's social development theory [78], complementary to Bandura's work on social learning, is a key component of the situated learning theory. Vygotsky believed that full cognitive development requires social interaction. Social interaction plays a fundamental role in the development of cognition. The primary theme of Vygotsky's [78] theoretical framework is that, "Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first, between people [interpsychological] and then inside the child [intrapsychological]. This applies equally to voluntary attention, to logical memory, and to the formation of concepts. All the higher functions originate as actual relationships between individuals" [p. 57]. Learner's awareness as the end product of socialization was addressed by this developmental theory. For example, in the learning of language, children's first utterances with others are for the purpose of communication, when they are mastered they become internalized and allow inner speech.

Social interaction is a key component in social learning according Vygotsky's theory. CMC has been found to be primarily devoted to social interaction [Reid 91], and it even outperformed a face-to-face group in social interaction because of a higher degree of social presence being perceived by users [Walther 95]. In the distance education setting, participants agreed that there were many social and personal interaction messages sent because of the high degree of social presence created by the teacher/moderator enhancing the social interaction, thereby increasing social learning [Gunawardena & Zittle 97].

Conclusion

Social presence is one of the most significant factors to examine in distance education. The social presence theory was proposed and examined in face-to-face, audio-conferencing, and videoconferencing environments. It was not, originally, proposed for computer-mediated communication technology, the newest education technology for distance education. The impact of social presence on learning must be examined because of the prevalence of CMC in education. Many of the studies dealing with social presence on CMC have been done in standard educational settings and organizational settings. None of them have redefined social presence for CMC. This theory must be operationally understood and clearly defined before knowledgeable studies occur.

The relationship between social presence and the social learning theory is also examined in this paper. Social interaction is fundamental to the explanation of this relationship. Social learning requires cognitive and environmental determinants, social presence is required to enhance and foster online social interaction, which is the major vehicle of social learning.

Integrating Online Interaction into Computer-Mediated Communication

Chih-Hsiung Tu
Educational Media & Computers
Arizona State University
chih@asu.edu

Abstract: CMC can enhance and inhibit interactions in distance education and communication. Characteristics of CMC, the design and use of instruction and the users' perception of the medium are critical points to be considered when utilizing CMC to enhance online interaction. Increasing all four types of interactions requires a thorough understanding of the strengths and weaknesses of each CMC system and the users (students and teachers) to integrate CMC technology into a virtual classroom.

Introduction

Interaction is a crucial component for learners, teachers, and researchers to examine. No interaction, no learning [Gunawardena 95]. Garrison [93] states that the "concern for quality in distance education has identified an emerging paradigm based upon two-way communication as a necessary and central component of an educational transaction" [p. 17]. In other words, interactive (two-way) communication is the critical component in distance education.

Computer-mediated communication technologies have been utilized in every learning situation, including traditional environments and distance delivery. The attributes of the computer technologies themselves do not change with use; the critical issue is how we integrate this new technology into classrooms. In other words, how humans interact with the technologies and how humans perceive the technologies will have major impacts on learning interaction processes. Many studies have concluded that technology-based instruction has positive impacts on interaction. However, few of them examine the negative impacts on interaction. To provide better utilization of computer-mediated communication, both positive and negative aspects must be examined thoroughly to provide a better understanding of relationships of CMC and interaction. This paper provides a comprehensive discussion on how interaction is increased or inhibited when integrating CMC into instruction based on four different CMC systems (e-mail, bulletin board, listserv, and real-time chat) within four different interactions, learner-learner, learner-teacher, learner-content, and learner-interface. CMC technologies in a distance education setting can be classified as synchronous (real time communication) or asynchronous (time-delayed communication) systems. Audio and video conferencing systems are not included in this discussion.

CMC Enhance Interactions

Appropriate instructional design of CMC based education enhances online interactions among students, teachers, content and interface.

Less Participating Students

Cyberspace allows one to have anonymity and multiple identities, also one can shift identities rather easily, taking on characteristics of others' identities. Users may feel anonymous, although using their real names, because they might pass their computer-conversation partners on the street without being recognized. Phillips [83] argued that the chance to speak anonymously could lead to the expression of honest opinion and to candidness of emotional comments. In fact online users tend to judge one's mind rather than their appearance, race, accent, etc. The online user is physically alone with the terminal attached to a telephone. The idea of "being alone with one's terminal" may lead to a reduction of barriers and a relaxation of face-maintaining behavior [McBride & Bazley 97].

Garramone et al. [86] conclude that the aloneness and the anonymity of CMC may encourage online users to connect more intimately to others in society.

Hartman et al. [91] insist that anonymity can give shy, critical, and considerate people the opportunity to comment without personal repercussions. The idea of being alone with one's terminal may lead to a letting down of barrier and face-maintaining behavior. Students who normally feel shy in a classroom setting often feel more comfortable, and less embarrassment, communicating electronically with the instructor and other students [Hoare & Race 90]. Interaction among instructors and students can be enhanced because students can reiterate or ask follow-up questions without the concern that their questions will be naïve [Manning 96].

Expression Equality

CMC has been described as a venue where participants can participate in discussions on bulletin boards and listservs equally [Sproull & Kiesler 91]. Van Gelder [90] referred to CMC as "egalitarian." The democratic openness of the computer conference environment allows all students an opportunity to contribute. Harasim [96] described the possibility "...for anyone to become an information provider for others, thereby both democratizing information access and enabling new roles for network users. In the most successful online courses, students assume some of the roles that traditionally belong to the instructor" [p. 208]. Democratic openness, the absence of nonverbal status cues, teacher-student role reversal, and learner-to-learner interaction within a CMC environment provide an opportunity for a more equal platform for communication and more stimulus for action than does a traditional classroom [Sproull & Kiesler, 91].

One-to-Many Communication

Listserv is a one-to-many communication that fosters online interaction among students and instructors. Many distance courses utilize listservs for class discussion. A number of studies have examined the use of listservs in this setting. Blocher [97] reported that students rated the listserv as having the highest ability for interaction with peers because of its one-to-many nature. Piburn and Middleton [97] also found that the listserv has generated an increasing volume of correspondence on a wide variety of topics. Some students have recognized the interaction as a means of collecting relevant articles and other tidbits of information. The students initiate the conversations, thus, reversing their roles with the teachers, the teachers answer questions, and the students react. This process increases learner control. Long and complex conversations develop on listservs, as students explore their developing understandings of both content and pedagogy that enhance learner-content interaction as well.

Listserv tends to be more readily available than bulletin boards. The listserv messages come to users' e-mail accounts, unlike bulletin boards, which require users to visit the board to retrieve the messages. As long as users check e-mail messages regularly, listserv users can be reached more easily than bulletin board members can; but the bulletin board provides better learner-interface interaction because of message threading.

Access-Availability

Accessibility and availability of CMC augment interaction among learners, teachers, and content. Internet instruction with hypertext is available continuously where ever there is Internet access. Students are able to access the content any time and anywhere. Kahn and Brookshire [91] integrated a computer bulletin board in a social psychology course; the bulletin board expanded the learner-teacher interaction as well as interaction among students, and it allowed students have easier access to their instructors. Hoare and Race [90] reported a similar finding that class discussion on a bulletin board could continue around the clock because students are free to enter comments any time that the computer system is available. The longer period of time allows greater student access to instructors and may increase learner-instructor interaction.

Collaboration and Student Publishing

Computer conferencing supports collaboration among learners, instructors (experts), content, and media. The learning and interaction that occur in environments that employ CMC encourage collaboration and teamwork and require active rather than passive participation. Blocher [97] argued that peer collaboration requires positive interaction and provides learners with dialogue that can help clarify confusing course material as well as grasp understandings that might go beyond the individual's conceptions. Good management of peer learning also includes making intelligent choices in selecting a peer. Collaboration should not be limited to peers only, computer conferencing supports the individual through a social network of peers as well as the instructor via collaboration and teamwork in which participants share the roles of both expert and novice [Harasim 96]. Through a computer conferencing system one collaborative group can link with other collaborative groups with similar projects both nationally and internationally, access experts or communities of practice, access resources and network with peers [Harasim 98].

Student publishing via CMC is another method of increasing learner-learner interactions, learner-content interactions, and the quality of the interactions in a technology based learning environment. Jonassen [96] argued that when learners have a wider audience for their writing or other scholarly activities, they tend to invest more effort in the process and learn more because there are more learner-learner and learner-content interactions involved. Cohen and Reil [89] found that assignments written to communicate with peers by using an electronic bulletin board and e-mail were more fluent, better organized, and clearer than those that were written merely for grades. Authoring newspapers and booklets collaboratively by collecting articles from partner schools around the world by using bulletin board and e-mail results in better use of grammar and syntax [Riel 90]. Student publishing also can be taken one step further by using an online database [Tu 99] to increase learner-content interaction and to enhance students' knowledge construction. Jonassen et al. [95] argued that in a distance education environment, remote access to online databases facilitate the construction of knowledge. Retrieved information can be used to support positions in a computer conference discussion, for elaboration on a particular topic, or for satisfying personal curiosity. Turning students' works into searchable databases can attain the construction of knowledge.

Time Delay

Asynchronous CMC tools, such as e-mail, bulletin board, or listserv, provide more time for students to reflect on their communication. The time delay allows students to prepare their comments and assignments more carefully, a definite advantage when English is a second language, as well as reducing the student's anxiety during examinations [Johnston 84]. This ability may afford users enhanced opportunities for selective self-presentation, rendering qualitatively different interpersonal impressions than they might convey in synchronous CMC or face-to-face communication. Students can take advantage of the time delay inherent in the asynchronous CMC systems to reflect and compose coherent responses. A study on the use of e-mail in a reading education class [Anderson & Lee 95] has shown that reflective thinking does occur among students in e-mail interactions.

CMC Inhibit Interactions

The attributes of CMC with an inappropriate instructional design are likely to inhibit online interactions among students, teachers, content and interface.

Less Computer Literacy Skill

Literacy skills are required to achieve desired activities and goals when CMC is integrated into the classroom. These computer literacy skills include keyboarding skills, reading skills, writing skills, and general computer operation skills [Perse et al. 92]. People who cannot read or write well (or who believe they cannot), or type will become the computerized society's new "handicapped" group [Phillips 83]. The nature of CMC is currently grounded in its emphasis on English writing skills because of its text-based orientation. The text-based character of CMC is an important issue for individuals of foreign origin. Communication written with a keyboard can be used as

an ideologically charged tool for either cultural domination or cultural survival [McLaughlin 91]. For cultures that have historically transmitted their teaching through oral traditions, such as Native Americans [Baldwin 95], and have been introduced to a typing keyboard, such as Asian students, the use of English text introduces a huge disadvantage for the student and inhibits interactions. Computer literacy skills apply to students as well as instructors or moderators. They should have the ability to resolve hardware and software problems encountered which affect the online discussion and create anxiety.

Privacy

The issue of privacy affects the social psychology of telecommunication. The debate regarding the private/public aspect of online communication is a major issue that deserves further scrutiny. All CMC systems are considered public [Witmer 97]. Computer conferencing should remind the online user of the spectrum of electronic surveillance and the negative impact eavesdropping produces on interactions. More than a third of the online users responded with the statements that "information can come into the wrong hands" and "outsiders can see private messages" [Kerr & Hiltz 82]. The communications and activities of an online course are largely public if the course is structured for collaborative learning and the students examine each other's work. This is very critical when the discussion topic is sensitive or personal. Some users are aware of this, while others are not. Steinfield [86] found that users were reluctant to employ electronic mail for confidential matters. Users generally perceive e-mail as not being private. When an environment is perceived as public, interaction and communication are curtailed. The public nature of a virtual classroom will have a negative impact on student learning.

Impersonal

De-individuation occurs when people have anonymity or when the situation lacks societal cues, mores and values [Sproull & Kiesler 91]. According to Kiesler [86], "without nonverbal tools, a sender cannot easily alter the mood of a message, communicate a sense of individuality, or exercise dominance or charisma.... Communicators feel a greater sense of anonymity and detect less individuality in others" [p. 48]. Saunders and Heyl [88] reported that some students complain about the disjointed nature of dialogue on computer conferencing systems. Recent studies have found that CMC technologies are not inherently personal or impersonal [Walther 96]. The amount of interaction among learners and instructors is inhibited if the communicators are technologically inexperienced, and if they are unable to emphasize the special stylistic [Sallinen-Kuparinen 92] and persuasive strategies required or if the teacher/moderator is unable to create a sense of social presence.

Longer Process

Both synchronous and asynchronous CMC systems tend to take longer process than face-to-face communication. There are data that demonstrate that CMC groups took longer to reach a decision than face-to-face groups; some CMC groups even failed to achieve consensus at all within the allotted time [Gunawardena & Zittle 97]. Walther [96] argues that on a CMC system interpersonal effects normally occur more slowly. Gunawardena and Zittle [97] examined this nature of CMC, and reported agreement among participants that there were more social and personal messages toward the latter part of a CMC conference than during the initial stages, because student responses are longer and more complex than those created through face-to-face discussion. This may discourage many online learners and produce a negative impact on interaction, particularly in e-mail, bulletin board, and listserv settings. Due to the time delay experienced in asynchronous CMC discussions; participants may have difficulty maintaining a clear impression about the topics being discussed.

Communication Style and Domination

Personal communication style may have a negative impact on interaction, if one is not familiar with the written online communication style [Bazerman 94]. Gunawardena and Zittle [97] concluded that instructors who rely on nonverbal cues to provide feedback, and who have a lesser-developed ability to project their personality, would need to learn to adapt to CMC media by developing skills that create a sense of social presence. Being unfamiliar with

online communication style will negate the socio-emotional sense and cause participants to sense a lower degree of social presence thus inhibiting learner-learner and learner-instructor interactions. Therefore, online users, teachers and students, must learn how to use "emoticons" to express the missing non-verbal cues in text-based CMC systems.

Although CMC systems have been found to provide equal participation for online learners [Gunawardena & Zittle 97], opposite findings have been reported. Domination of the discussion on CMC could have a negative impact on interactions. Selfe and Meyer [91] found evidence that men and high status participants dominate e-mail discussions. Herring [94] observed that in mixed-gender discussion lists men seemed to do most of the talking, attracting attention to themselves, although not all men were as adversarial as they were vocal; but, she found men often dominate discussions even when the topics were female oriented.

Uninhibited Behavior

Uninhibited behavior may have negative impact on interaction. Although "flaming" behavior is rare in the CMC environment [Lea et al. 92], insinuating and offensive messages can be spread easily in some newsgroups. CMC users are able to create multiple identities and socialize with different people with both pseudo and real identities at the same time. The user's self-awareness is reduced and inhibited behavior results. A number of researchers [Lea & Spears 91] focused on the perception of the medium it appears that a writer's relation to a screen and electronic communication seems different from a writer's relation to a written letter or memorandum. Writing on a screen will cause communicators to lose the sense of an audience, become self-absorbed, and lose the constraints and inhibitions that the imagined audience provides. Therefore, roles become less clear, and it is difficult to discern who is producing information for whom [Vian & Johansen 81]. This false sense of anonymity that students feel when using e-mail prompts some to send messages electronically that they would never dare say in a face-to-face interaction [Manning 96].

Conclusion

Computer-mediated communication can enhance and inhibit interactions in distance education and communication. Characteristics of CMC, the design and use of instruction and the users' perception of the medium are critical points to be considered when attempting to utilize CMC to enhance online interaction. Integrating CMC into classrooms requires an understanding of the relationship between CMC, the learners, and the instructors. Increasing all four types of interactions requires a thorough understanding of the strengths and weaknesses of each CMC system and the users (students and teachers) is necessary to integrate CMC technology into a virtual classroom.

Abstract: This paper describes a project funded by the commonwealth of Pennsylvania, Link-to-Learn technology testbeds. The purpose of this project was to design, develop, implement, and evaluate a hybrid information delivery system that integrates the broadband capabilities of direct broadcast satellite (DBS) and the peer to peer attributes of narrowband Internet technologies. The hybrid system was designed to integrate networked, broadcast, digital, interactive and multimedia technologies for delivery of media rich content to targeted users. This project demonstrated the use of these technologies in selected K-12 classrooms and community agencies in the Lehigh Valley of eastern Pennsylvania.

1. Introduction

The emergence of Internet technology as a transport for distributing and accessing teaching and learning resources has provided opportunities to create new and unique learning environment. Riley [Riley 1998], U.S. Secretary of Education, acknowledged this phenomenon by pointing out in his speech that connecting every school in America to the Information Superhighway, and helping every teacher develop the tools and skills they need to enhance student learning through technology are two of the goals of the technology literacy challenge for the U.S. Department of Education in the 21st century. However, limited bandwidth of the Internet is one of the obstacles that currently hinders the quality and speed of instructional materials delivered over the Internet. In addition to limited bandwidth, many of rural areas do not have the infrastructure to provide the Internet access.

For educational purposes, data transmission speed and bandwidth are crucial to high quality educational materials delivered via the Internet. Conventional LAN based network may provide the transmission speed needed, however, it is sometimes too costly for some schools who are not able to afford to implement or even impractical for the schools in rural areas. According to the Communications Industry Researchers (CIR) report, the broadband satellites provide a promising alternative to conventional LAN based network solutions. To facilitate students and teachers access to the Internet at low cost, thus enabling them to receive a variety of instructional materials, such as images, audio, animation, and video efficiently, the hybrid system of broadband satellite and the Internet may provide one solution especially for schools in the rural area.

2. Project Goals and Objectives

The goals of the this project were: to assimilate, deploy, and evaluate a hybrid Internet and Direct Broadcast Satellite (DBS) system linking digital content with targeted K-12 schools in the region with advanced digital telecommunications, computing, and information technologies for the purpose of creating and delivering enhanced interactive broadband learning media; to create networkable interactive digital multimedia learning materials to be deployed through a regional digital library; and to foster innovation and experimentation in the design, development,

and deployment of digital learning materials utilizing delivery systems capable of accommodating different learning styles based on either learner-controlled and/or teacher-controlled learning environments.

2.1 Objectives

The objectives of this testbed project were to create and evaluate the following infrastructures for the creation and distribution of digital media learning resources:

- (a) A single stand-alone DirecPC workstation with access to both the Internet and Direct Broadcast Satellite transmission of media resources (Test Sites: Bethlehem, Parkland, Centennial, Hispanic American Organization, WLTV Channel 39, Service Electric Cable Company, and Lehigh University),
- (b) A DirecPC workstation with access to Direct Broadcast Satellite transmission of media resources for distribution on a LAN (Test Site: Schnecksville Elementary School, Parkland School District),
- (c) Satellite digital video media (MPEG I) transmitted from the Direct Broadcast Satellite and redistributed to project partners.
- (d) A single stand-alone DirecPC workstation with a portable receive dish that can be repositioned as the Educational Space Shuttle travels to diverse and remote locations to redistribute media resources received from the Direct Broadcast Satellite,
- (e) Create curriculum-based digital media resources for archival to and distribution from a Regional Digital Distribution Center at Lehigh University.

The content delivered in these test environments were the Video feed and Internet resources created for the JASON IX: Oceans of Earth and Beyond expedition, the CNN video feed from the Hughes transponder, and digital media content, Coral Reefs, created as a result of objective (e) above.

3. Partners

Partners collaborating on this project include the Bethlehem Area School District, the Parkland School District, the Centennial School, the Diocese of Allentown, the Hispanic American Organization, the area public broadcasting station (WLVT Channel 39), Service Electric Cable Company, and the Interactive Digital Multimedia Research and Development Laboratory at Lehigh University. Major corporations participating in this project on a contractual or service basis are Hughes Technical Operations Company and Service Electric Cable Company.

The immediate beneficiaries of this project were selected middle school age children in the Parkland School District, high school students in the Bethlehem Area School District, elementary school age children at Holy Child Elementary School, the severely emotional disturbed learners attending Centennial School, and the learner constituents served by the Hispanic American Organization of the Lehigh Valley. While elementary, middle, and high school age children were the primary beneficiaries of this test project, the benefits of these technologies can be extended to any individual or group of individuals in either a formal or informal setting depending only on the nature of the content to be delivered and access to Direct Broadcast Satellite and the Internet, and in some cases access to high speed ATM fiber networks.

4. Technical Description

The computing and telecommunications industry has drawn considerable attention with the emergence of two different but complementary technologies. The Internet has captured the imagination of the educational establishment, corporate America, and the individual consumer. More recently Direct Broadcast Satellite (DBS) systems have gained some prominence by offering high-speed data transmission (DirecPC) and broadcast quality television (DirecTV) to corporate America and into the home. The Internet has been characterized by a narrow bandwidth technology in most cases inadequate for serious interactive multimedia interchanges; impregnated with html formatted content; governed by a set of standard protocols (TCP/IP and HTTP); and generally perceived to have limitations of speed and service to remote areas by conventional means. Direct Broadcast Satellite on the other hand offers Internet access at speeds exceeding ISDN connections by a factor of 3 and at considerably less cost.

Direct Broadcast Satellite technology can deliver video on demand and high-speed connection to the Internet today. Five services/bandwidths to transmit information based on the users' needs are provided: (1) Turbo Internet Service—based on TCP/IP protocol. Users can get 400kbps average bandwidth from the total 24 Mbps bandwidth. (2) Multimedia Service—provides 1.5 Mbps bandwidth for MPEG-1 or AVI video broadcast or real-time media streams. (3) Package Delivery Service—deliver file packages to users at 3Mbps speed. (4) File Broadcast—transfer files to unlimited number of users using push technology at speed of 3Mbps. (5) Package Explorer—Users can download information package at the speed of 3Mbps [Black 1998; Montgomery 1997]. Direct broadcast to a host server and distributed via high-speed (ATM fiber) local area computer networks and Intranets have been demonstrated to be an effective means for delivering interactive learning materials to the desktop [see Figure 1].

Figure 1.

Unlike the point to point connectivity model of the Internet, the digital broadcast medium has demonstrated its ability to be used in real-time or in download mode to broadcast, multicast, and pointcast a set of educational materials and content on a pre-arranged schedule or on demand. Methodologies to capitalize on the broadcast medium also include the use of cable. Broadcasting can fully complement access to the Internet or can be deployed stand-alone, that is, without a terrestrial network. Direct Broadcast Satellite and cable networks have demonstrated their capacity to enable broadcast applications and services. In addition, standard developments such as Digital Video Broadcast (DVB) and recent deployment of DBS systems such as DirecTV and DirecPC have created ready access to the technology and the services and applications of broadcasting to the classroom.

Figure II. DirecPC/DirecTV System.

Previously unrealized video on-demand, interactive television models and interactive multimedia applications have been replaced by the realities of the emergence of the massive deployment of DBS and the Internet. As a result

BEST COPY AVAILABLE

access to DBS and the Internet can offer a competitive alternative or complementary adjunct to terrestrial network systems for delivery of the same services.

5. DBS/Internet/LAN Infrastructure

The DBS solutions are ideal for massive distribution of educational content organized for delivery to a single point client device or a Video Server for subsequent dissemination. The broadcast delivery mode enables the universal deployment of broadcast, multicast, and pointcast media. This therefore makes it suitable for :

- uniform content delivery to all schools and homes in a geographic region.
- targeted content delivery to a subset of very disperse schools, or
- targeted content delivery to only one target school in a remote region.

This implies that in addition to providing access to all forms of content anywhere, the same deployment over DBS can be configured to provide multilingual capabilities via audio tracks, multimedia tracks, or different text tracks. The Model exploits extensively the educational potential of standard formatted MPEG content, because of the rich set of educational content that can be packed in short clips of multisensory media and its applicability for transmission via Direct Broadcast Satellite.

6. Value as a Testbed

Direct Broadcast Satellite technologies conform to standard data transmission protocols that are compatible with most telephone, cable, and computer network systems. Consequently, the DBS technologies can be combined with any of the standard network systems to form regional hybrid network configurations compatible with a statewide telecommunications system as envisioned for the Commonwealth PEN network system. DBS technologies are both competitive and complementary to terrestrial-based delivery systems. The DBS system offers the prospect of broad bandwidth distribution of curriculum-based media resources at an affordable cost to school districts. Indeed, DBS technologies provide the enabling technologies for video on demand or on a scheduled basis from regional, national, or international databases of mediated curriculum. In addition, DBS technologies promote the development of shareable curriculum-based media resources archived in digital libraries.

7. Evaluation Results

The outcomes and benefits projected for this project were measured against the following criteria: (1) system reliability, (2) information transfer rate, (3) ability to rapidly scale and deploy systems, (4) the quality of transmitted resources, (5) compatibility with existing terrestrial networks, (6) the competitive and complementary nature of the DirecPC system; (7) user acceptability; (8) efficacy of procedures for creating curriculum-based media resources for archival to and distribution from digital libraries, and (9) adaptability to other communities. Instrumentation for assessing the project outcomes was developed to evaluate the project relative to the criteria listed above.

7.1 System reliability

The project personnel experienced problems with the initial setup of the Compaq Theatre, primarily with the 36 inch monitor (two of four had to be replaced) and problems with the TV tuner card for the Gateway System. On May 19th, 1998, the Galaxy IV satellite disappeared from its orbit and could not be contacted. Subsequently, the DirecPC dishes had to be repositioned to point to a new satellite, Galaxy III-R. The new satellite required an update in DirecPC software and the implantation of a new PCI card. The new PCI card created hardware conflicts with both the sound boards and the video cards on both the Gateway and Compaq systems. These problems were resolved by the project technician. The type of hardware and software problems encountered were not the type one would typically expect the classroom teacher to fix nor for that matter many computer technicians. One must understand however, the convergent systems were basically new technologies. It should also be noted that on the other hand, Compaq has discontinued the production of the PC Theatre and Gateway has enhanced their Destination System improving both the quality and size of their monitor with an improved computer box design having the analog and digital connections on the front panel of the computer rather than on the rear of the computer.

7.2 Information transfer rate

Multiple readings on different media applications were taken at three different times during the day: morning, noon, and early afternoon. See the matrix chart of times, file formats, encoded bandwidth rates, and download speeds [see Table I]. Use comparison charts: 56, 300, 500 kps.

DirecPC transmission speed testing results

Time	Format	bandwidth	10/14/98	10/15/98	10/19/98	10/20/98	11/02/98	11/10/98	11/11/98	Average

Table I.

7.3 Ability to rapidly scale and deploy systems

The DirecPC is a wireless technology with MPEG I and Internet distribution capability to anywhere in the United States and into parts of Canada and South America. Large scale projects utilizing the small dish technology have been or are being established in the rural communities of California and Nevada.

7.4 The quality of transmitted resources

Direct broadcast of MPEG I encoded video to client station via DBS produced VHS quality video, 30 frames/sec in screen size 320 x 240 pixels. The best quality transmission of RealVideo encoded video was done at 300 kps.

7.5 Compatibility with existing terrestrial networks

The DirecPC convergent system is compatible with and requires connection to a terrestrial Internet distribution carrier to request information to be down streamed to the DirecPC dish for individual consumption, LAN distribution, or WAN real-time terrestrial distribution systems.

7.6 The competitive and complementary nature of the DirecPC system

BEST COPY AVAILABLE

1132

The DirecPC is competitive with terrestrial ISP providers on several accounts: First the DirecPC can be quickly deployed to geographically dispersed or remote users without an expansive infrastructure. And secondly, the dollar/speed trade-off is favorable for the DirecPC distribution system. New vendors such as Skystream Inc. and others are beginning to offer satellite services.

7.7 User acceptability

Users' responses to a likert type attitude scale revealed a positive predisposition toward system as well as quality of content delivered.

7.8 Efficacy of media-based Instructional Applications

The Coral Reefs application was developed for distribution on the Internet via DirecPC. The DirecPC system permits faster access to digital resources than either 28.8kps, 56kps, or ISDN distribution system. Hughes had recently joined forces with Apollo Group to provide multimedia instructional resources for schools.

7.9 Adaptability to other communities

During the past 18 months DirecPC system have been widely adopted by schools in remote areas of Canada, California, and Nevada.

8. Conclusion

Clearly, knowledge generation and learning now centralized and institutionalized will become distributed and individually paced. The combination of interactive television and the transition from a philosophy of mass communication to custom communication systems will increase both the level of user control and the complexity of design for distributed information and learning systems. It seems quite clear however, that these new systems are doomed to failure unless the learner is provided with some form of embedded help to acquire the prescribed domain knowledge. Hence the need to create new hybrid models for designing and delivering interactive mediated curricula.

The benefits of this testbed project included the identification of affordable communication structures that complement or extend extant infrastructures and add value to the educational process through the shared development and use of educational digital media resources.

Abstract

A basic understanding of copyright law is important for all who write, perform, create, conduct research, and teach. This issue is also becoming increasingly relevant to web developers and users of web pages. Because copyright law is frequently misunderstood, one can easily violate the law and risk the consequence of being sued for copyright infringement. This essay will address the aspects of copyright law pertinent to web users.

The Purpose of Copyright Law

The purpose of copyright law is to give authors an incentive to create literary, artistic and multimedia works by granting five exclusive rights to the original production. These intellectual property rights are granted to authors of copyrighted works by virtue of the 1978 Copyright Act (Title 17 US Code). These exclusive rights are (1) the right to reproduce or copy the work, (2) the right to prepare derivative works, (3) right to distribute copies by sale, transfer of ownership, rental, or lease, (4) the right to perform the work publicly, and (5) the right to display the work publicly.

What Can Be Copyrighted

Anyone who creates a work of original authorship can claim a copyright. In fact, an author owns a copyright the moment the work is fixed to a tangible medium (paper, computer disk, video tape, cassette tape, web pages, etc.). Works eligible for copyright protection include (1) musical works, (2) dramatic works, (3) literary works, (4) choreographic and pantomime works, (5) motion pictures and audio-visual works (most web projects are audiovisual-based), (6) pictorial, graphics, and sculptural works, and (7) sound recordings.

The following categories do not qualify for copyright protection:

1. Works not fixed in tangible form (ideas in your mind)
2. Titles, names, short phrases, slogans, familiar symbols and designs, and letters
3. Ideas, methods, procedures, systems, concepts, principles, discoveries, as distinguished from descriptions, explanations, or illustrations (must be the expression of an idea)
4. Works consisting entirely of information that is common property and contains no original authorship (information that is purely factual in nature)

Notice of Copyright

Once the work is fixed to a tangible medium, the creator is afforded all rights under the law (unless the work was created for an employer as part of the creator's job duties). A copyright mark is not required unless the work is published and copies will be publicly distributed for sale. Copyright law does not require advanced permission of the copyright office in order to put the copyright notice on those works. Actually, it is the copyright owner's responsibility to apply the copyright notice to the work. The Copyright Office recommends that the notice contain three elements: (1) symbol (c), the letter C in a circle (©), the word copyright, or the abbreviation "copr.", (2) year of the first publication of the work, and (3) name of the owner of the copyright.

By giving notice of copyright (such as at the bottom of a web page) and registering the works, legal advantages become available. Notice along with registration allows the copyright owner to defend his valuable copyrights in Federal Court. The owner is also entitled to greater remedies in the form of damages and attorney fees.

Copyright Infringement

Copyright infringement occurs when a person exercises another's exclusive rights without permission. Copyright infringement requires the claimant to show (1) proof of an existing copyright (expression of idea and fixation) and (2) the exercise of another's exclusive rights without permission.

When multimedia developers scan images and download pages off the Internet, they have exercised the owner's right to reproduce the work. The right to prepare derivative works is further violated when developers use the copied work in their new creations. When these rights are exercised without permission, the second factor of the infringement analysis is satisfied. Once these factors are established, the faculty member must be able to prove that his use is justified under the doctrine of fair use. The next section explains this defense.

Fair Use - The Educator's Defense

The fair use doctrine of the Copyright Act (Title 17 US Code, Section 107) permits certain uses of the copyrighted works without the owner's consent. The statute provides that a copyright is not infringed if copies of a protected work are made for purposes of (1) Criticism, (2) Comment, (3) News writing, (4) Education, (5) Scholarship (student use), or (6) Research.

The fair use doctrine is the affirmative defense to a copyright infringement claim. It is commonly misunderstood that all academic uses fall underneath fair use. Nothing could be further from the truth. Even if the use is educational, it must pass a four-prong test set forth in the Copyright Act. Congress created this test in order to balance the interests between the author's incentive to create intellectual property and society's need to educate the public. The four factors include (1) purpose and character of use, (2) nature of the work used, (3) quality and quantity of the work used, and (4) market effect.

Purpose and Character of Use

Educational use is looked at more favorable than uses for commercial gain, but this factor is not determinative. Where new creations are the subject of scrutiny, the work's transformative nature can also play into the multimedia developer's favor. Transformation occurs when work is taken from one form (painting or drawing) and expressed in a different form (like an audiovisual work). Transformation also occurs when certain elements of a work are changed in order to change the expression of the work. An example might be where the original work's colors are changed, or where certain tangible images in the work are added or deleted.

The Nature of the Copyrighted Work

Uses of works that are factual are looked upon more favorably than works that are fictional, imaginative, or creative in nature. For example, lets suppose that I scanned an image of a "Dilbert" cartoon character off a web page that I came across and placed the image in my own web page. This factor would not help me because cartoons are considered to be very imaginative and creative in nature.

The Quality and Quantity of the Work Used

Quantity is measured by comparing the amount of the work used to the entire work. While there are no established black-letter rules to us exactly what percentage of a work can be used, it is well established that copying an entire work is usually forbidden. As a rule of thumb, most legal experts recommend that users restrict their usage of copyrighted works to less than 5% of the entire work.

Effect Upon the Potential Market for the Copyrighted Work

Many copyright authorities suggest that this is the most important factor in the fair use test. The court takes into account all possible affects of the infringement upon the owner's ability to effectively market the work. For example,

let's suppose that I came across a very informative article about how copyright relates to visual art. Let's also suppose that I took most of the text from this article and placed it into my own web page or PowerPoint presentation. A court might decide that I should have paid a permission fee in order to use the work.

All four factors are considered by courts in determining whether a person's conduct falls within the scope of fair use.

FAQs About Copyright Law Applied to the Web

Use of the World-Wide-Web has raised new concerns relative to copyright law and fair use. Those issues relate to frequently asked questions (FAQs) about all types of resources available on the Web.

FAQ #1: Can I freely copy anything that is on a web page?

Making materials readily accessible to others via the Web does not mean a person has relinquished copyright. Works are considered public domain only if the author expressly puts the work in the public domain, the copyright has expired and was not renewed, the information is purely factual, or the information is a federal government document (report, statute, treaty, law, etc). Even though materials on the Web can be used freely by anyone, it is still important to consider fair use before copying anything seen on the Web. The amount of work copied will be very important in considering whether fair use applies. It is also important to remember that the nature of the work copied (factual or fictional) will also be important. When in doubt, ask permission.

Since it is sometimes difficult to discern whether or not material on a web page or even a web server is copyrighted, it is very important that ownership rights be considered. Many web pages now have the name of the WebMaster or other person to be contacted for questions regarding the content on the page and its subsequent use. Even if a person has permission to copy something from a web page, the entire resource may not be usable if the web page incorporates the work of multiple authors. Unless the person granting permission actually owns all right to the work, the person copying the web page could be held liable for infringement.

FAQ #2: Can I freely link to web sites?

Linking to other web sites raises several questions about copyright. It can be argued that a URL is not copyrightable because of its functional character for locating a web page. However, this type of link established for a web site is still a concern. Because of issues related to copying and displaying an image, it is recommended that an IMG link not be made to a web site without permission. Of course, practical concerns like the image being deleted or changed without your knowledge could also lead to problems for others utilizing your web page.

Most links used on web pages are known as HREF links because they reference other screens and cause them to appear when activated. This practice is acceptable because it promotes easy access to related groups of material and information. One exception to HREF links has evolved with the recent development of frames for web pages. The controversy centers upon others surrounding the content of a frame with advertising or editorial content, which can be misleading or confusing to the viewer relative to the original intent of the content.

FAQ #3: Can I freely download or print a resource posted on the Web?

Although information on the Web is easily accessible, one must assume that this information is protected by copyright unless it is known that the copyright owner has granted express permission to copy the work, the information is a factual government document, or the copyright has expired. Fair use limitations for materials found on the Web are essentially the same as the fair use of materials disseminated by any other means. Single copies of short items for a person's own study may fall within fair use. It has been argued that if the work is freely available on the Web, making copies will have little to no effect on the market because no commercial market for the work has been established or claimed.

However, some publishers argue that the potential market for charging Internet users for each copy means that any copying hinders the market. This is an issue of intense debate. Whenever in doubt as to whether the use qualifies for fair use protection, ask permission from the Webmaster or copyright owner.

FAQ #4: Can I freely scan images and text and use them on my web page?

The short answer is no, especially since it also depends upon the amount of materials being scanned and their intended use. While it is easy to scan images or text out of magazines, books, or other sources and place computer readable copies on one's web page, the fact that it is technically easy does not make it legal. Utilizing fair use is very problematic when it comes to images. It is arguable that fair use supports the use of images that make up a small part of the web page from which the image is taken. However, it is also arguable that the image itself constitutes a single copyrighted work, especially where the image is highly creative. The safest course of action is to obtain permission from the copyright owner before using any image found on the Internet.

FAQ #5: Can I use the Web to provide easier access to electronic documents?

Access restrictions has the greatest influence on tipping the factors in favor of fair use. A problem with making text available on any network is that it can be accessible by readers far beyond the intended audience. Restrictions on access through passwords or other systems can enable the instructor to argue that the purpose is solely to benefit the students and not to provide access for others. Restrictions can also limit the potential adverse effect on the market for the original. By limiting the range of users who may find the document, the instructor can minimize or eliminate any possibility that someone will retrieve the work from the network instead of purchasing a copy. Some critics of electronic reserves have argued that the educational purpose and the minimal market effects cannot be controlled because the electronic medium allows users to print, download, and transmit copies at little cost or effort and thereby undermine the restricted access. The instructor must closely monitor the nature of the material posted on reserves and the amount of material from the original source put on reserves.

FAQ #6: Can I freely post other people's e-mail on my web page?

No. To have a copy of the e-mail is not the same thing as to own the copyright. In fact, almost all e-mail, as written, is copyrighted. To qualify for copyright protection, a work must be an original expression of an idea fixed to a tangible form of expression. Most e-mail would meet this requirement. However, e-mail is not always confidential. One can usually report on what is sent by e-mail by spoken word. Also, one who sues over an ordinary message might not get damages because the message has no commercial value. However, to stay strictly within the law, get permission before using another person's e-mail message.

Summary

Issues related to copyright and fair use relative to the Web are still being discussed because of their complexity. While there is clearly implied permission to view web pages and to utilize web links, such an implied license does not authorize the public to do whatever is desired with material found on the Web. This approach is intended to protect the user as well as the developer, but the matter is far from resolved.

Each case concerning possible infringement of copyright brings a unique perspective to consider when judging an appropriate course of action. Clearly, one common sense way to solve the problem of potential liability is to obtain permission from the copyright owner. The legal system also permits some kinds of uses of copyrighted materials as long as it fits within the scope of the fair use test. The best solution would seem to be the creation and development of all of your own materials so that you own the copyright. Although the last option is not realistic for everyone, it is something to consider for the future as the copyright and fair use debate continues.

Preferences of Asynchronous Adult Distance Learners

Michael W. Usrey
Lockheed Martin Engineering Management Program
University of Colorado, United States
michael.usrey@colorado.edu

Abstract: The boom in distance education provides a unique opportunity to serve the growing adult education market, but current asynchronous distance education technologies constrain the teaching-learning exchange. A model of factors influencing the teaching-learning exchange is discussed. Several techniques have been proposed to overcome the limitations of distance education. An overview of some of these techniques is also offered. Finally, measurement of asynchronous adult student preferences regarding these techniques is presented.

Introduction

The imperative for learning organizations and life-long learning in individuals has been recognized for the better part of the last decade [Senge 1990]. Perhaps this is one reason why adult education is the fastest growing segment of the education market [Department of Education 1994]. The merger of collaborative learning and computer mediated communication (CMC) technologies is critical to ensure future educational success [Ben-Jacob and Levin 1998]. Asynchronous learning is the most flexible form of distributed education; that makes it well suited to adult learners [Black 1998]. However, the trappings of distance education have negative effects on both the education environment and the educational community [Hsu and Sammons 1998].

Learning Factors

There are five factors that have primary influence on the teaching-learning exchange [Heimlich and Norland 1994]. These include the teacher, the student, the content, the environment and the learning community. The teacher has primary responsibility for directing the exchange. Individual students are the primary targets of the exchange. The content is the knowledge to be exchanged or expected learning outcomes. The environment includes the physical surroundings and teaching artifacts. The learning community is formed by characteristics and social patterns shared by the students and with the instructor.

Studies have shown that distance education forces teachers to become better prepared, better organized, and therefore more effective [Souder 1993]. The more time that is spent up front, the more confident the teacher will be and, ultimately, the more successful the exchange [Bergmann and Raleigh 1996]. Distance education students tend to be older, more motivated, more self-disciplined, are more likely to possess a college degree, have expectations for higher grades, and, therefore, appear to be more successful than their on-campus counterparts [Champagne 1998]. In asynchronous distance learning, students take more responsibility for their own learning, reflect more deeply on the course content, and benefit from being able to tackle ideas at their own pace [Black 1998]. Learning outcomes are typically similar for traditional and distance versions of the same course, though technological issues can have an impact on the artifacts associated with content delivery [Hsu and Sammons 1998]. The technology associated with distance learning can have both positive and negative impacts on the learning environment. The availability of instructional technology may provide new tools and opportunities for concept visualization [Porter 1997], but learning exchange participants may not be comfortable with issues such as speaking into a microphone, appearing on camera, using an electronic pen or utilizing an electronic group discussion forum [Hsu and Sammons 1998]. Technology has a significant impact on the learning community

1139

[Brown and Duguid 1993]. Both teachers and students depend on non-verbal cues to ascertain, for instance, the level of student attention or whether the instructor would welcome a question. A bound set of the instructor's notes conveys more accuracy and authority than the same set of notes downloaded from a web site [ibid.]. Several techniques and tools have been proposed to overcome the impact of distance education on the learning community. Experiences applying some of these techniques in a graduate course for the management of research and development (EMEN5300) follow.

EMEN5300 is delivered in three modalities: a small number of on-campus students participate live in the studio classroom, a small number of regional students experience synchronous delivery via one-way video, two-way audio Instructional Television Fixed Service (ITFS), while the majority of students participate asynchronously via VHS videotape. The total enrollment was 20 students. The course production values most closely resemble the "you get what you see" (YGWYS) model [Cyrs and Conway 1997]. Students admitted to the program are required to have obtained a minimum of a bachelor's degree in an engineering or physical science discipline, so a higher than average student facility with computers can be assumed. Approximately 10% of the enrollment is believed to include non-native English speakers.

Techniques and Technologies

Course web pages can help synchronize delivery of some material to asynchronous remote students. A good course web page should include information about the course, information about the instructor, methods to facilitate course communications, assignments, text book information, distributed materials and links to related materials [Ackermann 1996]. The EMEN5300 course web page at <http://www.colorado.edu/EngMgmtProg/courses/EMEN5300/> includes these all of elements and more. Approximately 10 minutes were taken during the first course session to describe the course web site for the students.

Listserv is a common tool for CMC on the Internet [Kroll 1994]. Listserv also appears to be a CMC tool of choice at the University of Colorado. Unfortunately, listserv has several limitations, or at least unattractive trade-offs, for asynchronous learners. For international students, there is often a several week delay before they receive the first installment of course materials, including information about the course web site and the listserv. If the list is set up to reflect individual e-mail messages, then remote students tend to miss many of the early posts. If the list is setup to produce digests after a lengthy delay, then on-campus and regional students lose the sense of continuity between lecture delivery and subsequent discussion. In either individual message or digest mode, the asynchronous nature of student access to the course materials virtually assures that the sequence of message topics will be jumbled. HyperNews, a web-based, threaded discussion forum, was used in EMEN5300 in an attempt to address these shortcomings. HyperNews has the benefit of leaving all messages visible without cluttering the students' mailboxes. The hierarchical structure also allows students to view messages in context. Approximately 20 minutes were taken during the first course session to introduce HyperNews.

In a traditional classroom, the students provide dynamic feedback to the teacher through verbal and nonverbal cues [Hsu and Sammons 1998]. For many distance education situations, the feedback system is more like an autopsy where the instructor tries, after the course is over, to determine why assessment scores were lower than expected [Champagne 1998]. Frequent student surveys can help overcome the lack of immediate cues, but they must be convenient to encourage students' use and relatively inexpensive to encourage teachers and the administration [ibid.]. Web-based feedback forms were developed for each course session and linked to the course home page. As the semester progressed, some problems became apparent using specific browsers with the Common Gateway Interface (CGI) program developed for dynamic feedback. As a result, roughly one-third of the students were unable to use the dynamic feedback surveys. Approximately 5 minutes were taken during the first class session to illustrate the use of the dynamic feedback forms.

The instructor should help the students visualize course materials and should reinforce materials through analogy and metaphor [Gagne 1977 as cited in Markowitz 1990]. Clip art, "word pictures" [Cyr and Conway 1997] and PowerPoint animations were used in EMEN5300 to help create visual analogies for course concepts.

Instructors must motivate students to attend to the course materials as they are being delivered. Students who receive handouts can focus more attention on the lecture and tend to do better on tests than those that do not receive handouts [Howe and Godfrey 1977]. However, students that receive a complete transcript or set of instructor's notes can become too passive and attention suffers [Kiwera 1987]. Instructors can strike a balance by providing lecture outlines instead of complete transcripts and by leaving key words blank for the student to fill in [ibid.]. "Interactive" lecture outlines with key word fill-ins were utilized in EMEN5300. Approximately 5 minutes were taken during the first course session to describe the interactive lecture outlines.

Preferences

For most of the techniques in the preceding discussion, students had three opportunities to express their preferences. An online survey was provided after the first course session that provided either nominal or interval response scales. This survey was part of the first dynamic feedback opportunity, so the CGI problem mentioned previously was in force. A mailed survey also featuring nominal and interval scales was administered when the course was about two-thirds complete. After course completion, students had the opportunity to evaluate the course, including the techniques previously discussed, via the university's Faculty Course Questionnaire (FCQ). The FCQ utilizes 5 point Likert response scales from zero (very poor) to 4 (very good). The FCQ also invites open-ended remarks under four headings: most effective aspects, least effective aspects, best ways to improve, and other comments. Participation in all three of the surveys was voluntary and responses were anonymous. Response rates were much higher for the FCQ than for the other two forms of survey; possibly because the FCQ is familiar to the students and is administered by the university instead of the instructor.

The university's information technology service group (ITS) made an unfortunate decision to upgrade the campus web server in the middle of the semester. Students experienced problems accessing the course web site for approximately 1 week and problems accessing HyperNews for approximately 2 weeks. It is believed that this introduced some negative bias towards web-enhanced instruction into the student preference responses.

Web Site

In the initial online survey, students were given the opportunity to rate the course web site as being "Clear & Useful", "Confusing & Useful" or "Useless". Eight students responded to the voluntary survey; 88% characterized the course web site as "Clear & Useful" and one indicated the site was "Confusing & Useful". The respondent that indicated that the site was confusing made the open-ended remark, "In the beginning, the web system structure is confusing but it is just matter of time and hands-on experience." The other open-ended remark related to the course web site on the initial survey was, "I find it beneficial to read/look over the view graphs prior to class. They also help me focus on the key points of the references." This was probably a reference to the fact that the other instructors' hardcopy slides are distributed with the videotapes, but the online slides helped this particular student with the reading assignments which are to be completed before the associated lecture. This unexpected, but beneficial result reinforces the notion that the goal of handouts is to focus students on the key lesson points [Cyr and Conway 1997]

In the mailed survey, students could characterize the course web site as "More Convenient", "Equally Convenient" or "Less Convenient" than traditional distribution methods. Nine students responded with 67% opting for "More Convenient" and 22% choosing "Equally Convenient". Two respondents made open-ended remarks suggesting the addition of a key word search capability for the course web site.

BEST COPY AVAILABLE

1141

In the FCQ, students were asked to rate the feature of downloading course materials from the web site. Seventeen students responded yielding an average score of 3.8 out of 4. One of the responses characterized the course web site as "Neutral" and none characterized this feature as either "Poor" or "Very Poor". The remainder classified the course web site as either "Good" or "Very Good". There were four open-ended comments which all indicated that the course web site was one of the most effective aspects of the course.

Taken together, these results seem to indicate a consistent, strong preference for the "Ackermann-style" web site. Since links to all of the remaining tools and techniques described herein were provided on the course web site, there may be some confounding of responses between this category and the others.

Threaded Discussion Forum (HyperNews)

In the initial survey, students were asked to rate HyperNews as being "Clear & Useful", "Confusing & Useful" or "Useless". Eight students responded; seven deemed HyperNews to be "Clear & Useful" and one indicated that it was "Confusing & Useful". There were no open-ended remarks about HyperNews from the initial survey.

In the mailed survey, students had the opportunity to indicate whether HyperNews "Improves Interaction", has "No Impact on Interaction" or "Degrades Interaction". Nine students responded to the question with 78% indicating that HyperNews "Improves Interaction". The remaining responses indicated that HyperNews had "No Impact on Interaction". The only open-ended remark about HyperNews was that the student wanted to "roll up HyperNews by discussion topic group". It is not clear what capability the student sought, but they may have been able to achieve the desired result using some combination of the HyperNews "Inline Depth" and "Outline Depth" features. In the future, more time will be spent discussing these features during the HyperNews training.

On the FCQ, the average rating for HyperNews was 3.2 out of 4. Two students out of 17 responding rated HyperNews as "Neutral" and one student rated it as "Very Poor" while the remaining responses were either "Good" or "Very Good". There were three open-ended comments about HyperNews from the FCQ that would be considered favorable. Two remarks indicated too much of a lag between assignment of the discussion question and full participation. These remarks reflect the broad geographic distribution of the videotapes and the instructor's reluctance to have strict deadlines on weekly discussion questions. While some students clearly needed this flexibility to accommodate work-related travel and family issues, other students clearly abused the system. Imposition of some sort of graduated discussion deadlines will be adopted in future course offerings.

Acceptance for HyperNews averaged approximately 80%, though the lowest rates were recorded with the second survey. This might be attributable to sampling variation. This "dip" may also have been caused by the extended down time experienced during the mid-semester server upgrade.

Dynamic Feedback

In the initial survey, students were asked to characterize dynamic feedback as having the potential to "Improve the Course", have "No Impact on the Course", or "Degrade the Course". All eight respondents indicated that dynamic feedback would improve the course. There were no open-ended responses related to dynamic feedback reported from the initial survey.

Students were offered the same range of responses with regard to dynamic feedback in the mailed survey. Six of 9 respondents indicated that dynamic feedback had improved the course and the remaining responses indicated that dynamic feedback had no impact on the course. The students offered no open-ended remarks regarding dynamic feedback with the mailed survey.

For the FCQ, the average rating for dynamic feedback was 2.8 out of 4. Nine of 15 responses rated dynamic feedback as either "Good" or "Very Good", 5 responses indicated that dynamic feedback had no impact and one respondent characterized dynamic feedback as "Poor". The students offered no open-ended remarks.

There was a downward trend in student opinions regarding the effectiveness of dynamic feedback. This may reflect that fact that the dynamic feedback CGI was incompatible with the browsers utilized by some of the students. It may also reflect a difference in students' perception of the its potential early in the course versus the perceived level of execution or follow-up as the course progressed. One factor that is thought to have impacted the effectiveness of the follow-up is related to dynamic survey design. The instructor made an effort to incorporate all of the dynamic feedback provided, but the anonymous nature it difficult to "close the loop" with the student who provided the feedback and assure them that their feedback had been acted upon. There is a fundamental trade-off between anonymous surveys that encourage complete response candor and attributed surveys that give the instructor the most information and flexibility to address any issues that are raised.

Another factor appears to have been the lag in videotape delivery. In the case of international students, tape delivery lags were typically in excess of two weeks. There would be additional delays before the student actually viewed the tape, before the student completed the online survey, and before the next class broadcast. It is difficult to have the entire class "backtrack" after such a significant delay to clarify a point that may be confusing a single student. Once again, the anonymous nature of the survey precludes the instructor from pursuing one-on-one remediation. More research seems justified to characterize this trade-off between anonymous and attributed feedback.

Visualization

This technique was not explored in the initial online survey. In the mailed survey, students were asked to indicate whether clip art, word pictures and animation "Improved Understanding", had "No Impact on Understanding", or were "Distracting". Seven out of 8 responses indicated that the visualization aids "Improved Understanding" while the remaining respondent indicated that this technique had "No Impact on Understanding". The only relevant open-ended response indicated that the student liked the use of visualization techniques, but the thoughtful respondent was concerned about the amount of effort that visualization imposed on the instructor!

For the FCQ, the average rating for visualization was 3.5 out of 4. Two out of 17 responses were "Neutral" toward the technique with the remainder characterizing it as either "Good" or "Very Good". No open-ended responses were offered on the FCQ with respect to visualization techniques.

Strong, consistent support for visualization techniques is clearly indicated.

Interactive Lecture Outlines

For the initial survey, students were asked whether the requirement to fill in blanks on the handouts would "Aid Focus" or "Distract". Five responses indicated that the blanks would "Aid Focus" while one suggested that they would "Distract". There were no open-ended remarks regarding the blanks from the initial survey.

In the mailed survey, response alternatives ranged from "Increase Attention" to "No Impact on Attention" to "Distract". There were three responses in each category. There were no open-ended remarks about the handout blanks among the mailed survey responses.

With the FCQ, the average rating of blanks on the handouts for sixteen respondents was 3.0 out of 4. One respondent each characterized the blanks as "Poor" and "Very Poor" with the remainder rating them either "Good" or "Very Good". One student mentioned handout blanks as among the least effective aspects of the course in the open-ended FCQ remarks. Another indicated that the use of blanks was not befitting a graduate course. Under the "most effect aspects" heading, one student indicated all of the techniques mentioned in the preceding sections except for the handout blanks.

Average survey responses indicate that handout blanks are preferred by the students. However, the variations between survey results and within each survey are a source of concern. The option of either complete or "interactive" handouts is being considered for future course offerings.

Conclusions

Three of the five techniques investigated (web site, threaded discussion forum, and visualization) appear to be strongly preferred for students similar to those enrolled in our program. Dynamic feedback also appears to be an effective technique, but further research regarding anonymous versus attributed surveys may lead to further improvement. Blanks included with handouts should be applied cautiously; the survey results cited here indicate a great deal of variation in the acceptance of this technique. Further investigation of the factors that influence student acceptance of this technique is also recommended.

Finally, the importance of adequate support for this sort of activity cannot be overstated. The conclusions from this investigation could be much stronger if an unplanned web server upgrade (unplanned, at least, from the instructor's perspective) had not occurred mid-semester and if the commitment to a timely repair of HyperNews had been greater. Timely support to make the dynamic feedback CGI compatible with all of the students' browsers would have increased the sample size and enhanced the validity of the results reported.

Assessment of Alternate Delivery Mechanisms for Asynchronous Adult Distance Learners

Michael W. Usrey
Lockheed Martin Engineering Management Program
University of Colorado, United States
michael.usrey@colorado.edu

Abstract: Unrelenting progress in computer and telecommunications technology is creating new opportunities and new challenges in distance education. These technologies have the potential to free students and instructors from the bonds of time and space. However, the adoption of new technologies should not exclude prospective students. The development and evaluation of an online alternative to videotaped lectures is presented. Videotape usage factors, feedback regarding online alternatives, and barriers to adoption of online lectures are explored.

Introduction

Colleges and universities are rushing to implement distance education [Sherron and Boettcher 1997], but are our students ready? Utilizing technology is still problematic for some students [Ingebritsen and Flickinger 1998], so new delivery methods should be as easy to use as the technologies that they replace. Less than 23 percent of households had computer systems in 1993; if the growth trends at the time hold, approximately 30% of households will have computers by the turn of the century [U. S. Census Bureau 1993]. This suggests that adoption of emerging distance education technologies brings with it the risk of excluding large numbers of potential students.

The vast majority of Engineering Management students at the University of Colorado participate asynchronously via VHS videotapes provided by the Center for Advanced Training in Engineering and Computer Science (CATECS). Students return the videotapes at the end of the semester. Courses have low production values, referred to by the CATECS Program Director as "candid classroom". Students admitted to the program are required to have obtained a minimum of a bachelor's degree in an engineering or physical science discipline, so a higher than average student facility with computers and a higher than average rate of computer penetration into student households can be assumed.

Digital Lecture Design

Within a course addressing the management of research and development (EMEN5300), a comparison of alternate asynchronous delivery media was conducted. For the course session on the management of intellectual property (Session 12), asynchronous students were given access to the VHS tapes traditionally utilized with EMEN5300, plus web-based and CD-based (digital) lecture alternatives. The objectives of the comparison were (1) to determine student preferences, (2) to ascertain the penetration of the computer technology necessary to utilize the alternative digital delivery methods, and (3) understand the usage patterns for the current video tapes to improve the design of future delivery systems.

Steps were taken in the delivery media comparison to exert experimental controls over the five factors that influence the teaching-learning exchange [Heimlich and Norland 1994]. Each of the delivery alternatives featured the same instructor and was delivered to the same student population. The session slides, discussion forum and course artifacts were also identical for each of the delivery methods. The session was pre-recorded on VHS and the

audio was extracted for use with the digital media, so the lecture audio content was identical for each delivery vehicle. However, video content posed some interesting trade-offs.

Exclusion of the video from the digital media might cause the students feel as though they were "missing something" and bias them against the digital alternatives. However, inclusion of the video greatly increased the size of the digital files, requiring multiple CD volumes for a two-and-a-half hour lecture, and perhaps slowing content delivery to unacceptable levels. A review of the course video revealed that over 50% of the video content consisted of images of the session slides. These slides were to be available in another multimedia window in the digital delivery environments. Also, with all of the currently available streaming media encoding technology, the resolution of these slide video images would render them illegible. The prospect of over 50% of the video content being both redundant and illegible also presented the possibility of student bias against the digital delivery alternatives. The remaining video content consisted primarily of "talking head" shots of the instructor. One of the most fundamental conflicts in distance learning is whether the content should be adjusted to take advantage of the new medium or reproduced as faithfully as possible given the constraints imposed by the new technology [Ben-Jacob 1998]. Taking all of these factors into consideration, a decision was reached to exclude the video content from the digital delivery alternatives and include a question about the value of the video content in the student preference survey.

Simple navigation was a key design goal for the online lesson. Unlike books and videotapes, there are no widely accepted principles for organizing and navigating the multi-dimensional electronic information space [Bervit 1996]. Principles for organization and navigation were sought that would be applicable across course sessions and across courses. An effort was made to develop an interface that could be deployed via either the web or CD with a minimum of modification. Unix shell scripts were developed to automate the most redundant and time-consuming tasks. Audio for the CDs consisted of full resolution .wav files. Audio for the web was encoded using *VivoActive* because it permits audio streaming via the Hypertext Transfer Protocol (HTTP) so no special web server software or configuration was required.

The starting point for session navigation is the lesson home page. The lesson home page includes the course number and the session number within the course. The page also includes hyperlinks to the outline for the lesson, the table of contents for the lesson slides, a link to the first slide of the lesson and links to contact the instructor. The cover page also includes hyperlinks to download any viewers or plug-ins required for the handouts and the lesson.

Each lesson is decomposed into slides. Slides are generally intended to be viewed sequentially, but the table of contents for each lesson facilitates non-linear traversal of the slides. Each slide includes four areas: the slide image in the lower left corner, an icon returning the user to the lesson home page in the upper right corner, a horizontal navigation bar in the upper left corner, and a vertical tool bar in the lower right corner. The slide image presents the unique material to be covered at this point in the lesson, while the home page icon, navigation bar and tool bar are intended to be consistent across slides, across lessons, and across courses. The navigation bar and tool bar are orthogonal [MacLennan 1983] in the sense that the navigation bar represents movement within the current lesson and the tool bar represents resources outside of the current lesson. The Hypertext Markup Language (HTML) "ALT" and "ONMOUSEOVER" tags are utilized throughout the lesson, so that the buttons are self-documenting.

The navigation bar represents an ordinal scale [Agresti 1990]. The left-hand icon takes the student to an absolute location, the first slide in the lesson. Moving to the right, the second icon takes the student to a relative location, the slide immediately preceding the current one. The middle icon on the navigation bar provides the "origin" for the ordinal scale; it takes the student to another dimension composed of additional multimedia resources that elaborate on the current slide. In most cases, the middle icon takes the student to the relevant audio clip. The session topic was intellectual property management, so the middle icon sometimes linked to another web site with more detailed information, such as the US Patent and Trademark Office or the Library of Congress. The remaining two icons on the navigation bar are complementary to the first two icons. The fourth icon takes the student to the relative position of the slide immediately following the current one. The last icon on the navigation bar takes the student to the absolute position of the last slide in the lesson.

The top icon on the tool bar permits the student to contact the instructor via e-mail. Moving down, the second icon provides the student access to the threaded course discussion list (HyperNews). The third icon on the tool bar guides the student to the home page for the University of Colorado library system. Once there, the student can search for literature by title, author, subject and keyword. The fourth icon allows the student to search all web pages in the colorado.edu domain, including the library system. The bottom icon allows the student to search the entire Internet via the "hotbot" search engine.

Delivery Technology Assessment

Students had two opportunities to express their preferences. A mailed survey was administered immediately after Session 12. This survey featured nominal and interval response scales, plus the opportunity for open-ended response. The mailed survey was reviewed and approved by the University of Colorado Human Subjects Committee. After course completion, students had the opportunity for a less comprehensive follow-up assessment via the university's Faculty Course Questionnaire (FCQ). The FCQ utilizes 5 point Likert response scales from zero (very poor) to 4 (very good). The FCQ also invites open-ended remarks under four headings: most effective aspects, least effective aspects, best ways to improve, and other comments. Participation in both of the surveys was voluntary and responses were anonymous. Response rates were much higher for the FCQ than for the mailed survey; possibly because the FCQ is already familiar to the students and is administered by the university instead of the instructor which may, in turn, inspire more confidence that their anonymity will be protected.

With the mailed survey, students were asked for feedback in three categories: usage factors for VHS videotapes, preferences with respect to the digital delivery alternatives, and equipment barriers to utilizing the digital alternatives.

Videotape Usage Factors

All nine students responding to the mailed survey, from a total enrollment of 20, indicated that home was the primary location for videotape viewing. One student's open-ended remark indicated that they occasionally viewed videotaped lectures during business travel. Seven students indicated that they typically viewed the tapes in one sitting and rarely, if ever, rewound to review. One student indicated that they typically watched in one sitting, but rewound often. The remaining student indicated that they typically watched a single course session in multiple sittings. Two of nine students responding agreed with the idea that they reviewed the videotapes after the initial viewing to prepare for homework and/or tests, while the other seven disagreed with that notion. Three respondents indicated that they would rather be live on campus for the initial lecture delivery, while 6 stated a preference for videotape, and none favored either of the digital alternatives. For reviewing lectures, 3 students preferred videotape, 4 preferred the CD and two did not respond to the question. One of the unresponsive students made the open-ended remark that they preferred to review from the handouts, an alternative not provided on the multiple-choice question. Two students indicated that the audio and video quality of the VHS tapes was occasionally unacceptable. Four students indicated that they would value access to the lecture beyond the end of the semester, but the other five respondents did not attach any value to extended access to the lectures. It is not clear whether students currently enrolled in a course have the proper perspective to know whether they would want access to the materials at some point in the future.

Digital Lecture Preferences

The number of survey responses regarding the digital alternatives was typically smaller because some students lacked sufficient computer resources to fully utilize the web- and CD-based alternatives. Eight out of nine students found navigation in the digital lessons simple and intuitive, while one found it to be complex. Six of seven respondents said that the slides in the digital presentations had the right balance of legible size and fast loading, while one student indicated that the slides needed to be larger. Six of seven also indicated that the opportunity to

embed links to other web sites was valuable, though one respondent stated that there was no additional value to the links. Five out of seven students indicated that the synchronizing aspects of web delivery had the potential to make team projects easier to accomplish.

Three out of six students found that video was not necessary with the digital alternatives, but the other half of the responses indicated that video should be included. One student indicated in the open-ended comments that the student should be given the flexibility to choose small or large slides and audio-only or audio/video presentation. It is believed that if the students had the chance to observe the digital video resolution and recognized the fact that the majority of the video content consisted of slide images, that the students would ascribe less value to having the video available in the digital format. Fifty percent of the respondents also indicated that the digital audio resolution was satisfactory, while the other half stated that higher resolution was preferred. The fact that the digital audio was captured from the original VHS recording resulted in degraded digital audio quality. Subsequent investigation indicates that direct digital audio capture results in much better audio quality without increasing the size of the audio files.

One student indicated that, as long as they had to be at the computer to view the lecture, an on online editing capability for the handouts should also be provided. Another respondent indicated that the middle button on the navigation bar should consistently play the audio instead of occasionally leading to other web sites, and that an additional button should appear on the navigation bar when, and only when, there are links to additional information. With the suggested additional button, the navigation bar would no longer represent an ordinal scale; this would make the interface potentially less intuitive. Also, having a button that doesn't appear on every page violates interface "consistency" [MacLennan 1983]. On the other hand, a button that plays an audio clip on some occasions and links to another web site on others is also a "consistency" violation [ibid.]. Additional testing focused of this interface design trade-off is indicated.

On the FCQ, 17 respondents gave the videotapes an average rating of 1.8 and 13 respondents gave digital delivery an average rating of 2.9. The average rating for navigation in the digital lessons was 3.0 for eleven students responding. There were four open-ended comments related to the digital delivery alternatives. The comment "I liked the CD lecture too; very easy to get to the needed audio portion of a particular lecture" was included as one of the most effective aspects of the course. A second respondent also indicated that the CD was one of the most effective aspects of the course. "Web presentation ok" was included in the "other comments" section. One student indicated "Sessions on CD" among the best ways to improve the course, but it isn't clear whether they are indicating a need to improve the CD method of delivery or a desire to have the whole course delivered via CD. Under least effective aspects of the course, one student indicated that they could not use the CD, but weren't sure whether the CD or their computer was the source of the problem. Two respondents indicated under "other comments" their appreciation for the instructor's creativity in utilizing new tools for distance learning, but a third student indicated that the distance education "experimentation" was a source of distraction from the course materials. There were three comments indicating quality and/or delivery problems with the VHS videotapes.

Barriers to Digital Lectures

In the mailed survey, students were asked to indicate all factors that presented barriers to utilizing digital lectures. Subsequently, some students identified more than one barrier. Out of nine respondents, there were four indications of no sound capabilities, one indication that the computer was too slow, one indication that the CD player was too slow, and one indication that the Internet connection was too slow. In the open-ended remarks, three respondents indicated that they had computers at work that were capable of utilizing the digital lectures, but that their home systems were inadequate. One student indicated plans to buy a sound card. Another indicated that they typically didn't have Internet access during occasions of business travel. One student mentioned that they had to click "OK" in several dialog boxes each time they played an audio clip from the CD. At least one of these dialog boxes is probably associated with the browser; the most popular browsers prompt the user whether they want to save the file to disk or "view" the file with the appropriate application. It is possible to configure these browsers so that they don't prompt the user each time they access a new file, so this shortcoming may well be addressed by additional training. Virus protection software may be the source of another prompt. *Norton Anti-Virus* can be configured to

BEST COPY AVAILABLE

1148

limit the file types scanned based on the filename extension, so additional training may resolve this deficiency as well. If "several" dialog boxes implied more than two, it is not readily apparent what are the sources of the other prompts; the anonymous nature of the survey precluded further investigation of the student's situation.

Conclusions

Caution is recommended with respect to a shift of course delivery media to CD or the web. Based on the survey results, approximately 50% of the students enrolled in EMEN5300 lacked convenient access to sufficient computer resources to take advantage of these alternate delivery mechanisms. Dictating the need for sufficient computer resources as a course prerequisite is one way to address this issue, but the high cost of such a requirement could jeopardize enrollment levels. However, this situation bears close monitoring since Moore's law indicates that computer capabilities double in a mere 18 months [Ziems 1996].

The concern raised by one student regarding of the issue of distance education "experimentation" is a valid one. Many studies, for example [Barker 1998] and [Ingebritsen and Flickinger 1998], compare a traditional course taught in one semester or to one group with a revised course taught to another. Although such an approach makes it less obvious to the students that they are experimental "subjects", it is still likely that time is being taken away from course content to deal with the technology. Such an approach also makes it harder to control experimental variables and validate conclusions. In either case, some sort of risk/reward analysis is justified to make sure that the benefits of the research warrant the reduction in course content that the experiment may entail. It is also recommended that, unless it violates the research protocol, students should be informed of their role in the experiment and made aware of the potential benefits for future students.

Computer based instruction of professional psychological skill acquisition

R.J. van Ouwerkerk*, M.N. Hoebe*, F.L. Oldersma*, T.F. Meijman* & K.I. van Oudenhoven-van der Zee#

*Department of Experimental and Occupational Psychology, #Department of Personality Psychology, University of Groningen, Grote Kruisstraat 2/1, 9712 TS Groningen, Netherlands, E-mail: R.J.van.Ouwerkerk@ppsw.rug.nl

Abstract: The developments in information technology and multimedia gives new opportunities to increase the efficiency and quality of skills education. Three different applications are presented that are developed to enhance the professional skills learning in different areas of Psychology. The areas that are covered consist of the instrumentation techniques in biopsychology, job and task analysis, and selection and assessment in organizations. The applications use multimedia to enliven the course and to improve students learning of skills. The innovative features of the applications are illustrated in this paper. Furthermore, some results will be presented of the evaluation of students experiences with the programs and of the learning progress as a result of working with the programs.

1. Introduction

The acquisition of analytic and counseling skills is one of the preconditions to prepare psychology students for their professional career. Education of skills not only emphasizes the understanding of theories but also involves the qualitative understanding of concepts and the training of procedural knowledge. Training of skills is often regarded as highly work intensive. However, advances in information technology and multimedia have facilitated the possibilities to support skills acquisition and to promote self-instruction and computer-based instruction. Despite these new opportunities, only few applications exist that train psychological skills thoroughly.

In 1996, a large fund of the Department of Education of the Dutch Government (Dutch: Kwaliteits- en Studeerbaarheidsprojecten) stimulated several educational innovation projects to support the continuing development of ICT-based learning material and courses. Major goal of this fund was to encourage universities and colleges to innovate and improve their courses and thereby facilitating the flow of students through a four-year educational curriculum. A project, submitted by Lang & Meijman (1996) to enhance the professional skill acquisition in psychological education was granted. This project consists of four subprojects of which three will be presented at the WebNet99 conference.

BioPsy is an application that is developed to teach and train the technical and practical backgrounds of conducting biopsychological experiments. PAMA is a digital learning environment in which students can develop professional skills to analyze, evaluate and (re)design human work. The development of skills to conduct personnel selection procedures are taught with the application Selection.

This paper briefly outlines the structure of the projects and discusses the pedagogical background, the implementation of the applications and the evaluation of the courseware. In the associated poster and demonstration sessions, the applications will be presented.

2. Theoretical considerations

All courses are in addition to, or replace parts of the regular courses. Biopsy, for example, is an "add-on" module where students can study background information and make exercises. Selection provides the student with theory and exercises previously presented on paper and videotape, where the results are subsequently discussed in working groups. PAMA replaces regular instruction for a large part, integrating theory, examples and exercises in a digital environment.

Four general principles are present in all of the applications:

1. They are developed in a cognitive- and social-learning theoretical framework where students learn by example (modeling), practical exercises and feedback.
2. Several types of multi-media elements are presented in the applications, e.g. video- and audio-fragments, animations and illustrations.
3. Case-materials include real-life or simulated settings. This ensures transfer to real-life situations and makes the programs more attractive.
4. The programs allow students to proceed in their own pace and provides them with the possibility to choose extra exercises when wanted.

The theories of knowledge and skill acquisition underlying these principles consider learning as a result of a student actively understanding, selecting, comparing and judging information (e.g. Vygotski, 1978). This means that an active role is expected from students. The teacher's role is still important, but more a monitoring one, leaving more responsibility to the students. It is important for students to develop some metacognitive knowledge about the course subject, i.e., to develop general abilities they can apply to all problems they encounter, by learning by example. A consequence of this learning style is that an emphasis must be placed on learning in a meaningful context and that students can discuss the results with each other. All three programs provide a meaningful context by using real-life examples and cases. For example, in the program PAMA a time restriction in analysis time is included, just as in real life. Discussion between students is facilitated by working in couples and by creating the possibility for chatting or mailing.

Although all three programs are built around the same theoretical principles, some differences can be distinguished. These differences can best be described by the distinction between "whole" versus "part" learning. Partial learning is the breakdown of knowledge and skills in separate, selfcontaining elements which are presented to the student. These elements are studied, step by step, and in the end the student is instructed to combine those elements. Selection and BioPsy are examples of this approach. PAMA fits the description of whole learning better, as it provides the student with elements that are more intertwined with each other. This means that contrary to Selection and BioPsy, PAMA requires more the creation of a mental map of the subject matter and the combination and integration of the elements as they encounter them. Students are not completely left on their own to do this, as the program provides them with references to additional information and hints. Students have to search for this information themselves and it is expected that they not only learn from the information they find but also from the search-process self. In this context another distinction can be made between "explicit" and "implicit" learning. In contrast to e.g. Selection, where all relevant information is accessible in the program and is made explicit what has to be learned, PAMA focus more on implicit learning. In PAMA, the student has to create its own knowledge base and theoretical framework in addition to the information provided by the program. One of the tasks where this becomes apparent is in the construction of a personal textbook with all the documents and assignments a student has discovered and finds relevant. The assignments are constructed in such a way that the student individually discovers the necessity of a stepwise procedure and thereby improving theoretical and methodological insight.

Flexibility for the students is achieved by providing the program in a network environment. Selection and Biopsy and part of PAMA are traditional OS specific applications distributed via an Intranet, and a part of PAMA via the OS independent Internet. In addition, all programs are available on CDROM. Apart from the fact that different learning styles affect the pace of a student, practical issues are also at stake, especially in higher education: a significant amount of students have part-time jobs or are restricted in some other way to attend classes on a regular basis.

Although the possibility exists for students to use the programs individually, they will be encouraged to form teams of two. This enforces a way of collaborative learning where students exchange experiences, perspectives and discuss alternatives. The program PAMA is most advanced in this perspective, in that it provides different means of discussion like Internet newsgroups, mailinglists and chat. The student's own input is important in these fora, the teacher only monitors these discussions and stimulates them when necessary.

3. BioPsy

Students who specialize in Experimental Psychology are confronted with a substantial amount of technical information necessary to conduct biopsychological experiments in the laboratory or in field studies. Although mathematics at high school level is a precondition to enter psychological education, several students have difficulties understanding these technical aspects. BioPsy is developed to support

those students who are confronted with deficiencies in knowledge of physics and electronics. It is also developed as a remedial teaching tool for those students who have become a bit unacquainted on the technical area. The application is additional to face-to-face teaching with the lecturer and can be completed at any convenient time. Multi-media elements are used to enliven the course material.

The application consists of three different modules of retrieval and acquisition of information. The first module is the search-module in which the student can search on specific terms or within specific topics. All matches of the search term are displayed and can be sequentially selected and examined by the student. Several videos, animations and images are included in the application to support the course material. Students can also exercise the principles of signal processing in a simulation environment through the manipulation of filter and sampling parameters.

In the second module, the student can follow an introductory course on biopsychological experiments. This module is presented in a classic book-structure. The complete course consists of six books:

- a. Electronics
- b. Biopsychological signals
- c. Controlling experiments
- d. Personal Computer
- e. Safety and accidents
- f. Processing of signals

The progress of the course can be saved and retrieved. After studying a book the student can answer some multiple-choice questions to test the degree of acquired knowledge.

In the third module the student can apply the knowledge in different exercises that are related to a real experiment. Approximately twenty-five exercises are constructed for two different experiments, a classic reaction-time experiment and an experiment in which the electroencephalogram (EEG) is measured. Crucial aspects of these experiments are trained to prepare students in actual experimentation.

In the reaction-time experiment subjects have to design a memory-search task and the necessary technical and experimental prerequisites. Emphasize is placed on designing the experiment, preparing the stimulus material and programs, instructing the subjects, registering heart rate and heart rate variability and analyzing and interpreting the results.

The second experiment consists of a semantic task in which meaningful and meaningless words are presented in normal daily sentences. During this experiment the EEG is measured from which Event Related Potentials (ERP) have to be computed. Focus in this experiment is on the registration of the EEG-signals and the necessary steps to calculate ERP's. The two experiments are a good reflection of the technical problems that are encountered in biopsychological experiments.

The program BioPsy is demonstrated at the WebNet 99 conference (Poster/Demonstration of R.J. van Ouwkerk, T.F. Meijman & L.J.M. Mulder).

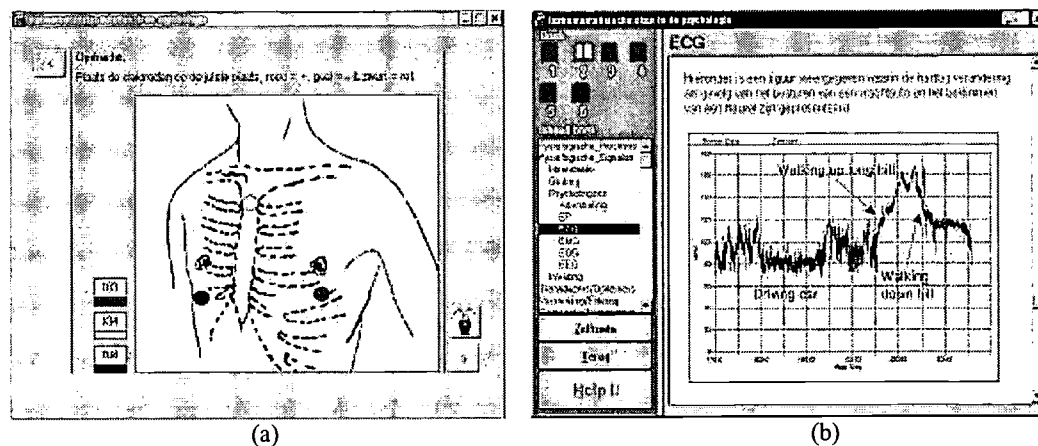

Figure 1: In the exercise module of BioPsy students have to place electrodes on the appropriate spots of the body (a). Illustrations are used to enliven the material in the course module (b).

4. PAMA

The acronym PAMA is made up of the initial letters of the Dutch terms "Psychologische Analyse van Menselijke Arbeid" and can be best translated as "Psychological Analysis of Human Task Performance". The PAMA courseware provides an introduction to the theory and practice of work and organizational psychology. The course offers work and organizational psychology undergraduates a computer-based interactive exercise of the analytical skills relevant to the execution of a psychological analysis of human task performance.

PAMA consists of three modules. The first module provides an introduction to models of workload and recovery, work satisfaction, work and physical and psychological health, et cetera. It draws on recent theory and research to offer students a perspective on work and organizational psychology. The second module provides students with models, theory, and methods of psychological analysis of human task performance, and provides students with practices of professional skills. It offers students a method of analysis that should be followed to perform an adequate analysis of work activity. It also includes the available instruments and techniques for performing a psychological analysis. The third module is designed to support the development and advancement of professional skills that are required as a work psychologist. Assuming that the power of a real-life case will make learning more attractive and effective, the actual skills can be practiced in a predefined and elaborated case that focuses on the job of nurse at a department of nephrology and kidney transplant. All materials provided by the application are the sources for carrying out the job analysis.

The modules one and two are made available in a digital learning environment that can be approached via the Internet. The introduction to theory and research is included in electronic books and can be printed to form a conventional paper textbook. However, the electronic book contains additionally educational material. The book of module one in particular includes several concrete examples to illustrate the subject-matter, and also exercises and assignments, whereas module two provides students with the opportunity to develop and practice their skills. Therefore, the second module calls attention to several psychological instruments for job and task analysis that can be explored and exercised, and several data-sets are available that provide the opportunity for students to consider the methodological and statistical aspects of job analysis. All in all, this requires the students to explore the literature on work and organizational psychology and it will prompt them to adopt an active, self-employed role in gathering additional subject-matter. Moreover, the modules allow the student to be responsible for his or her own learning to match the prior knowledge and learning style. As a consequence, each student composes his or her own unique textbook. As a side-effect, he or she will be able to visualize and increase his or her knowledge about the theory and research on work and organizational psychology and the methodology of psychological analysis of human task performance.

All the chapters with texts, the video and audio fragments and the exercises are present in a SQL-database for the Internet. A webserver translates the queries into readable html-pages, dynamic lists and multi-media elements. Teachers can dynamically add, delete and change the order of the educational material at the beginning of a course. Dependencies between chapters and exercises can be assigned to include restrictions in the accessible material. Also the correction of answers on open questions by the teacher is supported in the system. The login procedure of the student is secured by using a challenge response user authentication. The student can view all the material and can send answers on questions and exercises to the database to be reviewed by the teacher later. The student's progress of the course is tracked and administrated. This information is used in the evaluation stage of the project to determine individual learning strategies. In figure 2 the general layout of the digital learning environment is depicted.

Unlike the former modules, the third module will be available via the Intranet. Using a case-based learning application, the course provides the opportunity for students to act as a work analyst and to learn that job analysis is a complex task and involves efficient planning. In this module, students are presented with a case that requires them to perform a psychological analysis of human task performance. They are expected to apply their knowledge (acquired by examining modules one and two) to analyze the job of nurse at a department of nephrology and kidney transplant at the Academic Hospital Groningen in the Netherlands. As a result, all the basic knowledge should be integrated to facilitate execution of the psychological analysis of human task performance. This requires that students study all relevant materials in modules one and two as they pursue the case in module three. The relevance of the subject-matter in modules one and two is apparent, because students become aware of a need for accurate knowledge when proceeding with module three. This provides students with a course that reinforces what they have learned and encourage them to apply that knowledge in a virtual setting of a work and organizational psychologist.

All necessary information will be available via the Intranet and consists of reports and documents, auditory interview fragments, video-fragments, and data from questionnaires and behavioral observations, but also includes information that is irrelevant to the case. Furthermore, students will be required to carry out a complete analysis in a fixed (but fictitious) amount of "analysis time" and retrieving any information will reduce the remaining time. Thus, students need to carefully plan each step in the analysis and to consider which information is relevant. By doing so, they become aware of a need for an efficient research method, which makes the module a challenging exercise.

The job analysis involves several steps. In each step, the student is required to submit a plan. After the plan is checked by the application, the student is provided with feedback. The courseware was programmed to compare the submitted plan to a previously fixed analysis planning and to provide the student with different forms of preprogrammed feedback. So, the student is repeatedly receiving positive reinforcement regarding his or her skills as well as constructive feedback for rectifying any identified inadequacy. As soon as the plan meets certain requirements, the student can proceed and act according to the plan. After finishing each analysis step, and before proceeding, the findings should be summarized in a short written report. In conclusion, a full written report on the complete job analysis should be prepared that consists of the short reports prepared in each analysis step.

The program PAMA is demonstrated at the WebNet 99 conference (Poster/Demonstration of F.L. Oldersma, M.N. Hoebe, R.J. van Ouwkerk, A.H.G. de Vries-Griever & T.F. Meijman).

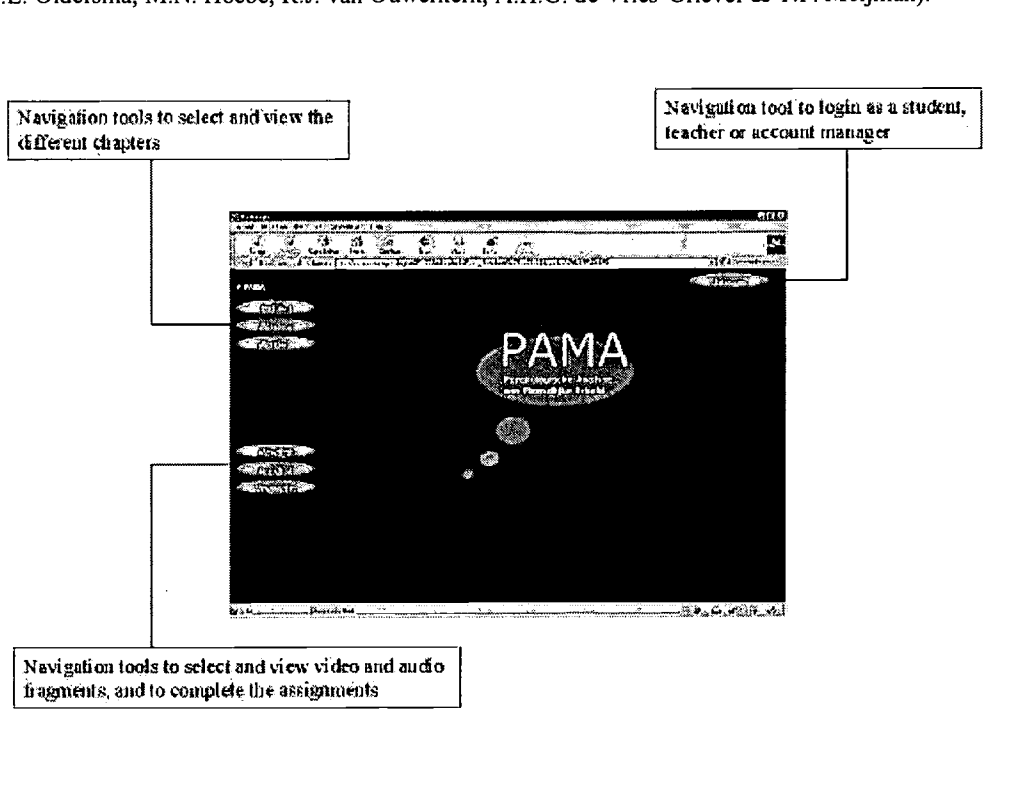

Figure 2: Introduction screen of the digital learning environment of PAMA. Several navigation tools are present to view and process information.

5. Selection

The application Selection is aimed primarily at students who are educated in the psychology of assessment and selection of other people at work. The program considers the process of selection (the activities involved) and the content of selection (the techniques, tools and methods used). The process and skills for professional consultancy are taught in a self-instruction course. The student acts as a junior adviser who has to select the most eligible secretary from a group of applicants. The entire selection procedure is stepwise completed by the student in which he or she is instructed and advised by a (virtual) senior consultant.

The selection procedure consists of nine consecutive steps. The first step of the program aims to clarify the question of the client. In the next step the content of the function is determined which is further specified in function requirements in the third step. After this step the necessary predictors are

determined. The tests that contain the predictors are selected (step 4) from a pool of tests and presented to the candidates (step 5). In step six the test scores of the candidates are interpreted and weighted. On basis of these results a few selected applicants are invited for a selection interview. The final suitability of the applicants is rated and determined in step eight. In the final step a rapport is written in which a candidate is recommended to the client.

The program makes extensively use of video- and audio-fragments that can be viewed or listened to by the student. Also several psychological aptitude tests are present to guide the selection process. After each step the student is provided with feedback on the results and he or she can correct the responses.

The program Selection is demonstrated at the WebNet 99 conference (Poster/Demonstration of M.N. Hoebe, K.I. van Oudenhoven-van der Zee & R.J. van Ouwerkerk).

Figure 3: The interface of Selection (a) that is used by the student is structured as an office environment in which several input devices can be used to collect and retrieve information e.g. calendar to make appointments, a phone to consult the senior etcetera. Several screens (b) are present in which the student can view video fragments, and can select and drop relevant items.

6. Evaluation

All applications that are developed in this project are evaluated by students. The evaluation is based on the students' attitudes towards the software, their ratings of usability and their learning as a result of the applications. The first step in the evaluation is a heuristic evaluation in which the content and usability of the interface of the application is rated. In a follow-up study the attitude towards the applications and the progress or decline in learning efficiency is examined in more detail. Two groups are compared: a group of students that did not work with the application and a group that worked with the application. The differences in test scores is used to determine the effectiveness of the innovation. The amount of time spent on mastering the skills provides information on the efficiency of the application. The group of users of the application further evaluates the usability, transparency, consistency and attractiveness of the application.

Abstract: This paper discusses a generic query tool that enables an end user to query a metadata store through filters that impose search criteria on attributes. The Metadata Query Tool (MQT) is generic in the sense that it dynamically creates its user interface, based on configuration files that define the metadata scheme and the query functionalities. Although the tool can in principle be used to query any (view on a) relational database, we have developed it to query educational metadata, stored in the ARIADNE^[2] Knowledge Pool System [Forte, Wentland & Duval 1997].

1. Introduction

Metadata can be described as "data about data". A good example is a library catalog, which contains information (metadata) about publications (data). Advantages of using metadata to describe electronic resources are numerous [Iannella & Waugh 1997] and include the possibility to efficiently search for data.

Creating an intuitive and powerful Web tool for metadata querying is not an easy task, the more so if we want to develop this tool in a generic way, i.e. without 'hard coding' a particular metadata scheme into it. Moreover, we also want the tool to be flexible in the sense that the query functionality itself must be configurable: the user interface should reflect the important metadata fields and provide a user friendly, yet powerful, mechanism to query the metadata instances. The ideal user interface may depend on the (type of) user and his/her interests and therefor should not be fixed given a certain metadata scheme.

This paper describes how we have developed such a tool. The text is structured as follows. The next section describes the approach of filter based queries. Section 3 explains the configurable aspects of MQT, both with respect to the metadata scheme, as well as with respect to the graphical user interface. Some details on the queries generated by MQT are presented in section 4. The next section covers some user interface aspects. Section 6 gives an overview of related research and tools. Before concluding, we briefly present the current status in section 7.

2. Filter Based Metadata Querying

The metadata we want to query is stored in the ARIADNE Knowledge Pool System [Forte, Wentland & Duval 1997], which basically is a distributed RDBMS. As we wanted to develop a user friendly query tool, we had to develop a reasonably intuitive mechanism, rather than asking the end user to enter SQL-queries. The approach we adopted in MQT is filter based querying (also called content-based filtering) [Mukherjea & Foley 1995]: users define filters on attributes to impose search criteria. A filter on the document title for instance leads to a search for documents, whose title starts with, ends with or contains a search string.

Available filters are defined in one of the configuration files of MQT. Different types of filters are available for different types of attributes, data types, conditions and functions. [Fig. 1] gives a short overview of the different types and their associated functionalities.

<i>Filter type</i>	<i>Fields</i>	<i>Attribute type</i>	<i>Conditions</i>
Basic	Textbox	String	Starts with, <i>Contains</i> , Ends with
		Number	<, <=, =, >=, >
		Date	<, <=, =, >=, >
List	Pulldown	NA	NA
Composed	Panel	NA	NA

Figure 1 : Different filters and their associated functionality

BEST COPY AVAILABLE

Basic filters enable the user to search on (sub-)strings, numbers and dates, based on conventional operators. A list filter contains all applicable values for the associated attribute. The relevant values for such a list filter are retrieved from the database when MQT is launched. Composed filters contain basic and list filters, or other composed filters (see below).

At all times, MQT displays a list of all active filters, which can be deactivated through a simple button associated with each filter. This is illustrated by the simplified screen dump presented in [Fig. 4].

3. Configuration

MQT is developed in a general way: it contains no hard coded references to the metadata scheme, in the form of tables or attributes in the database. This is achieved by a configuration file, which defines the metadata scheme (relations, attributes interrelationships between the relations), as will be explained in section 3.1.

Because not all database attributes are useful in search criteria, the query tool also uses another configuration file, which defines the queries to be supported on the database, as explained in section 3.2.

In this way, MQT can be used to query any metadata store accessible through JDBC (see below).

3.1. Data Scheme Configuration File

This configuration file describes the metadata scheme, in the form of its representation as a relational database scheme. It contains all information needed to generate the queries. More specifically, this configuration file includes the following information:

- Database relations
- For each relation:
 - Attributes
 - Primary key
- References between the database relations

[Fig. 2] illustrates the XML representation of this information.

<pre> <DATAMODEL> <ENTITY> <NAME> Pedagogical_Header </NAME> <ATTRIBUTE> <NAME> Id </NAME> <TYPE> STRING </TYPE> </ATTRIBUTE> <ATTRIBUTE> <NAME> Document_Title </NAME> <TYPE> STRING </TYPE> </ATTRIBUTE> <ATTRIBUTE> <NAME> Package_Size </NAME> <TYPE> INTEGER </TYPE> </ATTRIBUTE> <KEY> Id </KEY> </ENTITY> <ENTITY> <NAME> User_Comments </NAME> <ATTRIBUTE> <NAME> Comment_Id </NAME> <TYPE> INTEGER </TYPE> </ATTRIBUTE> <ATTRIBUTE> <NAME> Header_Id </NAME> <TYPE> STRING </TYPE> </ATTRIBUTE> <ATTRIBUTE> <NAME> Author </NAME> <TYPE> STRING </TYPE> <MULTIVALUED> YES </MULTIVALUED> </ATTRIBUTE> </ENTITY> </pre>	<pre> <ATTRIBUTE> <NAME> Comment </NAME> <TYPE> STRING </TYPE> <MULTIVALUED> YES </MULTIVALUED> </ATTRIBUTE> <KEY> Comment_Id </KEY> </ENTITY> ... <MAINENTITY> Pedagogical_Header </MAINENTITY> <MAINATTRIBUTE> Document_Title </MAINATTRIBUTE> <REFERENCES> <REFERENCE> <FROM> <ENTITY> User_Comments </ENTITY> <ATTRIBUTE> Header_Id </ATTRIBUTE> </FROM> <TO> <ENTITY> Pedagogical_Header </ENTITY> <ATTRIBUTE> Header_Id </ATTRIBUTE> </TO> </REFERENCE> ... </REFERENCES> </DATAMODEL> </pre>
--	--

Figure 2: Possible data scheme configuration file

The data model of [Fig. 2] first defines a 'pedagogical header', ARIADNE jargon for an educational metadata instance [Forte, Wentland & Duval 1997]. The ARIADNE approach for semantic interoperability in educational metadata is presented in [Forte et al. 1999].

Entities in the configuration file correspond with relations in the database. In the extremely simplified view of [Fig. 2], such an instance contains an identifier (Id), a title (Document_Title) and the size of the document being described (Package_Size). The key attribute of this entity is the identifier. The second entity defines user comments, which consist of an identifier for the comment (Comment_Id), the identifier of the

pedagogical header the comment refers to (Header_Id), the author (Author) and the content of the comment (Comment). The latter two attributes are multivalued. The <REFERENCES> section defines the relationship between the user comment and the pedagogical header it refers to.

Besides this kind of information, the configuration file also defines a main relation and a main attribute in this relation. Both of these are used to build the user interface (see below). The main relation is also used to generate queries, which retrieve a result list (list of metadata instances satisfying the search criteria) or a specific metadata instance from the metadata store.

3.1.1. GUI Configuration File

This configuration file describes the attributes the user interface should provide filters for. Filters are logically grouped, so that a well-structured user interface can be constructed. An example GUI configuration file is presented in [Fig. 3].

<pre> <GUIDATAMODEL> <FILTERCATEGORY> <DESCRIPTION> General information </DESCRIPTION> <TOOLTIP> General information of the document </TOOLTIP> <FILTER> <NAME> Document title </NAME> <ENTITY> Pedagogical_Header </ENTITY> <ATTRIBUTE> Document_Title </ATTRIBUTE> </FILTER> <FILTER> <NAME> Language </NAME> <ENTITY> Element_Language </ENTITY> <ATTRIBUTE> Language_Name </ATTRIBUTE> <TYPE> LIST </TYPE> </FILTER> <FILTER> <NAME> User comments </NAME> <TYPE> COMPOSITE </TYPE> <FILTER> <NAME> User comment by </NAME> <ENTITY> User_Comments </ENTITY> <ATTRIBUTE> Author </ATTRIBUTE> </FILTER> </pre>	<pre> <FILTER> <NAME> User comment </NAME> <ENTITY> User_Comments </ENTITY> <ATTRIBUTE> Comment </ATTRIBUTE> </FILTER> </FILTER> </FILTERCATEGORY> <FILTERCATEGORY> <DESCRIPTION> Technical Information </DESCRIPTION> <TOOLTIP> Technical information of the document </TOOLTIP> <FILTER> <NAME> Package Size </NAME> <ENTITY> Pedagogical_Header </ENTITY> <ATTRIBUTE> Package_Size </ATTRIBUTE> </FILTER> </FILTERCATEGORY> </GUIDATAMODEL> </pre>
---	---

Figure 3: Possible GUI configuration file based on the data scheme presented in [Fig. 2]

The simplified configuration file of [Fig. 3] defines two categories of filters, one to query on general information and one for technical characteristics. Both categories are described by tooltips that will be presented to the end user when the mouse is positioned over the category selector (see below).

The general category contains two filters, one to search on document title and one for the language of the document. For each filter, the corresponding attribute in the corresponding entity (i.e. database relation) is defined. Similarly, the filter category for technical data defines one filter, to search on package size.

The general category also contains a composite filter to search on user comments. A composite filter represents a composite metadata field. In this case, the composite filter consists of two sub-filters, to search on the author of a comment and the content of the comment (given by a specific author) respectively.

4. Metadata Queries

The queries generated by MQT can be divided into 2 categories:

1. queries that identify the metadata instances that satisfy the search criteria: the set of these instances is called the result list;
2. queries that retrieve one complete metadata instance from the database.

The query that retrieves the result list is roughly structured as follows:

```

SELECT <key attributes>,<main attribute>
FROM <main entity>,<relations with active filters on an attribute>
WHERE <conditions imposed by active filter>
AND <join conditions for relations in the from-clause>

```

The main attribute values are displayed in the result list (see the lower right area in [Fig. 4]). According to the configuration file of [Fig. 2], this would mean that the document title is shown for each document in the result list. The associated key values are used to retrieve the complete metadata instance from the database upon user request.

Retrieving one metadata instance from the database is somewhat more complicated, mainly because the interrelationships between the database relations can be optional and because there can be multiple

interrelationships between the same two relations. The basic approach to solve this problem is to execute separate queries for each relevant relation.

5. User Interface

[Fig. 4] displays a screen dump of the user interface of MQT based on the previously given configuration files. In reality many more categories and filters are present. The query window (upper left, with "Document Query" as title) basically enables the end user to activate or deactivate filters. For each attribute, a text box or pulldown menu can be used to indicate the search value and the operator ("starts with", "=", etc.) to be applied.

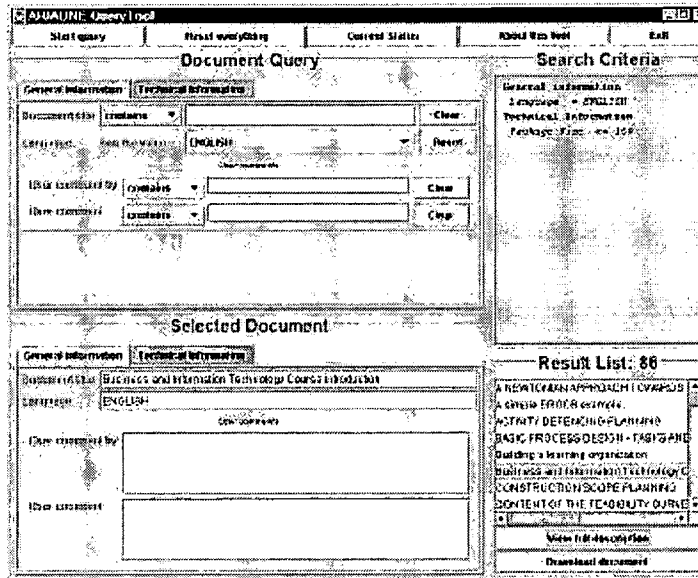

Figure 4: Screen dump of the user interface of MQT given the configuration files of [Fig. 2] & [Fig. 3]

The structure of the query window is identical to that of the data window (lower left, with "Selected Document" title) that displays one particular metadata instance. This was a deliberate design decision, as it makes it more apparent why an instance is included in the result set: the search criteria in the query window can immediately and intuitively be related to the instance values in the data window.

In the upper right area, the active search criteria are displayed in shorthand, so that users have an overview of all active filters at all times. We have added this functionality because of feedback we received on an earlier version of the MQT tool. Without this overview, users quickly lost track of the filters they had applied, and the search values associated with those filters.

Because the number of commands is relatively limited, all commands are available by buttons. Buttons for general commands are situated at the top of the window. These enable an end user to:

- start the query: this means that the query is actually sent to the database, processed, and that the result list is displayed;
- reset everything: all active filters are deactivated and the results list is re-initialized as an empty result list;
- current status: displays the database that MQT is connected to;
- about this tool: provides information about the goal and purpose of the tool;
- exit: the MQT application exits.

Those commands that operate on one specific metadata instance are placed under the result list, as users must select such an instance from that list before applying the command. These commands enable an end user to:

- view the complete metadata instance;
- download the actual document described by the metadata: this command prompts for a user identifier and a password, as only metadata are publicly accessible, but the actual documents are restricted to members of the ARIADNE user group <<http://ariadne.unil.ch>> (if they are free).

The GUI configuration file (as given in [Fig. 3]) defines the exact layout and configuration of the different graphical components. A filter category in the configuration file corresponds with a Tab panel in the query and

the data window. A filter in the configuration file corresponds with a graphical component in the query window that enables the user to activate/deactivate the filter, as well as with a graphical component that displays the value of a metadata instance in the data window. The type of the graphical component depends on the filter type and the type of the corresponding attribute. The filter type defines the layout and the attribute type determines the available operators.

A composite filter in the GUI configuration file results in a bordered graphical component, which contains the graphical components of the participating filters. The main entity and main attribute are used to indicate the metadata instances that satisfy the search criteria in the result list.

6. Related Research and Tools

Related research can be divided in three different categories: metadata query tools, other query tools (subdivided into XML and web query tools) and general metadata tools.

1. The field of metadata querying is still in full development and not many tools are available. All of the existing metadata query tools we could find either operated on a fixed metadata scheme (Dublin Core, ...) or used some "external" protocol for communicating with the data store (e.g. QUANTUM [Hindall & Haines 1997] uses Z39.50 for querying the database(s)). MQT has no fixed metadata scheme, but it does use JDBC (and SQL) for communicating with the data store.

2a. Since the data scheme configuration file (see [Fig. 2]) can easily be transformed into an XML-DTD, MQT is closely related to XML query tools. XML querying recently became very popular and the ongoing research looks very promising, but it's still in its infancy. One example of such a tool is Innerview <<http://www.t2000-usa.com/>>, but there still is no uniform, standardised query protocol and mechanism. This might change quickly as some proposals already exist [XML-QL 1998] [XQL 1998].

2b. One more developed research area concerns web querying. There are a lot of sophisticated web search engines available, but there exists no uniformity amongst different tools and the documents on the web don't comply to a standardised, uniform indexing method so that it's very hard to find what you're looking for. This could be facilitated by the use of metadata, but since this is not standardised for the web, web search engines use keywords indexing (and a fixed user interface).

3. Finally, there are general metadata tools. There is one tool in particular we took as a starting point in our design: Reggie [Reggie 1999] is a metadata insertion tool. It uses an input scheme (which ranges from Dublin Core to your own defined scheme) to describe its metadata set and builds its user interface (and associated functionality) based on the selected scheme. Contrary to MQT, Reggie is used to describe data (that is to insert metadata) and it is developed as an applet.

7. Current Status

During the development of MQT, we were confronted with the classical trade-off between functionality and user friendliness. We tried to keep the user interface as intuitive as possible while still supporting quite powerful search possibilities. The user interface also has its limitations though: the result list displays only one attribute for every hit,...

MQT supports any possible combination of active filters, but its functionality is limited in some ways. One of the main limitations is that only the logical 'and' operator is used in the queries: this means that it is impossible to search for documents, whose title starts with 'Behind the scenes' or 'A closer look at'. On the other hand, usability-engineering research consistently shows that users have great difficulty to use boolean operators in the correct way [Shneiderman 1998].

As mentioned before, MQT has been developed in the first place as a query tool for educational metadata in the ARIADNE project [Forte, Wentland & Duval 1997]. All metadata in ARIADNE are stored in a relational database, mainly because of technical reasons [Cardinaels et al., 1998]. MQT is a Java application that uses JDBC to interact with the database. The decision to use a Java application and not an applet or servlet is based on several factors:

1. Servlets generate HTML. Given the current limitation of HTML browsers, this is not a sound development base for an intuitive and powerful user interface.
2. Because of security restrictions, applets cannot communicate with databases that run on servers different from the one that serves the applet.

Java interfaces have been defined for different kinds of filters (see above), attribute types and conditions, so that it is relatively easy to extend the functionality of MQT by adding a new type of filter, attribute type or condition.

Since early 1999, MQT has been deployed within the ARIADNE community and is being used by several hundreds of persons. Based on feedback received in first user trials, we have added the "Search Criteria" window, as mentioned above. Other feedback indicates that this tool indeed serves its major purpose and does enable end users to zoom in fairly quickly on relevant reusable educational resources.

Future work includes the migration from a 2-tier to a 3-tier architecture and the use of introspection of classes in the middleware layer to enable an automatic configuration of the tool.

8. Conclusion

One of the main requirements for the metadata query tool in the Ariadne project [Forte, Wentland & Duval 1997] was that the metadata scheme should not be hard coded, as we wanted to develop a tool that was flexible enough to query metadata stores with different metadata schemes. Using XML configuration files describing the metadata scheme and the required query functionality provided us with the flexibility we wanted to achieve.

Our query approach relies heavily on refinement, through filter based querying. A user can activate and deactivate filters over attributes. Currently, our tool supports basic filters, list filters and composite filters, but new filter types can easily be incorporated.

The approach discussed in this paper leads to a generic query tool, which can be used to query any kind of metadata in any kind of store that can be accessed through JDBC.

Feasibility of the Internet in Collaborative Networks in Learning Communities.

Cheng-Yen Wang

Graduate Institute of Adult Education, National Kaohsiung Normal University, Taiwan, R.O.C.
chengyen@nknuc.nknu.edu.tw

Abstract: This paper is proposed to discuss the feasibility of the Internet in collaborative networks in learning communities. Referring to the international trends in developing learning communities and educational Internet, the author analyses advantageous and disadvantageous conditions for the usage of the Internet in community collaborative networks. The literature linking to practical experience and an experimental project mainly in the context of Taiwan is reviewed. Six strategies are finally raised as recommendations for promoting the feasibility of the Internet in learning communities.

Introduction

Setting up a learning society has been a popular target of education innovation in many advanced countries after the 1990s [Cresson, 1995; Van der Zee, 1991; Williamson, 1995]. In Taiwan, the Ministry of Education announced the year, 1998, to be the Lifelong Learning Year and published a White Paper called "Approaching towards a learning society", like the 1996 European Lifelong Learning Year. Twelve action projects in the White Paper have been carrying out [Ministry of Education, 1998]. A learning society is a lifelong learning society composed of diverse sub-organisations such as families, communities and different groups. Although the conception [Field, 1996; Jarvis, 1997] and the targeted group [Macrae, Maguire and Ball, 1997] of a learning society are still on debates, the significance of community in a learning society has been shown [Chapman and Aspin, 1997; Hemphill, 1996; Vincent, 1993]. As McNain [1999] stresses, learning is rooted in communities. Therefore, how to develop learning communities that can be seen as fundamental sub-organisations of a learning society is crucial. That is the reason why the Ministry of Education of Taiwan has programmed five communities to conduct the experiments of developing learning communities.

A learning community is a community where various learning resources are integrated to form a learning network. As Edwards [1995] points out, a learning society is as a learning network in which residents can pick up learning resources available to achieve their diverse targets. A learning network is formulated by different stakeholders working collaboratively as partners. Hence, how to enhance the collaboration between different stakeholders is an important issue for developing learning networks. For beneficial collaboration, there are necessary costs to be paid [Coffey, et al, 1988; Fox and Faver, 1984] by collaborators. The critical point will be how to conduct collaboration successfully to run learning communities. Namely, a successful partnership is demanded in a collaborative network of learning community [Friendstein, 1995]. Stakeholders who are included in collaborative networks can directly influence the function of learning communities.

In Taiwan, the total value of production of information technology has been occupying the third place in the world, just behind the USA and Japan. The Government has realised the importance of development and application of information technology in learning. The National Information Infrastructure (NII) was announced and a number of projects have been in implementation. In NII, how to apply the Internet is proposed as a significant part. The necessary equipment of information technology has been gradually enriched for educational providers like compulsory schools in communities. Linking to the implementation of lifelong learning in communities, the NII is helpful for the development of collaborative learning networks.

In this paper, the author will discuss how the Internet can be used in collaborative networks in learning communities. In addition to the literature review, empirical data and experience collected from a city community, one of the experimental communities supported by the Ministry of Education will be also included to reveal the practice in the real world. This approach is like an action research. The author will analyse relevant advantageous and disadvantageous conditions in terms of the application of the Internet in collaborative networks in learning communities and then raise recommendations for

improve the current situations.

Advantageous conditions for applying the Internet in collaborative learning networks

Advantageous conditions mean that these conditions are beneficial for using the Internet. They are in different dimensions and the followings are the major ones.

The central Government's promotion via its policy agenda

The principal advantage of the central Government's policy is that it can conduct its influence through the administrative system from central to local via remit powers. Additionally, the necessary budgets can be provided and have a comparatively stable financial support. For example, Taiwan's Ministry of Education and Ministry of Information and Transportation, which is in charge of the project of NII in the central Government, have a close relationship with the use of the Internet. The Ministry of Information and Transportation enriches computer facilities in communities and the Ministry of Education is devoted itself in promoting lifelong learning and information education via their policy agendas. Both Ministries have direct contributions to the application of the Internet in hardware and software equipment.

A larger popularity in the Internet usage

In Taiwan, there have been getting more people who use the Internet for different purposes. Taiwan's production of information technology plays a crucial role in the world. For example, in 1996, Taiwan's production of notebook pc (occupies 28% in the world market), monitor scanner (61%) and mouse (80%) were all in the first place in the world market [Young, 1996]. The achievements have paved a smooth way for utilising the Internet. A larger popularity in the Internet usage is helpful to enlarge its potential functions in collaborative learning networks. According to a recent global investigation, Taiwan's ratio of the Internet users in its whole population was 14.30%, which was the 12th place in the world [The Liberty Times, 1999]. In Asia, the ratio was higher than in Japan, South Korea, and Hong Kong. Both Taiwan and Singapore had the largest density of the Internet users in Asia.

Adequate computer facilities in community compulsory schools

Computer facilities are needed for application of the Internet. With the supports of the Ministries of Education and of Information and Transportation, computer facilities in compulsory schools have been greatly upgraded. Compulsory schools here mainly include public primary and junior high schools. Their chief strength in collaborative learning networks is that they are widely located in communities and have stable budgets from the local government. Since the popularity of pc is insufficient for most families, computer facilities in compulsory schools are therefore quite helpful for people in communities to use. For opening the resources of compulsory schools to their communities, the educational authorities have been planning remit regulations to schools.

A greater information literacy for all

Compared with their counterparts in the past, younger generations in Taiwan have higher information literacy, partly because of the success of information education in schools and partly because of the trend of information society. For applying the Internet, although the hardware equipment is necessary, the software one is much more significant. Internet users' information literacy is a crucial condition for a successful usage of the Internet. A good sign is that there are more young people who can learn basic literacy of information technology in different levels of schools. For older generations, they have more opportunities to improve their information literacy via adult education. The advancement of information literacy for all is a good basis for enlarging the use of the Internet.

More educational providers in communities

With the development of adult education and lifelong learning, there have been much more educational providers who can offer learning resources in communities. Compulsory schools have played an important role in learning communities but they are not the only educational provider. The others are like libraries, museums, profit and nonprofit organisations, enterprises, clubs, community groups and so forth. They are all potential providers of education according to their availability. The increase of potential educational providers in many different communities lays a strong background for using the Internet. For a learning community, a working collaborative learning network is significant to construct its framework. The appearing educational providers increase the possibility of forming a collaborative network in community.

Disadvantageous conditions for applying the Internet in collaborative learning networks

Besides the above advantageous conditions for applying the Internet, there are disadvantageous conditions that can affect the usage of the Internet. These conditions also come from many different

respects. The followings are the obvious ones.

The lack of a concrete framework of a learning community

A concrete learning community is still in experiment in Taiwan. In terms of the conception of the learning community, actually, it is in development even in the main advanced countries. The lack of literature and empirical experience relating to a learning community will affect the development of collaborative networks. One of the obvious drawbacks is that the context of a learning community is not clear enough to provide a foundation of the framework. Additionally, the stakeholders inside are difficult to be identified. It is harmful to distribute the responsibility and share tasks for collaboration. The messy situation results in that the framework of a learning community is still ambiguous.

The lack of any mature collaborative network in communities

Although there have been more potential educational providers in many Taiwan's communities, a mature collaborative network is still not available. Many current educational providers do not know fully that they can play a more significant role in learning communities. Many community institutes that are not set up originally for educational purposes have not recognised yet that they can have functions in educational services. It is still insufficient that there are different educational providers who are collaborating successfully in communities. There is rare successful experience in a mature collaborative network. In many communities, potential educational providers are still pretty not sufficient. The problem of inequality of resource distribution in Taiwan's communities is still obvious.

The lack of a recognition system for learning

A recognition system that can be used to certificate people's learning is crucial for developing collaborative networks in learning communities. In Taiwan, although like the Learning Passport is in development, the lack of a recognition system is an obstacle for people to learning in their communities. Their motivation of participation in continuing learning in community therefore will be affected. A recognition system is not only a stimulus but also a link for people's learning. No matter which kind of learning track people involved, formal, nonformal or informal, their results of learning need to be recognised and accumulate to be their achievements in learning for various purposes like employment and academic upgrade. The absence of this stimulus and link will decrease the possibility of developing collaborative networks.

The lack of professional lifelong education sectors and educators in communities

There are potential stakeholders who can be collaborators in communities but for a better quality of service, the standard of profession has to be advanced. In current Taiwan's communities, except local primary and junior high schools, there is no sufficient professional lifelong education sector and educator. At present, potential community sectors to be collaborators such as social education institutes, libraries, museums, community centres and other private organisations are not professional enough. Lifelong learning is unfamiliar for most of their members. Even teachers in local schools are not necessary with adequate professional literacy to conduct their role in lifelong education. There are only four relevant graduate institutes of adult education in Taiwan to provide professional education and training. In-service education and training via educational institutions is still not sufficient and that is not helpful for the improvement of educational services.

The lack of effective legislation

Legislation is the guideline and basis of administration. For working collaborative networks in learning communities, sufficient legislation is needed. It can be the basis of developing learning communities. It can also be the guideline to lead the administrative operation of the different levels of governments. Since the unavailability of legislation, current Taiwan's central Government's guides and involvement in developing collaborative networks are in a mess and cannot have efficient effects. The unavailability of legislation is also the major reason why people's learning results cannot be recognised. Legislation can also serve as a protector for collaborators in learning communities. It can be a basis of collaboration and a guideline for potential collaborators' working together through the rules of how to share responsibilities and obligations.

The way to go

For developing collaborative networks in which the Internet can be fully used in learning communities in Taiwan, there have been advantageous conditions to be the facilitating factors and disadvantageous ones to be clean out. Taiwan's educational authorities and relevant stakeholders need effective strategies to pave the way to achieve the above target. Six strategies are raised below to be the recommendations.

Enacting necessary acts and regulations

Enacting necessary acts and regulations are critical for a stable development of collaborative networks

in learning communities. The efficiency of legislation is low in Taiwan's Legislative Yuan. It is necessary to enact acts and regulations according to different levels of legislation. A national act is demanded for the use at national level and its procedure through the Legislative Yuan is required. The progress will be slow and it is difficult to say when it can be finished. If it is not necessary to go into the procedure in the Legislative Yuan, the regulations can be developed in responsible administrative departments with a comparatively higher efficiency. The Ministry of Education has to classify the needed legislation on basis of their levels and priorities. For regulations that do not have to be passed in the Legislative Yuan, the Ministry has to formulate as soon as possible or empowers its lower level departments to accomplish. For instance, the regulations regarding the open-door policy of local schools' computer facilities can be formed by schools themselves under the guidance of the local educational authorities.

Developing local school-based collaborative networks

The potential contributions of local primary and junior high schools have to be fostered further. Schools can be the centres for a learning community [Chapman and Aspin, 1997]. Due to their universality, these local schools have to get themselves much more involved in collaborative networks. For that, current acts have to be revised and relevant regulations have to be enacted. To formulate legislative responsibilities and obligations is necessary to develop local school-based collaborative networks. Legislation also needs to regulate how to evaluate, for rewards or punishments, their involvement in the networks. Especially, when required professional lifelong educators and learning resources are insufficient, local schools have to play a greater part. Educators including principals, school administrators and teachers need in-service education and training to enrich their knowledge and skills to conduct their contribution to the collaborative networks in community. They can be the leaders for new learning communities, as Castle and Estes [1995] recommend.

Expanding the use and popularity of the Internet

The use and popularity of the Internet have to be increased in Taiwan. Based on the achievements in NII and information technology, the Internet can become much more familiar to different users, especially in disadvantaged arena. For serving users who have been active visitors of the Internet, the responsible Government's departments have to help them conquer the possible barriers on the Internet such as the space of link and speed of operation. Their strong motive needs to be kept for continuing use of the Internet. For new and potential users, extensive courses of information literacy are needed to increase the possibility of their usage. In disadvantaged arena, extra supported resources are demanded. Special approaches like computer or Internet buses to countryside will be helpful.

Designing a system for accreditation of learning

A system that has legislative effectiveness for accrediting people's learning results is strongly demanded. The progress of experimenting Lifelong Learning Card or Passport has to get faster. Its merits or shortcomings are valuable for designing a system for accreditation of learning. The experimental usage in Taipei has started. For a national use, Taipei's experience can be referred to develop a national card or passport. No matter a Card or a Passport, it is a link of personal different types of learning. For its application, a system for accreditation of learning is required. The system should be developed on the basis of a multiple discussion process to form a consensus and to design its detailed contents. A comprehensive and broad recognition is very significant to enlarge the utility of the above Card or Passport. The system has to cover at least three types of learning ie formal, nonformal and informal tracks. Particularly, it is able to encourage individual's self-study and recognise the learning results for different purposes.

Enriching the achievements of the experiments of learning community

A collaborative learning network is rooted in a learning community. It is important to make the conception of a learning community as concrete as possible. The results of the five experimenting learning communities have to be carefully assessed for an extensive application. After the experiments have been conducting, the issue of developing collaborative networks can be a research question to be answered. Actually, it is impossible to ignore the role of different stakeholders in communities. A collaborative learning network is a place where stakeholders can get themselves involved. Thus, when the experiments have been carrying out, there can be valuable findings coming out, which are able to contribute to the formulation of collaborative networks.

Programming an encouraging system to have more key stakeholders

The involvement and participation of different stakeholders in learning communities has to be encouraged. As Rutledge, Swirpel and Tray [1996] suggest, networking is a significant step for the learning community. To find out the key stakeholders to form the networking is a critical task. For different stakeholders, some of them have stature obligations to take part in the collaborative networks. But, for the others, usually private organisations, may not have the remit responsibility. Their participation is based on their availability in intention and resource. No matter which kind of

stakeholders, the Government's encouragement is helpful, especially for those who have no legislative obligation. The governmental institutions have to be the models to lead the involvement of private partners. Necessary supporting resources, financial or spiritual, are needed from the responsible governmental departments whose powers can be regulated in relevant legislation. For example, local public schools have to actively invite other stakeholders in community to set up a partnership.

The above strategies are recommendations that can be used to enlarge the contributions of advantageous conditions and delete the influences of disadvantageous ones for developing collaborative networks via the Internet in learning communities. They cover many tasks in different dimensions for diverse stakeholders.

Conclusion

Collaborative networks can not appear unless the necessary conditions are already available. Hence, it is crucial to analyse different conditions, including helpful and harmful, to see how to formulate the networks. For achieving a lifelong learning society, collaborative networks can play a critical part. When there have been five learning communities in experiment and a growing usage of the Internet in Taiwan, it is a good time to develop collaborative networks inside. From collaborative networks and learning communities to a learning society through the application of the Internet is a direct and necessary road. There have been advantageous conditions in Taiwan, which are helpful to pave the way. But, there have been also disadvantageous conditions, which are barriers on the way. The author has analysed these two groups of conditions and raised strategies as recommendations to enlarge the potential contributions of advantageous conditions and delete the possible impacts of disadvantageous ones. The author's vision is to establish a lifelong learning society, which has been the focus of Taiwan's educational innovation and an international trend of educational development. For achieving the vision, the Internet is playing a critical role via the collaborative networks in community.

Abstract: This study, in the absence of a literature foundation on implementation of the National Educational Technology Standards and the use of new technologies to supplement traditional methodologies in teaching technology competencies, was designed to explore the influence of multimedia and web-based supplements on various learning styles and student motivation. Seventy-five undergraduate education majors in four Applied Educational Technology Courses were administered both Honey and Mumford's Learning Styles Questionnaire and Roedel's Goals Inventory at the beginning of the course. The students were also given the Goals Inventory at the conclusion of the course. Since this study is still in its infancy, the results from an initial pilot study and preliminary data analysis will be presented at WEBNET. The development of the shocked multimedia unit to be delivered via the World Wide Web, the instrumentation and research methodology will also be presented.

Introduction

According to the research by Sheingold & Hadley [1990], as well as many others, it takes an average of five years before teachers feel in command of new technologies and know: (a) how to use them; (b) when to use them; (c) how to assess their benefits; and (d) how to evaluate the usefulness of new technologies in the curriculum. However, national accrediting bodies are pushing for rapid integration of technology in teacher education. Consequently, faculty in teacher preparation programs are looking for new methods for helping their students acquire knowledge and skills to meet the recommended technology standards. Advocates of new multimedia and web-based technologies argue possible benefits of such technologies include increased intrinsic motivation, and the opportunity for students to learn in their own "style" and at their own "pace". An additional argument is that interactive multimedia and web-based materials provide media and visually rich material that is more likely to correspond effectively with students' individual learning "styles" [Crosby & Stelovsky 1995].

Goal Orientations

Educators are confronted on a daily basis with students who lack the necessary motivation to be successful in school. This has been a recurring concern in public education. The 1989 Gallup/Phi Delta poll of teacher attitudes showed lack of student interest as one of the top four mentioned programs in teaching [Elam 1989]. Student apathy and lack of motivation are also a concern in college age students [Cohen 1991; Cubbison 1993]. Recently, the study of students' goal orientations, or goal theory, is an area of student motivation that has drawn considerable interest. The goal orientation construct focuses on the types of learning goals that students adopt in academic situations [Ames 1992].

In referring to goal orientations, Ames [1992] defines achievement goals as an "integrated pattern of beliefs, attributions, and affect that produces intentions of behavior" and further adds, "that is represented by different ways of approaching, engaging in, and responding to achievement-type activities" [p. 261]. The two goals that have

received the most attention are mastery and performance goals. The following definitions of the mastery and performance orientations are based on descriptions proposed by Dweck and Leggett [1988].

Students who are oriented toward learning goals (i.e., mastery goals) are interested in learning new skills, improving their understanding and competence, and utilizing self-regulatory strategies. These students are concerned with improving their ability, and they seek challenges in the learning process. Therefore, mastery goals are concerned with actual learning and understanding. Individuals with mastery goals believe that competence is malleable and controllable, are more likely to be intrinsically motivated to learn, view errors as opportunities to learn, and persist in the face of failure.

In contrast, students who orient towards a performance goal perspective are more concerned with proving their ability. These students are concerned with being judged able. Further, they believe that competence is a stable characteristic, are not as likely to be intrinsically motivated, view errors as a sign of failure, and give up easily when they fail. These students avoid opportunities for challenge.

The following are some of the achievement behaviors of elementary age students that have been associated with each goal orientation [Dweck 1986 & Dweck & Leggett 1988]. Students with mastery goals seek out challenge and persist in the face of difficulty. These students view errors as opportunities to learn, to increase their effort, and re-strategize. Children are focused on effort needed to successfully complete a task and experience pride with their accomplishment. Therefore, they see competence as malleable. They choose challenging tasks even if they perceive their ability for those tasks to be low. These students are more likely to be intrinsically motivated to learn. In contrast, students with performance goals see intelligence as a fixed trait. They tend not to select challenging tasks in an effort to avoid negative evaluations. They are less likely to be intrinsically motivated to learn. Satisfaction is based on the ability they have displayed rather than the effort involved to achieve mastery. These students are focused on issues of ability. Errors indicate failure and lack of ability. Therefore, they tend to withdraw when they encounter these obstacles.

Most recently, research has begun to clarify the relationship between goal orientation and achievement behaviors with older students. In the college context [Archer 1994; Hagen & Weinstein 1995; Jagacinski & Nicholls 1987; Pintrich & Garcia 1991] investigations have led researchers to conclude that students in the college context are probably using both goal orientations simultaneously. The mere presence of performance goals does not necessarily lead to maladaptive achievement behaviors as long as mastery goals are salient. However, it is still the adoption of mastery goals that leads to the most beneficial achievement behaviors, and the thrust of this research still emphasizes the superiority of mastery goals. The findings from the studies that have been conducted in the secondary schools produce similar conclusions [Ainley 1993; Ames & Archer 1988; Wentzel 1989].

While this goal orientation theory of motivation has more recently been used in the study of student achievement in traditional college and university classrooms, it may also provide valuable insight into teacher education programs that choose to employ the use of high-quality, multimedia and web-based course supplements in addition to traditional teaching methodologies. The use of such multimedia technologies in teacher education has recently increased due to the availability of user-friendly courseware design software, the relative ease-of-use of the internet, and the push from national accrediting bodies such as the International Society in Technology Education, to train pre-service teachers in the integration of technology in their classrooms.

Student Learning Styles

The capability of multimedia and web-based technologies may in fact allow the instructor and the student to adapt teaching and learning strategies to enhance instruction. Such technologies can be used to provide numerous learning activities that represent each of the four dominant learning style categories as proposed by Honey and Mumford [1986]. The learning styles, in no order of importance, are: (a) activist; (b) reflector; (c) theorist; and (d) pragmatist. Activists involve themselves fully and without bias in new experiences. They enjoy the here and now and are happy to be dominated by immediate experiences. They are open-minded, not skeptical, and this tends to make them enthusiastic about anything new. They tackle problems by brainstorming. Reflectors like to stand back to ponder experiences and observe them from many different perspectives. They collect data, both first hand and from others, and prefer to think about it thoroughly before coming to any conclusion. Their philosophy is to be cautious. They are thoughtful people who like to consider all possible angles and implications before making a move. Theorists adapt and integrate observations into complex but logically sound theories. They think problems through in a vertical, step by step logical way. They assimilate disparate facts into coherent theories. They tend to be perfectionists who will not rest easy until things are tidy and fit into a rational scheme. Pragmatists are keen on

trying out ideas, theories and techniques to see if they work in practice. They positively search out new ideas and take the first opportunity to experiment with applications. They respond to problems and opportunities as a challenge.

Consequently, this study utilized Honey and Mumford's questionnaire to predetermine students' preferred learning styles. This data produced by the administration of the questionnaire allowed the researchers to correlate individual learning styles with each multimedia, web-based instructional unit developed by the researchers to enhance students' skills and knowledge in the use and integration of technology in one introductory college-level course on educational technology. This required course is part of a teacher preparation program.

Development of Multimedia, Web-Based Instructional Units

In conjunction with this study, several multimedia and web-based instructional units on the introduction to educational technology were developed by the principal investigators using Macromedia's Authorware and Director software programs. These multimedia units were designed to help students meet the National Educational Technology Standards (NETS) for all students (International Society for Technology in Education, 1999). The technology foundation standards for students are divided into six broad categories including: (1) Basic operations and concepts; (2) Social, ethical, and human issues; (3) Technology productivity tools; (4) Technology communication tools; (5) Technology research tools; and (6) Technology problem-solving and decision-making tools. Standards within each category are to be introduced, reinforced, and mastered by students.

The multimedia units were also designed to incorporate each of the four learning style categories identified by Honey and Mumford including: (a) Activist; (b) Reflector; (c) Theorist; and (d) Pragmatist. Activists involve themselves fully and without bias in new experiences. They tend to act first and consider the consequences afterwards. Reflectors like to stand back and ponder experiences. They postpone reaching definitive conclusions for as long as possible. Theorists think through problems in a vertical step by step way. They tend not to rest easy until things are tidy. Pragmatists try out ideas, theories, and techniques to see if they work in practice. They take the first opportunity to experiment with applications.

Purpose

This study, in the absence of a literature foundation on implementation of the National Educational Technology Standards and the use of new technologies to supplement traditional methodologies in teaching technology competencies, was designed to explore the influence of such multimedia and web-based supplements on various learning styles and student motivation.

Methodology

Participants

The participants were 75 undergraduate education majors in 4 sections of an undergraduate educational technology course entitled "Applied Educational Technology" at a southeastern university. This course employs a systems approach to using traditional and emerging technology in instruction. Its emphasis is upon the integration of instructional design principles with uses of technology as instructional tools to enhance the quality of classroom instruction and to facilitate the work of the teacher.

Data Collection

Data are to be collected using 2 instruments: (1) The Goals Inventory (Roedel et al., 1994); and (2) Honey and Mumford's Learning Style Questionnaire (1986). This Goals Inventory is designed to measure older students' mastery and performance orientations. It contains 25 items using a 5-point Likert scale for each item. It has two scales, and it yields two separate continuous scores. One represents an individual's score on the mastery orientation, and one represents a score on the performance orientation. These two scales are statistically independent and are

uncorrelated. Roedel et al. report respectable reliability and validity estimates for this instrument. The test-retest reliability estimates for the mastery and performance scales were $r=.73$ and $r=.76$ respectively. Internal consistency estimates were $.80$ and $.75$ respectively, using Cronbach's alpha. Adequate convergent and divergent validity conclusions were supported by comparing this instrument with other important constructs. The Goals Inventory takes approximately seven minutes to complete.

The Learning Styles Questionnaire is a self-administered questionnaire consisting of eighty, single sentence questions and is grounded in Kolb's theory of a four stage process of learning. This learning style inventory like most others, was developed to help a person discover general trends or tendencies that run through his/her behaviors, without placing undue significance on any item. The LSQ was designed to identify the relative strengths of four different learning styles.

Both instruments will first be administered in August, 1999. Participants will have a choice of how to complete the survey. The survey will be posted on the Internet and will also be available in a traditional paper and pencil format. The questionnaire available on the web site will be linked via an active server page to a Microsoft Access database. When submitted by the participants, the data will automatically be entered and filtered in the database. The Goals Inventory will be administered in a pre-post format and thus will also be administered upon the completion of the fall semester, circa December, 1999. For the purposes of this proposed paper session at WEBNET, preliminary data will be presented.

Courseware Use

Students enrolled in 2 of the 4 sections of the educational technology course will complete assigned units on the previously identified multimedia interactive introduction to educational technology in addition to traditional classroom instruction and use of a textbook. Students enrolled in the other 2 sections of the educational technology course will not have access to the multimedia materials. All of the sections will be taught by the same instructor using the same teaching methodologies, content, and materials.

Results

For the purposes of this presentation, the results from an initial pilot study and preliminary data analysis will be included. The development of the shocked multimedia unit to be delivered via the World Wide Web, the instrumentation and research methodology will also be presented. A more detailed description of the results of this study will be included in a full paper to be handed out during the WEBNET conference.

Conflict Resolution in a Virtual Environment: Exploiting the Affordances of a Multi-Object Oriented Environment

Kimberly Weiner, Ed.D

Pepperdine University, Graduate School of Education & Psychology, Culver City, CA
Tel: (310) 396-7556, Fax: (310) 396-7047, E-mail: kweiner@pepperdine.edu

Abstract: This paper describes the research and study concerning the concepts of conflict resolution and computer mediated communication. The purpose of this study was to assess the effectiveness of incorporating a text-based virtual world, a Multi-Object Oriented environment, with a conflict resolution curriculum centered around constructivist role-playing. Qualitative and quantitative results reveal positive answers to the research question. Future research is recommended on a broader scale, including longitudinal follow up assessments that include the sample's families.

1. Introduction

Research shows that most youth related violence is either directed at or perpetrated by one's friends or acquaintances (Bilchik, 1995; Lovett & Walzak, 1997; The problems of juvenile violence are multi-dimensional, involving the child, his/her family, friends, school, and community.

How can adults teach children to protect themselves in a proactive fashion? One possible answer is a skill set known as Conflict Resolution Management (CRM). Such tools as win-win outcomes, peer mediation, and emotional diffusement fall under the CRM heading (Johnson & Johnson, 1995). These skills enable children to stem violent conflicts, thus, transforming the emotional climate around their circle of contacts. One issue with conflict resolution training is the difficulty children often experience when discussing personal or painful issues (D'Andrea & Daniels, 1996;

Today, there are tools that make it possible to offer children a safe space within which they can explore the issues surrounding conflict. The anonymity of a virtual environment offers a sense of security that enables children to explore ideas and emotions that in a face-to-face environment would be to embarrassing or personal.

2. Background

2.1 Conflict and the Child

"Conflict is a natural human state often accompanying changes in our institutions or personal growth" (Ferrara, 1996, p. 29); unfortunately, this understanding is being lost on our children. Conflicts of insignificant relevancy, when considered against the broad spectrum of a child's life, are resulting in increasing numbers of violent episodes (Kelley, 1997). In and of itself, conflict is neither negative nor positive, it is how one resolves a conflict that leads to positive or negative outcomes (Brunner, 1990; In 1995, the greatest jump in the percentage of children perpetrating violent actions came between the age groups of 10- to 12- year-olds and 13- to 14-year-olds (FBI, 1995, p. 240). The need to reach children before they become accustomed to relying on violent behavior to deal with conflict is critical. The sooner a child is understands that conflict can be managed constructively, the less the possibility of a violent reaction to a disagreement or misunderstanding (Johnson & Johnson, 1995, p. 16).

Creating an atmosphere that affords the attainment of conflict resolution skills, where a student feels safe from peer rejection, is complicated. This is where technology can play a powerful role; a virtual environment allows a student to explore aspects of the self that are not associated with his/her in-class persona. Specifically, a Multi-Object Oriented environment (MOO) provides a virtual world that supports this type of learning.

2.2 A Multi-Object Oriented Environment

A MOO is a software program that accepts connections from multiple users and provides access to a shared database of "rooms" and other objects. It is a virtual reality, an electronically represented place (Curtis & Nichols, 1993). Within this world, participants are known as players. Players can not visually see each other; the entire world is text, so anonymity and a feeling of physical and emotional safety is preserved. It is thus that this study proposed to harness the potential of a MOO to create a learning experience that would positively impact student behaviors regarding conflict in the classroom. As a MOO was the focal environment, the project was named MOOSylvania. The name was designed to the appeal to preadolescents, and emit the essence of a far-off place. This helped establish the reality of the environment.

2.3 Constructivist Role-Playing

The primary tool used to acquire first-hand knowledge of conflict resolution concepts within the MOO was constructivist role-playing. A term coined by this researcher, constructivist role-playing has three separate, yet interrelated steps. First, in small groups, the children act out a given scene. Second, they discuss the scene; characters, actions, and choices are questioned and examined. The students decide on a desired outcome. Finally, the students replay the scene, experimenting with different actions and strategies related to CRM to experience how their choices affect others.

This offers an opportunity to discover how differing actions lead to differing outcomes. Through this type of role-playing, students have the opportunity to identify behavioral cues, expand their vocabulary regarding feelings, and work toward identifying nonverbal, emotional cues. Acting and experimenting with the use of verbal and nonverbal actions toward a positive resolution of a conflict allows a child to construct personal meaning and individual incentives for resolving conflicts positively.

2.4 Why an On Line Environment Is Better for Conflict Resolution Skill Attainment

As computers permeate adolescent life (Tapscott, 1998), it becomes logical that technology be used to support conflict resolution training (Carruthers et al., 1996). Technology offers the opportunity to (a) build personal knowledge through simulated experiences and (b) have one's thoughts visible so one can reread, rethink, and revise reactions to stimuli (Rosenberg, 1992). "Immersion in a simulated environment can provide an environment for working on important personal issues that feels less threatening than a face-to-face situation" (Turkle, 1995, pp. 188-189). Dede (1995) feels that immersion of the self in virtual worlds can enhance learners' understanding of phenomena in our shared reality because the experience is real, but is cushioned by the feeling of physical solitude.

Technology allows children to manipulate symbols and organize communication in more autonomous ways (Morrison & Collins, 1995). "For young adolescent students, with their increased cognitive abilities and developing sense of identity, a sense of autonomy may be particularly important" (Anderman & Midgley, 1998, p. 32).

This autonomy is supported by the anonymity of a MOO. There are no commands to discover the real-life identity of others. This privacy makes players' self-presentation crucial. Players can only be known by what they explicitly project and are not locked into any factors beyond their control, such as personal appearance (Curtis, 1992). The textual environment allows the creation of a distinctive self and the rehearsal of it (Young, 1994).

As well, this environment offers the opportunity to see one's words and actions before such things are visible to others. Communication in the computer-mediated MOO is synchronous but digitized. This gives the conversation a quality entirely different from the timing one experiences when chatting face-to-face. One cannot share a communiqué until they finish and hit the send button. Such an on-again off-again process has an impact on the communicative structure of virtual conversations, making it a more reflective experience (Marvin, 1995).

3. The Study

The intended population for this project is school children between the fifth and seventh grades. There were two groups involved in the creation/testing of MOOSylvania. The sample, the students whose behaviors were assessed, were called MOOers. The second group, older student volunteers, only met the MOOers on-line, and were identified as the Mentors. They facilitated the daily work and provided social role modeling.

3.1 Research Question

This study attempted to answer one question that was designed to assess the power of an online environment as a setting for what Bruckman and others have termed identity work, i.e.: learning through experimentation with representations of the self (Bruckman, 1998; Turkle, 1995) in relation to conflict resolution.

Question 1

What is the impact of constructivist role-playing in a virtual environment on the manner in which a child uses language and deals with conflict within the real environment of the classroom?

3.2 Assessment

MOOers completed a pre and post questionnaire, the Coping Responses Inventory (CRI) Youth Form. The CRI-Youth Form can “help to describe an adolescent’s coping responses to a specific stressful life circumstance” (Moos, 1993, p. 5), such as conflict. It is an appropriate tool for measuring changes in how a youth chooses to deal with conflict. Classroom behaviors related to student conflicts were observed. Interviews were conducted with students and teachers. This study generated both qualitative and quantitative data.

Research question	(Quantitative) CRI Youth Form	(Qualitative) Observations	(Qualitative) Interviews with teacher & assistant	(Qualitative) Focus group
1	X	X	X	X

Table 1. The research question and assessment data. CRI-Youth Form = Coping Responses Inventory – youth form.

3.3 Procedure

The “Safe Schools, Safe Students” report on successful anti-violence programs states that students should receive a minimum of ten 30-minute sessions (Cohen & Verber, 1998; Drug Strategies Weekly, 1998). With this in mind, the MOOers received twelve 45- minute MOOsylvania sessions.

4. Results

4.1 Sample

Twenty-nine children from Los Angeles, California participated in MOOsylvania (see Table 2).

	Group A	Group B	Total Sample
Gender			
Male	5	8	13
Female	9	7	16
Age (years)			
12	7	7	14
13	7	7	14
14	0	1	1
Grade			
6	7	8	15
7	7	7	14
Ethnicity			
African American	6	5	11
Latino	8	10	18

Table 2. Demographics of the sample.

4.2 Quantitative Data

While individually the results of the CRI components revealed no statistical significance from pre to post testing, it was clear that each subscale had moved in a positive direction with the hypothesis. A trend analysis method was used to determine the extent to which this trend was likely to be significant. For the six categories related to research question 1, the scores on all six changed in a fashion consistent with the research hypothesis. The probability of such consistency is $p < .002$, ($1/26 = 1/64$) where six out of six results changed in the hypothesized direction (see Figure 1).

CRI-Youth Inventory Category	Actual pre-testing average	Actual post-testing average	Direction of change of averages (pre to post)
Logical Analysis (LA)	8.793	9.655	Positive, agrees with hypothesis
Positive Reappraisal (PR)	7.103	8.689	Positive, agrees with hypothesis
Problem Solving (PS)	8.965	9.172	Positive, agrees with hypothesis
Cognitive Avoidance (CA)	8.143	8.137	Negative, agrees with hypothesis
Acceptance or Resignation (AR)	7.482	7.260	Positive, agrees with hypothesis
Seeking Alternative Rewards (SR)	8.172	8.344	Positive, agrees with hypothesis

Figure 1. Changes in pre and post testing of CRI-Youth Form, actual version, and the relation to the research hypothesis

4.3 Qualitative Data

4.3.1 Observations

Pre and post program observational data were collected in exactly the same fashion. Both sets of observations were conducted over two consecutive days for four hours a day, making a total of eight hours of observations before and another eight after the program.

4.3.2 Pre Program

Of the 20 classroom incidents noted by the observers (see Figure 5), only 3 ended in a win-win situation. Four noted conflict situations ended in a lose-lose outcome, and the remaining 13 incidents were noted as a lose-win situation outcome. Several of these incidents were resolved only through teacher intervention.

4.3.3 Post Program

Sixteen classroom incidents were noted in the post program observations. All 16 were noted as ending in win-win outcomes and were resolved without any teacher intervention. In particular the observers were struck by the change in the way the students communicated with each other. The observers noticed the students reacting less emotionally to each other and expressing their feelings as opposed to the earlier observed behaviors of emotional reactions to words or perceived disrespectful behaviors by striking back with name calling or angry slang.

4.4.4 Significance of Observations

The observational data demonstrates positive changes in how the students related to each other in the classroom after participation in MOOSylvania. The number of lose-lose outcomes dropped from four to zero; win-lose dropped from 13 to zero. Win-win outcomes improved from 15% of observed incidents to 100% (see Figure 5).

Figure 5. Sample's scores in observable behaviors pre and post program.

Situations that resulted in verbal altercations or negative emotions before MOOsylva, were treated as minor moments or opportunities for self-expression after the program. The observers noted in their second observations that the students appeared to think and reflect before reacting; pre-program observations noted students using language to push people away, "you mind yourself boy", "you better back off". Post program observations noted less instances of such use, finding language being used for inclusion, "we could do it like this", "we have to talk about it", "we can share". These data are consistent with the hypothesis that participation in MOOsylva would afford a positive change in how the sample would deal with conflict in the classroom.

4.4.5 Teacher and Classroom Assistant Interviews

When questioned about changes in classroom behaviors, the teacher said things "seem a little better." The teacher was pleased that all 29 students were all able to abide by the guidelines of conduct and complete the program, and that alone should prove that the program "does help students with conflict on some level."

The classroom assistant offered several changes in behaviors and attitudes that he believed were direct results of MOOsylva. One specific behavior relates to research question 1: an observed increased use of words to diffuse conflict. "Some kids, especially the girls, have gotten much better about explaining why they want someone to stop bugging them. Instead of just getting mad, they are using words, explaining why whatever the other kid is doing is bugging them."

4.4.6 Student Interviews

Twenty-seven students were interviewed; 17 of the students reported actually using the CRM skills (see Figure 8). Nine students reported using the skills at school. "I liked having something to say when stuff got hard with my friends"; "it was better to know what to do when a fight was gonna begin so I could stop it before we all got into trouble". When asked what they had used, one student said she tried to end a fight in a "win-win way so me and my friends would all be happy." Another reported listening and expressing feelings so that she could "keep communicating without getting into a big argument." When asked whether they thought they would continue to use these skills, each of the 17 who had tried the skills or strategies replied in a fashion similar to one girl. She said it was "good that I learned how to respect people more because now they respect me back more too."

Number of students in focus group	Used conflict resolution skills (anywhere)	Used conflict resolution in classroom	Used mediation in classroom	Used trying to find a win-win outcome in classroom	Used explaining their feelings in classroom	Used problem solving skills in classroom
27	17	9	4	2	1	2

Figure 6. Focus group comments on use of conflict resolution skills in classroom, post program

4.4.7. *Unanticipated Student Benefits Inside the Classroom*

The teacher credited MOOsylvania with teaching his students to work independently. He believed that it was the motivation to work at their own computer and participate in conversations that gave them the experience of working alone, and that experience transferred into the classroom. The classroom assistant echoed this idea with comments on improvement in the students writing skills. He also noticed an increase in student self-esteem and an increase in the class's enthusiasm for school. Several students mentioned improvements in the spelling and typing. As well, an increase in overall computer skills was mentioned in four of the post program interviews.

5. Conclusions

The combined findings from the CRI-Youth Form, interviews and observations all provide evidence that the MOOsylvania program, based upon constructivist role-playing in a text based, virtual environment, had a positive effect on how the students dealt with conflict in the classroom. The specific impact has been documented as a quantitative change in how the students chose to react to conflict, qualitative changes in observable behaviors and choice of language when dealing with conflict, and self-reporting of the use of conflict resolution skills and strategies in the classroom. The research behind the study supports the belief that it was the unique opportunity of exploring behaviors, actions, and different aspects of individual identity that afforded a learning experience that was powerful and meaningful enough to transfer from the realm of cyberspace into the reality of a child's everyday existence.

Implementing a Large Scale, Web Based Distance Education Course

Dr. M. J. Weller

Faculty of Technology

The Open University

Milton Keynes

MK7 6AA

United Kingdom

e-mail: m.j.weller@open.ac.uk

Abstract: T171 *You, your computer and the Net* is a large-scale distance education course produced at the Open University in the UK. It offers an introduction to computers and the Internet, and is aimed at a wide audience. The course is tutored entirely online and is delivered via the World Wide Web. This paper outlines the strategy for implementing such a course and the related pedagogical issues. These issues included developing appropriate student's skills, maintaining quality control, facilitating easy updating of material, ensuring student interaction with the material and making the material accessible and meaningful to a broad range of students. The manner in which each of these issues has been addressed is outlined. The course structure is a modular one based around accessible set texts, with wrap around academic material on the course web site. The course was piloted in 1999 with 900 students and demand for the course has been very high.

Introduction

Use of the Internet and the web in particular for distance education has been on the increase, with the rise of third generation courses [Nipper 1989]. The use of the Internet as the delivery mechanism for distance education offers a number of advantages over conventional methods, including quicker production and alteration of material, increased opportunity for feedback and interaction with students and flexibility in study patterns.

It has a number of limitations also, which mean it is not suitable for all types of material, or teaching methodologies. It is poor in comparison with most conventional methods of delivery when issues of access and cost are considered. The types of suitable media are also limited, for instance restrictions on bandwidth mean that delivery of video is still largely unrealistic for any meaningful educational purposes.

It has been suggested [Bates 1995] that there is a tendency with new technologies to add new technologies onto an existing model. This negates any advantages offered by an Internet based delivery method, whilst increasing the cost of the course production. The use of web delivery has met with mixed success. For instance, [Ward and Newlands 1998] report that students exercised a greater choice over study time, and had less time and financial expenditure with web based material compared to conventional lectures. However, they did not utilise the web fully, and often resorted to simply printing out the materials. It has also been reported [Warren and Rada 1998] that in order to duplicate the productive interchanges found in face to face sessions it was necessary to impose certain practices on computer conferences, including stringent deadlines for participation.

T171 *You, Your Computer and the Net* is an ICT foundation course developed at the Open University in the UK (OU). Its aim is to take computer beginners, and provide them with the skills needed to function productively with a personal computer and the Internet. It also aims to provide knowledge to place these technologies in context, so that by the end of the course students are comfortable both with using them and conversing about them and their wider implications.

Production of ICT courses has traditionally posed something of a problem for distance learning establishments, in that it is a rapidly changing field. A traditional print based OU course typically takes three to four years to produce and will be in presentation for eight years. This means the course material needs to have a shelf life of up to twelve years (although partial rewrites are often undertaken to modernise material part way through a course). The traditional print based production has meant that the OU has concentrated on getting its material as close to perfect on first presentation as is possible. The feedback from students combined with the production methods means that changes to course material can take some time to put into effect.

Given the factors outlined above, there were several aims for T171, which can be summarised as:

1. To produce a large scale, broad appeal ICT course.
2. To design a working method which allows for rapid production and alteration
3. To utilise an effective teaching methodology which would maximise the advantages the Internet offers as a delivery mechanism.
4. To teach both traditional study skills and those required to work effectively with the new technology.

In order to achieve these aims we were therefore faced with a number of issues which had to be addressed:

1. How to ensure that students develop new skills of working with this technology, for example avoiding the 'Print it all out' strategy described above.
2. To develop material which matches the OU's usual high standards but in a shortened time scale
3. To ensure that material can be updated or replaced easily without extensive course rewrites.
4. To ensure that students engage with material effectively, when they are unfamiliar with the topic.
5. To make material accessible to a wide range of students with different backgrounds and different needs.

The manner in which these five main issues were addressed in the course will be detailed separately.

Developing new skills

One method of ensuring students develop skills is to integrate them within the assessment of the course. T171 requires students to produce their assignments as HTML documents, and their working notes are also in this format, thus enforcing a familiarity with HTML and issues of web design. Students were required to formulate their notes so that they developed into a study journal over the course. They were directed by exercises at various stages to develop this journal. For instance, one activity requires them to reformulate their journal, producing a new index page according to categories of their own devising. This notion of organising material in different ways and use of hypertext as a means of thinking about and working with material is a skill the course team believes will be of value as the information content students are required to deal with continues to grow.

Assessment in T171 is ostensibly web based, in that students are required to develop a small web site for their end of course assessment, as well as 'web-essays' for their continuous assessment component. This is assessed not only on its content, but also its structure, design, use of the Internet as a resource and so forth. In this manner the importance of producing material for this new medium is reinforced.

By using interactive material, such as simulations of a modem connecting to a remote computer or microprocessor operation and interactive questions additional benefit is placed within the material. This provides an educational motive to engage with the material in its presented form, rather than reverting to prior study patterns, such as printing large quantities of the content.

The course team realised that students often need to work away from their computers. Two independently published set texts were therefore used in the course [Cringely 1996] & [Hafner & Lyon 1998]), which tell the basic story of the development of the personal computer and the Internet respectively

There was a strong emphasis on collaborative work via CMC in the course. Students were therefore required to engage in communication with other students and to co-ordinate their efforts. This was one aspect of the emphasis on computer conferencing in the course, which has no face to face tuition.

Producing high quality material in a short timescale

In order to produce teaching material in a shorter timescale than has been previously possible a number of decisions were taken. The first was to make the web the central method of delivery for course materials. This allows for a quicker production cycle than is usual with printed course texts. A second major decision was to create a modular structure. T171 consisted of three modules, with one academic author assigned per module, with the other authors and course team performing the task of critical review. The modules were largely independent of each other, thus allowing parallel production. The modules forming T171 can be summarised as follows:

- Becoming a confident computer user – an introduction to basic computer skills and applications, using the Internet and group working. The material was taught in a generic manner, so it was not software package specific.
- The story of the personal computer – using the set text, *Accidental Empires*, [Cringely 1996] to tell the basic story of the development of the computer, the module explores technological, social and economic issues raised by the material.
- The story of the Internet – using the set text, *Where Wizards Stay Up Late*, [Hafner and Lyon 1998] again to tell the basic story of the development of the Internet, the web site material explores issues such as the development of protocols, paradigm shifts and social impact of the Internet.

Another important feature of the production model was the use of set texts. These formed the function of telling the ‘basic story’ of modules two and three. Both books were very readable accounts of their respective stories, and not traditional academic texts. The web site represents the academic content, which wraps around the set texts.

The production of material was a more iterative process than in standard production, with less clearly defined roles. The use of design templates means the author can quickly produce material which is close to the finished article, although it still requires editing, reviewing and some fine-tuning of design.

Easy updating

The use of web based material over print means material can be updated much easier and at considerably less cost. This is particularly relevant in a rapidly changing field. By making the course web based the course team could make use of external web sites which maintain up to date material on issues which are developing during the course.

The modular approach offers the advantage of easy updating as well as quick production. The modules were independent to a degree, which means material in any module can be easily altered without inducing large changes throughout the course. This independence of modules was not absolute, as there was some integration to allow for the development of study skills through the courses.

Engage with material

Module one in particular was structured around an activity based learning model. For example using the web was formulated as a scenario where a group of four students were required to create a web site for a fictional

client. This formed part of the assessment for module one, so students were required to partake in the activity. A portfolio of evidence formed part of the end of course assessment, so students were required to produce evidence of conferencing, note taking, summarising and so on. In this manner the assessment reinforces various methods by which students can engage with the material, and with each other.

This emphasis on conferencing and group learning places learning as a social function [Bates 1995]. It is therefore important to introduce students to the use of CMC, and to increase their communication skills. This was done through exercises in module one, gradually developing the student's communication skills. The material in modules two and three could therefore rely on these skills being in place, and utilise discussion as a learning method.

Throughout the course 'study guides' are delivered fortnightly as an e-mail attachment. In modules two and three the students adapt these to create their own study journal on their hard disks. There are also a number of tutor group activities which allow students to share information, and to compare study approaches. As has been mentioned the assessment model reinforces the importance of this approach.

Accessibility

T171 was aimed at a broad audience, not just technology or computer science students. One key aspect in achieving this accessibility was the use of the readable set texts mentioned above. This approach uses a narrative based method as a means of exploring the issues raised by the material. The importance of narrative as an educational methodology is emphasised by the use of multi-media, where many students feel 'lost' without a conventional narrative structure to guide them through [Laurillard 1998]. The narrative led teaching methodology also places an emphasis on demythologising the subject, by placing it within a context. It also allows the material to naturally cover a broad spectrum of issues, including the technology (for example the architecture of a computer), the social impact of computers and the Internet (for example the implications of the 'Information society'), the industry (for example the role of Microsoft) and so on.

There was some preparatory material, to familiarise students with the basic operation of a computer, and the Windows operating system. There were a number of other exercises including a web browser tutorial and a keyboard tutor. This allows students with a broad range of experience to study the course.

Once again the use of conferencing aids the realisation of this aim. Within the material there are a number of 'embedded conferences' that focus on a seeded discussion relating to the material students have just read.

Course presentation

The course has the overall structure of three modules, with a web site adding academic wrap around material to readable set texts. The course lasts for 32 weeks, with four tutor marked assignments (TMAs) and one end of course assessment. Students are guided through the material by regular study guides which are delivered as e-mail attachments. Tuition is conducted online and a number of group activities are embedded within the material.

A pilot study of the course was presented in 1999, with over 900 students. Demand for the course was considerable, and estimates for student numbers in 2000 are in excess of 5,000. The demographics of the current cohort of students show that the course is divided fairly evenly according to gender (approximately 44% female), there is a broad age range from 18 years old to 82, a large proportion of students are new to the OU, and many of them are principally taking non-technological degree profiles. Evaluation of the course is being undertaken.

Conclusions

We can now review the original aims of the course, and see to what extent these have been satisfied by the model outlined above. The first of the aims was to produce a large scale, broad appeal course. The student demand for the course, and the diversity of the student cohort seems to indicate that, at this stage at least, this has been achieved. The second aim was to devise a working method to allow for quick production and alteration of material. The course was produced in a year, which represents a considerable improvement on most OU course

production cycles. Much of the time was spent in devising the working model, and setting up a suitable technical structure for the course. Much of this is a one-off investment, and future courses which adopted a similar model could improve upon this time frame even further. There are a number of such modules now in development in diverse topics. The third aim was to utilise the Internet as a delivery mechanism by adopting a suitable teaching strategy. The use of the web material plus set text, in addition to the emphasis on conferencing and group work suits the material, and offers the advantages of the Internet outlined at the start of this paper. Whether it is an effective learning mechanism for students can only be known in detail when full evaluation of the course has occurred. The last aim was to teach both traditional and new study skills. The use of exercises, group work and the assessment strategy has been the means by which this has been implemented. Again early feedback is positive, but firm conclusions must await the outcome of the evaluation.

In conclusion the model developed by T171 seems to support large-scale web based distance education courses, which are distinct from 'campus' models.

The Design and Development of an Evaluation System for Online Instruction

Tim L. Wentling
Scott D. Johnson

Department of Human Resource Education, University of Illinois at Urbana-Champaign, USA
Tel: (217) 333-0807, Fax: (217) 244-5632, E-mail: wentling@uiuc.edu

Abstract: With the growth in popularity of online instruction has also come the concern for accountability and the need to make adjustments and improvements in online programs. This paper describes the conceptualization and development of an evaluation system that can be used to monitor and evaluate online instructional efforts. The evaluation system addresses concerns of both program administrators and course instructors. Computer technology is used to provide partial automation to reduce respondent burden and to efficiently use evaluation resources.

1. Introduction

Online or web-based learning is an education and training phenomena that is growing rapidly around the globe. As with any innovation, there are questions about effectiveness, efficiency, and utility (McCollum, 1998). With online instruction, the issue of evaluation and accreditation is especially important due to various threats commonly perceived by educators and trainers. These threats include a change in student campus life and the roles of professors (McCollum, 1998), the fear that the push for distance learning comes from entrepreneurs and university “bean counters” rather than educators (Mendels, 1999), and whether virtual students feel more isolated than their traditional counterparts (Arenson, 1998). These concerns can only be addressed through systematic research and evaluation efforts.

Human resource development professionals (educators that are typically situated in nonschool settings) are blessed with a rich history of evaluation thought, development, and research, primarily derived from the fields of education (Patton, 1997; Scriven, 1967; Stake, 1981; Stufflebeam & Shinkfield, 1985; Stufflebeam, Foley, Gaphart, Guba, Hammond, Merriman, & Provus, 1971) and human resource development (Holton, 1995; Kirkpatrick, 1976; 1996; 1998; Kaufman & Keller, 1994). From these foundations, specialized evaluation processes and systems have been designed and implemented for HRD interventions, including training programs (Raab, Swanson, Wentling, & Clark, 1992; Wentling, 1980, 1993).

The design of evaluation systems for online instruction has been attempted by a number of professionals, including instructional designers of CBT systems (Clark, 1994; Draper, 1996; Simonson, 1997) technology experts (Jackson, 1990; Kimball, 1998; Middleton, 1997), and HRD practitioners (Magalhaes & Schiel, 1997; Pisik, 1997). The work of these individuals demonstrates progress in applying intuitive principles and practices of evaluation to online environments. Other authors have provided practical applications of evaluation theory by offering suggestions and guidelines for the evaluation of online instruction (Khan, 1997; Nichols, 1997; Oakes, 1997; Ravitz, 1997; Thorpe, 1993).

The evaluation of online instruction is an important part of the design and implementation process. Even though practitioners and academics currently evaluate online instruction, their attempts have been limited to the use of traditional research methods and intuitive approaches to evaluation. Additionally, much of the inquiry focused on web-based learning is done as research studies with limited scope and of highly situational utility. There appears to be a lack of systematic evaluation of online programs built on evaluation theory and practice. The activity described in this paper is an attempt to conceptualize and develop a transferable, adaptive evaluation system for online instruction.

2. Conceptualization and Development of the Evaluation System

The purpose of this project was to design, develop, and implement an evaluation system that would meet the needs of the developers and sponsors of online instructional programs. The activities of the project reflect major efforts to obtain information, design components of the evaluation system, and test and revise the evaluation system. The specific activities were to (1) develop a conceptual model for online evaluation, (2) identify specific

vital signs for an online program and determine appropriate measures, (3) automate the collection and analysis of evaluation data using knowledge engineering, (4) create an electronic performance support system to assist in program evaluation, and (5) conduct a field test of the evaluation system. The following sections describe each of the five major activities being accomplished in the formulation of the Illinois Online Evaluation System. At the time of this writing the evaluation system is evolving. Many of the tasks are complete, while some are underway.

2.1 Activity 1: Development of a Conceptual Model for Online Evaluation

This activity involved the conceptualization and design of the overall evaluation system, with the identification of major components and their functional relationships. The evaluation system, as currently designed, occurs in three stages: (1) vital sign assessment, (2) in-depth analysis, and (3) program improvement planning (see Figure 1). The evaluation system can best be explained using a medical analogy in which a physician examines a patient's vital signs to determine the patient's current state of health. Vital signs that are below acceptable standards are examined in more detail, utilizing more precise information and investigative techniques. As a result of the analysis, a plan is developed to facilitate improvement.

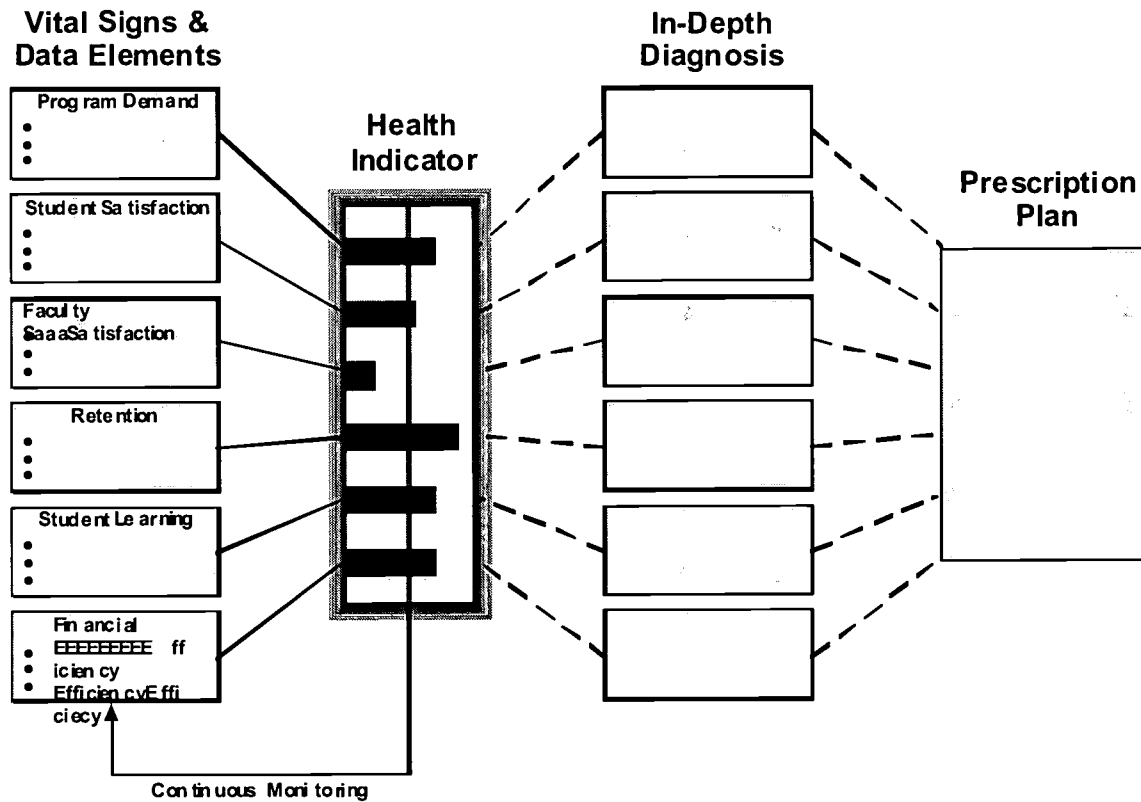

Figure 1. The Online Evaluation System.

Vital sign assessment (Stage 1) diagnoses the general health of the online program and individual online courses using data collected through routine activities. Example data include the number of inquiries about the program, the number of applications received, and the performance of students in the individual courses. The data are used to calculate a program's "health" rating in six areas: (1) student demand, (2) student retention, (3) student satisfaction, (4) faculty satisfaction, (5) student achievement, and (6) financial efficiency. The ratings help program personnel and sponsors monitor the overall performance of the program and individual courses to identify areas that may be problematic.

During the *in-depth analysis* (Stage 2), any vital signs that are identified as substandard are analyzed in detail. A thorough investigation is conducted to determine underlying problems or causes. Often this investigation requires the collection of additional data, or the use of data from related vital signs. For example, a low rating in student satisfaction might lead to the further analysis of the individual items that comprise the student rating indicator. Additionally, a review of data related to student learning and faculty satisfaction might be done.

Program improvement planning (Stage 3) provides solutions to the problems that are investigated during the in-depth analysis. Alternative strategies for solving the problems are identified, along with resource requirements for implementing the solutions. Program personnel are able to select various courses of action and develop plans for addressing the identified problems.

2.2 Activity 2: Vital Sign Identification and Development of Instruments and Procedures

The major activity in the development of the evaluation system involved several inquiry endeavors to identify “quality indicators” for use as assessment criteria. Lists of quality indicators drawn from the literature on computer-mediated education, outcomes of education, and evaluation were identified and prioritized. An initial list of 18 “vital signs,” developed from the results of the literature was reviewed by a group consisting of HRD and evaluation experts. The list of vital signs was reduced to six by determining the relative importance of each to the stakeholders of the evaluation.

Instruments and procedures for gathering, summarizing, and analyzing vital sign data have been developed by project staff. Data used to calculate vital sign ratings are obtained through analysis of electronic archives, document review, surveys, student testing, and expert review. Sample data elements used to calculate each vital sign rating are described in Table 1. The actual vital sign ratings are calculated from student test scores, mean scores on survey instruments (i.e., student satisfaction and faculty satisfaction), and data comparisons (e.g., enrollment, retention, financial data). Standard transformations of the data are performed to provide a common scale for each vital sign to facilitate portrayal and comparison across the vital signs.

<i>Vital Signs</i>	<i>Data Elements</i>
Program Demand	<ul style="list-style-type: none"> • Number of applications requested per semester • Number of applications received per semester • Number of telephone contacts per semester
Student Satisfaction	<ul style="list-style-type: none"> • End of course student ratings of program content, quality of instruction, instructional resources, technology used, amount of interaction, instructional methods • Mid-semester student ratings • CISS data regarding perceptions of course interaction, course structure, and technical support
Faculty Satisfaction	<ul style="list-style-type: none"> • Faculty ratings of technology, technical support, interaction with students, quality of student work
Student Retention	<ul style="list-style-type: none"> • Percentage of dropouts from beginning to end of each course and the program
Student Learning	<ul style="list-style-type: none"> • Self-assessment of learning and transfer • Course project scores • Quiz and Test scores • Course grades
Financial Efficiency	<ul style="list-style-type: none"> • Total unit cost, direct cost, overhead cost, • Tuition revenue

Table 1: Data Elements for Vital Sign Rating Calculation.

2.3 Activity 3: Knowledge Engineering

As work progressed in conceptualizing the evaluation system and identifying vital signs, alternatives for automating the system were explored. Literature on artificial intelligence, decision support software, electronic performance support systems (EPSS), and expert systems was reviewed by project staff. Due to the technology potential for the evaluation model, its focus on internal rather than external evaluation, and its purpose as a self-evaluation tool to be used by a variety of online personnel, including program administrators, instructors, and instructional designers, it was ultimately decided to utilize performance improvement technologies to automate much of the data collection and analysis functions. Performance improvement technologies make dynamic use of technology to facilitate data collection and analysis tasks and to improve individual performance by providing timely information, advice, coaching, and training. An electronic performance support system is an example of a performance improvement technology that “captures, stores, and distributes individual and corporate knowledge assets throughout an organization to enable an individual to achieve a required level of performance in the fastest possible time and with the minimum of support from other people” (Raybould, 1995, p. 11). EPSS technologies often include an information database, an expert advisor, customized tools and templates, and the potential to run simulations. Beyond a few efforts in corporate settings, this technology has not been widely applied in education and training for evaluation purposes.

Available literature on performance improvement technologies was reviewed. A key component to any expert system is the knowledge base of a recognized expert in the problem area (Hayes-Roth, Waterman, & Lenat, 1983). Focus groups of recognized online education experts from the University of Illinois were held to ascertain their perceptions of what constitutes effective online education and evaluation. These experts worked through simulated evaluation problems to test their ideas and were asked to develop specific guidelines and suggestions for improving the vital sign assessment and in-depth procedures. The framework for the expert system was based on the outcomes of this activity.

2.4 Activity 4: EPSS Development

The investigative framework gleaned from the knowledge engineering activity was developed into a series of If-Then rule process charts (one for each vital sign) by the developers. One partial example of a vital sign rule process chart is shown in Table 2 where a variety of “then” statements are provided in response to the low indication of student satisfaction.

<i>Vital Signs</i>	<i>Data Elements</i>
<p>IF:</p> <ul style="list-style-type: none"> • Student Satisfaction as indicated by Student Rating Form is Low, 	<p>THEN:</p> <ul style="list-style-type: none"> • review subscores for student ratings results. • identify the subscores that reveal the area of problem. • review results to individual items in the problem subscore(s).
<p>IF:</p> <ul style="list-style-type: none"> • If more information is needed to determine the problem, 	<p>THEN:</p> <ul style="list-style-type: none"> • develop an interview questionnaire and contact a sample of students by phone. • develop an e-mail questionnaire with relevant questions and send to a sample of students. • summarize new student data. • present the summary of all results to the instructor and discuss potential causes of the problem.

Table 2: Sample EPSS Rule Process Chart for One Vital Sign.

The probable causes identified by the online instruction stakeholders were incorporated into the rule process charts to complete the exploration diagrams. Sample computer display screens were also developed that simulate what each screen on the finished performance system program should look like. Using the rule process charts and sample screens, project staff created the performance support system. Prototype system routines were reviewed and revised to correct programming errors, to improve interface inadequacies, and to ensure user friendliness.

2.5 Activity 5: Field Testing

The performance support system shell was reviewed by selected professionals as a preliminary step to pilot testing. Data were programmed into the system to allow users to explore all possible investigative paths in the in-depth analysis. Formal and informal feedback was provided, which resulted in minor revisions in the programming (elimination of “bugs” from the system) and content of the evaluation system. The evaluation system is currently being tested within an online masters degree program in HRD at a large U.S. university. Following this initial testing, there are plans to expand the field testing to other university level online programs and in corporate settings.

3. Implications and Discussion

What truly separates the vital sign concept from traditional evaluation is its use of specific outcome measures with minimal data requirements to create a cursory picture of the general status of a program. The six vital signs are measured for each individual online course. Efficiency is maximized because initial data requirements are minimal, only specific programs are examined, and only problematic vital signs are subjected to further examination.

The most obvious technical feature of this new evaluation system is its use of the electronic performance support system. Used primarily in medicine, manufacturing, and engineering up to this point, this is one of the first attempts to adapt advanced technology to educational evaluation. This application, of course, has its limitations. Attempting to set limits on variables in social science research always causes consternation, for fear of eliminating some possible responses from consideration. In developing investigative paths for the expert system, limits had to be set. However, the data collection instruments and procedures were carefully developed and extensively field tested. The knowledge and skill of recognized evaluation and online experts were incorporated into the system. These factors, coupled with the extensive field testing still to be completed, result in an evaluation system that is as true to human expert evaluation as possible. It is also important that the system will be operated by human evaluators and all final judgments will be made by personnel of the program online. Thus, it should not be construed that the computer is replacing the human evaluator. It is only providing valuable assistance, which will facilitate self-evaluation of online programs.

The broad applicability of the vital signs gives this system utility for online program evaluation beyond the University of Illinois. Ultimately, the model developed for use in this system, along with the computer technologies that are applied, could be adapted for use in evaluating any online course or program in the public sector as well as in private sector training and human resource development programs.

Abstract: The authors, between them, have helped create ITCampus, a collection of resources for students and professors, and Clyde Virtual University (CVU), one of the first virtual universities. They have combined their forces during 1999 to build The University of the Third Millennium. This new work develops on the lessons learned with CVU and offers a new metaphor for next generation virtual universities. There are many difficult educational challenges associated with the future of online higher education. The Universities of Glasgow and Lund have joined forces in an attempt to tackle some of them.

In this paper we outline some fundamental ideas for our work during this year. We examine the economic forces, educational requirements and technical possibilities that will shape the next decade of university development. We suggest a new model for education that:

- the cost per student will decrease radically as the numbers of students increase,
- new features will increase the quality of education,
- new forms for assessment will be critical to success.

1. Economics

The Universities of Lund and Glasgow have both been around for hundreds of years. They have gone through many developments over the last few hundred years. Now a more dramatic change both in scale and speed is expected. Neither University can rely upon a local population who will opt to study locally. Neither Lund nor Glasgow or any other higher education institution can ignore the economic forces that will have profound influence over the next twenty years.

The economic pressures on both institutions and students will not abate. Institutions will be expected to educate more students at lower unit resource, they will also be expected to broaden their reach to include lifelong learners. They'll need to develop courses more suited, in both structure and content, to the needs of the employed. The economic pressures on students may have the greatest influence on how higher education evolves. In the future, students may have a stark choice to make: wait years before embarking on a career, in the mean time accruing significant debt or start work after leaving school and study for a degree in parallel with their developing career.

Seen from a global perspective there is a tremendous shortage of teachers on all levels. The traditional model for education is not scalable to the needs of the future when we must educate a larger fraction of the population. We can simply not afford it. Our current model is not affordable in the countries of Africa and Asia where the majority of the world's population is living. This creates a challenge for universities now fighting with financial problems and laying off professors as its income decreases. There could be a large market in exporting education.

Staff development will be all-important. Most faculty today are valued for what they know of their discipline. Maybe tomorrow they'll also be valued for what they can teach of their discipline. They may then go on to teach it to the world. We have to start to think globally.

2. A Shift of Paradigm

During the 20th century we have seen some shifts of paradigm. An agricultural society became an industrialized society and then to today's knowledge society. These shifts have always been associated with threats and possibilities for the individual. Perhaps one of the keywords in the transitions is rationalization; producing more of better quality to a cheaper price. Looking at education we can see the same trends and the challenges of today is to:

- Educate many more students (most will be lifelong learners),
- with higher quality courses,
- which are more targeted to their individual needs,
- at a much lower cost.

In the next century the power and the decision over education will move from the producer, the teacher or university to the consumer. For example, this shift of power to the consumer has already happened to the car industry and news media. Newspapers today have to write what the readers want to read or they will not buy the papers and those papers will go out of business. Imagine a future where the universities have to give courses that the students want if they are to stay in business. Is this a development we would like?

One of the challenges for today's education systems is that they are not scalable in the sense of mass production. To double the number of students often means doubling the costs. This is not possible for most countries. This creates an exciting challenge to learn from cooperation, mass production and rationalization in other areas and find models for education, where the cost per student is decreasing as the number of students increases.

Let's think about a scenario parallel with the shoemaker (new role of the teacher). To get an idea of what the paradigm shift could mean to the teacher, we can look at the old time shoemaker. He produced individually hand-stitched shoes for the people close to him. When the first machine-made shoes arrived people said that they could not suite your foot and would be very uncomfortable. Today we all wear machine made shoes and think they usually fit well, they are much cheaper and we have many more shoes than our grandfathers ever did.

Today we talk about the impossibility of being taught by a machine and the importance of the teacher. The authors can see a future where we buy our tailor made education from future education factories. Let us compare this with the car industry. When you buy a car today you sometimes design your own car and it is manufactured for you. We also expect education to be better, cheaper and closer to our needs. The roll of the teacher could change either to education shop assistant (like the car showroom assistant) or to education designer in a big education factory (like the car designer).

3. Educational Requirements

Having discussed the economics that will make change inevitable, let us next consider the educational requirements of the online learner in the next millennium. In particular we need to address problems of assessment, community and courses.

3.1 New Ways of Assessment and New Ways to Study

Virtual universities need a new way of assessment as this is always the factor that most influences learning. Students often only focus on those aspects that are likely to appear in exams. To focus the student's learning on all aspects of a course we are challenged to develop new forms of assessment as success with assessment will change the way we learn [Bennet 1997].

In the future, employers will have applicants to choose from with degrees from all over the world. How should these degrees be compared? If employers really want to know what skills and knowledge any particular degree or diploma represents they will either rely upon documentary evidence or have to hire external expertise.

The Portfolio concept will therefore be of central importance. The student will have to be able to convince their future employer that they are the right person for the job. Online education, with term papers and assignments kept online, will give possibilities for the student to easily direct an employer to their work.

In many online courses today the assessment must be taken in the traditional form, this can be a requirement that makes it impossible for the student to successfully complete those courses. Assessment online is therefore a necessary ingredient in future online distance courses and we have to find forms for that.

To stimulate the discussion we will demonstrate an assessment of open-ended questions without the need of a human marker - a tool that could reduce costs and increase quality.

We would like to shift from assessment as a scary and intimidating experience to look at assessment as a learning tool. In this transition it is important to ask: What do we assess? What do employers ask for? Can the assessment be used as a tool to find a match between the students' and employers' needs? In a rapidly changing society we must answer these questions ourselves; what kind of assessment do we really need in the 3rd millennium?

Investigations [Kjöllström 1974] have shown that traditional exams often only address the lower levels of cognitive skill in the Bloom's taxonomy [Bloom 1956]. We are trying to find forms of online examinations that address higher levels.

Exercises for teachers who want to prepare for education in the third millennium

Preparing students for working life

- Look at ads for jobs that your students could apply for. Find and list at least ten qualifications/skills that are required in several of the ads!
- For each of the qualifications/skills write down where and how you prepare the students!
- What could you do to help your students show and document that they have these qualifications/skills?

Preparing for exams of tomorrow.

- On your next exam ask your students to bring and use their own telephone and computer.
- How will that change the questions?
- How will that change how students learn?

3.2 New Learning Communities

How will students studying an online course be helped to feel less isolated? How do we address the loneliness of the long distance learner?

Online courses will probably be most popular among adult learners who want: to learn more, to qualify for promotion, to be retrained for a new job or just have fun. One of the most difficult problems in distance education is that today only 20-30% of the starters manage to complete their studies. This could be due to: lack of fellow students to talk to, not interesting enough study material, too few sticks and carrots, personal change in circumstances.

We have to build the University of the Third Millennium to tackle all these problems. We need to develop and deploy sophisticated messaging systems that will allow the same very broad range of communication channels that exist in traditional face to face education. Using the same basic notice board system for announcements, questions about the course, group work and private discussion is probably not sufficient. Something new is needed.

3.3 Course Quality

Through diagnostic testing we can find out what the student really needs and provide a course suited to the needs of the individual. In the continuation of this we foresee tailor made individual courses on demand. Through the computer the students' activities will be monitored and students and teachers will get an early warning when someone lags behind.

The quality of the courses has to rise substantially. One way of achieving this is to ask teachers who today develop their own, but similar courses, to form teams and share the work differently. Each takes responsibility for a more narrow part and has thus more time to tie the course closer to modern research and pedagogical methods, borrowing ideas e.g. from TV. To increase quality in media production and still stay within present cost we suggest a redistribution of the teacher workload. Instead of having 20 teachers taking 3 hours to prepare a similar lecture they could spend 60 hours preparing different lectures that they share among themselves.

3.4 Skills for Life

To improve the quality of the degrees from the university of the third millennium, it will offer free courses in areas that are intensely asked for by employers in their ads for new personnel. Here we think of courses like:

- How to write a report
- How to communicate
- How to present on posters and overheads
- How to get on with the press
- How to give a talk
- Study skills
- Cooperation skills
- Managing cooperation
- Managing your time

These courses will contain interactive exercises to develop the skills, teacher support, online examination and credit will be awarded. In Europe there is already an initiative to encourage everyone to take a computer driving licence [ECDL 1999]. Perhaps this idea could be extended to provide other types of driving licences. They could cover communication skills, organizing your own work, teamwork, leadership etc.

4. Computers and Information Technology

Computers and information technology have already transformed many businesses and industries. Many businesses have closed and many have opened. Some people have lost jobs and some have found jobs. Most jobs have changed almost beyond recognition. We can expect their impact on higher education to be no less profound [Coopers & Lybrand 1998].

Satellite in low orbits will, in about three years, enable high bandwidth Internet access from everywhere on the globe. The computer will be small as a matchbox and cost much less than today. The screen will have a resolution 300 times better than today making it the preferred medium for the book. Speakers, microphone and video will be included on each screen making live communication with people all over the globe possible.

Globalization will cause current national rules to be abolished. Prerequisites will be largely meaningless. A global market economy will prevail. Some universities will become smaller, others will become larger. Some faculty will lose their jobs while others will do well. All our jobs will change dramatically.

The Australian Government's Department of Employment, Education, Training and Youth Affairs was cautious in their study [Cunningham 1998] of the impact of globalization on their domestic post-compulsory education sector. They identified a "Death Star Scenario" where global media organizations join forces with high tech companies and top-rated universities to deliver killer degrees and totally dominate lucrative disciplines. However they found little evidence of an immediate risk. There may have been "little evidence" in 1997 but the situation is changing rapidly.

In 2005 students (or however they'll be referred to by then) will enrol on courses as and when they want. Their virtual university will be a global university. It will include all the online offerings of every remaining university. Quality, accessibility and value for money will be key criteria when a student decides which courses to purchase.

The virtual university is a tremendous challenge!

Building good online courses will be tough but the elements of good courses are starting to appear. The development of sophisticated new question types [Whittington 1998] make it possible to build open ended questions that help students reflect on their grasp of the subject. Work on automated essay assessment [Chung & O'Neil 1997, Whittington and Hunt 1999] is looking promising and could have dramatic impact on how we assess within online courses.

Building systems that overcome the isolating effect of studying online will be much harder. Today's virtual university is typically a lonely place and effort has to be made to meet people. The metaphor for most virtual universities has been that of the campus with graphical representations for the various features: lecture theatre, lab, seminar room etc. Application of this metaphor usually involves different areas of the Web site providing different functions and we end up with communication tools only being available in certain areas. On a real campus people talk everywhere, they don't have to "go to the cafe" to join in a discussion.

A new metaphor might involve a student's desk. On the desk would be current work. There may be a calendar or timetable to one side with a list of the student's courses. From their desk the student can contact other students, messages can be left for friends, video links can be made at the touch of a button. The student's videophone, answering service, and address book are built into their desktop. Tools such as ICQ [ICQ 1999] suggest a way forward but these tools will have to be deeply embedded within the structure of the virtual university.

Our university of the third millennium will be built with some key unique features:

- Students (not the campus) will be in the center, in a learning community where student interaction is an important learning tool.
- Skills for life will be a free integral part of the diploma.
- All assessment is a learning experience and all learning is assessed.
- Online assessment will target higher levels of Bloom's taxonomy.
- Templates will help teachers cooperate in building modularized courses.
- Reuse of modules will allow us to produce tailor made education on demand.

5. Tools developed

- Assessment Engine, <http://cvu.strath.ac.uk/ae/>
- Clyde Virtual University, <http://cvu.strath.ac.uk/> one of the first virtual universities, with Assessment Hall, Cafe, Lecture Hall, Library and Admin Office
- EVA <http://bengt2.citu.lu.se/eval/>, a web-based evaluation tool for editing questions, publish the evaluation and the results of it on the web.
- ITCampus, <http://itcampus.org/>, an international virtual student campus with resources collected by students for students to develop the quality of education.
- KNUT, <http://knut.kks.se/>, Knowledge Network for Education in Schools
- LUVIT, Lund University Virtual Interactive Tool, <http://www.luvit.com/>, a tool for teachers to create and publish courses on the web, for students to learn and communicate to record student progress

An Exploratory Analysis of the Career Enhancing Aspects of an Internet-based Program

Joel Wilkinson

Director, Media Learning Systems, Faculty of Education, The University of Calgary
Tel: 403-220-8168, Fax: 403-220-6494, E-mail: joelwilkinson@pobox.com

Abstract: Educational initiatives designed to capitalize on the rapid growth of the internet and associated technologies have created the promise of diverse learning opportunities. The vast amount of web-based courseware currently available via the WWW has created numerous opportunities for non-traditional learners to gain valuable career-enhancing training. However, there has been, to date, little research conducted to determine whether web-based courseware has actually been successful in fulfilling its promise of effectively addressing the career development needs of this population. This paper discusses the findings and implications of a research project conducted on an innovative distance education project at the University of Calgary. In particular, the paper discusses the extent to which the web-based educational program designed to be career-enhancing for non-traditional adult university students was able to meet the program objectives. Implications for web-based courseware in general are discussed.

Introduction

With the rapid growth of the internet and the ability for interactive media-rich on-line experiences, there has been a push to capitalize on the potential of these new technologies as a means for delivering on-line distance learning opportunities [Ibrahim & Franklin 1995]. The enrollment of adult students in higher education programs is expected to increase significantly in the foreseeable future. Given that adult students bring with them the additional responsibilities of work and family, the internet presents an opportunity to provide accessible learning opportunities to meet a growing demand, allowing learners to acquire specialized training, knowledge and skills in the comfort of their homes, workplaces and communities, regardless of geographical locale [Palmieri 1997]. Career development and career enhancement are, by their nature, inextricably bound up with the web of various roles and responsibilities that each individual constructs as part of their "life space" [Super, Savickas & Super 1996]. Adult students, by their very nature, enter the educational process with many 'life-roles' and responsibilities well established. The majority of adult students return to college and university educational programs with the goals of developing more marketable skills in order to earn higher salaries, secure better lifestyles and obtain specific [Rose 1996].

For this reason, on-line learning opportunities offer the potential for radically new career enhancing learning experiences that, it can be argued, may revolutionize education and career training practice by providing a never-before-seen structure for maintaining life balance and overcoming barriers to the preparation phase of the career development process.

Background

The Community Rehabilitation Studies distance education project at the University of Calgary, provides an ideal environment for research in this area. Implemented in 1994, the program offers adult students, working in the field with a two-year college diploma - in seven different locations or "communities of learners" throughout Alberta - the opportunity to obtain the last two years of a Bachelor of Community Rehabilitation degree via distance over a four-year period. The BCR degree allows students to further their career aspirations in their current or related field while continuing to live, work and raise their families in their communities. Since the majority of the distance BCR program students are women, this group also presents a unique opportunity to study the career enhancing aspects of such preparation strategies for the career development needs of women, who are, traditionally, expected to fulfill the bulk of the family child care responsibilities.

Opportunities for Innovation

With the growth of new communications technologies, there is an opportunity for innovative approaches to counseling, career development and training programs [Sampson, Kolodinsky & Greeno 1997]. Along with the rapid technological developments is a concurrent radical change in the world of work as many companies are changing their hiring and employment practices in an increasingly competitive economy. At no time in history have workers faced such instability in finding secure and safe career paths. Yet, at no time have workers also had a range of opportunities for molding a career that is at once, meaningful, satisfying and fulfilling. The foregoing events signal a need for career training opportunities and career development practice that allow for a more diverse population to access these services that are accessible for individuals of all walks of life, both in terms of cost and in terms of physical accessibility [Hoyt & Hughey 1997]. According to Sampson, Kolodinsky and Greeno [1997], the internet, or the "information highway", may help to overcome the problems posed by distance and time constraints, allowing access to opportunities that are not otherwise available. In doing so, the internet may allow learners facing career barriers the option of choosing to access career enhancing learning opportunities in their homes, communities and workplaces.

There has been a rapid growth in academic institutions offering on-line learning opportunities that are hoping to reach those who cannot or choose not to come to the urban campuses for conventional Monday-Friday programs. These learners could include those already employed and looking to upgrade their credentials without leaving their job or their home community, or those who want new skills or careers but cannot leave home because of child care and family responsibilities [Thompson and Chute 1998].

Preparation barriers

Career barriers are those circumstances which hinder the fulfillment of career plans and goals. According to Manuel London, "career barriers may stem from the individual, the work environment, or a combination of the two" [1997 p.25]. Such barriers may include: disabilities, discrimination due to gender or race, lack of sufficient funds, childcare responsibilities, work location/geography, spousal responsibilities, stress, etc.

A critical component of career planning is the preparation/skill development stage. When an individual has gone through the first three stages of career planning, they are ready to move on to the process of implementing their career preparation action plans. These plans may simply include a decided method for looking for work and preparing for interviews; or, if they are lacking the necessary skills and knowledge to pursue their career of choice, then the preparation phase would begin with the necessary actions to obtain this training and qualifications. Barriers to obtaining this training could include those limitations that would make it difficult for an individual to access and take part in the training programs. One of the present problems is access to specialized training in an increasingly qualifications-dependent world of work. Many specialized training programs are only offered in specific geographical locations. These problems may be exacerbated for women, who have traditionally been expected to maintain the household and family duties even when working full-time, and who, due to discrimination resulting in traditionally lower pay rates than their male partners, may have less say in the ability of a family to up-root and move for educational reasons [Tipping, 1997]. These barriers may also be augmented for disabled individuals who have difficulty with mobility to travel to and attend formal classes.

This model of offering formalized courseware and educational programs over the internet and at a distance to people working and living with their families in their home communities, can be seen as one possible solution to the problem of overcoming barriers to preparation/skill and knowledge acquisition [Hipp, 1997].

Career Development as Maintaining Life Balance

According to Donald Super [1990], another critical component of career development is the task of balancing one's various life roles – one's "constellation of life roles"- that together make up one's "life-space". Super defined life-space as the "constellations of positions occupied and roles played by a person" [p.218]. He believed that these positions and roles combine to create a person's career. Earlier career theories ignored the fact that "while making a living people live a life" [Super, Savickas, & Super 1996 p.128]. While the work role is critical in modern society, it is important to realize that it is only one of many roles that a person occupies that fill up their "life-space". For this reason, people make decisions about the kind of work roles they wish to take on and the training they will engage in to obtain the qualifications for these work roles "within the circumstances imposed by the constellation of social

positions that give meaning and focus to their lives” [Super, Savickas, & Super 1996 p.128]. Career development, then, is the process by which “people explore the meanings of these roles implement their self-concepts within these roles, and balance them in a way which is satisfying to the individual” [Robitschek 1997 p.133].

This model of offering formalized courseware and educational programs over the internet and at a distance to people working and living with their families in their home communities, can also be seen as an attempt to balance the various important life roles that make up a person’s life space. Furthermore, Super stated that “Multiple roles can enrich life or overburden it” [Super, Savickas, & Super 1996 p.128], while Brown [1996] argues that life satisfaction depends upon balancing a number of life roles that satisfy all of a person’s essential values. Adult learners, and in particular those who are parents, have more roles and responsibilities to consider when making career and educational decisions. Women tend to face greater challenges to balance their various roles, without becoming overburdened, while pursuing their career path. According to Fitzgerald, Fassinger & Betz [1995] “women’s relationship to work is more complicated than men’s... because of the intertwining of work and family in their lives [p.67]. Given that multiple roles can enrich one’s life, internet-based distance education programs can be seen as an attempt, or an opportunity, to enrich people’s lives - and women in particular - without overburdening them with the constraints imposed by traditional education, while continuing to allow for collaboration, interaction and media-rich learning experiences.

Summary

It is evident from the research examined in this section that there is a need for exploration and inquiry into the preparation phase career development programs that may enhance the ability of individuals to overcome career barriers and balance their various life roles while in the process of advancing their career paths.

While it seems obvious that increased offerings of training programs should be experienced by learners as career enhancing, there is no evidence to date that these programs actually enable adult learners to overcome career barriers while strengthening their ability to balance their various life roles. Numerous authors praise the benefits of on-line learning, while others caution the potential problems. However, based on the review of the literature, it is evident that very few, if any studies have explored adult learner perceptions and experiences of on-line learning as they relate to their career development and career enhancement needs.

Some educators consider distance education to be one of the solutions to the problems of overcoming barriers and maintaining life balance. However, traditional print-based distance education programs have tended to leave students quite isolated from each other and have, generally, lacked the self-directed conversational type of learning that adult learners prefer. For this reason, highly interactive, media-rich on-line internet-based training and educational programs offer immense promise to transform education, training and career development practice in a positive direction

Method

Subjects

Students who had completed the BCR degree while taking a combination of on-line and in-person courses were mainly adult learners between 25 – 40 years of age who constituted the “post-strategy” group (n=25). A new group of students who were beginning their program were designated as the “pre-strategy” group (n=40).

Instruments

Surveys were used with both pre and post-strategy groups to collect demographic information in addition to measuring student attitudes, and experiences or perceptions regarding the effectiveness of the internet-based program as a career enhancing strategy.

Procedure

Quantitative data capture and analysis techniques were employed initially with follow-up focus groups to discuss and augment the study findings.

- 1) Each student was asked to complete the survey instrument using a Likert scale for quantitative analysis. Other questions asked for short answer responses to identify salient themes and to capture specific examples.
- 2) Data collected:
For group 1 (post-strategy) – individual perceptions of the *experienced* effectiveness of internet-based training as a career planning strategy
For group 2 (pre-strategy) – individual perceptions of the *perceived* effectiveness of internet-based training as a career planning strategy
- 3) The analysis explored perceived strategy effectiveness within each group and across groups, in addition to comparing between groups. Focus was also placed on the perceived effect on issues of life balance, overcoming barriers to career enhancement, overall life planning, increased opportunity generation and recommendations for future research.
- 4) Follow-up focus groups were held with participant volunteers to collect impressions of the survey results and anecdotal information to be added to the study discussion section.

Data Analysis

Descriptive and inferential statistics were used to assess the research questions. These procedures included the reporting of group means, variance and standard deviations for survey questions as they relate to the research questions under investigation. Correlational analyses and t-tests were used to compare survey questions between groups to address the question of differences between expectations/perceptions and experiences between the two groups. Chi – square cross tabulations were used in an attempt to identify student variables that may be possible predictors of the research findings. Short answer survey questions provided were summarized, categorized according to major themes and presented in the discussion. These same questions were used as the basis for follow-up focus groups, from which anecdotal and qualitative data were summarized and inserted into the discussion.

Discussion

According to the expectations of most distance educators, web-based courseware holds the promise of creating new and exciting career-enhancing opportunities for learners who would normally be unable to attend facilities-based classroom programs.

The findings of this somewhat limited study support these assumptions in demonstrating that web-based educational programs can, in fact, provide a valuable career development resource by allowing non-traditional learners access to specific skill training opportunities while continuing to work and live in their home communities. The majority of both pre and post-strategy students rated the perceived and experienced career-enhancing aspects of the program as significant. However, interestingly, comparisons between groups showed that there were significant differences between the perceptions of the pre-strategy group and the experiences of the post-strategy group. Most notably, the pre-strategy students rated significantly higher in their expectations for both enjoyment and performance using the web-based model than the ratings given following the actual experiences of the post-strategy group. In addition, while pre-strategy students expected to spend less time interacting with their instructors and other students during the web-based program, post-strategy students reported spending significantly more time interacting when compared to traditional classroom educational experiences.

Most importantly, the majority of participants in both groups reported that the web-based program enabled them to overcome a number of career-limiting barriers including juggling work, childcare and family responsibilities in addition to geographical distance. In fact, many reported that without the availability of such a program they would have found it extremely difficult to make any progress with respect to their career development needs and desires. However, while the majority of students reported that the program allowed them to maintain the various relationships and responsibilities that together can create a balanced life, they also expressed their overwhelming view that having to juggle coursework in addition to all of these other daily responsibilities added a great deal of stress to their lives.

Conclusion

The general purpose of this study was to evaluate the effectiveness of web-based learning as a career enhancing strategy by collecting the experiences and perceptions of learners who had completed or were embarking on a specific web-based degree program.

The findings of this study, with a limited sample, seem to support the growing assumption that web-based learning programs may, in fact, be a revolutionary delivery mechanism for educational training programs designed to meet the needs of non-traditional learners. However, given the limited nature of this study and the reality that there are a multitude of different methods for offering and teaching web-based programs, there is a need for further research in this area. Specific attention should be focused on determining the elements required to make a web-based program successful in the eyes of the students enrolled.

Benefits of further research in this area may include the emergence of useful information for 1) career counselors who wish to utilize advances in on-line learning technology for suggesting a wider range of preparation phase skill development options; 2) a variety of individuals and groups who wish, or are forced by their circumstances, to find more accessible, geographically independent specialized skill development opportunities in order to further their career opportunities in the rapidly changing world of work; 3) women, disabled individuals, and other groups who may find accessibility to such traditional learning opportunities to be difficult or impossible, given their limitations, child care responsibilities, etc., and; 4) organizations, academic institutions and their administrators who wish to implement more accessible and widespread learning opportunities to a greater number of potential learners.

Abstract: This paper describes a Java-based framework for reporting HTTP server statistics. The framework allows users to view page access statistics as they browse the corresponding pages. By plugging in new analysis packages, the framework can be extended to offer more reporting features and interfaces. System configurations and page statistics are all stored in XML, which makes the framework flexible and configurable.

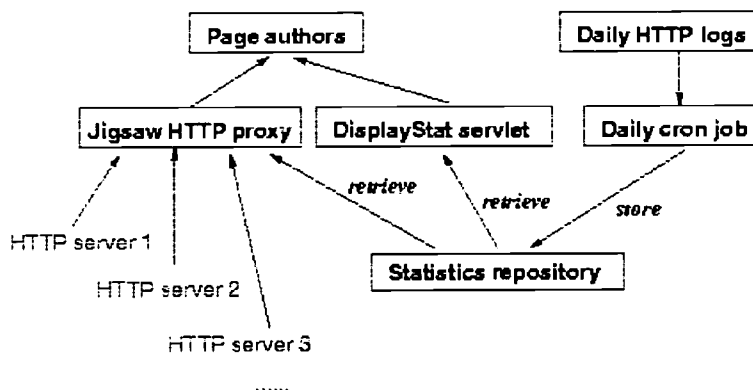

1. Introduction

Web servers generate access logs that contain valuable information for page authors, such as the page URL, remote host, user name for authentication, time of access, referrer name, and client software (browser and operating system). It is desirable that this information be available in a convenient form for authors and web site managers.

Many commercial and free HTTP access log analysis tools exist, such as WebTrends [2], MKStats [3], Wusage [4], WebSTAT [5], and Analog [6]. Those traditional log analysis tools all require authors to visit a special web address in order to view page statistics, and they all impose their own user interfaces. There is no way to change the look of the statistics reports, and there is no way to extend the tools with new reporting functionality without substantially modifying the original source code.

The Footprint proxy described in this paper presents access statistics intuitively by attaching the information to the HTML pages as a prefix; therefore it is easy to correlate the statistics to content. Also, the Footprint framework is dynamically extensible with analysis packages to configure report generation and presentation.

2. Architecture

The Footprint proxy front-end is responsible for presenting access statistics to page authors, which the back-end computes from daily web server access logs.

The front-end includes an HTTP proxy server and a Java servlet [7] named DisplayStat. The HTTP proxy is implemented by a Jigsaw [8] HTTP server. The DisplayStat servlet can be run within any servlet-enabled web server with access to the statistics repository. When the Jigsaw proxy receives a request for an HTML page from a user, it first retrieves the page from the real HTTP server and the abbreviated statistics of the page from the statistics repository, then attaches the statistics to the page and returns the page to the user. The DisplayStat servlet is used to retrieve more detailed information from the statistics repository. The back-end is run by a daily cron [9] job. It parses logs from multiple HTTP servers and computes data to augment the statistics repository.

Both the front-end and the back-end share a central configuration file, which is defined in XML. The configuration file specifies the analysis package to use, thus allowing different reporting features and styles.

3. Daily Computation And Storage

The statistics repository is a hierarchical store, which replicates the directory structure of the web host: segments in the URL path represent directories. E.g, the statistics for "http://www.research.digital.com/SRC/HPAS/index.html" are stored in the directory "stat-root/SRC/HPAS/index.html/", where stat-root is the path to the root statistics directory of the server " www.research.digital.com".

The back-end cron job runs every day. It first parses the daily log for every HTTP server defined in the central configuration file. The log contains a series of log lines, each corresponding to an HTTP request made to the server. Each log line is appended to a per-page log file. For instance, the file "stat-root/SRC/HPAS/index.html/log" contains all the log lines for the page "/SRC/HPAS/index.html". After per-page log files are built, the statistics directory tree is recursively traversed. While visiting each directory, daily statistics are computed from the per-page log file and stored as an XML file in the directory. Each directory contains up to 31 daily statistics files, which allow the cron job to compute weekly and monthly statistics of the page. On a week boundary, the cron job parses the last 7 daily statistics files and generates a weekly statistics file. Similarly, on a month boundary, the cron job parses the daily statistics files of the last month and generates a monthly statistics file. Up to 12 monthly statistics files are kept in the directory, and on a year boundary, all the monthly statistics files are parsed to generate a yearly statistics file.

We keep statistics files in XML format because they need to be readable, extensible, and easy to parse. XML is a meta-language from W3C, which allows for the definition of new markup languages. We use IBM's XML Parser for Java [10] for parsing and statistics generation.

4. Analysis Packages

The Footprint framework provides a flexible architecture for statistics computation and presentation. For each HTTP server whose log is processed by the framework, a Java package name can be specified as an attribute of the <server> element in the configuration file. Each such package computes statistics and generates a report in a specific format. By merely changing the package name in the configuration file, different statistics reporting schemes can be selected. Since this is server specific, each server's statistics may be computed and reported in a unique manner.

An analysis package must have four classes named DailyStat, WeeklyStat, MonthlyStat, and YearlyStat, all of which implement the fpp.stat.Stat interface:

```
public interface Stat {
    public void generate(String URL_of_page, Server server_config_object);
    public void parse(String URL_of_page, int num, Server server_config_object)
        throws FileNotFoundException, IOException;
    public void html(Writer out);
    public void htmlHeader(Writer out);
}
```

The generate() method generates a statistics file for a particular page in XML. For example, DailyStat.generate() would output to a statistics file named "6.d", if the previous day of the month is the sixth. The parse() method parses a statistics file identified by a number, which represents a day, week or a month. For example, DailyStat.parse() would parse a daily statistics file based on the page URL and the date (from 1 to 31), and stores the parsed information in the DailyStat object. The html() method writes the content of the Stat object as a formatted HTML segment to a character stream. The htmlHeader() method writes an abbreviated HTML segment, which is suitable for displaying in the header of a web page.

The framework dynamically loads the analysis package for each HTTP server. Calls made on the Stat interface are dispatched to the appropriate implementing classes. Since the analysis packages are in charge of parsing and generating statistics files, the file formats may be freely changed or extended by different packages. Note that a significant change in the statistics file format may render previously computed data unreadable. Therefore, by adding or modifying analysis packages, we can extend the framework to support more reporting features.

As analysis packages may need reporting options (level of detail for statistics collected, font and color choices for rendering, etc.). To support this each package may optionally contain a class named Directive, which implements the fpp.config.Directive interface:

```
public interface Directive {  
    public void loadFromElement(Element XML_element_to_read_options_from);  
}
```

The Directive object is used to define reporting options for the analysis package. The method loadFromElement() fills the content of a Directive object from an XML element. While parsing the central configuration file, the framework will call the loadFromElement() method if an unknown element appears within the scope of a <server> element. It is then up to the implementing Directive object to parse the unknown element to retrieve the statistics options. An example of this is given at the end of section 6 (the "domain" element is parsed by the Directive object).

5. Report Presentation Interfaces And The Jigsaw HTTP proxy

The framework provides two ways to access the statistics information. First, abbreviated statistics can be viewed as authors browse their pages (by inserting the statistics in the beginning of HTML pages). Second, full statistics can be accessed via the DisplayStat servlet.

In the first approach, when a user requests a page through the Jigsaw proxy, the proxy fetches the page and inserts abbreviated statistics after the <body> tag. These are computed by calling the htmlHeader() methods of the classes DailyStat, WeeklyStat, MonthlyStat, and YearlyStat of the analysis package specified for the HTTP server

The HTML statistics header contains a hyperlink for accessing detailed statistics information about the page. The hyperlink points to the DisplayStat servlet. To show more statistics to the user, the servlet calls the html() method of the classes DailyStat, WeeklyStat, MonthlyStat, or YearlyStat of the analysis package specified for the HTTP server.

To support the statistics header insertion mechanism, we implemented a Jigsaw resource filter in the Jigsaw HTTP proxy. The resource filter can be configured to handle multiple HTTP servers. If a page request is not for any of the servers, the filter simply returns the page unparsed and unmodified.

To use the Footprint statistics service, a user simply modifies her browser's proxy configuration to point to the Jigsaw proxy (manually, or via a Proxy Auto Configuration [11] file). Pages from servers defined in the Footprint proxy will be augmented with statistics headers, while other pages will simply bypass the proxy.

6. Sample Analysis Packages

We have implemented two analysis packages to demonstrate how the framework can be used and extended. The first

package, "fpp.stat.disthost", lists hits by distinct hosts; the second package, "fpp.stat.domain", lists hits by domain names.

The daily, weekly, and monthly statistics files of the package "fpp.stat.disthost" contain the total number of hits and a sorted list of hits from distinct hosts; the yearly statistics file contains the total number of hits of the year and the total number of hits of each month. Here is the daily statistics file for 2/12/1999:

```
<daily-stat total-hits="43" timestamp="2/12/1999">
  <host name="paprika.wwwcache.ja.net" count="7"/>
  <host name="eec6.pa-x.dec.com" count="5"/>
  <host name="cache-dc13.proxy.aol.com" count="2"/>
  <host name="194.85.254.111" count="2"/>
  .....
</daily-stat>
```

When computing daily statistics, a table of hits indexed by hostname is created by parsing the per-page log file and sorting on the count field. Weekly and monthly statistics are similarly computed by parsing daily statistics files. No table of distinct hosts is built for yearly statistics, as the table might be too long.

When a user browses to "http://www.research.digital.com/SRC/publications/" page (a) below will be displayed:

<p>Yesterday: 2/14/1999 Total number of hits: 8 Number of distinct hosts: 7</p> <p>Last month: 1/1/1999 - 1/31/1999 Total number of hits: 1047 Number of distinct hosts: 456</p>	<p>Last week: 2/7/1999 - 2/13/1999 Total number of hits: 227 Number of distinct hosts: 158</p>
--	---

Clicking on the link "12" under "Daily statistics" shows detailed statistics for the page on 2/12/1999 as in (c) below:

Daily statistics for
/SRC/publications/index.html

2/12/1999

Total number of hits: 43
Number of distinct hosts: 30

Here's the sorted list:
paprika.wwwcache.ja.net: 7
eec6.pa-x.dec.com: 5
cache-dc13.proxy.aol.com: 2
194.85.254.111: 2
.....

(c)

The package "fpp.stat.domain" requires additional configuration directives in the central configuration file, since a list of interested domain names needs to be specified. Here is a sample central configuration file:

```
<fpp>
<server name="http://www.research.digital.com/"
  stat-pkg="fpp.stat.domain"
  log-path="/footprint/logs/research/access_log"
  stat-root="/footprint/stats/research">
  <domain name="com"/>
  <domain name="edu"/>
  <domain name="org"/>
  <domain name="pa-x.dec.com"/>
</server>
<server ...> ... </server>
.....
</fpp>
```

Since the <domain> elements are unknown to the Footprint framework, they will be passed to the Directive object of the package "fpp.stat.domain". When computing statistics, hits will be sorted in descending order and listed by the domain names stored in the Directive object.

These are only some examples of the types of analysis packages that one can plug into the framework. More sophisticated packages can be developed and deployed in the same fashion.

7. Conclusion

We designed and implemented the Footprint proxy as described above. This allows authors and web site managers to view page statistics as they navigate their own web site. Developing new analysis packages is a relatively simple process, since the framework provides basic instances of statistics collection and reporting facilities, complemented with an extension mechanism to produce customized reports.

The framework can be used in both the "intra web" as well as the external web of an organization. We have run the Footprint proxy to collect statistics for the site "http://www.research.digital.com/SRC/" since January, using the package "fpp.stat.disthost". The daily log from the site is about 5 Mbytes in average, or 25,000 hits. The per-page log distribution and daily statistics computation take about 10 minutes on a 433 MHz AlphaStation running Digital Unix 4.0D. On a week boundary, the weekly statistics take 10 more minutes to compute, and on a month boundary, the monthly statistics need about additional 30 minutes. Once generated, statistics can be rapidly presented via the DisplayStat servlet.

Currently, statistics generation is relatively slow. For a daily log of 50 Mbytes, or 250,000 hits, it would take the system 100 minutes to finish the per-page log distribution and daily statistics computation. In the future we will focus on performance issues and scalability.

Abstract: This paper aims at representing an initial study assessing the problem of how to find valid and pertinent information from the Internet. We describe a trade platform prototype for certification and validation of digital documents. Our objective is to provide a service that can handle a user's query about document validity on the Internet with added quality information. It is therefore necessary to create tools and mechanisms to allow experts to certify information (inalterable certificate: Digital signature). Those experts will be selected according to their profiles (Expertise fields) and skills. They should give their opinions (labels) on either document existing on the Internet or on specific documents presented to experts for evaluation. Service providers and Internet Certification Bodies should first come to an agreed platform or a standard in order to ensure the credibility of the documents dealt with. We offer a general certifying service architecture. This must take into account the existing mechanisms implemented on the Internet, such as those proposed by X509 for certification aspects, PICS (Platform for Internet Content Selection) for the label model, and technologies of encryption (RSA, MD5) to ensure the signature and the integrity of the document.

Keywords: data quality; evaluation; validation; labels; security

1. INTRODUCTION

Because of the huge amount of information available and the freedom of access, Internet users might think they can find anything on the net, and that what they find is credible. Nevertheless, the issues are now how to choose high quality and relevant information and how to handle the mediocrity of documents on the Internet.

In the future the trade will consist in providing valid credentials, reliable, authoritative and pertinent information and guarantees on its nature, content and source to the users, who will then be able to trust Internet documents.

The quality of information is not only defined through its selection or validation; it also depends on how you select among the various opinions available for any given piece of information. The initial goal of this project is to provide the general architecture of an Added Value Service, independent and with multiple controls, able to validate and to certify digital documents according to evaluation criteria previously established. Thus, it will be necessary to implement tools, capable of providing users, with opinions and ratings about the content and reliability of documents, from renowned experts, each belonging to their respective fields. The design includes a database containing the accurate data after it is rated and validated by the experts, accessible from a search engine through a defined request (topics, scope of use...).

2. RELATED WORK :

Work associated with such a service refers to projects which focus on evaluating educational web sites and making these results available to teachers who wish to make the best of these sites. It also aims at extending and developing the notion of a Universal Design Criteria for Educational World-Wide Web sites that can then be used to guide the creation of future educational websites, such as [Poland et al. 98].

Concerning the quality of information, a number of research works have considered criteria for the evaluation of the Internet information sources. Most of them take traditional criteria as a starting point, but there are particular aspects and concerns in the Internet environment that cause some new criteria to arise [Rettig et al. 96]. Besides,

the selective gateways add value to Internet information because users can choose resources from the Internet with regard to subject matter or criteria of quality [Adam. 96].

To assist auditors assessing data quality, both formal and judgement-based approaches have been used for Accounting Information Systems [Kaplan et al. 98]. Some work focuses on rating services whose the reason is filtering systems against boring and dangerous web sites such as SafeSurf [Resnick. 97].

3. THE SERVICE COMPONENTS :

The service will be designed to respond to two kinds of user requests [Fig.1]:

- The list of a previously reviewed documents about precise subject,
- The assessment of a given document.

In both cases, the service will have to indicate the possible framework of these evaluated documents. Indeed, the relevance of the answer to a request depends on its accuracy and clarity.

However, how can we represent the level of accuracy of validated document in terms of subject, quality, domain, sub-domain, and formulate the query so as to extract more detailed information on the related query? In this case the service will work on two different levels to answer the request.

First on a local database containing a large catalogue of documents already validated and rated, and second on the Internet, following the model of a search engine in the case when users are not satisfied with the query results, or when the service wants to offer an exhaustive research of documents. When a document is submitted for validation, the concerned experts will validate and label this document. The experts can have a different opinion or assessment on a given document (It is interesting as a first step to find a way to generate a final document rating in the form of points and crediting them to the document's score).

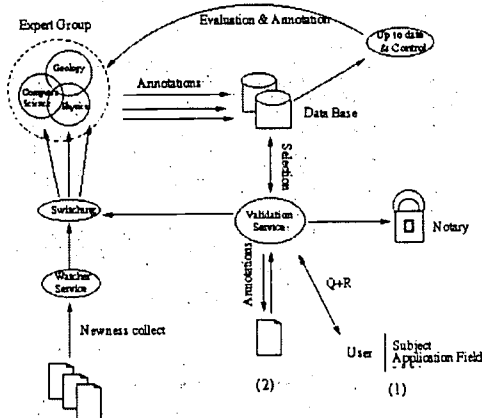

Figure 1: Service description

The service will be updated and operated 24 hours a day, 7 days a week. The support team will operate with shifts around the clock, the off peak hours team will have the duty of searching new documents on the internet and submitting them to the experts for validation (it is important to keep the labeled documents updated to detect any changes made and check the links on the search engine). If any document alteration is found, the document will be resubmitted to the concerned experts later on by the peak hours operating team.

Users who have requested the information will be updated with the changes (this is an optional issue for a limited period of time). In the case when users are not satisfied, the service will request other experts for a validation.

This service will include the infrastructure of other different expert services (education, science, health...) complementing the main service. The service will provide the web infrastructure, including secure facilities, technology (security protocols, cryptography, and secure e-mail 24 hours 7 days a week, redundant system...), as well as customer support.

BEST COPY AVAILABLE

A code of practices based on a trusted model will provide online electronic credentials legally binding the users and the experts by contract within a framework defining mutual responsibilities.

On line verifications of the payment are performed once the digital contracts are signed. These verifications are built upon emerging technologies such as Java, modern cryptography techniques.

3.1 Annotations

The validation of the Internet document will be labeled (label is a set text information related to the document proprieties and contents, it can be included in the document or related document or stored onto a database). This label can be represented with different mechanisms [Schickler et al. 96] such as RDF [Lassila et al. 96] (*Resource Description Framework*). RDF is a set of specifications, which allow metadata applications to be combined and to operate with a common way of expressing the semantics, which they share. RDF is a further layer in top of XML. Currently there is not only a large industry on applications to put information from legacy information systems onto the web, there is also an industry in applications which surf the web and, programmed with some idea of how the web pages were automatically generated, retrieve the information and reconvert it into hard well-defined machine-processable data. RDF will allow this long route to be short-circuited, and allow programs to gather data directly. Dublin Core [Weibel et al. 97], another mechanism, is a 15-element metadata element set intended to facilitate discovery of electronic resources. Originally conceived for author generated description of Web resources, it has also attracted the attention of formal resource description communities such as museums and libraries. PICS (*Platform Internet Content Selection*) [Resnick et al. 95, Miller 96] is a mechanism in use in several web servers, it offers a simple labeling format. It is a resource which gives the Internet user the possibility to associate data to the documents. It does not include a text but only the URL of the document containing the text.

A PICS label can describe all the characteristics of a document or a web site; it can be specific or generic. The PICS labels are issued from an independent authority and the document authors have no control on them. It has a proven reliability when it comes to detecting indecent web sites content (nudity, violence, etc), even in the documents indexing (label containing the subject of the documents). In our case, this description mechanism can be chosen among the others, because it is already in use on the Internet and it is possible to adapt it easily to our usage. It corresponds to the desired format for the expert's opinions. Once generated, the PICS labels will be stored onto a database and when a request is submitted, the service proceeds to the selection of all the documents related to that request. Note that different PICS labels can correspond to the same document, and consequently to one or more different opinions.

Our starting point is to know about the value of the information in terms of usage and utility. The evaluation criteria are established by the experts depending on the quality of the information, its application fields and the various possible uses of the document, which contains this information.

Other information can be added to the document including the expert's identity and selected profile.

3.2 Evaluation criteria :

We need criteria to use in evaluating the information found on the Internet because knowing how to judge the quality of those resources is even more important than to find them.

Many Internet sites that select and review Internet information resources rely on subjective values of style. In our work, we focused on information content and it is the experts who determine the information's quality based on style definition, contents accuracy control, public audience, source of the document, author... [Grassian 98]

Some of the criteria listed from different sources set up by librarians, which are used in the evaluation of books, journals, and other resources [Roscheisen et al. 95], are appropriate for our needs.

Authorship and Publishing Organization:

- The Identity of the author (who is providing this information?)
- His reputation and credentials (is the author qualified to write the document?)
- What is his experience in the field?
- If the author is not recognized, does another author or another respected source cite him?

- Is the name of the organization, which is publishing the document, recognized in the field?
- Is the author affiliated with particular organizations or associations?

The Scope:

- What is the scope of the information?
- How broad and deep the content coverage is?
- Is the information on target with its purpose?
- Is there any point of view or bias in the information? Are they noted in the document?
- Who is the target? Is it clearly stated in the document?

The Content:

- Is the content of resources objective?
- Is the information original?
- Does the information conform to its title or keywords (original aim of its author or site)?
- Is the information current? (Date of creation and last update)
- Does the document compare well with others on the same subject?
- What is the source of the information?
- Is the information reliable, truthful?
- Is the information revised?

These are few questions extracted from a full guideline, which will be used by the experts, or the known subject specialists about the topic. The experts must determine the information of a document using their knowledge and their judgement.

In general a Label is trusted only if the author has issued a digital signature [Lipp et al. 98] from a trusted third party (Certificate Authority). It is then possible to apply the X509 norm [X509], which acts as a framework for providing the authentication through the X500 [X500] directory, and the distribution of the public keys for the service users. This directory should be able to responds to the users authentication needs (PKI: Public Key Infrastructure).

Every expert will have a unique name in the directory listing, assigned to him by a trusted third party authority. A part of the label must contain a crypted digital signature of the document in question, giving the possibility to verify the integrity of the document or its obsolescence.

3.3 Expert/Client's description

A trusted service provider will recruit experts who will be chosen on the basis of their areas of competence, and on the credibility and a high standard of morals; they will be legally bonded to the service provider. A list of experts by domain will be established and made available to the subscriber to query.

Proficient mechanisms must be setup to avoid frauds. The digital signature of the certifying expert will be issued on the document involving the responsibility of the expert. The user will be able to access the service by formulating an accurate request.

In fact the precision of the answer provided by the service depends heavily on how precise is the request. The user interface will contain a main menu organized by topics of domains, sub-domains, and any useful information, which can help to extract other information about the request.

Prior to use of the service, a legal agreement for the subscriber's activities is recommended. Users accounts will include an activities log to avoid any fraudulent use, or dispute, and a feedback system will be used to inform the customer on the latest updates, and giving the possibility of feedbacks of comments on the service quality from the clients.

4. THE SECURITY MODEL

It is important to see how to secure a transaction between the client and the service [Shneider 96], the labels (annotation) emitted by the experts to the clients, the payment transaction from the client to the service, and finally a certification issued from the service to the client (including the issued certificate and the key enabling

the decryption of the first message). Several security systems exist nowadays several security systems. The most interesting solution is to design and implement a sort of secure envelope containing the crypted contents, and the most important is to deploy and activate other security functions related to the e-commerce, crypting and digital signature. The crypting makes the content of a transaction more secure on the network. It will be based on the principle of the asymmetric crypting algorithms, RSA [Rivest et al. 78]. This is a public key and private key coding. This secure envelope will contain in itself the public key used to crypt its own contents. The private key, which will be used to decrypt the envelope content, will be delivered by a trusted third party (Independent Authority). Its role is to deliver it to the clients once they accepted to pay and the requested service delivered the necessary decryption key. In our case, the digital signature has as main goal the authentication of the client and the service (even the experts), the integrity of the transaction and the non-repudiation. The annotation of the document involved by the user has an encrypted form. Upon agreement and signatures of the contract by the user, the key is forwarded to unlock the envelope containing the label.

5. EXCHANGES SECURITY

Security controls must be established to protect the exchange of information between the client and the service. These measures must comply with the OSI model X.800 [X800] and provide:

- Authentication: which has two levels. First the process which verifies the identity of the person that logons to the service, and only the user who paid for the service should have access to it, and the second when a client uses the service he must be able to verify the expert identity, who validated the document.
- Integrity: in general, any sensitive information must be protected from any form of forgery. Therefore, it is essential to implement measures to prevent users from make any documents modification during the service session.
- The Non Repudiation: the engagement taken by the experts during their session must be proven and verified. The origin of the document must be provided by the expert and ascertained in the sequel. Proof of the origin of document is required (the expert is accountable for) to protect the client from any denial from the service provider for issuing the document. This will be the proof of receipt to protect the service provider if the client denies the document reception (During an update, for example).

6. THE PROTOTYPE SYSTEM

A first prototype version of the service has been implemented and is able to respond user query about document concerning environment [Agora21].

The digital contract, once signed, may first travel to the server hosting the annotation about the referenced document. When the document is available, the digital contract will be moved to the notary server, which will check if the user who signed the contract is a member, and finally travels to the online payment service to complete payment.

With regard to the evaluation, the document evaluation is done through a questionnaire that the expert has to fill-in depending on the indications provided.

In order to allow the evaluation of the documents, a form generator has been elaborated. The form is a whole of questions that the expert will answer. The form is enriched with a descriptive text regarding each question and the meaning of the related answer in order to guide the expert in his answers. This description is written in XML (eXtensible Markup Language) [Bradley 98]. XML is concerned with describing the content of documents that are stored in electronic format. It is an ideal format for a structured and semi-structured representation of data. The form itself is generated after a compilation of a QAML description (Query Answer Markup Language). Once the form is filled, the expert, the expert will have to submit this form to an HTTP server, from which a cgi-script runs. This script is designed to store the information provided by the expert into a Mini SQL Data Base, the information provided by the expert. The scripts are written in LITE (mSQL's Scripting Language).

7. CONCLUSION

At present the information available on the Internet is mainly free. Information of all sorts (inaccurate data, sometimes obsolete) is accessible by all the users. There is a need for information credentials, of good quality for the user ready to pay for its accuracy. This work is based on the need to offer a validation service, giving a guarantee on the nature and the origin of any document on the Internet.

This paper attempts to provide an overview of such a service and the state of art of tools, which can be implemented. A first prototype evaluates WWW sites that specialize in Environment [Agora21]. Therefore, in adapting traditional criteria to the document on the Internet, a list of evaluation criteria has been defined to determine the quality of information including reliability and credibility checking of the document. This list may be extended because of the changing environment of the Internet.

Short Papers

Dealing With Structured Documents In Information Retrieval Systems

Fernando Aguiar, Bich-Liên Doan, Michel Beigbeder
RIM Dept. - Ecole des Mines de Saint-Etienne - France
E-mail : (aguiar , doan , mbeig)@emse.fr

Abstract : *With the increasing acceptance of XML in the WEB and digital libraries domains, the need for information retrieval systems (IRSs) dealing with structured documents is evident. Taking into account the structure has strong implications in the whole process of an IRS, from the creation of the document corpus until the query language adopted by the system. In this paper we are interested in expliciting these implications and proposing how the performance of an IRS may be increased taking benefit from the structure.*

1. Introduction

In the 80s, there has been a growth of interest in applications involving structured documents. In this context, two important developments are the ODA (Office Document Architecture) and SGML (Standard Generalized Markup Language) ISO standards. Since 1997 the W3C works in the development of XML, meta-language based on SGML functionalities. All these propositions explicit the logical structure of the documents by embedding tags in it.

In this paper, we are interested in the way that the structure knowledge can be exploited for improving the performance of Information Retrieval Systems (IRSs). The structure may be helpful to the retrieval process in three aspects. First, as the structure allows the document to be decomposed into different elements, specific indexing methods may be applied according to the different element types. Second, since the structure permits the document to be viewed as a set of elements, the response for a query may comprise only some elements of the set rather than the entire document. On the one hand the user may ask explicitly for specific parts of a document (if he knows the structure). On the other hand, rather than return a whole document, the system may find itself more suitable to return a part of it. Third, the simulation of contextual queries is possible. In a XML document, the context of one element may be determined by its inclusion relationships with other elements. With the advent of XML, the possibility of structured documents circulating in the WEB is becoming real and thus new methods for indexing, evaluating and querying them must be developed. Implications of dealing with structured documents for the design of the different phases of an IRS are dealt in the next sections.

2. Building the corpus

One difference between a typical IRS and an IRS dealing with structured documents can be observed in the corpus of documents to be indexed. The corpus of documents in a typical IRS is a set of documents not related to each other. In terms of granularity, all the elements of the set are situated in the same level, i.e. the documents are seen in a flat way. IRSs applied to the WEB such Altavista consider one single granularity of data, the HTML page. On the other hand, IRSs dealing with structured documents have a corpus whose elements have different levels of granularity and are related to each other by inclusion relationships. A document whose logical structure is represented by a tree-hierarchy of "n" nodes, is translated in the corpus into "n" new documents related to each other by inclusion relationships.

3. Indexing structured documents

Structured documents are represented and described by three features : the structure, the external description (attributes) and the content. The structure is represented by a tree-hierarchy whose arcs correspond to inclusion relationships between the nodes (notion of context). The external description is a set of attribute-values pairs such as author and date. The attributes may be static or dynamic. Static means that the values associated to these attributes are local. Dynamic means that they are propagated upwards and/or downwards. Each feature of a document may be associated with a specific indexing function depending on its type. Usually, the attributes are of the same type whatever the document type (image, text, video) and are thus indexed by a single function. However, the content feature should be indexed differently depending on its type (image, sound, text, etc.).

Let's assume three structured documents, d_0 , d_1 and d_2 . d_0 is composed of d_1 and d_2 (two granularities) and their virtual indexes are $I'd_0$, $I'd_1$ and $I'd_2$. They are virtual because depending on the approach used to index a structured document (replication or not of the data), real indexes have to be defined later during the evaluation phase. To build the indexes of these three documents four possibilities exist : replicate the content and attributes along the tree, replicate only the content, replicate only the attributes, not replicating at all. The choice should be based both on the tradeoff between the index access time and the storage requirements and on the type of the documents and subdocuments. In the case where the indexes of different document types (chapter, reference, figures) are expressed in different indexing languages, they cannot be kept together in the same index structure.

4. Evaluating queries against structured documents

To calculate the similarity between a document d_0 of the corpus and a query Q , the IRS uses an evaluation function f_{ev} . Suppose that d_0 is composed of d_1 and d_2 , and that their indexes are $I'd_0$, $I'd_1$, $I'd_2$. The equations below stress two different models for the evaluation function.

BEST COPY AVAILABLE

1214

$$\begin{aligned} \text{Sim}(d0, Q) &= f_ev(I'd0, Q) \quad (I) \quad \text{or} \\ \text{Sim}(d0, Q) &= f \left(f_ev(I'd0, Q), f_ev(I'd1, Q), f_ev(I'd2, Q) \right) \quad (II) \end{aligned}$$

The first model (I) applies to $I'd0$, the real index of the document $d0$. If the indexes have been previously propagated, $I'd0 = I'd0$ at the evaluation time, otherwise $I'd0$ is computed thanks to the structure feature of the index $I'd0$, i.e. $I'd0 = I'd0 \langle + \rangle I'd1 \langle + \rangle I'd2$. Here we suppose that f_ev is common to all subdocuments of $d0$ and the operator $\langle + \rangle$ that sums up the indexes is defined. The second model (II) addresses multi-typed components of a document. In this situation, both the indexing function and the indexing language may be different according to the type of the components. Let's $d0$ be of type text with subdocuments $d1$ and $d2$ of type image and sound respectively. The evaluation function then results from the combination of the f_ev applied to each document, say $d0$, $d1$ and $d2$. It may be a weighted average where the system or the user associates a weight to each type of document in order to quantify the relative importance of the types between them.

5. Querying structured documents

In this section, we show how the structure can be exploited to enrich query functionalities. Let's assume that the "structure-induced" modifications have been taken into account in the creation, indexing and evaluation phases. In the following, we cite three functionalities an IRS taking into account the document structure can offer..

First, the answer of the system may be composed of documents not having the same granularity. The granularity of the documents responded (a chapter, a section, an image, etc.) may be not established in the query but determined by the IRS itself at the evaluation time based on exhaustivity and specificity criteria. It may be extremely useful when the documents are not typed or/and when the user doesn't know the structure of the documents. For example, instead of responding a whole encyclopedia, the system can respond a subpart of it. Second, the user can formulate contextual queries. For example, the query "Find documents about spine in the context of orthopedic" may be formulated. Third, the user can formulate multi-typed queries. This query may be decomposed into sub-queries and the system may evaluate each of them separately. For example, "Find books or chapters about "medicine" containing an image like $\langle \text{image_input} \rangle$ ". The user and/or the system may associate weights to the different parts of the query. These weights have an influence in the evaluation of each part.

6. Related work

IRSs described in the literature take benefit from the logical structure in different phases. The passage retrieval [Kaszkiel & Zobel 97] is a domain where the structure is only used during the creation of the corpus of documents. The structure may be also utilized both in the corpus creation and indexing phases. For example, a system may exploit the structure in the presentation of the results in order to permit the user to situate the documents retrieved in the document space. Indeed, this may be very helpful to the user as he can disregard one response straightaway depending on its locality in the "document space". For instance, Yahoo responses are presented with their corresponding place in the context hierarchy. The structure may also be used in the query evaluation phase. Yahoo and Altavista rank higher sites with keyword matches found in the title than those found in the comments, body, or URL. Query languages adapted to IRS dealing with structured documents must allow access to the content, structure and attributes of documents at any level within their structure. We can find in the literature SQL-like languages (data represented in the relational model), OQL-like (data represented in the object-oriented model) and some specific languages such SGQL (Structured Generalized Query Language) [Moore et al. 95] that manipulates documents represented using the ELF model.

7. Conclusion

The structure is a document component as well as the content. They both reflect the document's semantics. However, just the content is considered by typical IRSs. The interests and implications of using the structure through the different phases of an IRS were shown. They are related to the building of more powerful indexes suitable to multi-typed documents, the combination of evaluation functions on documents multi-typed and query languages supporting more complex requests. We suggest how the system can benefit from an indexing function applied to logical parts of documents instead of to the overall document and the implications of it in the evaluating function. We also outlined that according to the element types of the documents and to the tradeoff between the index access time and storage requirements, different index structures can be used. Finally, the request phase is enriched thanks to the possibility of expressing contextual requests, multi-typed requests and to the fact that results are function of the granularity of information either asked by the end-user or dynamically determined by the system at the evaluation time.

Department of Operations and Decision Technologies, Kelley School of Business, Indiana University, USA

Abstract

The great promise of web-based technology is to provide effective personalized educational content. Providing students with personalized feedback and support is a difficult and time-consuming task for any instructor. It is even more difficult when enrollment is high and students are relatively inexperienced in the substantive area. In one such introductory technology course in the Kelley School of Business at Indiana University, the instructional staff has developed an academic support system using web technology that is now built into common server software packages. The results have been well received by both students and instructors. These consistently positive results have not been without problems. In this paper we describe the support system, identify the problems and some of the solutions, and explore possible extensions of this work.

Background

The Kelley School of Business at Indiana University requires all undergraduate students to demonstrate proficiency in working with spreadsheet and database applications software, and to display a basic understanding of the importance of information systems technology in business. Most students accomplish this by successfully completing the introductory technology foundation course for students entering the School of Business.

The significant increase in student enrollment has been keenly felt. Five years ago the introductory technology course was comprised of thirty-two sections per year. This year we will offer and fill over ninety sections. The demand for this course is substantial. Prospective business students, as well as students from other schools within the university pushed enrollment above one-thousand four hundred students for the Fall 1998 semester. This level of enrollment requires forty-two lab sections and six lecture sections, utilizing thirty-four instructors and more than sixty other support personnel. This steady increase in demand has required increasing attention to course administration, instructor training and evaluation, and the leveraging of information technology to continue to bring students a measurable high-quality instructional product. We have been innovative in our strategies for administration and teaching. An example is the course web site and the support system built into it. The web site provides students with access to course information and resources; distributes assignment, lab and tutorial files used in the course; and is the tool used to coordinate access to help and support for students.

One component of this support system is a one-on-one peer tutor program. Peer tutors are students who have successfully completed the course with a B+ or above. Most peer tutors are assigned to provide classroom support under the supervision of an instructor. Peer tutors with at least a semester of experience and the recommendation of their former instructor supervisor can be assigned to provide intensive individual tutoring to students in the one-on-one tutoring program. There are currently thirty one-on-one peer tutors assigned to sixty-one different one-hour sessions per week. While this program has been in place for several years, managing the process was a very labor-intensive process. Even with the widespread use of email, there was general discontent on the part of both the students (clients) and the peer tutors (service providers), primarily around issues of scheduling, matching, and notification. This general discontent deeply affected the potential of the program and turned a good educational initiative into burden for staff and students alike. Web-based technology has driven a process improvement that has substantially addressed the problems and allowed students to begin to realize the real potential of the peer-tutoring system. The result is an online tutor scheduling application, described below.

Description of System

The course web server runs on Windows NT 4.0, so Active Server Pages was a natural development platform. Furthermore, given the size of projected demand for the system, a decision was made to use the Access database as the engine of the scheduling application. While this application has worked well with the Access engine, other more demanding applications have prompted us to begin the migration of this system to a larger database platform.

An automated on-line scheduling system is used to match students with peer tutors. A student logs into the password protected web site and selects the one-on-one tutor scheduling system. If this is the first time a student has registered for a tutoring session, information is taken about the student's experience with computers and the software used in the course. A student selects the week they are interested in receiving assistance. The student selects the day of the week and then they may select a time period or select a particular peer tutor if that tutor is available. The student is then taken to a screen where they can enter a description of the problem, making it possible for the tutor to prepare for the session. When the information is completed, the student submits the tutoring request. A match is made in real time and all the necessary changes are made to the schedule of tutor availability. The application then generates an e-mail message that is sent to both the student and the tutor confirming the scheduled session and the topic to be covered. It is also possible for the system to be modified remotely by tutors, who may need to adjust their schedule. After the date of the scheduled session has passed, the scheduling application automatically sends a follow-up message to the student inviting comments, both structured and open, about the tutor session.

Results

The web-based scheduling application greatly enhances our ability to provide quality academic support to our students. It provides students with real-time information about the availability of help, prepares tutors for the session, grants students and tutors the flexibility to change appointments, and dramatically decreases the administrative work required to maintain the system. Descriptive statistics based on actual system use as well as self-reported measures of satisfaction will be presented as supporting evidence of the positive student response to the application.

The development and implementation of this scheduling application has also allowed several insights into both its existing problems and its potential for improvement. We are currently working on improving the remote administration features, allowing tutors and program administrators more control over system changes. We are also looking for a more effective way of evaluating and summarizing the follow-up email responses. Another area of improvement involves the scalability of the application. As the demand for the system increases, it is clear that the database engine will not be adequate. This will require a platform migration, most likely to either Oracle or SQL server.

The most significant improvement, however, will involve an extension of the application beyond its mere administrative function. In its current iteration, this scheduling system is solely an administrative tool. While this tool has served its purpose, the next major development of this application is to use the web technology to actually provide tutoring content. It is our hope that this content could be cataloged, reused and reviewed by students with similar problems. We are currently working on ways in which this can be effectively done on a large scale. To date, we have identified two possible approaches. The first, with relatively low bandwidth requirements, uses a slightly modified discussion-thread approach to provide a text-based tutoring session. While this could be easily delivered, cataloged, archived and re-delivered, there are some questions about the efficacy of the results. This is especially true when the substantive focus of the tutoring session is on the hands-on use of technology. The second approach requires the use of more advanced collaborative technology, and comes with an increase bandwidth requirement. This technology allows file sharing, the use of an electronic whiteboard, and one-on-one videoconferencing technology. The expected benefits and costs of these project extensions will be discussed. Examples of the scheduling application and the possible extensions will be provided.

Web-based Study Environments: Online Digital Collections Designed to Promote Authentic Historical Inquiry

Dr. Lynne Anderson-Inman
Center for Advanced Technology in Education, University of Oregon, Eugene, OR.
Tel: 541-346-2657, Fax: 541-346-2565, Email: LynneAI@oregon.uoregon.edu

Abstract. This paper describes a web-based study environment on Spanish colonialism designed to support sustained exploration of online primary source documents for the purposes of authentic historical inquiry. Design, development, and evaluation of the web-based study environment is being conducted by the Center for Advanced Technology in Education at the University of Oregon, funded by the National Endowment for the Humanities.

Introduction

"Web-based study environments" are online collections of primary source documents interlinked in ways that promote sustained exploration, in-depth examination, and authentic inquiry. Web-based study environments provide students and scholars with digitized collections of normally inaccessible materials and support those materials with specially designed navigational features and educationally relevant hypermedia resources so as to enhance comprehension and extend learning. The Center for Advanced Technology in Education at the University of Oregon is engaged in a multi-year research and development project funded by the National Endowment for the Humanities to design, develop, and evaluate a web-based study environment appropriate for teaching and learning in the humanities. It is experience from this project that serves as the foundation for the present paper.

Use of the Internet for the purposes of providing access to materials that enrich and enhance the curriculum is no longer a novelty. Unfortunately, many online digital collections or websites providing archives of educationally relevant materials are not structured or supported in ways that facilitate progress toward instructional goals. The purpose of this paper is twofold: (a) to describe the design, development and evaluation of a specific web-based study environment created to support the teaching of historical inquiry and (b) share findings that are generalizable to a more broadscale creation and adoption of web-based study environments as a means to educational reform.

Web de Anza: An Example

Web de Anza is a multicultural, bilingual website (<http://anza.uoregon.edu>) dedicated to providing teachers, students and scholars with an organized online collection of information about Juan Bautista de Anza and his two 18th century overland expeditions from northern Sonora to *Alta California*; expeditions that led to the founding of San Francisco and the settlement of California. The first expedition (in 1774) opened an overland supply route from Mexico to the missions and presidios being developed by New Spain along the California coast. The second expedition (1775-76) brought 240 colonists (men, women and children) by horseback to the mission in Monterey, for the purpose of settling the San Francisco bay area. The first expedition has been compared to that of Lewis and Clark, while the second is somewhat analogous to later emigrant movement along the Oregon Trail.

The core of the website is an archive of primary source documents in both Spanish and English, presented in ways that are designed to support sustained exploration and foster historical inquiry. For example, there are a total of eight diaries pertaining to the two expeditions. All diaries are maintained in a database so they are served out as dynamic web pages as needed. For each diary there is a hyperlinked calendar, providing instant access to the diary entry for any given day. In addition, internal links between diaries allow the reader to toggle back and forth between the English and Spanish versions of a single diary or between multiple diary entries for the same date. In this way, a student can study the various perspectives of expedition diarists as they describe the events of a single day, or they can compare the English translation with the Spanish original.

Supporting the archive of original diaries, letters and maps are various types of hypermedia resources, designed to enhance the readers' comprehension and extend their learning. For example, resources such as definitions,

explanations, pictures and even video are linked to words in the text that may be unfamiliar to the user. These types of resources can be used to provide students with information and pictures of 18th century articles (e.g., a saddle or uniform) or link the reader to information about a specific place, person or Indian tribe mentioned in the text. In addition, use of the website as a whole is supported by specially drawn maps, timelines, synopses, etc. Biographies are provided for key people, and the text of related secondary sources such as journal articles and chapters are provided for easy reference. Links to related websites help users extend their exploration and inquiry to other online sources.

The goal is to provide users of Web de Anza with the materials and supportive resources they need to investigate their own questions concerning this period in Spanish American history. By having access to primary source documents, students and teachers can draw their own conclusions about historical events, persons, and processes. Students are able to play historian, interpreting the data they find in the primary source documents and drawing conclusions as to their significance. This gives students a new understanding of what history is, what role historians play in interpreting history, and how they too can conduct authentic historical inquiry on topics of interest.

Topics for Web-Based Study Environments

Web-based study environments can be constructed for any purpose that requires sustained exploration of multiple documents. Because the Internet is used as the mechanism for distribution, students and teachers can be brought into contact with online collections of primary source material that would never otherwise be available to them. In addition, they can be provided with the embedded resources necessary to enrich their understanding and support their exploration. To assist teachers and students in the design and development of web-based study environments, we have created a list of criteria for selecting appropriate topics.

1. There should be a large quantity of primary source documents related to the topic that are either in the public domain or for which copyright permission can be obtained.
2. The primary topic should be appropriate for the school curriculum and suitable for integration into multiple disciplines or supportive of an interdisciplinary approach to instruction.
3. There should be an element of drama, mystery or intrigue surrounding the topic or events - something that can be used to motivate sustained study on the part of students.
4. There should be a lack of familiarity with the topic on the part of teachers as well as students, hence providing a platform to support authentic historical, literary or scientific inquiry.
5. There should be a high potential to expand inquiry into numerous related fields, requiring research outside the system and possibilities for bringing back new information to the system.
6. There are unanswered questions, thus providing an authentic need to think reflectively about the documents and an authentic possibility that students could pose novel solutions or contribute to the construction of new knowledge in the field.
8. There is a human element to the topic and/or events - something to bridge the gap across time and create empathy for the people involved.
9. There is a community of scholars/experts/collaborators willing to engage and affiliate with the project for the purpose of supporting and assisting teachers and students in their inquiry.

Integrating web-based study environments into the curriculum is an excellent way to foster school reform. They provide a vehicle for restructuring out-dated curriculum and an authentic way for teachers to engage students in real-world learning. They can be tied to state and national standards, and used to support authentic assessment of learning. And they encourage higher order thinking by promoting the active cognitive manipulation of information, a prerequisite for turning information into knowledge.

Making Peer Review in Large Undergraduate Courses an Option

Per Asberg and Urban Nulden
Viktoria Institute, Goteborg, Sweden
E-mail: per.asberg@hgus.gu.se, nulden@informatics.gu.se

Abstract: In this paper we describe research in progress on web-based peer review of reports and essays. The research is a part of a larger research project on computer supported examination. We have developed an application for administrating peer review of essays and reports in large university courses. The application was evaluated in an undergraduate course with eighty students. This paper discusses our experiences, findings and further research.

1. Introduction

In university and other forms of higher education, different types of collaborative activities are slowly becoming the basic block of education. These collaborative activities are often building on the model of collaborativism. The basic premise in collaborativism is that learning emerges through shared understandings of more than one learner [Leidner and Jarvepaa 1995]. The goals of collaborativism are active participation and communication. Collaborativism assumes that the control of the learning should rest with the peer group, that learning is the sharing of knowledge among learners.

Peer review is one possible way to engage learners in collaborativism. The value of peer review is widely recognized. "Students are found to plan more extensively and write more carefully when they are communicating with an audience of peers than when they are being evaluated solely by the instructor" [Bagley and Hunter 1992]. Similarly, "It's worth emphasizing that it is not always necessary for academic staff to give feedback: students can often learn more from formal or informal assessment by their peers or by themselves" [Ramsden 1992].

Focusing on higher education practice, peer review in large classes is by default problematic as it creates an, in many ways, unbearable administrative burden on the educator coordinating the peer review process. Imagine administrating one hundred students writing papers and reviewing each other's within the current course budget. Networked environments can be a solution to overcome, at least, some of these problems. Peer review in an online environment has been suggested by for instance [Harasim et.al. 1995]. They suggest that students can work together in dyads or in small groups, using email or computer conferencing, for example for the first draft of their course paper. The instructor, they continue, provides a framework to guide peer critiques, and the grading assesses both the quality of the draft and the quality of the critique. We take these ideas a little further and suggest a web-based application for conducting peer review in large classes. In the remainder we describe the application, how it was evaluated, and finally we outline further research.

2. PeeR

PeeR (Peer review of Reports) is an application designed for publishing and reviewing short essays on the net. PeeR was designed and developed on a standard PC with Internet Information Server (IIS) and Microsoft Access. The functionality of PeeR is the following: (1) Reports or essays (2-4 pages) following the specific instructions are submit to PeeR. (2) The reports are published in PeeR where everybody participating in a course have access to read all other essays. (3) Each student is assigned one or more reports to review and PeeR also optionally email him or her of the result. (4) The students read, reflect and make constructive comments on their assigned reports and optionally on any of the other. (5) Reports and comments are stored in the PeeR database. (6) The teacher assesses both the report and the comments made. Grades are dependent equally on the report and on the quality of the comments. (7) The decision of when to close the posting (of reports and comments) may be preset in the application or changed at any time. (8) PeeR is web based and available regardless of time and place.

3. Evaluation

Students: We have previously surveyed 400 students about preferred form of examination. This research showed very diverse examination preferences among the students. However, when asked why they prefer a certain form of examination three categories of answers emerged after analyzing and coding their responses: (1) Learning (during examination), (2) Fairness, and (3) Convenience. In the PeeR research about 80 undergraduate students attended an introductory course in informatics. They were asked to write a short essay as examination at the end of the course. Thorough information about what was expected was provided in class and on the web - both instructions for the report but mainly for how to peer review. The aim was to have the students to view the report and the peer review as nonseparable entities of an examination. The three categories above were then used in the evaluation of PeeR. A 1-6 (absolutely not – absolutely) Likert scale were used and the distribution of the answers (n=61) were the following: First, if PeeR was perceived as learning, 25 gave it 1-3 and 36 gave it 4-6. Second, if PeeR was perceived as fair, 20 gave it 1-3 and 41 gave it 4-6. Third, if PeeR was perceived as convenient, 8 gave it 1-3 and 53 gave it 4-6.

Course Coordinator: *Report* - The open assignment invited the students to relatively freely structure their report. From a qualitative perspective most of the reports did not follow academic standards. More connection to the material covered in the course was however expected. *Peer review* - Apparently many students experienced difficulties in being constructive when commenting on their peers' writings. This was expected. However, very few destructive comments were made. Summarizing the report and the peer review we find that the student achievement overall must be considered as meeting the quality expected of second year business students.

Administrator/Developer: *Report* - Due to rather extensive online help and JavaScript validation, the need for active participation from the administrator was limited during this phase. It was more a question of providing information about the content of the essay. *Peer review* - The administrator played a more active part. The major reason to this was the use of cookies in PeeR and the fact that many of the students had disabled them in their browsers. In addition to this the campus computers, administered by the computer department at the university, didn't allow the students to accept any cookies. This was a matter of misconfiguration and easily solved.

5. Findings and Further Research

Our main findings from the evaluation of PeeR can be summarized as follows: (a) The survey of the students showed, as we interpret it, that our use of PeeR was successful. The participating students found PeeR to support learning in addition to being a fair and convenient form of examination. All in line with the findings in our previous research. (b) From the perspective of the course coordinator peer review was a new form of examination to most of the students. However, by a more thorough discussion with the students about the purpose of peer review as examination, as well as more structured instructions and guidelines, PeeR is believed to be a viable complement to other forms of examination in large undergraduate courses. (c) We also claim that peer review is possible to administrate even when the number of students is substantial. The next steps of PeeR are: (1) To design and develop the full application with an administrative interface. (2) To increase the number of settings controlled by the administrator. (3) An option to convert essays to portable document format (pdf), to enable PeeR to email documents to reviewers. (4) Have the comments instantly mailed to the authors.

Abstract: The web-based visualization tool, PharKinS, simulates multiple drug concentration/time profiles in blood and tissues for most real-life situations. The system responds to the user's selection of the input route and the rate of plasma/tissue equilibration with a depiction of the corresponding compartment system and an indication which rate parameters to specify. This specification and a dosage regimen (up to three consequent single, repeated or continuous doses) represent the input for the simulation. Up to six different scenarios can be plotted simultaneously and compared. The applet is suitable for teaching pharmacokinetics and similar disciplines.

1. Introduction

Pharmacokinetic models serve for prediction of the fate of drugs and other biologically active compounds (e.g. toxicants, conserving agents, food additives, all referred to as drugs for brevity) in biosystems and, more specifically, for optimization of drug dosage regimens. The models are frequently simplified using the compartmentalization of biosystems that leads to the use of sets of linear differential equations for description of the concentration/time profiles. Sometimes the solutions to the sets of equations can be obtained in analytical form.

Teaching of pharmacokinetics conventionally relies on the use of the analytical concentration/time profiles. The profiles are useful for delineation of basic relationships between individual pharmacokinetic parameters and for illustration of the influence of the parameters on the shape of concentration/time profiles. There are situations, however, when the use of analytical concentration/time profiles is not sufficient. The situations include (1) more complex drug/biosystem interactions that cannot be described analytically even after compartmental simplification (e.g. presence of several compartments and/or nonlinear processes) and (2) parallel or serial combination of several simple events with analytical description (e.g. multiple dosage regimens, dosage regimens including more than one route of drug administration). A visualization tool for quick and convenient generation of concentration/time profiles is required to provide students with basic understanding of the concentration/time profiles in the more complicated situations and to allow them to study the influence of the model parameters on the shape of the profiles.

2. Approach

A cheap, easily accessible and upgradeable visualization tool, PharKinS (*Pharmacokinetic Simulator*), was constructed using the Java applet technology. The simulation is run using numeric integration of the corresponding differential equations and therefore it is not limited to the situations for which analytical solutions to the set of underlying differential equations exist.

2.1 Applet Description

The applet window is divided into five areas. The largest section is occupied by the plotting area for the concentration/time profiles. The rest of space is used for five blocks. Three blocks (Model Selection, Model Parameters, and Dosage Regimen) serve for input needed to run the simulation. The fourth block, Compartment Scheme, is used for graphic representation of the model that is created using the input information. The fifth block, Plot Control, color-codes up to six different scenarios for which the concentration/time profiles can be compared. The following description of a typical simulation outlines the function of individual blocks.

2.2 Applet Function

2.2.1 Model Selection

The user starts the simulation by selecting the model corresponding to the respective drug/biosystem interaction in the Model Selection block. The choices currently include intravascular/extravascular route of administration and fast/slow distribution from plasma to tissues. The fast/slow release from the dosage form is being considered. The selection in this block will determine the number of compartments characterizing the system: one central compartment for intravascular administration and fast distribution; addition of the dosage form compartment for slow release from the dosage form; addition of the dosing compartment for extravascular administration; and addition of the tissue compartment for slow distribution. In summary, the biosystem can be represented by one to four compartments depending upon the complexity of the drug/biosystem interaction.

2.2.2 Parameter Input

Specification of the model in the Model Selection block results in automatic adjustment of the Model Parameters block and in the Compartment Scheme block. The values of the model parameters (the rate constants of individual processes and the volumes of compartments) need to be entered in the input windows in the Model Parameters block. To guide the user, only the input windows for the required parameters are accessible and contain reasonable default values. The model parameter being entered is highlighted in the Compartment Scheme block until the cursor is in its input window.

2.2.3 Dosage Regimen Input

The Dosage Regimen block allows for combination of three different dosings: single dose, repeated dose (dose and dosing interval), and continuous dose (dosing rate and duration). The waiting times between individual dosings can also be specified. The block consists of three lines starting with menus specifying the dosing. The input windows following the menu are adjusted according to the selected dosing and contain reasonable default values. This layout provides for creation of variety of different scenarios. They include many practical situations, e.g., the intravenous infusion or repeated oral dosing preceded by a loading dose, intravenous infusion followed by repeated oral dosing, or a change in the dose or dosing interval of the repeated oral dosing regimen.

2.2.4 Comparing Different Scenarios

The Plot Control block contains, in addition to basic commands like Plot or Delete, a device for comparing different scenarios. Up to six color-coded concentration/time profiles can be plotted simultaneously. The device allows for review/change of parameters of individual simulations: when a color is selected, the Model Parameter block and the Compartment Scheme block adjust to show the corresponding data that can be modified. Color-coding is also used to connect the compartment in the scheme with its respective concentration/time profile.

3. Summary

PharKins is a free, versatile yet sufficiently simple tool for the use in the classroom for teaching Pharmacokinetics or related disciplines and for homework assignments. The use in pharmacy practice to compare concentration/time profiles for different scenarios requires further testing and validation. A current version can be previewed using the link at www.ndsu.nodak.edu/instruct/balaz/teaching/phkin470/frame.htm.

Facilitating Learning in the Virtual Classroom

Beate Baltes
Department of Teacher Education
National University
Los Angeles, California, USA

Abstract: The integration of technology for educational purposes provides teacher education institutions with powerful tools not only for the delivery of courses to geographically distant students but also for enhancing classroom learning. Online education should not be understood as the downloading of information followed by the passive and solitary activity of staring at a computer screen. Instead, online education advances the pedagogical principles of constructive learning through providing opportunities for constructive sociocultural interaction.

Teaching Philosophy for the Virtual Classroom

The integration of technology for educational purposes provides teacher education institutions with powerful tools not only for the delivery of courses to geographically distant students but also for enhancing classroom learning. Online education should not be understood as the downloading of information followed by the passive and solitary activity of staring at a computer screen. Online education promises superior results because: (a) students actively construct knowledge by exploring web sites, experimenting with search engines or new ways of seeking information, manipulating things, and engaging in discussion; (b) students are able to explore other learning styles and find out what works best for their cognitive abilities; (c) students work not only with the teacher but also among themselves which leads to additional learning; (d) students improve their critical thinking skills by examining ideas found on the world wide web and using the entire class time for critical analysis of a topic rather than information delivery; (e) students gain better understanding of a topic by searching for more web sites and exploring different perspectives of a subject; and (f) students learn how to learn [Bazillion & Braun, 1998]. To make the online classroom successful, learners need to have meaningful and constructive sociocultural interaction.

Sociocultural Interaction

The most dramatic difference between online classes and traditional face-to-face classes is how students will participate in discussions with their professors and peers. Fundamental to computer mediated communication is the concept of being able to use technology to simulate the human communication process. Online communication tools develop and improve almost daily; for example, text-based environments are evolving into graphical and even multimedia environments. The most common tools that can be used for online collaboration are e-mail/World Wide Web, synchronous and asynchronous communication. Instead of leading a typical discussion in a classroom with his/her students, the faculty member now serves as a discussion moderator who helps students understand the material from lectures and readings.

E-mail and the World Wide Web

E-mail and the World Wide Web are used for the transfer of information, either privately through e-mail or publicly through a web page. To a certain extent, these tools provide students the opportunity to solve a problem, to learn from each other by sharing the problem-solving process, and to gain experience in teamwork. The main advantage of this method is that messages, such as papers, personal thoughts, pictures, software programs, etc. can be transferred any time as well as read anytime. This information exchange happens almost instantaneously and is certainly faster than regular mail. However, if e-mail and the World Wide Web would be the only communication tools, constructive sociocultural interaction in an online class would be almost impossible or, if at all, only be possible with very few participants. E-mails could easily get lost among other e-mails irrelevant to the online class or they are misunderstood and misinterpreted because of the out of context delivery of messages.

Synchronous Communication

Synchronous communication is real-time communication, often referred to as chat, meaning that participants are online at the same time and messages are transferred immediately among all the students. Many synchronous communications are primarily text-based. Probably the most important function of synchronous communication for facilitating collaboration is the opportunity of students to brainstorm, sometimes even supported by a whiteboard on which every student can write, draw, or demonstrate a concept. Synchronous communication is helpful for decision making purposes, such as voting on a topic, splitting up group work, assigning specific tasks, etc. because it enables participants to make decisions immediately instead of waiting for responses sent by e-mail. Also, synchronous conversations seem to promote a feeling of belonging and to decrease isolation of group members. Synchronous communication, however, tends to become chaotic easily. Even where the communication is in real-time, there is still a short time-delay caused by students' typing speed. By the time a student finishes typing a response to another student's message, several other messages might have been posted already and the discussion might have moved into a different direction already. Anecdotal evidence suggests that collaboration through a synchronous communication is only possible in a one-on-one situation or probably small groups of up to four students.

Asynchronous Communication

Asynchronous communication is the most common tool used. To realize the advantages of asynchronous communication, one might compare it to face-to-face conversations: some students process the presented information immediately and respond with interesting and valuable comments; other students might have interesting comments but not right away; and some students talk all the time without having anything to say. Asynchronous conversation allows every single student to participate in the class discussion without being forced to respond immediately, without being interrupted by another student, and without being cut off by the sound of the school bell. Students and instructors have time to think before speaking/responding to the class discussion and also do not have to wait for the next class to express their views. And they can do all of this when they are personally in "top form" instead of during scheduled classroom face-to-face hours. As appealing as asynchronous communication might sound, potential problems need to be known in order to counteract them before they turn into real problems. Since asynchronous conversations allow every student to say/write what they want, students could easily get off the topic or even become insulting to others. Thus, the rules for asynchronous communication need to be clear to all participants, just like rules in the traditional classroom need to be clear to the students too, for example no harassment or rudeness will be tolerated and mutual respect is obligatory. Furthermore, the communication needs to be very organized and structured so students do not get off the topic or "get lost" in the conversations. Every computer mediated communication tool should provide students with an outlet for discussions outside of the range of topics just as a student lounge or student center provides.

Conclusion

All of the above mentioned methods of virtual sociocultural interaction have in common that they are neither limited by time nor place. Students from different cultures and/or different nations could discuss their thoughts and ideas and utilize a variety of resources from many more places, for example, in an environmental project where students from the northern end and the southern end of the Rhein river (Germany and Switzerland) take water samples to determine the river's pollution level and the countries environmental policy to avoid pollution. The three methods also have in common the potential for misinterpretations because of the lack of physical cues, such as gestures or body language, which is part of communication in face-to-face situations. Attempts to express body language, mood, and gestures by using so-called emoticons have had doubtful success. Aside from the suggested limitations, first experiences with online courses show that asynchronous conversations produce the most constructive sociocultural interaction.

Abstract

New Media has been widely used to deliver course content to students, either over the internet, on CD-ROM or in hybrid CD-ROM/Web format. Yet, little work has been done that is helping students use New Media technologies to create content as a part of their learning experience.

The class in this study consisted of 18 students in the Visual and Performing Arts Programme. Very few had previous exposure to computers beyond the standard word processing. The professor teaching the course was not a computer savvy person, but was willing to experiment with New Media, adjust the lecture style and change her evaluation methods. From the onset of the course it was planned to include a media specialist who would provide all the technical support and train students on the use of the New Media.

Why Opera and why New Media?

Although not a very popular subject in itself, opera has great potential for study and analyses using New Media technology. Surprisingly, there are few commercially available productions that use and explore New Media technology. At present only Wagner's "Ring Cycle" is available. In this course, Rossini's "Barber of Seville" was chosen for the New Media project and Verdi's "La Traviata" was used for traditional teaching and evaluation methods.

Faculty Perspective

Prof C. Clarke, who was teaching the course, found that students do appeared to engage in the potential of the medium. In particular, digitized sound provided good opportunities for dissecting musical lines, voices and instruments. Linking audio with textual discussion of the libretto, dramatic

action, characterization and instrumentation illustrated the dramatic potential of the medium far better than was possible in a traditional linear analytical essay. As well, students provided more astute observations in their musical analyses and in their discussions of all the parameters of operatic production. Aspects of opera that were discussed included staging, scenery, costumes, voice types and singing styles, as well as plot development. Most importantly, because the nature of the medium forced the students to operate in sound through time, they seemed to experience the "performative" elements central to the operatic genre. They acted as "operatic designers" when creating their websites. In addition, by conducting research outside the traditional arena of biographies, operatic histories and print sources, students were able to incorporate other related materials. This exercise was seen as a great benefit to the student learning process. This process of using New Media, allowed several of the participants, with apparent disadvantages to contribute to the project in unusual ways; "There were several students, who I knew from past courses, that I didn't expect to do very well" observed Prof. Clarke. In another observation, she notes: "The students were actually teaching me in the way they presented the material. They astounded me with new ideas, states of mind and psychological development rarely seen in conventional student presentations and writings".

Student Perspective

From their immediate feedback students spent more time working on the assigned projects than they would normally spend on an essay type assignment. They appreciated the new skills they developed working with New Media, and derived a greater sense of satisfaction from their collaborative work since they were able to reach a much larger audience than a single professor or grading assistant. Some of the quotes from students obtained at the end of the term:

“A Web/CD-ROM project is a fun way to approach a course or area of study that has a lot of visual and audio information.....”;

”The technical aspects of the project itself, was for many, a new and worthwhile learning experience...”;

“Appart from the new technology itself, putting together Web/CD-ROM helped me to link research, musical excerpts and score together in a way I might not have done in a formal essay...”;

“educational value also existed in the fact that during the development and once it was complete we could see how one’s contribution related to the project as a whole...”;

"we were encouraged to explore the WWW to incorporate various link with our own site and this enabled us to think how our web site fits into rest of the world...".

All students agreed that in spite of more hours spent on the project, it was worthwhile for them to learn New Media technology, problems associated with use and design of the Web/CD ROM and clearly the benefits and pitfalls of collaborative projects. Since their comments came after they received their final mark for the project, it was surprising that there were no major negative comments.

Conclusion

Since this was not planned study, no formative design and evaluation was conducted. We viewed it as a “just-in-time” or exploratory project that would help us to identify some of the underlying issues that are important in teaching a rich media course. The technology was not the focus and the classical goals of a traditional course were observed:

1. Knowledge of the subject area
2. Ability to analyze and make deductions
3. Clarity and relevance of expressing the above.

However, in addition to these, students learned to work with various media by using Adobe Photoshop 5.0, Macromedia SoundEdit 2, Macromedia Dreamweaver 2.0, Netscape 4.4, and a flatbed scanner. In the process, they learned some concepts of media quality, delivery and hypertext design. The project was placed on a secure web site due to the copyright issues with various media. At the conclusion of the project, each student received a CD ROM version of the project.

To conclude our observations, it is possible to launch this kind of course assuming that the class is small, you have an appropriate facility, faculty that is willing to experiment and intensive technical support available to the students. In the end, it has been a rewarding experience for students, faculty and the technical staff.

Acknowledgements

I would like to extend my deep appreciation to Prof.Caryl Clarke for her willingness to enter “uncharted waters” and allow the experimentation to take place. She also contributed with her observations and analyses of the whole process.

Of course, my appreciation extends to all 18 students in VPAC80 course, who were more than enthusiastic about the whole project with many long hours spent in the multimedia lab.

Integrating Web-Based Learning Into The University Curriculum

Phil Benson, The English Centre, University of Hong Kong, Hong Kong, pbenson@hku.hk
Pat Desloge, The English Centre, University of Hong Kong, Hong Kong, patrick@desloge.net

Abstract: This paper will outline the pedagogical and organisational methodologies arrived at in the process developing web-based courses and resources in the context of the digital campus initiative. The major issues addressed are (1) how web-based instruction can raise rather than lower the quality of pedagogy and learning, (2) how web-based learning has been integrated into classroom-based courses when the students do not have access to computers in the classroom, and (3) how the use of human and technical resources are being maximised to deliver web-based learning within a complex curricular framework. In discussing these issues, we will draw on the experience of the English for Professional Communication web <<http://ec.hku.hk/epc/>>

1. Raising the Quality Of Pedagogy and Learning Through the Web

A typical early response to the demands of integrating IT into the curriculum is for academics to place their lecture notes or course materials on the web. It is questionable, however, whether this leads to any real development in IT literacy beyond the ability to browse a web site, or whether it represents any pedagogical advance over paper handout and overhead transparencies.

A second early response is include review and testing features within course web-sites in the form of on-line quizzes and feedback. Although technically feasible using web-based learning packages, it is again questionable whether any real advance in IT literacy or pedagogy results. In particular, the technological constraints on question and answer routines over the web (largely limited to true-false and multiple-choice quizzes) may well lower the quality of pedagogy when the subject matter calls for complex and fine-grained evaluation of student responses. In the context of language learning, in particular, the use of web-based technologies for teaching input and testing is often based on simplistic or retrograde methodologies. The rich communicative interaction inside and outside the classroom that is at the core of many current language teaching approaches has so far proved difficult to replicate on the web.

In sum, there is a genuine risk of actually lowering the quality of pedagogy and learning when web-based materials are integrated into a course. This appears to be particularly the case when the effect of IT integration is to convert a classroom-based course into a quasi-distance course. In language learning, as well as in other areas of the curriculum, the loss of the benefits of classroom interaction is unlikely to be outweighed by enhanced access to materials. In the light of these concerns, one the driving forces behind our development of English language learning resources has been to examine how to enhance pedagogy and learning. Among the key elements of the approach we have taken are the resource centre model, the exploratory learning model and authenticity of interaction.

The *resource centre model* implies that a web-site developed to fit in with a particular course should not necessarily attempt to replicate the content of the course, but rather function as resource for learning. This model corresponds to an approach to pedagogy which that emphasises the learner's construction of knowledge through interaction with a rich bank of resources. While users are able to find content and tasks used within the classroom in the web-based resource centre, these are not necessarily presented to them sequentially and they are likely to find considerably more than can be covered in the classroom.

The English for Professional Communication web, which focuses on job-seeking skills is, organised into seven modules. Within each module, there are pages covering general advice on the topic (with each key point accompanied by an online task to develop language and reinforce meaning), models and links to additional resources on the web and within the university. As a matter of principle, we have adopted a policy of moving from the more simple to the more complex, so that drilling down into the web through hyperlinks leads the learner to an increasingly rich range of resources.

The *exploratory learning model* implies that learning is not confined to content delivered in the classroom, but rather begins in the classroom and continues through a process of web-based exploration. This model is supported by providing a broader range of resources on the web than can possibly be covered in the classroom and by a problem-solving approach to course work. Faced with a specific problem such as writing a resume, the student receives some instruction in the classroom but the final quality of the resume is determined in part by the extent to which she explores the resources available on the EPC web.

Authenticity of interaction implies that use of the web and interaction with web-based learning tasks leads to real world outcomes for the student. By the nature of its subject matter, the EPC web is oriented towards the real world outcome of exploring possible careers and getting a job. Within the modules of the web, interactive tasks are also designed to give the learner usable linguistic output which can serve as a basis for discussion with teachers and careers advisors.

2. Integrating Web-Based and Classroom Learning

A typical initial response to the idea of integrating IT skills into the curriculum at our university was the idea that lecturers and students would be using their computers in the classroom. This has proved impracticable both because students have tended not to bring their computers on to the campus and because computer projection and network facilities are currently limited, especially in smaller classrooms typically used for language classes. It is not clear, however, that use of computers in the classroom is either necessary or desirable from a pedagogical viewpoint. While there are undoubtedly advantages to being able to demonstrate a web-site and how it works in the initial stages of a course, there is no reason to suppose that the loss of face-to-face interaction implied by extended use of computers in the classroom carries benefits for teaching and learning.

The model of integration adopted is essentially one where classroom instruction is supplemented by web-based work carried out between classes. However, in initial experiments with this model, however, it was found that students were inclined to view web-based work as 'extra work' not essential to the completion of the course. In the model represented by the EPC web, this has been addressed in two ways.

First, a teaching approach has evolved in which classroom learning incorporates materials from the web-site and is intentionally left 'incomplete'. This is supported by the inclusion of a 'downloads' page in each module of the EPC web, from which teachers are able to download and print Word and PDF versions of interactive tasks for use in the classroom. Learners are made aware that the materials they are using in class are a selection from a richer range of resources available on the web, and thus that what happens in the class is not the sum total of their learning.

Second, an approach has evolved in which learners are rewarded for use of the web in the form of improved quality of task outcomes. In classes on resume writing, for example, it has become clear that students who have made use of the web produce better resumes for themselves than those who don't. In follow-up classes this is pointed out so that students are made aware of the practical value of web-based research to enhance their effective use of IT tools.

3. Curriculum Organisation

In a small department required to teach a complex range of courses, it was clear that a model needed to be developed for effective allocation of human and technical resources. This model equally has implications for the organisation and structure of web-sites provided by the department. It appeared evident that the department would need a core of specialised staff to work on major web projects and staff development. Initially funded by the university, this core seeks to extend its life span through competitive bids for consultancies and development grants. At the same time, it was evident that all the teaching staff of the department needed to be involved to some degree in the development of web-based resources if these were to become the major teaching resource of the department.

The model for web-site development adopted is illustrated by the relationship between the EPC site and one course site that makes use of it. The EPC web, which is designed to serve a number of courses, is essentially a showcase web designed to be technically sophisticated and embody high production values. Its development has been dependent on the expertise of the core of specialised staff, but a process has also evolved whereby the content of the web, and particularly the conversion of text-based tasks to online interactive tasks, is dependent on negotiation with teachers whose expertise is more pedagogical than technical. The course web, which is less sophisticated from a technical point of view draws its pedagogical content from links to the EPC web.

4. Conclusion

As pressure mounts on educators to integrate IT into the curriculum there is a danger that sound pedagogy will fall victim to technological and budgetary limitations. By focusing on learning objectives the creators of the EPC have developed pedagogical and organisational methodologies that allow learners to access resource webs that foster an exploratory learning experience and authentic interaction.

Queuing Model for Performance Analysis of a Web Server

Indranil Bose

Abstract: The World-Wide-Web has become synonymous with a mega warehouse of information. Of the many problems reported in using the Web, waiting for availability of Web sites seems to be the most common. In this research a queuing theory based model is proposed for studying the waiting time for accesses to Web sites in terms of arrival rate, service rate and number of connection ports. This analysis will be helpful in predicting load and accessibility of Web sites.

Introduction :

The World-Wide-Web has helped in the sharing of information between Internet users throughout the world. Though it was initially started as a project for enabling easy exchange of information between researchers who were geographically distant from each other [Berners-Lee et al. 1994], it has now taken the role of an international information superhighway. However, in spite of the apparent simplicity of use the users have reported several problems in the use of the Web. Among the top three problems reported in a survey [Lightner et al. 1996] are searching for specific information, speed of data access and locating and navigating sites. Inability to retrieve documents during an active search procedure has been a growing cause of user dissatisfaction with the Web. In most cases, users wait a significant amount of time and are then refused connection. This is largely due to the fact that information on availability of sites is difficult to obtain as it depends on a number of factors. In this research we propose a queuing theory based methodology that allows the users to get an estimate of the load on specific Web servers which in turn gives an idea of whether the users will be able to connect to the requested Web server when requesting for connection.

Principle of Operation :

The basic mechanism of operation of the Web is the same as that of a client server system [Bhargava and Sridhar 1997]. The three main components are a client site that requests for specific information, a Web server and a network connection that allows communication between the client and the server. The underlying network may be a corporate intranet or it can be the Internet itself. In case of the client server model based on the Internet the problem of communication is extremely complex as it involves a large variety of client sites (some client sites are Web sites) that request the server for information. The delay experienced by the user when requesting for information is a function of the client, the server and the network. In most cases, the site provider has no control over the network or the client sites. Keeping that in mind we only look at the server side of the scenario in this research. The delay of the server can be attributed to a number of reasons that include current load on the network, the available memory and also the speed of the processor. Among these the load on the network is usually a variable quantity and has a crucial role to play in allowing users to connect to the Web sites. If the load on the network can be estimated with a certain degree of accuracy then we can provide the client sites an estimate of whether they will be able to connect and also how much time they would have to wait before the connection is established.

Queuing Analogy :

Using a queuing theory based approach the Web servers can be modeled as a finite capacity queuing system. The queuing model that could be of use is an $M/M/c/N$ model. The requests for connection arrive at the Web server and if there are ports available then the requests are satisfied and a collection of hypertext markup

language (HTML) files and inlined multimedia files (i.e. image, audio and video files) that are embedded in the HTML files are sent to the requesting client sites. It is assumed that the requests can only be served if there are available ports on the Web server. If not, then the requests are lost from the system. If the client sites repeat the request process, then the recurring requests are treated as new arrivals to the Web server. In the terminology of queuing theory, the requests for connection can be looked upon as 'customers' and the downloading of Web pages can be treated as 'service to the customers'. The service is provided by the main and the multiple proxy Web servers. In an $M/M/c/N$ queue, the arrival and the service processes are assumed to be Poisson. Since there is a finite capacity waiting room with capacity 'N', hence all customers are lost from the system if there are 'c+N' customers in the system. Closed form analytical expressions exist for the analysis $M/M/c/N$ model [Tijms 1994]. Of particular interest are the expressions for the steady-state probability (which gives the probability that there are 'j' customers in the system, the rejection probability (which gives the fraction of customers that are refused service because the waiting room is full), and the average utilization (which gives what percentage of servers are busy at any time and is a surrogate measure for the utilization of the servers), and also the average waiting time for a customer before start of service. The significance of these analytical expressions is that they can be used for a 'quick' calculation of the various parameters and can be broadcast to the users who are requesting connection to the server. Of most importance is the figure on average waiting time. Users are usually frustrated when they have to wait for a long time before getting a notice that the server is unavailable. With this queuing model, it is much easier to inform the customers when the requested server has a long waiting time. Once the users receive this information, they can decide for themselves whether to wait for the connection or to try at a later time.

Validation of Model :

In order to validate the proposed queuing models we take recourse to log-file analysis for collection of necessary service parameters and conduction of numerical experiments. Traditionally Web server and common graphical interface (CGI) log-file analysis is typically used by Web site administrators to keep track of who is accessing the Web sites, what documents are being downloaded, and how the users are navigating through the various hypertext links on the Web pages. As noted in recent literature, [Eschenfelder et al. 1997] there are various log files which might be used by the webmasters. These include Access log for obtaining the internet protocol (IP) number of the user, date and time of access and user action taken during the access period and Path analysis log for obtaining detailed information on the browsing pattern of the user. In order to validate the correctness of this model we have analyzed the log files of accesses made to the homepage for a university. The log file analysis is done over a period of five months and some summary statistics are obtained from this analysis. During a week the number of visits tend to peak around the middle of the week and is lowest on Saturday and during a day the visits are lowest during midnight and early morning and highest during the afternoon. The summary statistics is next used for validating the model by conducting various numerical experiments. In particular we look at the summary statistics for obtaining estimates of two different parameters for the experiments – these are the average arrival rate and the average service time. Log file summary statistics usually report visits/day. We convert them to visits/second to enforce consistency of dimensions in the arrival and service rates. The average service time is reported in terms of the average time spent by users per visit and is recorded in seconds. Some preliminary results include computation of average waiting time, probability of rejection and average utilization of servers for various arrival rates. It is observed that even at 49.5% utilization of the Web server the average delay is quite significant (i.e. 233 seconds). For the same utilization of the Web server the probability of rejection is observed to be 0.00913.

A Web-enabled Communication Environment for the Education Community

Christos Bouras, Antonis Bazaios, Spiros Kontogiannis, Anna Zoura
Computer Technology Institute-CTI, Kolokotroni 3, 26221 Patras, Greece;
Department of Computer Engineering and Informatics, University of Patras, 26500 Rion, Patras, Greece
Tel: +306-1-960375, Fax: +306-1-996314, E-mail: bouras@cti.gr

Abstract: The research and development of computer-based, networked learning environments will be built around electronic communication and collaboration services that will play a significant role in the improvement of the learning procedure. Applications of this kind provide tutors and trainees with the ability of continual, close and efficient cooperation, en masse as well as individually. The goal of this work is the presentation of a communication environment that was developed in the framework of Odysseas project. The flexible design and implementation of basic communication services, accompanied with a friendly user interface, comprise an ergonomic environment and ensure the introduction of information technology in education as a daily communication and collaboration tool.

Introduction

Most developed countries endeavor in introducing network technologies and network software into education. Modern educational networks support a set of general-purpose elementary network services that provide some essential communication facilities to the end users. These facilities include collaboration, navigation into information resources, as well as interpersonal communication among the members of the education community. A recent project of this nature is Odysseas [Bouras 1997]. Project Odysseas (Integrated Network of School and Educational Regeneration in Achaia, Thrace and the Aegean islands) started in 1996, under the guidance of the Greek Ministry of National Education and Religious Affairs (YPEPTH). ("Odysseas" is "Odysseus", the Greek mythical hero.). The goal of this project is the design, development and pilot operation of an integrated network of 60 school laboratories located in three remote Greek geographical areas, Achaia, Thrace and Aegean islands. According to a research that took place in Greek education community, basic network services, such as email, discussion groups and bulletin board [Bouras 1996] are regarded as substantial components of a communication process. The basic network services that have been implemented in the framework of Odysseas, are the email service, the bulletin board service, the discussion groups service and the directory system. Altogether, they comprise a sufficient solution for interpersonal communication that will satisfy the goals of synchronous learning theories and methods, result in the improvement of the provided education and familiarize students with information technology. A Web browser was chosen as the interface platform for the basic network services. WWW-based tools are easily accessible through a URL. This contributes to the integration of the educational working space in terms of a Web browser.

Design Issues

The major design principles for our environment were obtained as a consequence of the needs expressed by end users and experts in a project like Odysseas, which aims at the introduction and exploitation of network communication services in education community. The present environment is designed in a hierarchical, two-level structure, the *school level* and the *regional level*. The communicational needs of users of the same school are served on a school level basis, whereas the communication between users that belong to different schools is dispatched on a regional level basis. This way, the applications are fully operational within the school environment, even if the communication link between the school's NT Server and its corresponding main access point (regional level) is not available. The email service interacts only with the school's email server and therefore it is implemented on a school level basis. The bulletin board and discussion groups are implemented on a two-level basis: the bulletin boards and discussion groups concerning all Odysseas' users are stored in a remote

level, whereas those concerning the users of one school are kept in local level (here, the NT Server.) The directory service is a complementary application that operates as a directory system for the three basic services. It provides searching operations through white/ yellow pages and it is designed in a two-level fashion. This application may be used independently, but it is also launched by the other three applications, where a searching operation among Odysseas' users is available.

Functional overview and scenarios

Project designers took into consideration all the existing technologies in order to invent new ways of evolving basic services environment into a learning tool. It was also taken into account that emphasis should be given on the pedagogical value of these services and not on the unproductive incorporation of the available technologies. Following this rule, the basic services applications were designed and implemented according to the international standards. They offer all elementary and advanced features, presented in a way that would reduce the users' cognitive overload. Special features are also available, that would contribute to the better understanding of the communication procedure.

Implementation Issues

Most innovative Web technologies are used for the retrieval and storage of information. Particularly, activeX platform, vbscript and cgi scripts are used to overcome the disadvantage of WWW passive protocol, HTTP. ActiveX platform is based on the tested COM Windows technology. It provides a wide range of effective, easily adopted features and tools, such as activeX controls, which contribute to the deployment of a fancy user interface. A wide variety of activeX controls-clients of several network protocols are also available. SMTP and POP3 clients of email and discussion groups applications are substantially based on a SMTP and a POP3 activeX control. ActiveX components co-operate harmoniously with other WINDOWS applications. The only restriction is that taking advantage of activeX technology requires the use of Microsoft Internet Explorer 4 as a Web browser. For storage and retrieval of information, both *local access* and *Web access* is used (Figure 4). Local access is used in the school-level for reading/ modification of user's personal information, such as the user's profile or the personal email messages. Web access is used in the school and regional level for reading or modification of shared information, such as the bulletin board announcements.

Graphical User Interface

The environment has been designed, so as to provide a great degree of flexibility, without causing navigational difficulties and cognitive overload for users. The gradual presentation of the complete set of potentials for each application is achieved through the provision of several scenarios, that is different versions of the applications. In this way, the user will familiarize with substantial functions, using the easiest scenario, and gradually get acquainted with all the functions provided, using the most elegant scenario. Consequently, users enjoy a feeling of immediate confidence in their ability to master their new applications.

Conversational Video Interaction

Norbert Braun
Digital Storytelling, ZGDV, Darmstadt, Germany
Norbert.Braun@zgdv.de

Abstract: The aspects of conversational video interaction with sonic hyperlinks are discussed. As a test application sonic hyperlinks are integrated into an interactive application.

1 Motivation and Goals

The mainly used user interaction for the web is the hyperlink. When transferring the hypermedial interaction metaphor to a conversational human computer interaction scenario the audio channel is of great importance for a conversational interaction to video in respect to the dialog aspects of conversations. However, video hyperlinks like done with the Real Media Video System only annotate the graphic information of an audiovisual presentation. The information provided via the audio channel remains un-annotated. This lack of annotation for the audio channel is overcome by the use of an acoustic form of audio annotation, the sonic hyperlink as described by Braun [Braun et al.]. Without an acoustic annotation the audio channel can not be used as interactive information channel in a conversational way. (Hence, the user can not interact with the information he hears in an intuitive way). In the following paragraphs the use of sonic hyperlinks for the building of conversational interfaces for audiovisual presentations within the Web is shown. A authoring- and presentation prototype is presented, finally a evaluation scenario and first evaluation results are described.

2 Conversational Interaction System

The classic use of a computer is as tool controlled by humans to work on a task. This alters to the use of the computer as assistant who works for the human by delegation of tasks. In consequence the way the user interacts with the computer changes, altering from the use of commands given without the awareness of a context (direct manipulation) to a conversation with the computer in order to get information and to delegate work in relation on that information. The relevance of information in a context is defined as part of the Cooperative Principle, see [Grice]. A information exchange by conversation between two actors like a human and a computer has a couple of specific maxims, the maxims of relation, quality, quantity and manner

A conversation scenario with a fully enabled human conversation part needs a natural language processor to interpret the commands of the human within a context. The use of a natural language processor can be avoided by a simple context based interaction scenario with a given context on the possible commands of the human. The commands semantics differ in relation to the context. The hypermedia interaction metaphor is useful if one wants to create such a simple context based interaction scenario because of the known context that is annotated with hypermedia structures. This approach implicates a limitation of the human's conversation strength to a set of commands and the hypermedia interaction metaphor. In most cases conversational interfaces set the conversational strength to the user actions (i.e. natural language processing), ignoring the context information of the computer's reaction. But this conversational HCI scenario seem to be limited on the computer's part of the dialog too. A truly conversation scenario has two full enabled conversational parts of human and computer.

The benefit of a system that focuses on given context is the usability of content that was not created for conversational purposes, like the content of web-sites, traditional TV content or the content of multimedia presentations. For the impression of a conversation the user should be able to interact acoustic with the multimedia presentation by asking questions on the presentation's topics. If questions are accepted the acoustic topics are annotated by sonic hyperlinks. The user can activate the hyperlink by demanding more information via her voice. Of course the voice control can be stretched to other media too in order of multi modal input for a multimedia presentation. This leads to a conversational video interaction, based on sonic hyperlinks for acoustic conversational interfaces.

An acoustic hypermedia approach that supports conversational interaction to video has to constitute a sonic hyperlink and exhibit the requirements of a adequate sonic hyperlink conversation system. A sonic hyperlink is defined as a sonic hypermedia annotation of sonic information, see [Braun et al.].

3 Applications and Evaluation Scenario

As an impact of the upcoming change on user interfaces to assistant interfaces, many applications using audiovisual information have established them self in the past years. In the near future, the broadcasting of TV will grow into the WWW. Nowadays there are several well known media content providers that distribute audio-visual presentations through the WWW, e.g. the Encyclopædia Britannica Inc., the US TV station CNN. As image quality is not very high due to limited bandwidth, the focus of applications lies not in the movie sector but in the area of information supply (news services, business TV), entertainment (video clips), education (museum TV, product training) and marketing (advertisements, commercials, product presentations, promotion). Accordingly, the users of assistant systems stem from a widespread area and are especially interested in information access and presentation. This can be accomplished by using the sonic hyperlink methodologies as presented in [Braun et al.].

The evaluation of a system for conversational video interaction with sonic hyperlinks should allow (with the application scenario in mind) the test of the system acceptance and the performance increase for the user. The following test scenario is built: The user sits in front of a desktop computer using a microphone (head set), keyboard and mouse to interact with the test application. The test application shows a modular structure:

First level, low detailed information (via audio/video and text) is presented to the user. This level gives an audiovisual overview on information topics with the opportunity to access more detailed information. Second level, medium detailed information (via audio/video) is presented by user's demand; Third level, high detailed information (all kinds of media) is shown by user's order. Linkage of the levels: The Sonic hyperlinks (and others, like video hyperlinks and text hyperlinks) are used to connect the different levels of detail. The scenario can be controlled by commands via voice. Due to the use of hypermedia interaction, the user can step through the demo at the level of detail he chooses and thus as fast as he likes.

A first set of usability evaluations with a small number of 10 test candidates showed that although users are not familiar with sonic hyperlinks they quickly get used to them. In fact, users seem to prefer sonic hyperlinks if they have no previous knowledge about the topics given in level 1 of the test application. Primarily if the information topics are close related the user is able to speed up his search for information because of the context information access via video. A second test scenario with varying connection bandwidth showed that users seem to prefer sonic hyperlinks if both, video and acoustic hyperlinks are presented. It seems that with decreasing bandwidth the video quality is reduced by a higher amount than audio quality. This is because video servers have a higher priority for audio than for video as users tolerate low video quality rather than low audio quality.

4 Conclusion

First evaluations of conversational video interaction have been discussed. In order to strengthen the results we will enlarge our test series in the future. As a second aspect we will investigate in the area of ergonomic, like suitable sounds for sonic hyperlinks, other types of sonic information that are useful to annotate and further user reaction scenarios.

How Community College Faculty Learn How to Teach Online Instruction

Phyllis J. Broughton, Ed.D. Chair of Office Systems Technology
Pitt Community College, Greenville, NC
Pbrought@pcc.pitt.cc.nc.us

Abstract:

This study examined the learning strategies of faculty and how they learned to use online course delivery as an instructional delivery strategy. The purpose of this study was to examine the learning strategies used by faculty in learning to use online course delivery. Research for this study reviewed the process of self-directed learning, the resources used by learners, the quality of both the process and the end product of learning, and the competencies of learners. Data was collected by conducting interviews with various North Carolina community college faculty who were currently teaching online courses delivery. The comments gathered were analyzed by means of applying the individual instructor's comments about learning to forms of learning as studied by Tough, Knowles, Mezirow, Marsick and Watkins, and Kolb. Emphasis for identifying learning processes looked at demographic characteristics, as well as reasons for participation. Data collected from the interviews also explored major ideas and concepts that influenced how the educators learned. Findings of the study identified incidental, informal, and experiential learning as prevalent means of learning for faculty. This study also identified faculty learning to use online course delivery as being unique to their learning with emphasis placed upon collaboration and cooperative learning among the participants. Participants in this study agreed that online course delivery as an instructional strategy was a means of reaching more nontraditional students, and they were proud to be considered pioneers in this field of learning and change.

In recent years the interest in online courses through the Internet for the delivery of higher education has increased considerably. This expanded interest is related to the challenges facing today's higher education institutions such as increased operating costs, reduced traditional student enrollments, reduced yearly course offerings to cut costs, reduced financial support for upgrades of computer equipment and software, and the reduced numbers of faculty in an effort to restrain rising costs. To overcome these hurdles, particularly at the community college level administrators are faced with the challenge of being able to identify the changing needs of the students and to meet these needs effectively and efficiently by including the increased use of technology.

With the Information Age upon us, research has shown that computer-based instruction has proven effective in post-secondary courses, addressing the student-centered learning and the self-paced, and individualizing study for adult learners. Adult educators have researched instructional strategies and how various classroom procedures help students to learn and understand information. The computer and the Internet have provided a means of a new vehicle for instruction and learning. Little is known yet about how instructors employ learning to adopt this new technology in the classroom.

The study reflected upon instructors who have been innovative and experimental in choosing to learn a new instructional strategy -- online course delivery. In conclusion of the findings of this study, faculty reflected a feeling of fulfillment through their teaching profession and the students. These faculty members were open to new ideas and experiences through their learning, and they examined their inner feelings and concerns about change and adapting to the technology associated with this change. The faculty in this study commented that the more they began to learn, the more they realized they did not know; therefore, they became self-directed in locating organized learning activities and opportunities to help them meet their learning needs. With new technology available, education is now more than just learning content and technical skills, faculty are learning how to learn and how to adapt and change.

At-Risk in Cyberspace: Enhancing Engagement of High Risk Students in Internet-Based Courses

Roger Bruning, PhD

Christy Horn, PhD

Steve Lehman, MA

Abstract: Concern has grown about the utility of technology based education for at-risk learners. This study explored effects of enhanced motivational and relationship building communications on at-risk students' engagement in an internet-based multimedia course. Patterns of engagement and moderate to strong effect sizes point to the need to systematically incorporate motivating dimensions into teacher-student communication.

Introduction

Many current designs for technology-based instruction presuppose learners with successful learning histories—learners who are at ease with written language, goal-oriented, intrinsically motivated, and self-regulated. Successful, goal-directed learners may represent only a minority of potential consumers of internet-based and other technology-based instruction, however. One especially neglected but important group are those learners who are at risk because of past school failure or other factors.

In many ways, technology-based education seems to be ideal for at-risk students. Instruction presumably can be shaped to meet almost any learner's needs and increasingly delivered to almost any location at any time. Many at-risk students, however, are likely to lack some key qualities needed for success in today's technology-based learning. These include high literacy levels, the ability to set goals, and holding a mastery view of learning (Dweck & Leggett, 1988). They may also not understand or chose not to exercise the conventions for communicating effectively in dialogic settings (e.g., Graesser & Person, 1994). Research is urgently needed to identify approaches that help at-risk students succeed in technology-based learning environments. Failure to identify such approaches can only widen the gulf between the "haves" and "have nots" in an increasingly technological society (Dede, 1998).

Background

This paper presents results of an experiment exploring factors affecting delivery of effective technology-based instruction to high-risk high school students. We previously had observed that students classified as at-risk and those not so classified responded very differently to internet-based courses, spending fewer hours working in the courses, having lower attendance, demonstrating more frustration, and achieving at a significantly lower level. Findings appeared to be independent of courses in which students were working. This experience led to the development of a series of studies focusing specifically on high-risk learners. The study described here examined the kinds of teacher-student communications likely to be most facilitative of at-risk students' learning and motivation.

Most technology-based courses involve live teachers who monitor student performance, provide guidance, and give feedback on student work. This study used both experimental and observation-based approaches in an internet-based multimedia course to identify effective relationship-building and motivation strategies that on-line teachers might profitably use in courses targeted at at-risk students. This research involved an experimental comparison of enhancements to a baseline professional condition in a 2 X 2 design: (1) lower and higher levels of personal investment in students (e.g., Bosworth, 1995; Noddings, 1995) and (2) lower and higher levels of motivation building (Bandura,

1997; Weiner, 1995). Student responses to teacher feedback were monitored by means of on-line response forms and direct observation and were further probed through focus groups.

Results

The internet teacher carried out interactions with the students with high fidelity to the treatment conditions, with reliability indices of .84 on the extent to which the motivation condition was implemented and of .90 on the extent to which the personal investment condition was implemented. Four variables measured different aspects of student engagement: ratings of student effort on e-mails, lab monitor ratings of engagement, hours worked in the course, and course grade (based on completed work). Effect sizes are reported for all variables. Results are presented in Table 1. For student effort on e-mail, effect size analysis showed a moderate effect for motivation-building ($\eta^2 = .06$) and a large effect for the motivation-building x personal investment interaction ($\eta^2 = .17$); in lab monitors' ratings of engagement, that motivation x personal investment interaction had large effect sizes ($\eta^2 = .26$ and $\eta^2 = .29$ respectively); and, in course grade, that motivation building ($\eta^2 = .13$), personal investment ($\eta^2 = .25$), and the personal investment x motivation-building investment ($\eta^2 = .13$) all had large effect sizes. Above and beyond effects for treatment, individual differences played a significant role in at-risk students' engagement. Writing ability and e-mail engagement were significantly correlated ($r = .47$, $p = .03$), while the relationship between writing and lab monitors' engagement rating approached significance ($r = .39$, $p = .07$), suggesting that teacher interactions are subject to the influence of individual differences

Table 1. Means and standards deviations by motivation and personal investment condition

Condition	Low Motivation		High Motivation	
	Low Personal Investment	High Personal Investment	Low Personal Investment	High Personal Investment
Effort				
M	1.52	2.07	2.23	1.88
SD	(.47)	(.47)	(.52)	(.79)
Engagement				
M	2.38	4.38	3.50	3.44
SD	(1.35)	(.43)	(1.02)	(.66)
Hours				
M	43.56	47.81	45.5	50.94
SD	(19.06)	(6.42)	(5.01)	(13.74)
Grade				
M	52.25	83	90.75	90.25
SD	(44.31)	(5.32)	(9.34)	(5.44)

Abstract

Literary works are the products of a dynamic process in which many factors may influence the changing content of the work. The study of literary change can impose stringent demands on students, even to the extent that many students are prevented from seriously entering this content area because of cognitive challenges. We report an interactive multimedia environment that has been developed to foster (1) student entry into the content area through an information format that we have coined "substitutional hypertext", (2) student experience of the process of scholarship in this field, and (3) emulation of the authoring experience in the style of the author being studied.

This suite of interactive programs for creating, exploring, and editing hypertexts demonstrates how multimedia learning environments can be crafted to open access to contents areas from which students would ordinarily be barred. Students, and even some literary scholars, assume a teleological view of literature, as if a work of literature could be represented as an idealized static entity toward which the author was striving. In reality, the development of a work of literature is dynamic process in which the authors' creative energies may undergo formative changes that reflect the authors changing attitudes and skills, interactions with collaborators, errors of transcription, and the influence of the author's perceived audience.

The learning system that we will illustrate here, the "Hypertext Explorer", elevates student experience of the content area in three ways:

- i. *Providing access to a challenging content area.* Traditionally, changes in literary works are documented in editorial editions. In these texts, alternative variants of modified passages are represented in an index-like structure (the editorial apparatus) at the end of a version of the entire text. This process requires that students memorize variant passages from the editorial apparatus, then substitute them in their mind's eye when they return to the position of the passage in the entire text. This is a demanding task for professional scholars and usually represents an impenetrable barrier to the content area for novices.

This learning system introduces a hypertext tool that allows students to substitute passage variants simply by clicking on the passage. We refer to this interface device as "substitutional hypertext". Substitutional hypertext entries are "smart" hypertext links in the sense that they elicit context sensitive responses. For example, let's assume that a certain passage has been represented differently in two successive versions of a piece of literature. This entry could be displayed in the text three alternative ways. First, both passages may be represented side by side, circumscribed by delimiters that identify which version of the text each string represents. Clicking on this marked text will cause the entry to be replaced by just the string of just the first variant. Clicking again will result in the replacement of the first variant string with the modified string of the second variant. Clicking a third time cycles the string back to the two delimited variants of the passage. Substitutional hypertext eliminates the necessity of envisioning a text substitution in one's mind. Moreover,

students can create text that never existed by creating a new text with variant combinations that were never published.

- ii. *Providing experience in the process of scholarship.* We lament the fact that students too often experience a discipline as an outsider looking in, learning lists of facts without developing an appreciable skill in the methods of critical inquiry utilized in scholarship. The hypertext environment illustrated in Figure 18 not only offers students access to the content area through substitutional hypertext, it contains assessment tools that students to approach the text as a scholar would. When a variable passage is selected, the student must click one or more buttons that reflect the student's estimate of the authors motivation for that change, and the student must justify their decision in a brief essay in the "justify interpretation..." field. Thus the student is thrust into the role of a scholar, a task which was virtually impossible with traditional editorial editions.
- iii. *Providing experience in editing/creating texts.* The variants in critical editions, which currently exist in inaccessible lists in appendices to print edition, actually contain the most important information for students-as-scholars to process. Separated in space and dependent on prodigious acts of memory, the variant lists in print resist a scholar's attempts to interpret and then create holistic structures. In our hypertext interface, however, the variants are not only available within the span of an eye but also open to (re)interpretation by the student-user. Once all the different variant "hotspots" in a certain text have been identified as belonging to one or more of the categories, the user is given the ability to edit the entire text on the basis of an interpretation which has been explained or defended in the annotation space. The result is a unique text that draws on editorial knowledge and results from a collaboration between author, previous editors, and the present user.
- iv. *Fostering the student's experience of writing in the style of the author being studied.* The Mix and Match environment invites the student to assume the role of the author. Most authors write parallel alternative story lines during the crafting of a story, finally focusing on one linear product. With hypertext, the alternative parallel passages can be linked together to create a literary space in which the story line branches and re-fuses. In this authoring environment the student can consider a larger creative canvas, more than just word-crafting, but story crafting in a unique way. The Mix and Match module (Figure 20) is the first such educational tool ever created. Moreover, once the student has chosen a linear sequence of story modules from within one or alternative versions of a text, she is encouraged to immerse herself more deeply into the author's individual style in the process of authoring transitions from one story block to the next. For example, in the Ten Indians (Hemingway) project, students create a new story line and then they must craft its transitions in their best Hemingway-esque style.

Recently, two modules have been added to the system that extend the student's experience of the process of scholarship. Indeed, these two modules can be used as powerful research tools. "Variant Collator" compares alternative versions of any text, detecting and marking the variant passages for conversion to active substitutional hypertext. This marked text can then be imported into the Hypertext Explorer, where it is converted to substitutional hypertext. No longer is any text safe from our intrusion.

Technology meets Pedagogy in Online Distance Education

Dr. Mark Bullen

University of British Columbia, Distance Education & Technology, Vancouver, Canada

E-mail: mark.bullen@ubc.ca

Abstract: This paper discusses the experience of making the transition from custom-built web course development to the use of WebCT. The experience revealed the strengths and weaknesses of WebCT for delivering a learner-centered, discussion oriented graduate course. The two key issues that emerged were the impact of the underlying educational metaphor of WebCT on course design, and the impact of some of the default settings of the "bulletin board" on student cognitive access. Our experience also demonstrated the importance of using pedagogy to drive the technological decisions in web-based course development.

1. Introduction

This paper examines how technology and pedagogy came together to both facilitate and thwart attempts to develop an interactive and collaborative networked learning environment that was designed to promote higher level thinking. The literature on web-based distance education, online learning and educational computer conferencing is replete with references to its potential to create a new learning environment in which interaction, collaboration, knowledge building and critical thinking are the defining features [Harasim et al. 1997; Haughey & Anderson 1998; Hiltz 1997]. Although, [Bullen 1998] found that creating an interactive online learning environment that promoted critical thinking depended on more than simply creating the appropriate technological environment.

In September 1997 the University of British Columbia and the Monterrey Technical Institute in Mexico, launched a collaborative online postgraduate *Certificate in Technology-based Distributed Learning* that sought to exploit the interactive, collaborative and knowledge-building potential of web-based instruction [Bullen & Salinas 1998]. The first three courses in the program were custom-built web-based online courses. However, in the fall of 1998, a decision was made to use WebCT for the fourth course and the revised offering of the second course which were both offered in January 1999.

One course, *Social Issues in Technology-based Distributed Learning*, made full use of the WebCT environment while the other course, *Selecting and Using Technologies for Technology-based Distributed Learning*, could be called a hybrid WebCT course.

Moving from the custom-built environment to WebCT posed some interesting challenges for both the instructor/developers and the students. The experience revealed the strengths and weaknesses of WebCT for delivering a learner-centered, discussion-oriented graduate course. Two key issues emerged from this experience:

1. How the underlying educational metaphor of WebCT affects its functionality and the impact this has on the type of online learning environment that can be developed.
2. How some of default settings of the "bulletin board" feature of WebCT appear to have affected students' cognitive access.

2. The Online Environment

For the first three courses a custom-built interface was developed that provided the organizing structure for the online course. For online discussions and group work, Hypernews, a freeware, Unix-based discussion forum was used. This was integrated into the course by applying the same navigational interface. Moving from the pages of course content to Hypernews was seamless. The interface was designed to be graphically lean to maximize download speeds, but also to be as functional and efficient as possible. All major sections of the course were always within a maximum of two "clicks". Synchronous chat was not a required component in the course, but a link to ICQ was provided and students were encouraged to use this to communicate amongst themselves when organizing their group work.

Student reaction to the custom-built interface was overwhelmingly positive. Most commented that they appreciated its functional efficiency and our deliberate decision to avoid the use of unnecessary graphics. Initial reaction to Hypernews was mixed. Some students found it slow and the interface confusing. However, as the course progressed and students became familiar with how it worked, the complaints diminished. This feature did not figure prominently in the post-course evaluation.

With the fourth course in the program, *Social Issues in Technology-based Distributed Learning*, a decision was made to use WebCT, a web course development package that provides an integrated set of course development and administrative

tools. We had avoided WebCT initially because we felt it was too inflexible and linear in its earlier versions. However, we were sufficiently impressed by the updates and we were also looking for a way to decrease the amount of technical and administrative time that was being spent on web course development.

3. Problems with WebCT

Two major problems emerged in our use of WebCT: the inflexibility of the navigational interface, and the confusing structure and interface for the “bulletin board”. On the positive side, course development was speeded up considerably and the course management tools have made course administration much easier.

The WebCT navigational interface makes it very difficult, if not impossible, to create a course structure that does not conform to the default WebCT structure. So, for example, we found it was impossible to map our “maximum two clicks away” feature of our custom-built environment onto the WebCT interface. In the end, we had to make some compromises that resulted in a less efficient interface.

But the most serious problem we encountered was with what WebCT calls its’ “bulletin board”. This is perhaps the most critical feature of these online courses because we are trying to exploit the unique interactive features of online instruction in order to promote and facilitate collaboration, and higher order thinking. The bulletin board interface and underlying structure frustrated these attempts and student reaction, at least initially, was overwhelmingly negative. Some examples of the problems:

1. Links to the “bulletin board” from a page of notes automatically takes students into a default forum called “Notes” and it is impossible to change to another forum without first returning to the home page and reentering the bulletin board. There is also no way of eliminating or renaming the Notes forum.
2. When students first enter the bulletin board they are presented with a list of ALL the unread messages in ALL the forums. The poorly designed interface does not make this clear and students are usually bewildered by the list of apparently unrelated message titles that appear on their screen.
3. The first person who posts a message in a thread creates a subject line and this cannot be modified by respondents. All messages except the initial message are only identified with the student’s name. This makes the list of message “titles” absolutely meaningless and makes returning to review the transcript very difficult since no contextual clues are provided. This was a particular problem with the Technical Issues forum where it would have been useful if each message had a subject line that indicated the nature of the technical problem so that students could use this a reference source.

4. Conclusion

The underlying issue with many of the technical problems is that WebCT was initially developed as a web-based adjunct to a traditional teacher-centered classroom model of teaching. It was essentially developed as a way to post course notes on the web. Over the years it has gradually evolved away from that, but it still has not been able to completely shed its origins. This creates serious problems for course developers who are trying to move away from a teacher-centered model and are trying to exploit the unique features of web-based instruction. In the end, I think pedagogy has triumphed over technology and we have been able to create a collaborative, interactive, learner-centered online environment, but it has taken a lot of effort, particularly on the part of students.

rardtke@hawaii.edu

Abstract: Using the Internet to deliver distance learning has the potential of reaching everyone, including instructors and students with a wide range of abilities and disabilities. Maximizing access is a worthy goal and is mandated by law in the United States. Universities and other institutions should take steps to assure that their distance learning offerings are accessible to people with disabilities. Making programs accessible is not difficult when universal design principles are applied during the design process.

The Internet provides a medium for the delivery of distance learning with the potential of reaching everyone, including instructors and students with a wide range of abilities and disabilities. Maximizing access is a worthy goal. It is also mandated by law in the United States, where the Americans with Disabilities Act of 1990 requires that programs and services be accessible to people with disabilities. In 1996 a Department of Justice ruling clarified that ADA accessibility requirements apply to Internet resources. Universities and other institutions that offer distance learning courses should give serious thought to the accessibility of their programs. Almost anyone can access the Internet thanks to recent developments in adaptive technologies. Special hardware and software that allow people with a wide variety of disabilities to operate computers include voice output for individuals who are blind or have reading-related disabilities; screen image enlargement for those who have poor vision; and voice input, mouse replacements, and keyboard alternatives for those with physical disabilities. Equal access requires that all of these individuals be able to participate in a distance learning program, regardless of the adaptive technologies they might use with their computer systems.

Course Design and Tools

Applying “universal design” principles to distance learning means to design a course so that it is accessible to students and instructors with a wide range of characteristics, including disabilities. Making Internet-based distance learning programs accessible is not difficult when universal design principles are applied during the design phase. This approach is in contrast to the typical approach of considering only the largest market segment when designing the presentation of Internet resources and services. The following paragraphs summarize some of the access challenges and demonstrate how universal design principles can be employed to make an Internet-based distance learning class accessible to individuals with disabilities.

Electronic mail is an excellent way to distribute information and communicate with students who have a wide range of disabilities because it is text-based and simple in format. Those with visual impairments can read the materials using voice output or screen enlargement. Furthermore, students with hearing impairments do not require interpreters. Other communication systems, such as electronic bulletin boards and conferencing software, are not always accessible to individuals with some types of disabilities; they should be evaluated and tested to assure that they are compatible with voice output and other adaptive technologies.

For a distance learning class, course lessons and other materials are often placed on a series of World Wide Web pages. Some people who use the World Wide Web cannot see images or hear sounds. If graphics and pictures are included, ALT attributes, captions and transcriptions should be provided so that the voice output systems of blind students and instructors can read the text. Advanced features, such as image maps, may require that alternative text versions of the content be provided. For example, when a blind student using a text-based browser such as Lynx encounters an image map, her voice output system speaks the words "image map". She does not have access to the graphic display nor the embedded links unless the page developer provides an alternative text-only presentation of the content and navigational features. Similarly, video and audio presentations should include captions or transcriptions for deaf participants. In addition, simple and consistent page designs and clear, simple language benefit everyone, but particularly those with visual impairments and/or learning disabilities. All buttons, links, and other standard materials should be placed on each page in the same position. Contrast between background and text should be maximized for those with visual impairments and designers should consider that fact that some users of their sites might be colorblind. In addition, screen buttons should be large enough for selection by people with limited fine motor skills.

The Web Accessibility Initiative (WAI) of the World Wide Web Consortium (W3C) has published guidelines for making Web pages accessible to people with disabilities. The guidelines are:

1. Provide equivalent alternatives to auditory and visual content.
2. Don't rely on color alone.
3. Use markup and style sheets and do so properly.
4. Clarify natural language usage.
5. Create tables that transform gracefully.
6. Ensure that pages featuring new technologies transform gracefully.
7. Ensure user control of time-sensitive content changes.
8. Ensure direct accessibility of embedded user interfaces.
9. Design for device-independence.
10. Use interim solutions.
11. Use W3C technologies and guidelines.
12. Provide context and orientation information.
13. Provide clear navigation mechanisms.
14. Ensure that documents are clear and simple.

The WAI guidelines, explanations and examples can be found at the WAI Web site at <http://www.w3.org/WAI/>. Other useful guidelines and resource links can be found at many sites on the Web. They include DO-IT (Disabilities, Opportunities, Internetworking and Technology), <http://weber.u.washington.edu/~doit>; EASI (Equal Access to Software and Information), <http://www.isc.rit.edu/~easi>; the National Center for Accessible Media (NCAM), www.wgbh.org/ncam; The Trace Research and Development Center, <http://www.trace.wisc.edu>; and WebABLE, <http://www.webable.com/>.

The Web pages for a distance learning class should be tested for access using a variety of monitors, computer platforms, and Web browsers (including a text-only browser such as Lynx) and, ideally, by individuals with disabilities. In addition, a site can be tested for accessibility using "Bobby." Bobby, created at the Center for Applied Special Technology, is an HTML validator program that tests for accessibility and identifies non-standard and incorrect HTML coding. Bobby is located at <http://www.cast.org/bobby>.

The Internet has a unique place in providing information access to everyone. It provides a means for people to access courses that are not taught locally and to access courses that, due to their disabilities, would be difficult to take in another way. Choosing and developing course materials with access to disabled students and instructors in mind is not difficult, but requires forethought. With this forethought, it is possible to deliver a distance learning class that is available to all students, with and without disabilities.

Angela.Carbone@csse.monash.edu.au

Yap Chee Seng
School of Computer Science and Software Engineering
Monash University, Australia

Abstract

In a tertiary education environment with a lecture/tutorial teaching method, there is often a need to recruit casual teaching staff and allocate them to tutorial and laboratory classes based on their preferred teaching times. This process can be simplified and automated using the Web-based tutor recruitment package to capture preferred teaching times and using a Web-based teaching timetable scheduler to perform the allocation of teaching staff to classes. This paper presents a web software application that will assist academics responsible for the allocation of casual teaching staff to classes. The paper describes a teaching timetabling process, identifying the major components of the scheduler.

1 Tutor Recruitment Package

Traditionally, assistant lecturers in the School have been responsible for the generation of teaching timetables and scheduling of meetings. To assist in this responsibility a tutor recruitment package was developed on the Web [Carbone, 1997]. The tutor recruitment package can be viewed by any Web browser that supports forms and Hypertext Markup Language (HTML). It was designed in accordance to the four design principles for creating interactive multimedia news Web sites [into the following four components:

- An outline of the requirements and qualifications needed by a candidate.
- List of subjects requiring tutors.
- An outline of the teaching duties and administrative responsibilities expected of front line teachers.
- The tutor recruitment form. The form lists the possible class times and meeting times planned. Each postgraduate enters their personal details including a contact number, previous teaching or related experience, and the subject they wish to teach with a list of preferred teaching times. After submitting the form, a script is invoked which produces a series of text files as output. Each text file represents a subject and contains a list of applicants with their personal details and a ranking of their preferred class times.

2 Scheduling methods for the Teaching Timetable Scheduler

Although timetable scheduling has been a source for much research [de Werra 1985; Selim 1992; Costa 1994] the scheduling algorithms used in this application are based on methods used to manually allocate tutors to classes such as; First-Come-First-Serve (FCFS) and a Priority-based. Both methods are described below and are used to automate the preliminary teaching allocation. The Teaching Timetable Scheduler uses one of the text files generated as output from the Tutor Recruitment form. A CGI program reads the tutor's preference list, executes a scheduling algorithm and creates a HTML timetable (see Figure 1) on a new screen using JavaScript commands. There are four components of Teaching Timetable Scheduler, namely the File section, the Edit section, an Auxiliary section and Help section.

Academic Integrity and Web-Based Instruction

Abstract: This paper focuses upon the issue of academic integrity as it pertains to on-line, distance learning, or web-based courses. This type of instructional delivery system is proliferating throughout higher education because it offers freedom from traditional class schedules, allows students to work at an independent pace, and creates additional revenues while requiring few resources. While these aspects of on-line coursework are attractive the open access, the electronic medium, and the unsupervised environment associated with distance learning create situations where plagiarism and cheating can easily take place. Anecdotal examples of web-based cheating are cited along with methods used by the author to identify instances of cheating. Ways and means to design web-based courses and ensure academic integrity are discussed.

A search on the Internet demonstrates that institutions of higher learning are developing courses for the World Wide Web at an exponential rate. These on-line, distance learning, or Web-based, courses can appeal to a wide and diverse geographic area, offer freedom from traditional class schedules, and allow students to work at an independent pace. From an institutional perspective, these courses create additional revenues while requiring few campus resources such as classroom space, heat, lights, or ventilation. While many positive aspects of on-line coursework are attractive, both pedagogically and financially, the open access and unsupervised environments on the World Wide Web create situations where plagiarism and cheating can easily and effortlessly take place. Academic institutions involved in on-line coursework should plan and implement procedures to ensure that the same academic standards that are applied to traditional classes are similarly applied to on-line courses.

The ability to provide educational opportunities to individuals who would otherwise have limited ones is rewarding and exciting. In expanding academic offerings and in making education more accessible, many colleges are enrolling students who live in remote locations. Individuals located in the Amazon basin or at a military post can enroll on-line, obtain instructional materials, submit assignments, and complete course requirements without ever setting foot on campus. Educators, however, must be cognizant of the fact that in giving up the traditional classroom managerial role, they create potential situations that also jeopardize academic integrity. In assessing skills and awarding academic credit, academicians must face the reality that the person taking the course may not be as represented or may be receiving assistance on submitted materials.

From a purist's perspective, the pursuit of learning benefits only the learner. It would thusly seem contradictory to suggest that someone would enroll in a course only to receive assistance and cheat, thereby only cheating him/herself. Those of us who are more experienced and perhaps more cynical understand the reality of coursework deadlines and of striving for top-notch grades. Some companies or organizations offer incentives in the form of promotions or bonuses for attainment of degrees. High grades can assist students in receiving scholarships, grants, and fellowships. In many states, elementary and secondary schoolteachers must complete additional coursework to receive permanent teaching certification. In other cases, any knowledge gained from coursework is ancillary to the actual job, no additional tasks, job advancement, or job knowledge will result from completing these courses. Advancement or salary increments are based upon the completion of a specified number of credits from an accredited institution.

As an example, one school district provided cash stipends for teachers who completed a specified number of credits from an accredited college or university. Six teachers enrolled in the same on-line course at a college. Once they had received the assignments, they divided the work, each assuming responsibility for one or two units of study. They exchanged completed materials and then submitted all required units, completed the course requirements, and received their cash stipends. While this is a particularly sad commentary given the profession of the persons involved, a loosely supervised on-line course provided too easy a vehicle to accomplish the goal.

In another instance, an employer provided similar educational incentives to upgrade worker skills. The accumulation of ten (10) college credits would qualify workers for a pay grade increase and consequently, more money. A grade of B or better, however, was required for monetary reimbursement. Two employees sought to receive the pay increase and each one enrolled in two five-week distance courses. Each worker completed one course. They then exchanged course materials and resubmitted them. Unfortunately for them, the instructor compared submissions, found similarities, and failed both students in both courses.

In seeking to ensure academic credibility there is much at stake, both from the student and from the academic perspectives. To prevent abuses, instructional developers can design courses with alternative assessment methods that will help ensure academic integrity. Such assessment methods include structuring timeframes, reviewing submissions comparatively, and requiring a proctored final exam.

Web-based courses can include a structured timeframe similar to that of traditional classes. Web-based instructors should not fall into the immediacy mentality of the Internet where information and exchanges are expected on a moment's notice. At the outset, interactive on-line sessions can be planned in advance so that students can count on receiving assistance at designated times. Instructors can post and keep Internet "office" hours where students "chat" and interact with the instructor on a regular basis. While this will not prevent cheating, it will provide students with ample access to the instructor and set a pattern of interaction. In this manner, instructors will become "familiar" with each student's style.

When assignments are received, submissions should be reviewed comparatively. Each student will leave a unique signature in a submission. It may be as subtle as the style of entering a date or the location of their name. Some students will always include a cover page or graphic image; others will repeatedly misspell or misuse the same word, even with the assistance of a word processor spelling or grammar checker. In a time crunch, copying another student's file is a very easy alternative to spending long nights completing the work. A publicized policy addressing the commitment of dishonest acts and the penalties for doing so provides the instructor with the necessary enforcement tools.

Final course assessment is another tool available to assist the instructor in assessing learned skills. One option is to stipulate that passing a comprehensive final exam is a requirement for passing the course. In cases where a student copies and submits all assignments completed by another student, proficiency must be demonstrated on the final, regardless of the number of points already accumulated through other assessment methods. Instructors can also require that students take a final exam on campus. If the student can not come to the campus, a designated proctor can supervise the exam at an off-campus site. At remote locations, teachers or clergy can be employed as proctors. When students appear for exams, they should provide a valid form of identification such as a driver's license or a passport. If the final assessment is a demonstrable skill, live video in real-time over the Internet is a viable alternative. If such equipment is unavailable, proctored videotaped demonstrations may be an acceptable substitute.

Academic institutions are responsible for establishing standards. These standards have meaning to the members of society who place importance upon the acquisition of knowledge and the achievement of excellence. As web-based instructional modalities become increasingly commonplace, academicians must preserve learning standards. These standards can be preserved through planning and implementing measures that ensure on-line courses have the same integrity and credibility as do traditional classes, thereby protecting the reputation of the college or university.

Building "My City"

Luca Cernuzzi*, Fabián Laufer⁺, Lilia Riveros, Gustavo Quiñonez
Department of Computer Science Engineering - Catholic University
Asuncion - Paraguay

*lcernuzz@uca.edu.py , ⁺flaufer@conexion.com.py

Abstract: "My City" is an educational hypermedia application designed to stimulate meaningful learning. The application, in contrast to the traditional ones, presents an open scheme based in an external data source that has the possibility of automatically generating a WEB interface. There are exposed some aspects of model based design for hypermedia applications, and an innovative metaphor is proposed for the developing of hypermedia learning tools. Finally, a proposal of methodological use of "My City" is discussed.

1. Introduction

In the last years, we have witnessed a growing use of hypermedia software in several educational areas [Jacobs 92; Kafai et al. 94; Sánchez et al. 95; Müldner et al. 97]. This tendency is gradually integrating, and even substituting the traditional approaches of computer assisted education and the intelligent tutorial systems. The current work presents "My city", an open hypermedia approach based in web technology, that provides an educational framework to explore (maps, photos, history, sightseeing, etc.) and learn about a town.

According to the hypermedia software taxonomy proposed by [Lumbreras et al. 97], "My City" can be classified as presentation, representation or building of knowledge, and can be used in civic and research education activities.

"My city" is postulated as an open system. In effect, the multimedia database that supports the information presented in the application can be easily expanded or changed by learners engaged with the application. For instance, the version presented here is based on Asunción - Paraguay, but the information represented here can be easily substituted to offer relevant data about any other city like New York.

The open nature of the application allows the use of a workbook metaphor instead of the traditional multimedia encyclopedia. The initial information is organized according to a well-defined structure, and stimulates learners to enrich it depending on new discoveries.

2. Designing "My City"

The traditional hypermedia encyclopedias present some problems. First, their content does not change in time. This implies that the information can be read and browsed but not edited by learners. Secondly, in general, these applications do not separate the presentation mechanism from the data. This implies that the contents must be global enough to be shared by a large group of learners. Another inconvenient is the difficulty to develop activities in which the learner is allowed to build his own information and knowledge.

So, if "My City" were organized as an encyclopedia, it would probably suffer of the same weaknesses. Moreover, it will not fulfill the most relevant feature that we expect for this application: to facilitate change in content. In effect, it is expected that teachers and learners will be able to customize the database, with the specific characteristics of their own cities, neighborhoods, etc.

The metaphor of a workbook was chosen to provide a basic organization to present information, a database and tools to construct new information and knowledge according to educational goals. In order to achieve the later, the main design requirements proposed were:

- * integrate relevant information about the city
- * organize the information in well defined structures
- * facilitate the change of the content to adapt it to specific situation
- * offer accessibility to a wide range of learners
- * stimulate the construction of new information based on the previous one
- * propitiate an adequate navigation system and
- * assure the possibility of using an effective searching tool to find particular information.

Several authors have proposed different models and methodologies for the design and development of hypermedia applications and systems [Garzotto et al. 93, Halasz et al. 94, Isakowitz et al. 95, Schwabe et al. 96]. Those models offer to the designers different advantages to face in an efficient way the structural and navigational complexities. Considering that "My City" shows a regular structure, (a city is formed of neighborhoods that have streets, point of reference, etc.) and foresees a volatile content, RMM (Relationship Management Methodology) [Isakowitz et al. 95] is the model that suits best to the requirements of this application.

3. Using "My City" in Learning Process

At a basic level, it can be used as a source of information about Asunción. However, this usage, even though important, it is not the most interesting one because it is limited to the presentation of the information but not improving the learning in a significant way. A very interesting learning level could be reached if the student acquires skills such as reading and orienting himself in the virtual map.

Moreover, this can be easily integrated with challenges like solving problems to find things, i.e., children could identify a convenient path from their houses to the school; considering that the streets could have related information about their respective traffic jam, number of available lanes, etc., it also can help more advanced students to solve real life problems of operative research as finding the shortest path between two points or the hypothetical urban transport paths.

The most interesting feature of "My city, is that the learners could generate more information to be added to the one already available. For instance, they could produce information about their own neighborhoods or even imagined one, display it in a convenient format, and finally publish it, so they are building their own city on the base of a predefined structure.

4. Final Discussion

This work presents a building experience of "My City", an hypermedia web based application, connected to an external database, that leads to the presentation and representation of information and relevant knowledge concerning Asunción, capital city of Paraguay.

However, the most interesting feature of "My City" is that it is an open system that presents a well-structured organization of the information that can be easily widened.

In this way, it is possible to stimulate students from different places, encouraging them to build projects about their own cities, being it the reflection of their own reality or a product of their imagination.

It also has to be mentioned that this experience has allowed a first analysis of the utilization of RMM [Isakowitz et al. 95] in the design of these kind of educational hypermedia applications. In the future, "My City" will be used in several educational centers for its evaluation.

Design as Learning; Design as Teaching: Embedding Pedagogy in Web-based Course Design

Margaret A. Chambers

Director, University System of Maryland's Institute for Distance Education,
University of Maryland University College, USA, mchambers@umuc.edu

Abstract: Most Web-based courses are delivered by systems that are designed for information delivery and retrieval with no evident teaching or learning strategies apparent to the student. A menu offers access to various components in no apparent sequence or order of importance. To assist faculty members in creating and managing more effective learning environments for students, we need templates that are designed to present content or manage interactivity in specific formats that enable specified outcomes. This session will examine several approaches to "pedagogically informed software" and will look at how individual Web-based courses have been customized.

Web-based learning environments can become more effective when they are designed to use their rich hyper-media potential to achieve particular learning outcomes and when media templates ease the task of translating content for the Web. Too often courses are being developed as media conversion tasks, taking classroom elements such as lectures, question and answer opportunities, a textbook, and exams and placing these on line with a syllabus and schedule. Too little thought is given to the essential differences between a physical classroom and the asynchronous, multi-media communications environment of a Web-based learning experience. Faculty authors rarely have assistance reconceptualizing the course to take advantage of these media possibilities for interaction, either within content presentations or sequenced interaction to facilitate specific cognitive or social learning. Approaching the development of a Web course as a design challenge, rather than a resource gathering exercise, allows us to see how learning and teaching issues get reshaped.

This session will examine several approaches to "pedagogically informed software" and will look at how individual Web-based courses have been customized. It will offer insights and demonstrations from the Web Initiative in Teaching, a faculty leadership and courseware development program, for all thirteen diverse institutions in the University System of Maryland with teams from a dozen disciplines. This project started with a summer of design inquiry to help reconceptualize courses, focusing first on learning and teaching issues. www.umuc.edu/ide/wit.

Designing for Learning. Design must begin not merely with *what* is to be learned, but also *how* prospective students will learn. As all teachers know, students often don't grasp ideas that teachers think are clear. So much of our teaching is correcting misconceptions, probing ideas, helping students perceive relationships, or make connections to their own life experience. Where a classroom teacher may rely on puzzled looks or restlessness to shift gears, an online course designer needs to consider how such feedback loops are embedded in course processes.

Interaction may be faculty to student, student to students, student to resource, and student to content. Most good Web instructors are conscientious about providing feedback to students through email, chats, or course conferencing. Most appear to include some form of group discussion, usually asynchronous conferencing. Many encourage students to use the Web's search capacities to find resources and people. Few structure material or content to guide students through cognitive processes designed to enhance or deepen learning. Rarely are the interactive processes of online courses designed to engage students over time in a series of interpersonal and content interactions toward particular cognitive outcomes.

Discussion in the online classroom is often used loosely to see "if the students have questions about the material." While clarification is a worthwhile activity, is it sufficient? Some professors even pride themselves in having class discussions in which they don't participate. Yet colleges and universities that have begun looking at outcomes for graduates, usually specify something related to critical thinking or thinking like a professional in the target discipline. How can online courses support or structure dialogue or discussion that promotes these higher order thinking processes? Jon Dorbolo at Oregon State University created his own course structure to achieve the desired

sequence of interactions among students and between himself and students to induce them to practice certain patterns of logical thinking and philosophical inquiry in his highly-acclaimed Philosophy 101 course online. The learning process he named “guided autonomous learning,” can be used in teaching other disciplines.

Case studies are popular today to teach students how to think like professionals in business, social services, medical studies and other areas. Harvard’s business case study methodology is very different from others in juvenile justice or nursing. On the Web most case studies are still primarily presented as text with occasional visual illustrations. What are the possibilities when we take a specific case study methodology and its case-based reasoning and build a template for multimedia learning experiences? This might incorporate certain simulations not possible in the classroom and provide precise feedback on breakdowns in case-based reasoning. How can this template help the instructor not only present the case study “material” but structure the student’s learning interactions progressively to challenge and deepen understanding?

Embedding Teaching Strategies. Three decades ago Bruce Joyce, then at Columbia Teachers College, wrote a classic book on Models of Teaching. Each model is based on a learning theory, with a teaching strategy, specific syntax for implementing this strategy with students, and principles for teacher interaction. For example, Harvard psychologist Jerome Bruner’s (1960) theory of how concepts are learned led to a strategy for inductive learning. The instructor selects and sequences a set of exemplars of the concept to be taught. These exemplars together with non-exemplars are presented to students. They are encouraged to look for attributes that are shared by positive exemplars but absent from the negative ones. Then students are asked to guess or name the concept illustrated. This hypothesis is then tested with additional exemplars. Either the hypothesis is confirmed or new hypotheses must be generated. After the students have discovered the concept, the instructor helps them reflect on the thinking strategies that they used. This model for “Concept Attainment” makes students more aware of their cognitive processing of information, can aid in memory of large data sets, and can provide provocative, active learning. The generic strategy can be used with students at any age in any discipline. It has particular applicability online where exemplars can be text, images, or video segments of biological specimens, human behaviors, political events or computer objects. One creative variation of this strategy is a CD-ROM component of an Art Exploration course for Britain’s Open University.

Diane Laurillard, also at Open University, articulates another generic framework for conversational interaction between teacher and student that is comparable to the syntax of a teaching model. First the teacher presents conceptual knowledge, elicits students’ restatements of their understandings, and then helps clarify students’ ideas. The teacher guides students toward translating understanding into formal means of representation, such as academic writing, mathematical or logical notation, modeling, computer code, etc. Students act on these representations by solving problems, experimenting, interpreting, etc. Next the teacher assists them in comparing results and restating their understandings hopefully at a greater depth based upon their expanded experience. Finally the teacher helps them reflect upon the process. These steps can be used to design original presentation of material, structure how students continue to interact with these ideas until they achieve some level of competency desired.

These are a few examples of how knowledge of learning and teaching can be translated into software templates designed to facilitate particular pedagogical outcomes. Such templates can enlarge the repertoire of faculty’s teaching skills and their Web authoring options, while increasing active student learning and achievement.

Designing Graphics-Based Online and Web-Enhanced Statistics Courses

Faith Chao
fchao@ggu.edu

James Davis
Jdavis@ggu.edu

Department of Mathematics
Golden Gate University
536 Mission Street
San Francisco, CA 94105

Abstract: A sound instructional design is the foundation for a successful course. This is particularly true for courses delivered through the online medium where web sites replace face-to-face contact, where conferencing replaces classroom discussion, where written narratives replace the spoken word and where the desktop replaces the chalkboard. Rather than attempting to replicate the traditional classroom, instructors must take the familiar elements of the classroom experience and recast them into the on-line medium in such a way to best use its unique features.

In practice, Math courses present special challenges. Math courses are graphics-based with symbols, formulas, tables, charts and graphs of all sorts. Delivering graphic-based content verbally with the use of the blackboard requires little technical skills. When the material is broadcast over the Internet, instructors must be technically savvy and be familiar with equation editing and graph-generating software, gif files, bit map files, not to mention HTML. The task is daunting enough for the instructor. It is impossible to expect the average student, who is already struggling with understanding the Math content, to also acquire these skills in order to communicate with the teacher and fellow students.

To help a student understand a concept or solve a problem, a series of questions and explanations in real time are often helpful. Conferencing online is conducted in a written format with online interactivity taking place asynchronously. When dialogue is asynchronous, other methods and/or techniques will have to be developed.

Before deciding on the optimal balance between using the broadcast and interactive modes, one must first address that which is possible within the context of a graphics-based online course. In this paper, the authors present some of the techniques were used and provide an assessment for comparing a classroom statistics course with one that is offered online.

The design of this online statistics course involves the following steps:

1. Set the Goals and Objectives of the course.
2. Decide on the depth and breadth of the content to be covered.
3. Decide on Text Book(s), software, and/or other materials to be used.
4. Decide on the logic of the structure of presentation.
5. Develop the content and structure for interactivities and the appropriate techniques.
6. Develop assessment tools to determine whether the goals and objectives have been achieved.

The objectives and content of the course are pre-determined and must be consistent with sections offered in the classroom due to the fact that the online course is one of several sections of our statistics course offered to our business majors. Excel was chosen primarily because of its popularity and ease of use to accommodate the wide geographic distribution of the students (an Excel-supported text was used).

The most daunting task for the designer was to come up with a logical structure. Unlike a live classroom situation, the online modality is asynchronous with the student facing a computer screen rather than a live instructor. The online course was structured around the logic that the student needs four steps in learning and retaining the material, regardless the modality. They are: 1) 'Tell me about it' 2) 'Show me how to do it' 3) 'Now, let me do it', and 4) 'Give me a review to reinforce what I have just learned'. The next challenge is to develop the content according to the four steps in the online modality.

Our courses are taught over fifteen weeks with one module assigned per week. Each module contains reading assignments, PowerPoint slides, and the instructor's supplemental notes. These are considered the 'Tell me about it' portion. Step-by-step examples satisfy the 'Show me how to do it' requirement. Homework assignments with solutions and feedback provide students with the opportunity for 'Now, let me do it'. The prepared *Interactive Excel files* and an online Excel Guide fit into all three of these categories. The use of case studies with simulated authentic situations, 'real' data and role playing activities prompt a good deal of student interactivity, add depth and force students to be reflective. Listing of key terms, symbols and formulas are part of the 'Review'. In addition, 'conferencing' software is used for student interaction and feedback with 'suggested topics for discussion' posted each week. The topics are carefully stated to minimize graphic input required.

Simply having all elements of the structure is not enough. The structure must be immediately evident to the student and the coverage must be friendly and thorough. Math is daunting enough for the average business student. The student needs to feel that the course material is accessible and that what the instructor has placed on the web is sufficient to gain a full understand of the subject matter.

Assessment

Having taught the introductory statistics course both online and in the classroom affords an opportunity to do some comparisons. The following are some qualitative findings from both instructors. Online students must be more self-directive, and although they use online conferences and email, they still need to dig out the material for themselves. As indicated by the grade distribution, the online students either understood the material or they did very poorly (evident by the few C's and no D's). Many of them withdrew. Other interesting findings were that students were not shy in expressing themselves in writing and the level of participation exceeded that of the classroom students.

One draw back for the online students is that when students do not even know enough to begin to ask useful questions, they are lost. This is not the case in a live classroom where the instructor can intervene, and through a series of questions and answers in real time, help the student. This is especially important when the student in trouble. Below is a comparison of the grade distributions for two introductory statistics courses.

	A	B	C	D	F	I	Total
Live	7	5	6	6	4	2	30
Online	5	11	4	0	4	1	25

A web-enhanced statistics course was offered last semester with a mixed mode course planned for the fall. It will be possible in the near future to make three or even four-way comparisons.

Cognitive and Motivational Effects of Computer-based Simulations on the Learning of the Human Respiratory System: A Study from the Dual Coding Perspective

Toh Seong Chong, Ph. D
Center for Instructional Technology and Multimedia
University of Science Malaysia
e-mail: tohsc@usm.my

Abstract: This study examined the cognitive and motivational effects of two multimedia simulation modes on factual information, concept learning and problem-solving performance of 156 Malaysian science learners. They interacted with a series of multimedia simulations presented in two different modes. In the concurrent mode, animated graphics and textual information were presented concurrently with redundant audio narration. In the consecutive mode, textual information and redundant audio narration were first presented followed by animated graphics. Students who received the concurrent mode of multimedia simulation obtained a higher gain score compared to students who received the consecutive mode. There was also significant difference in learning gain score amongst the low, medium and high trait-anxiety students in both the simulation modes with medium anxiety students obtaining the highest gain score. The conclusion of this study was supportive of the positive value of the contiguity effect in learning.

Introduction

Visualisation in all modes of instruction continues to be an important variable of research in instructional design. The task now is to determine what combinations of visualisation that is most effective in facilitating student achievement while taking cognisance the student's individual difference. In spite of advances in educational technology, the field of educational psychology lacks a corresponding research-based theory on how to design computer-based instruction using visualisation of words and pictures [Mayer & Sims, 1994].

Aims

Given the research concerns in the preceding section, the purpose of this study was to investigate the cognitive and motivational effects of different modes of multimedia simulation on the topic entitled "*The Human Respiratory System*", on Malaysian students of different aptitudes. In particular, the goal of the present study was to identify the role of the student's spatial and verbal ability in learning from words and pictures in a multimedia environment. This study also attempted to find out how the cognitive styles and anxiety levels of learners affect their learning in a multimedia environment.

Methodology

In the first part of the experiment was to find the cognitive effects of the two instructional treatment modes on students with different spatial and verbal abilities, cognitive styles and anxiety levels. The second part of the experiment was to find the motivational effects of the two treatment groups on the learners. A 2 x 2 quasi-experimental factorial design was used. First, the simulation modes (concurrent mode versus consecutive mode) were crossed with the spatial abilities of the learners. This was repeated with verbal abilities, cognitive styles and anxiety levels. In the second part of this study, the motivational effects of the two treatment groups (concurrent versus consecutive mode) on learners were studied. There are seven instruments in this study. They were the pretest questions, the posttest questions, the Cattell "Culture Fair" Intelligence Test, the Keller Instructional Materials Motivation Survey [Keller, 1987] and the Group Embedded Figures Test, the Trait-Anxiety Tests, Verbal Ability Test and the Spatial Ability Test.

Subjects

Subjects consisted of 156 high school students chosen randomly from six Malaysian schools. For each school, two intact classes were chosen. The subjects were randomly assigned into any one of the two instructional modes. The first mode is the concurrent mode where animated graphics and textual information on *the Human Respiratory System* was presented concurrently with redundant audio narration. In the consecutive mode, verbal information and redundant audio narration was presented first followed by animated graphics consecutively.

Results

Students who received the concurrent mode of multimedia simulation obtained a significantly higher gain score than the consecutive mode (gain score: $7.96 > 5.98$). In the concurrent mode, learners with high spatial ability obtained higher gain score compared to the low spatial ability learners (gain score: $8.43 > 7.39$). In the consecutive mode, learners with higher spatial ability obtained high gain score than the low spatial ability learners (gain score: $6.90 > 5.17$). Learners with high spatial ability consistently obtained higher gain scores in both simulation modes than the low spatial ability learners. In the concurrent mode, learners with high verbal ability obtained higher gain score than the low verbal ability learners (gain score: $8.36 > 7.64$). In the consecutive simulation mode, learners with high verbal ability obtained gain score than the low verbal ability learners (gain score: $6.90 > 5.10$). Learners with high verbal ability consistently obtained higher gain scores in both simulation modes compared to the low verbal ability learners. Field independent learners obtained a higher mean gain score than the field dependent learners. (gain score: $7.90 > 6.26$). Medium anxiety learners obtained higher mean gain score than the low anxiety learners and high anxiety learners (gain score = $7.98 > 6.51 > 6.21$). Learners obtained higher motivational scores when exposed to the concurrent mode compared to the consecutive mode (motivational score: $136 > 129.85$).

Conclusions

The results of this study were supportive of the positive value of the contiguity effect. In a multimedia environment, students presented with the concurrent mode will obtain significantly higher gain score than students presented with the consecutive mode. This study found significant differences in gain score between field dependent learners and field independent learners in both the concurrent and the consecutive mode of simulation. As the concurrent mode was better structured in terms of providing students with a framework for organising knowledge, the field dependent learners would find it more helpful to learn from the concurrent mode than from the consecutive mode of simulation. The study found significant differences in motivational preference between participants in the two modes - students showed higher motivation when presented with the concurrent mode. This finding was consistent with previous studies on motivation and design of instruction conducted by [Toh, 1994] and Rieber [1991]. It is possible that using multimedia simulations with concurrent text and animated graphics and narration as a method of instruction did enhance the motivation of the students in the four areas of attention, relevance, confidence and satisfaction. Second, placing the text contiguously with the animation would cue the learner's attention to the learning task.

Why Are We Training Professors to Become Web Designers?

W. Stanley Conrad, Educational Technologies, James Madison University
USA, conradws@jmu.edu

Abstract: Many universities are using diverse approaches for training faculty in the use of HTML editors to put class materials on the web. This paper will outline some of the reasons why this process is taking away from more productive endeavors. The paper will address how educational technology personnel need to re-think how they are functioning and provide a new paradigm for preparing faculty to incorporate the web into their teaching. In addition, the paper will address one alternative method that the College of Arts and Letters at James Madison University is using to transfer the burden off faculty.

The Problem

There is escalating pressure on faculty members at all institutions of higher education to produce web pages/sites for their courses. The Chronicle of Higher Education, in an article dated May 27, 1999 taken from a panel discussion on student expectations for technology that was sponsored by the Software and Information Industry Association, states, "some students say the best professors are the ones who bother to make web pages for their courses. And a growing number of students use the quality of course web pages as a deciding factor when picking classes." The editorial goes on to say that some students are also mentioning course web sites in their reviews in student-published course guides. In the commentary, Sue Kamp, director of the education-market division of the software association, says during the panel discussion: "They (students) are coming in technology-literate and are expecting the university to be equally literate."

The above remarks are compelling, and they are placing an increasing demand on faculty to establish their class materials on the web; and it is not adequate anymore to put just a syllabus and some links on a class site. There are certainly some impressive reasons to have particular class materials available to students twenty-four hours per day. A professor's slide presentation can be a great learning tool for students to access anytime they need it; and readings for the class can be distributed in a much more efficient mode. However, it has thrust researchers and teachers into an environment in which they are totally unprepared to confront. Not only do they have to learn a different manner of presentation/delivery, but they must also become designers, technologists and developers overnight to prepare themselves for the new delivery system. Those that leap into the process are frequently unaware of the time it will take to learn the basics, the time it will take to develop a good site, and are more unaware of the time that will be expended to manage and update a site. The above tasks can only take away from the work on subject-matter content, work on curriculum development, work on research, etc. that these people were hired to perform.

Current Solution

James Madison University, like many universities, has chosen to deal with this problem centrally. We have elected to offer "free" training to all faculty and staff that desire to learn how to prepare their course materials on the web. For us, this involves the training of an HTML editor such as Frontpage and learning to transfer files to a web server. In many instances like at James Madison University, the faculty are required to purchase the software to accomplish this activity after the training is finished, are left with the problem of finding time to accomplish the task, and are left dealing with the computing arm of the university to get space on a web server, etc.

The Myth

I have worked in educational technologies and have observed over the past ten years the lack of effectiveness that web training and instructional centers have had on the use of instructional technology for teaching and learning. I have identified several reasons for this fact: training is normally not knowledge-based training (it is geared toward staff training); the faculty does not have the time to train in certain time slots as staff do; and faculty members do not receive the follow-up training that is so important. These factors are all independent of the constraints encountered by the faculty member: time, lack of design abilities, lack of reward, etc. These are powerful reasons why using our content experts as web developers is superfluous.

As an example, I use web pages extensively for my classroom teaching: <http://cal.jmu.edu/smad232>. I have observed that students lack the visual abilities that are required because they have not looked at enough good design. I have found the web to be a perfect solution to this problem. I have designed my web site so they must look at good design. Although this is a more extensive site than most web sites (although students are coming to expect more), it takes far too much time to develop it. A faculty member could not afford to put the time I invest in my web site and expect to also perform well in the areas he/she is required by the university system.

Alternate Solution

The College of Arts and Letters at James Madison University has created a tool that will allow faculty to drag-and-drop digital classroom material in its native format (Microsoft Word as opposed to HTML) into a folder on the desktop. This instantaneously makes the material available on the web. It allows for faculty to put syllabi, handouts, readings, take-home tests, PowerPoint presentations etc. on the web for access twenty-four hours per day. There is no training necessary since the drag-and-drop process is inherent to all computer users. The material does not need to be formatted (converted to HTML) so browsers can display it. Organizing the material is again fundamental to the user. He/she simply makes folders/directories within his/her desktop folder and drags the material (files) into the folders. He/she can organize according to class, assignment, etc, simply by labeling the folders appropriately. All material can be password-protected if desired.

The student then goes to a page on the web (<http://cal.jmu.edu/classmaterials>). The student uses the pull-down menu to choose his/her instructor from the list. The learner will then click the "Display Classes" button. The student will be directed to that instructor's web page that will contain the folders/directories and files as the instructor has organized them. The student simply finds the material he/she needs and clicks on it. The student may download the material/file for transport or open it immediately. The application that the file was developed in must be on the computer. This is not a problem at James Madison University since most all applications are standardized.

The instrument also allows for an instructor to upload the class material anywhere in the world. The instructor will go to a page on the web (<http://cal.jmu.edu/upload.asp>). The page allows the instructor to create directories/folders, delete directories/folders, upload files and delete files. At this point, the faculty member has to know more than just the "drag-and-drop" process. The instructor must understand how to fill out and submit forms on the web. Although this seems trivial to many, it does take a small amount of training for some educators in the College.

Summary

Although the tool has been slow to catch on (developed in the Spring semester of 1999 and not advertised), many in the history department are now using the tool. Mostly developed for PowerPoint presentations to be made accessible on the web, the History Department at James Madison University used it to distribute take-home final tests at the end of Spring semester. The faculty members that use it find it to be very useful. The Fall 1999 semester will be the first time in which faculty are able to have the site available to them the entire semester and able to make plans on how they might use it during the semester.

The paper is not to discourage faculty from developing extensive class sites for their classroom teaching. This is certainly an individual decision. However, it is the conclusion of the author that faculty have enough important items on their plate that it is asking too much for them to become web designers, an activity that is totally foreign to most. If we are to have faculty members effectively use the web for classroom teaching, we must change the tools and not have the tools change them.

Teaching a Large Undergraduate Statistic Class. Phase II: Developing a Web Support Site.

Robert M. Corderoy
Centre for Educational Development and Interactive Resources
[bob_corderoy@uow.edu.au]

Anne Porter
School of Mathematics and Applied Statistics
[anne_porter@uow.edu.au]
University of Wollongong, Australia

Abstract: In this paper the authors recount the process of developing an html based trial web site at short notice, designed to support the presentation of lectures and tutorials to a large undergraduate student cohort with minimal funding and a short time frame. The decision to embrace the process emanated from the need to find a mechanism that may alleviate some of the logistical problems associated with presenting a first year statistics subject 'using an experiential approach', to over 300 first year undergraduate students in the traditional face to face delivery mode.

Few academics appreciate the fact that migration to a web based delivery mode of their subject materials is an involved process which can only be successful if several demands are met including: thorough planning; a commitment to the restructuring of materials; re-assessment of the pedagogical approach taken and an awareness that their workload will increase.

Background

The rapid rise in the development of sophisticated and improved technologies has been without doubt one of the key driving forces behind the widespread embracing of the concept of flexible delivery and the application of the many and varied tools upon which it is based, in particular the world wide web, in the field of education. Researchers including, Simbandumwe (1997), and Parson (1997), suggest that there has been widespread increase in the level of interest and use by academics of on-line, instructional systems in the last few years.

"An understanding of the techniques and protocols of on-line teaching and learning and the processes of both the design of new and the conversion of old courses has become essential for academics, as universities throughout the world embrace alternative delivery methods in response to the globalisation of education." (Corderoy & Lefoe 1997)

Development Issues

By default, the academic must often assume the roles of designer, developer and presenter without the necessary skills base or supporting infrastructure. The acceptance of these roles has been eased and supported by the proliferation of 'easy to use' subject building systems currently referred to by many as 'cookie cutters'. However the problems arising out of inadequate instructional design often negate the worth of the resulting teaching and learning environment. It is suggested that "...the main reason for this is that, very few academics have the expertise in the varied disciplines involved in the production of an effective web based subject. While the 'cookie cutter' development systems generally base their 'templates' on sound pedagogical models, the templates must by necessity be 'one size fits all' in structure. This in itself would not necessarily represent a fatal flaw if it were not for the fact that these development systems do not generally have a sufficient level of in-built user support to allow an untrained academic to use them correctly and efficiently in various situations.

The problem is exacerbated by: time and funding restraints which force individuals into the adoption of a 'cheap and quick solution and the mistaken belief that providing a subject on-line involves little more than providing the content of the subject as a web based document. The authors contend that the most successful methodology is the 'team approach'. "Such a team would have a minimum of four members: a content expert (the academic or lecturer); an instructional designer; a programmer and a graphic artist." (Corderoy & Porter 1998)

The Development Key Issues

The issues are many and varied and may be categorised as:

Logistical

Issues including: aspects of student access; financial resources and the availability of developmental expertise.

Instructional Content

Issues including: appropriateness of materials for the delivery mechanism chosen; and media utilised

Management of delivery

Issues including: individualisation of instruction; facilitation of interaction; security and feedback to students.

Recommendations for Prospective Developers

Organizational

Allow sufficient time for, planning; materials preparation; conversion of materials, and testing. Ensure sufficient funding to cover the production cycle and release time for the academic during the curriculum/materials development stage.

Technological

In terms of technology developers should: ensure that they select seamless technology; maintain close collaboration with the 'technical delivery platform' providers; carry out extensive testing early; provide 7x24 support for students; provide staff and student training and, use one of the many Information Management Systems currently available.

Pedagogical

This is a new medium for both the student and the lecturer. Both need to be prepared to be accepting of the problems of all involved.

Conclusion

"Innovative practice will always provide challenges for early adopters of new strategies for teaching. As web-based instruction moves beyond the early adopter stage, institutions will need to put structures into place to support teachers in this new role." (Lefoe & Corderoy. 1998)

Being Orientated in the Cyberspace, Could it Be a Problem?

Ana Paula Correia
Institute of Education and Psychology
University of Minho, Portugal

Paulo Dias
Institute of Education and Psychology
University of Minho, Portugal
pdias@iep.uminho.pt

Abstract: This paper intends to discuss some metaphors used to promote navigation and to prevent disorientation in the cyberspace. We analyze two of the most common familiar contexts to the new space: the book and the physical space. These are often used to help users to understand the purpose and function of the information access structures and to help the user to easily build an internal model of the cyberspace (for example, of the World Wide Web). To adapt these familiar cues to promote orientation in the cyberspace is not an easy or a consensual task and there is some controversy in relation this theme.

The Cyberspace

The cyberspace is a new kind of "space" and it can be described as a new electronic territory, as an information space. It emerges mainly from the Internet and its associated environments (World Wide Web, gophers). [Staple 1995] defines cyberspace as "an imaginary world, an artifact of computer software whose form may be as varied as the human imagination". In this new world the challenge for the cybernaut is similar to the one the first Portuguese navigators who discovered the New World had to face: they have to know what they are looking for, how to find it and which is the shortest/easiest path to get to it. For instance, navigating in the WWW can be confusing specially when the users are novices or do not have a clear objective to drive them during the browsing process. Navigation tools as "previous" and "next" buttons are basic forms but there are more tools such as maps, book/ landmarks and history lists. The most sophisticated mechanisms to navigate through the Web are, as described in [Barlow 1998] the Web search engines such as Alta Vista, Infoseek, Excite, Webcrawler, Lycos, HotBot and the Yahoo Directory. They all aim at orienting whoever is browsing in the information in order to help them find what they need, so that they can move on to their next task.

The non-linear principle, which is the most important feature of the hypertext, is the basis for WWW. One breakthrough in this new medium is the linking together of information nodes as a true hypertext. However hypertext creates a contradiction: links to other sources add depth to a Web site, but it can also send the readers away mid-sentence and mid-thought by encouraging them to click somewhere else and thus creating a great confusion in their minds. On the contrary, when we read a book we can hold it and touch it and we also have several visual and tactile cues about the information it offers us. They are called discourse cues and consist in [Kim & Hirtle 1995] aspects such as: organization into chapters and sections, conventions concerning the placement of topic sentences, and typographical conventions that help the reader decide which parts to read in detail, and which parts to skim over. Such conventions have not been established in hypermedia environments yet. This situation grows worse in the cyberspace where the quantity of information and the number of links among the nodes of information can be almost uncountable. Feeling lost, not knowing where to go, not knowing where we are, and finding difficult to select the next node of information, these are some of the problems the users must face each time they interact with a hypermedia system. This "disorientation feeling" [Dias, Gomes & Correia, in press] is bound to cause frustration, since decisions about the node or sequence of nodes to be explored are difficult to make in complex environments.

To this scenario we can add, if we are referring to the cyberspace, the absence of physical context, the increasing need for graphical context cues and the variety of ways a user can arrive to any page of the Web.

How to Use Familiar Contexts to the New Space

The use of a navigation metaphor may be a way of helping the novice user to understand the purpose and function of the information access structures and to help the user to easily build an internal model of the system. The *book metaphor* has often been used to design hypermedia environments, called electronic books. An electronic book [Barker 1995, p.2] is "essentially a collection of pages of electronic information that is organized (conceptually) just like the pages of a conventional book". According to this author most electronic books use some form of graphical user interface and the quality and bandwidth of visual display within such interfaces depends enormously on the spectrum of delivery platforms available. But in almost all computer screens (until now) users read about 25% slower than on a printed book, as [Nielsen 1998] referred. Even when electronic books gain the same reading speed as printed ones, Nielsen claims that the book metaphor will still be a bad idea and justifies this statement saying that: the basic problem is that the book is too strong as a metaphor because it tends to lead designers and writers astray. "Electronic text should be based on interaction, hypertext linking, navigation, search, and connections to online services and continuous update. This new-media capabilities allow for much more powerful user experiences than a linear flow of text" [Nielsen 1998]. However some of the terminology (for example, "page") related to the WWW reminds us of similar elements in a "book". The use of titles, headings, sentences, paragraphs, table of contents and bookmarks in the design of Web pages is very common. But we need to consider that the WWW alters the way we perceive a book or a magazine. Therefore since the computer limits the amount of information visible at any given time on a screen and as this screen depends on the individual WWW browser used as well as on the resolution of the screen, the traditional concept of page has changed. This constraint does not normally occur in text-based print media that allow the reader to leaf through a lengthy reading, and commonly two pages of text are simultaneously on view.

There is also some controversy involving the hypertext discussing whether navigation should or should not be conceived as spatial. [Stanton 1994] classifies the *spatial metaphor* as dangerous. He bases his opinion on the electronic space definition. According to Stanton, majority of the studies done in relation to the hypermedia environment, seems to use the word "space" with the same meaning it is used by everyday-sense where it corresponds to a physical relationship between objects. In this perspective, the electronic space would be equivalent to the physical space. [Stanton 1994, p.288] supports that starting from the concept of hypertext as a multidimensional space, which can be explored in various ways, "space", in this context, must be defined as "the collection of objects and activities contained within a specific domain". [Dias & Sousa 1997] claim that the electronic environments present intrinsic characteristics that do not permit a linear transfer and appropriateness of the geographical environments characteristics'. They suggest that the use of a navigation map in an electronic environment is not as efficient as the use of a map in a geographical environment. The cyberspace has another interesting feature that makes it hard to map. It is infinitely mutable. All maps begin to lose their accuracy as soon as they are printed, as [Staple 1995] referred. However some attempts to design the geography of the cyberspace have been made as we can see on the Web site entitled "An Atlas of Cyberspaces" (URL: <http://www.cybergeography/atlas/>). This site [Dodge 1999] intends "to help us to visualize and comprehend the new digital landscapes". Some maps we can see in this site use the cartographic conventions of real-world maps, but they are much more abstract representations of electronic spaces, using new metrics and grids to create the so called cybermaps.

Multinational Web-based Training: Issues to Consider

Dr. Michael Corry
Educational Technology Leadership Program
The George Washington University, USA
mcorry@gwu.edu

Dr. William Lynch
Center for Distance and Mediated Learning
The George Washington University, USA
wlynch@gwu.edu

Abstract: The World Wide Web has tremendous potential to dramatically change the way training is designed and delivered. It can save money for management and increase flexibility for learners. This is particularly true when training is being delivered to multinational locations. This paper reflects on one multinational Web-based distance training experience. The authors examine lessons learned and share recommendations for future Web-based training.

1. Introduction

Training was traditionally delivered in face to face contexts either by sending trainers to remote locations where learners were congregated or by bringing learners to centralized training facilities. Distance technologies present several alternatives to these practiced configurations. This paper reflects on one multinational Web-based distance training experience.

The Web-based training project was initiated in conversations with a large hospitality provider with training needs around the globe. The challenge was to initiate regional directors of training to principles and strategies for distance learning along with specific structures for supporting distance learning in their regions. An initial meeting was held with the directors of training to introduce the basic system of information and delivery that would be utilized for the training and to conduct a basic substantive and technical needs assessment. A full-day seminar style approach was used to establish basic assumptions about distance learning and potential outcomes. An evaluation of the participant's motivation, prior experience, availability, technology access and local training needs revealed a high degree of enthusiasm and commitment to the proposed experience.

The original design included content posted on the World Wide Web (Web), Web-based learning activities, and an asynchronous discussion forum to support discussion and information exchange. There was no attempt to arrange synchronous activities due the fact that the participants were literally located around the world in dramatically different time zones.

Even after the initial basic needs assessment and technology training, several key obstacles occurred during the training. Through dealing with these obstacles, the trainers learned several key principles about Web-based asynchronous training. The purpose of this paper is to share the experiences and solutions learned by the trainers.

2. Asynchronous Training Learning Curve

One of the initial issues that surfaced during the orientation and first week of the training dealt with the learning curve associated with nature of asynchronous distance training. In the beginning of the training some of the learners felt that Web-based asynchronous training was similar to participating in a correspondence course over the Web. They envisioned participating in the training experience once a month when they had available time. Asynchronous distance training does afford a great deal of flexibility for learners; however, the structure designed and developed by the trainers required more frequent participation. The trainers had designed an asynchronous environment full of weekly lectures, activities, assignments and online discussions.

The learners accepted the fact that more participation than they had initially envisioned was necessary for the Web-based training to be successful. In an attempt to meet the needs of the learners, the trainers changed the format of the materials so that the learners would only be required to participate every other week instead of every week.

3. Interface Design

The second issue that arose in the training involved the interface design of the Web-based materials. The trainers chose to utilize a new software product that facilitated the posting of Web pages and asynchronous conferencing. The software allowed the trainers to simply fill in HTML form boxes with pertinent information and the software would then generate the appropriate Web pages. Prior to the training only limited pilot testing had been done with the software product. While that pilot testing had been successful, it did not address all of the issues. Of particular consequence was the interface design for the asynchronous conferencing piece of the software.

The interface design worked fine when there were few users and limited discussions. However, when many users started posting multiple weekly messages, the interface made the process of posting and reviewing others postings extremely difficult. The posting of messages and reviewing of other's messages was so important to the training exercise that the trainers were forced to abandon the initial asynchronous conferencing software. A different asynchronous conferencing software package, which had undergone extensive usability testing, was identified and implemented. The trainers observed that in the future all Web-based products should go through extensive usability testing prior to their use in a training environment. Additionally, as previously mentioned, designers should involve learners early and throughout the design process.

4. Needs Assessment

As discussed, early in the process the trainers participated in a basic needs assessment with the learners. However, a substantive needs assessment dealing with the learner's expectations, technology requirements and previous computer experience should also have been completed. The learner's management team assumed that the learners had enough time to participate in the Web-based training. However, it quickly became apparent that many of the learners did not have the necessary time available to fully participate in the training. After several weeks of partial participation in the training, the management team and the learners agreed that the Web-based training format was more time consuming than initial envisioned. This obstacle is directly tied to the learning curve associated with asynchronous training. Designers of Web-based training should do a thorough needs assessment of management and learner's expectations concerning the time necessary to fully participate in this type of training. This is particularly important for first time Web-based learners. Additionally, Web-based trainers should also do a thorough needs assessment of the hardware, software, internet connection speeds and learner's previous computer experience necessary for successful participation in the training.

5. Conclusions and Recommendations

Web-based training has tremendous potential to dramatically change the way training is designed and delivered. It can save money for management and increase flexibility for learners. This is particularly true when training is being delivered to multinational locations. However, Web-based training involves more than simply creating Web pages. The project described in this paper resulted in several key recommendations for those designing, developing and implementing Web-based training. The key recommendations are:

- Prior to the beginning of the training project, trainers should thoroughly explain to management and learners the prerequisites necessary to successfully complete the training. Of particular importance is the time necessary to participate in the training. In some cases, Web-based training is more time consuming for learners than traditional training.
- Designers should involve learners early and throughout the design process. This can be accomplished through pilot and usability testing.
- All Web-based materials and software should go through extensive usability testing prior to implementation. Interface design is of particular importance to the success of the training experience.
- A thorough needs assessment of the hardware, software, internet connection speeds, and learner's previous knowledge of computers should be completed prior to the design and implementation of the training materials.

Using The Web For Facilitating Problem-Based Learning And Case-Based Reasoning In The Training Of Pre-Clinical Medical Students

Abstract: Medical schools are continually seeking innovative ways to educate future physicians. Many schools have integrated problem-based learning into the curriculum. Web technology provides a new environment for complementing this educational strategy. This paper discusses problem-based learning as an instructional methodology and shows how the World Wide Web can be used to facilitate the process.

1. Introduction

Medical schools internationally are experimenting with new ways to educate future physicians. In 1986, medical educators from five different countries (China, Mexico, the Philippines, Thailand, and the United States) met at a conference held in Albuquerque, New Mexico, to introduce new methods of educating physicians. The aim of this conference sponsored by the World Health Organization was to discuss establishing an innovative curricular track, distinct from, but running parallel with, the already existing traditional curriculum (Kantrowitz, et. al. 1987). The predominant teaching methodology of this innovative curricular tract was problem-based learning (PBL). Since 1986, several medical schools and institutions that train health care professionals have adopted the innovative curricular track or used PBL and case-based reasoning. Over 80% of medical schools use PBL to teach students about either real or hypothetical clinical cases (Vernon and Blake, 1993). The recent development of web technology has provided impetus to use this environment for facilitating PBL. The paper discusses PBL as an instructional methodology and shows how the World Wide Web (WWW) can be used to facilitate PBL. Examples are drawn from the training of medical students and physician assistants using this approach at Wake Forest University School of Medicine. This medical school merged the problem-based and traditional curricula and is using the web for case-based tutorials. Issues related to using the web for PBL are discussed.

2. What is problem-based learning?

Mayo et. al. (1993) describe PBL as a pedagogical strategy for posing significant, contextualized, real world problems, and providing resources, guidance, and instruction to learners as they develop content knowledge and problem-solving skills. In PBL students collaborate to study the issues of a problem as they try to come up with viable solutions. Unlike lecture-based instruction, with the instructor being in control, PBL occurs in a small group facilitated by a faculty tutor (Aspy, Aspy, & Quimby, 1993). PBL is learner-centered; learners are given more and more responsibility for their own learning and become increasingly independent of the tutor as they acquire self-directed learning skills. PBL is based on real-life, unanticipated, and ill-structured problems, problems that reflect life beyond the classroom. The problems in PBL are designed to challenge learners to develop effective problem-solving and critical thinking skills. Learners encounter a problem and attempt to solve it with information they already possess allowing them to appreciate what they already know. They also identify what they need to learn to better understand the problem and how to come up with a solution for it. These are called learning issues. Once they have identified what they need to learn to understand the problem better, learners engage in self-directed study and research using textbooks, journals, the web, and talking to a variety of people with appropriate expertise. The learners return to the problem and try to apply what they have learned to resolve it. After they have finished their work with the problem, learners assess themselves and each other to develop skills in self-assessment and constructive peer-assessment. Self-assessment is an important skill that leads to effective self-directed, independent learning. The principle role of the tutor in PBL is one of facilitator who guides learners through the learning and clinical reasoning process. The tutor may also serve as subject matter expert, resource guide, and group consultant.

This arrangement promotes group processing of information (Vernon & Blake, 1993). The tutor encourages student participation, keeps students on track, avoids negative feedback and assumes the role of learner (Aspy et. al. 1993). As students learn to take more control of the learning process, the facilitator becomes less active.

PBL in medical education is similar to the process described above. Medical students meet in small groups of five or six students with a trained faculty tutor. Patient problems are presented in a variety of ways, on print, computer-based formats, as well as simulated patients. Interacting with simulated patients enable the students to develop both clinical and interpersonal skills. Students approach patient problems just as a physician does. They are able to ask questions, carry out a physical examination, and order diagnostic and laboratory procedures, as in the real clinical situation. Faculty tutors guide students in reasoning their way through the patient's problem. The need for information required to understand the problem generates learning issues for further study. Learning issues represent all relevant disciplines. Students are expected to consult a variety of available resources while pursuing the learning issues. As students return with the knowledge they have gained, they apply it to the patient problem and are able to either confirm or reject hypotheses.

3. The web and problem-based learning

The web provides a versatile environment for fostering PBL. Patient cases can be posted on the web; simulated patients can be interviewed via conferencing technologies. Each group can use the conferencing features of the web to form and discuss learning issues. The web is also an excellent medium to point them to additional resources such as databases and experts. Experts in a specific area can be consulted via e-mail for an opinion. Using the techniques of telemedicine, students can review diagnostic information over the web. The application of information gained from the study of learning issues to solve a patient problem can be discussed in a group conferencing format that will facilitate collaborative learning among students and instructors. Web sites that provide good information on PBL are Southern Illinois University School of Medicine found at <<http://edaff.sinumed.edu/dept/pblcur.htm>>, <<http://www.pbli.org/resurces/cases.htm>>, and San Diego State University's web site <<http://edweb.sdsu.edu/clrit/learningtree/pbl/WhatisPBL.html>>.

Wake Forest University School of Medicine just began to use the web for case-based reasoning. Patient cases are posted on the web; the tutors display the page of the case as students request information. The groups can post the learning issues they form and discuss them across the groups (via the web) to get a broader perspective of the level of discussion within each group. In the first year there were twelve groups. There are issues related to both the technological environment of the web for PBL as well as issues students have with the process of PBL. Currently, medical students are not as active in the discussion of learning issues over the web; they interact less over the web than the physician assistant students do. Medical students are still more lecture driven and spend more time studying lecture material. This is because this program is a combination of traditional lecture-based and problem-based formats. To some degree they have a "we'll learn that in the next lecture" mentality, rather than using case material to explore new information on their own. Since this is the first year of the hybrid curriculum, many of the issues that have surfaced will be resolved as faculty and students gain confidence in learning via this new medium and methodology. Medical students need to progress more in terms of the self-directedness of problem-based and discovery learning. This is the problem with many learner-centered instructional methodologies as many learners are still very instructor-dependent. Both faculty and students need to be trained to move toward new formats for learning.

Abstract: Education is a profession that has a living, breathing life of its own; it is constantly changing and developing towards the future. But numerous issues pertaining to education are in existence now, not the future, and these issues must be ascertained, discussed, questioned and considered, so that these current issues will mold, not hold back, the life of education. One area that has significantly impacted education recently is instructional technology and, by all accounts, will continue to have a vast impact on the future. Therefore, instructional technology is one area within the educational realm that impacts the changing, developing structure of education and offers copious points towards current issues and future considerations. As educators, the changing, developing structure of education is an exciting time; however, we must meet current issues, overcome such issues, and move towards future considerations.

Instructional technology is a relatively recent subject matter within the arena of education; however, the impact of instructional technology upon the education of elementary, secondary and postsecondary educational environments have been enormous. The independent school districts and universities alike are scrambling to update their resources and make available technologies to their instructors/facilitators and learners within their distinct communities. But this is only one major concern; once this issue has been met, numerous other current issues are on waiting in the wings. One issue is the training that must ensue so that instructors/facilitators, learners, administrators and other persons intimately involved with the technologies will be cognizant of the abilities the technology will offer their educational situation.

Yet with so many current issues involved within the instructional technological impact upon the educational environment, future considerations must also be a part of the discussion. Questions must be asked and plans must be implemented that will lead the education profession towards not merely the twenty-first century but will offer such theoretical, epistemological, and realistic structure as to develop a basis of understanding concerning where we are now, where we would like to be someday soon, and where futurists view our educational environment in the future. As educators, the changing, developing structure of education is an exciting time; however, we must meet current issues, overcome such issues, and move towards future considerations.

Hardware and Software Availability

Although great strides have been made over the past several years concerning the hardware and software availability within an educational environment, the necessity to remain updated is clear. Governmental moneys have been a viable influence upon the improvements attained in classrooms at all levels of

professional education units; however, what will be the future of the hardware and software availability once the governmental moneys have shifted towards tomorrow's area of interest? Will we as educators be left with obsolete hardware and software, as was the case merely a few years prior to the latest accomplishments, or will the educational profession come together to demand equal status as other professionals that work towards a better tomorrow? The students, whether at elementary, secondary or postsecondary levels require the ability to obtain current information. Therefore, hardware and software availability will continue as areas of current as well as future consideration.

Curricular Integration

Curricular integration of technology has recently become highlighted as an area that may be difficult for many educators. Although the hardware and software may be available to the educators and students, the knowledge concerning the integration of technology into the curriculum may be lacking. Educators may have never had the opportunities to integrate technology into the curriculum and, now that technology is available, may be unaware as to the ease of integration.

Conceptual changes in the educators' perception as to not only the educators' place in a classroom environment, but also the students' and technologies' place in a classroom environment may be developing for the educator. Needless to say, conceptual visions and changes take time to occur. Therefore, the educational environment is in a state of flux and may well take several years to successfully integrate technology into the curriculum; however, educators must receive support in order to attain such high expectations of not only themselves and their students, but also of the changing structure of the educational environment.

Distance Education

Although distance education has been an influence over several decades, from postage mail through telephone conferencing through instructional television and then on to interactive television, it was rare to find a high level of interactivity among such conceptions. However, with the booming growth of the Internet, distance education has reinvented itself to offer a higher motivational standard and, perhaps, a higher level of interactivity and quality of educational experience than was previously imagined. Such optimistic beliefs are not without their detractors, but the future will offer the justification towards the formative years of distance education.

Training

Future considerations would not be complete without discussions surrounding the training of professional educators within the realm of technology. Without such training opportunities, the whimsical belief that educators have the unencumbered time to "figure out" the educational implications of technology is naïve. Along another line of thinking, training situations are excellent opportunities for research into the implications and effectiveness of training sessions at all levels of education.

Conclusions and Future Considerations

Numerous current issues surround the educational profession, of which technology is one. But for technology being only one of many issues, the technologically related areas of interest at the moment are numerous. But what of the future considerations? The future is, at best, unpredictable. Yet we must venture to hypothesize as to the levels of importance that each of our current issues will attain in the future. Through numerous considerations and professional discussions, we as a profession may come together as a strong body who will mold the future of education, and the technological implications therein, for the betterment of not only our own profession but also the education of our students. Herein the strength of our endeavors lie.

Crossing Over Disciplines: Three Academics Share Distance Education Design Experiences in Education, Administration and Health Sciences

Caroline M. Crawford
Assistant Professor
University of Houston-Clear Lake

gannoncook@cl.uh.edu

Abstract: The purpose of this paper is to relate the findings of three researchers who observed distance education curricula in the environments of education, administration and health sciences to see if there was congruency in the delivery of distance education amongst those venues. The theoretical framework for the study is constructed on the principle that distance education can crossover academic and vocational disciplines to mediate with technology and provide congruence in learning. Using a qualitative approach, the authors chronicled the design, developmental and evaluative periods, triangulated their data and then compared their findings for parallels.

There have been many questions raised about the efficacy of on-line distance education, but the delivery system is still too young to assess which measurement tools are meaningful in the collection of data, let alone the long term effects of on-line course delivery (Dillon, 1996; Jurasek, 1993). Still, the advantages of availability to students who might not otherwise be able to attend "face to face" classes have been widely acknowledged (Brande, 1993). These authors investigated distance education to assess how distance education was utilized from each of their areas of expertise: education, administration, and health sciences. What each author discovered was that, beyond the similarities of technological application, there were also similarities in philosophical, communicative, and discursive practices (Gannon-Cook, 1998). Moreover, while the delivery of on-line distance education was designed to be transparent in the three environments, the interstices between technology utilization and content delivery uncovered motivational considerations that did merit further investigation within all three environments. This paper reports their observations, and also discusses how theory both supports and fails to support, distance education in the venues reviewed.

The story of distance education is a very old one, albeit the technologies of today offer distance education as being a young, innovative delivery system. Stories have been passed on of students on the Frontier getting their textbooks and courses via Pony Express (MacKenzie, Christensen & Rigby, 1968). Over the next century, distance education graduated from those mail order courses to the dujour method of communication, telephone course transmission, and on to the contemporary electronic courses delivered via television or videotape. Most recently, the newest generation of distance education has introduced us to the merits of the World Wide Web (Web); Internet, applications and these courses have been embraced and increasingly adopted by colleges, corporations and individuals around the world.

Philosophical Environments

The philosophical, also described as epistemological underpinnings, of an environment offer numerous similarities within a distance education experience. The metaphorical understanding that develops the learning environment for a learner sets the tone for the course structure and is altruistic in its attempt to aid the learner in understanding the nuances of the knowledge to be obtained. Through such a metaphorical environment, the philosophical environment may be developed and the motivation of the student is further enhanced.

Accessibility and Convenience

It is clear that accessibility and convenience are key reasons for distance education's recent surge in popularity. Demand is a key driver for so many of the distance education courses becoming available on the Internet and on Intranets of colleges and corporations. But the merits of distance education alternatives also include access and cost-effectiveness. While there are still many challenges to designing and offering distance education courses, legal and learning style issues, it seems unlikely that the trend for more distance education will abate at any time in the foreseeable future.

Discursive Environments

The environment through which discursive opportunities may develop is also of utmost importance to the distance education situation. Discussion lists, listservs, chat rooms, private electronic mails (e-mails) serve to offer not only communications between the learner and instructor as well as other learners, but further defines the educational situation. The uses of such discursive environments are found to be positive aspects of an educational environment within a traditional classroom setting and may be seen as even more important when the knowledge acquisition and understanding is taking place at a distance.

Conclusions

The emphasis upon philosophical environments, accessibility and convenience, and discursive environments can not be emphasized enough within a distance education situation. Through the careful consideration of such clearly articulated issues, future considerations will become further defined and discussions will surround the importance of these considerations.

Cooperative Searching on the Internet

Raymond D'Amore

rdamore@mitre.org

Manu Konchady

manuk@mitre.org

The MITRE Corporation
1840 Dolley Madison Blvd.
McLean, VA

Abstract: The problem of obtaining relevant information on the Internet is becoming increasingly problematic due to the rapid growth of the web. This whole picture is complicated further where it is necessary to exploit large numbers of queries in order to ferret out information on complex topics spread across multiple domains, disparate locations, and long timelines. This task is often too complex and costly for a single searcher to perform effectively.

We have addressed the problem through a prototype, which supports cooperative searching by a group of users. The main focus is on providing users with an environment that supports problem segmentation and tasking while still encouraging serendipity and collaboration. The prototype is a server-based tool for multiple users to submit queries to commercial search engines and share the information. Users can build a collection of queries for a topic in a folder and identify relevant documents. This information can be shared among all users and additional descriptive information can be included. Overall, initial results suggest that cooperative searching has advantages over single-user searching when topics are complex and large volumes of relevant information must be reviewed.

Cooperative Searching-- Research Context

Experience with actual analysts suggests that collaboration is natural for information discovery and some stages of analysis. For example, in many intelligence environments, analyst workgroups often work in close coordination to ferret out useful information, organize it and disseminate it to end-users. Workgroup activities can include tightly coupled, synchronous shared analysis activities (e.g., team rooms) as well as loosely coordinated, asynchronous searching using automated search technology, Grudin [1]. Overall, although collaboration exists amongst workgroups addressing a specific problem, it is largely unsupported by current work environments. In particular, users often have little sense of what colleagues are searching for at any given time and, similarly, have little insight into what knowledge has been gained.

Cooperative searching is easily motivated given the complexity of many search tasks, the volume of information available, and the range of queries needed to provide reasonable coverage on a topic space. This overall complexity makes single-threaded analysis problematic. In some sense, cooperative searching provides a sort of parallelism that allows users to adjust or distribute workloads, combine complementary search strategies, and to corroborate relevance findings -- all working within a problem or group context. Many of the systemic issues central to effective collaboration have been addressed early on by Swanson [2] and more recently by Twidale & Nichols [3], and others. However, current retrieval technology is essentially designed for single use and does not support collaborative work directly.

The core research will be to identify effective automatic approaches for combining evidence (e.g., relevance judgements) from multiple users as the basis for generating a "relevance" context or map that can support query generation, query refinement, and topic categorization. There is an extensive literature on query generation/evaluation [e.g., 4,5] and relevance feedback [6,7]. However, the overall focus has been on single user environments and generally resulted in "simple" (e.g., binary) relevance assessments. With cooperative searching the relevance feedback model may involve multiple feedback loops containing information from various search and analysis contexts. Overall, the core research is focused on what we call the Cooperative Search Hypothesis:

The Cooperative Search Hypothesis holds if successive retrieval iterations exploiting a shared (or group) relevance context show improved performance (e.g., precision/recall) over incremental searching that has no memory (i.e., that lacks a global relevance context to draw on).

The General Model

Work is organized around projects or tasks. Each project has a shared workspace used to manage users, queries, documents, and associated metadata to include document ratings, and annotations. In addition, each project workspace is mapped to a global context that supports referrals to related users and queries.

The underlying computational framework has four main components-- automated collection using multiple search engines and link traversal methods; organization based on URL analysis; clustering and offline classification, user-specified web page monitoring; and end-user annotation and communication.

Lessons Learned

We have just begun to formalize testing with the initial version of the system; however early work with small user groups contributed much to the current design. Some selective observations follow:

- Although most users felt the cooperative search user's interface provided an overall more effective environment for searching and analysis, some users preferred to use special features of specific search engines (e.g., AltaVista) directly.
- Although users preferred interactive searching and results review; many distributed the bulk of their analysis effort (reading, assessment, annotation, distribution) across several days.
- Folder caches, containing group-rated relevant items, were found useful in characterizing the overall topic and in generating an output report for dissemination to consumers.
- Users effectively used the integrated email to forward analysis (with attached search results) to members of the group or to targeted consumers while working within the folder workspace. This directly supported notification and sharing.
- Search teams wanted tools to reduce the amount of overlapping work performed across the group.

Conclusions

We have described a collaborative tool, which can be used by a group to research a topic on the Internet. The tool eliminates duplicate searches, partitions the task of locating relevant information, and provides a peer review based approach to identifying key sources of information. This tool provides functions not currently available in commercial products. Further testing with users and research experiments focused on effective methods for combining multi-user relevance judgements are planned for the next phase of work.

Tibetan Bonpo Refugee Clergy Use Digital Media Archive to Preserve Indigenous Religion

Roslyn Dauber, Associate Professor, School of Journalism & Mass Communication. University of Colorado, Boulder. USA. Ph. 303 492 1324. Email: Roslyn.Dauber@Colorado.edu

Abstract - The Tibetan Bonpo Media Archive, a digital archive project, is in the University of Colorado's Norlin Library Human Right's Archive. Using video as primary research material, the Archive has over 100 hours of footage, 1500 photographs, and 27 hours of digital audio of the pre-Buddhist indigenous Tibetan Bonpo. The goal of the project to have scholars and visitors to Bon sites share their media in the Archive. A sister Library is being established in Dolanji, India at the only fully accredited Bonpo teaching monastery in existence. As the project grows, sacred texts in Dolanji will be digitized for preservation and duplication. Materials will be available on the WorldWideWeb. Cyberspace holds the potential to be their cultural treasure trove.

I a. Methodology for the Tibetan Bonpo Media Archive Project

The Bonpo Media Archive Project documents these Tibetan indigenous people, 750,000 live in China, 1000 refugees in India and Nepal, with only 180 fully educated monks. That a digital archive is the best hope for their cultural survival tells us something about the technology, culture, and times in 1999. One of the oldest religions in the world, it has survived via dialectics, sacred art and ritual. This project adapts media technology to support existing methods the monks use for cultural communication. To the Bon whose religious worldview is seamlessly enmeshed in their symbols, ritual practice, and geographical sites - preserving ritual, song, and holy sites in digital media is an adaptation to fragmented modern life. To the Bon, the knowledge essential to preserve is that required to comprehend transcendent "Objective" reality. The Bonpo do not base their beliefs on science, but on religious constructs. They have their own ideology and reasoning techniques.

The Media Archive Project uses electronically mediated forms of communication to shape cultural identity for today's Bonpo. The project has five phases: 1.] The principal investigator shot digital video and trained a monk to shoot while in China; 2.] A monk visited the Boulder campus to catalogue and translate visual material. He learned digital editing, and archiving techniques. 3.] Further fieldwork reliant on the monks shooting; 4.] Creation of dvd's, video, and interactive web-based archive. 5.] Study how the media is employed in India and Nepal, and the cultural result.

1b. Collaborative Bon Project for Indigenous Media

The guidelines for the Bonpo Media Archive Project that can be used in collaborative indigenous media projects: 1. Outside involvement by invitation; 2. The Bonpo select the subject matter; 3. The leadership learn what could be captured on video; 4. Training local people on site; 5. Obtain equipment, in this instance, a video camera; 6. Ongoing input from Indigenous knowledge-based expert; 7. Interactive teaching and learning style; 8. Indigenous Demand for Dissemination of Information; since living in exile, they've been housing copies of texts in libraries, including the Library of Congress. Now they can use a video archive; 9. Experiential Learning: Video allows for a visceral experience.

The Bon have relied on visual artifacts for thousands of years. They search for tools to maintain cultural continuity and now use modern means to preserve their indigenous knowledge base. This is a culture where people are the purveyors of information rather than technology. Their reality incorporates the possibilities of divine intervention, magic, and telepathic communication. They comment that electronic media is a powerful tool, but trivial compared to the potential of the human mind. They have easily accepted working in multiple mediums.

II. a. History & Context:

BEST COPY AVAILABLE

1273

The Web provides new opportunities for cross-cultural communication via continuous access to cyberspace. There has been a concurrent evolution of thinking, where a "native" media is evolving in which the subject is the object, as in the dominant mass media. Traditional indigenous artists are adding electronic media to their toolkit. An entire generation of indigenous media makers has arisen in the past fifteen years. In teaching the Bon monks how to use media technology we don't impose methods, but allow the Bon to decide what is taped, how, how it is edited and used. The Project is undertaken to explore how they share meaning through creation of media. Using Western media represents a hope for permanence of their culture which otherwise could be lost forever. The use of technologically mediated communication is one, if not the only chance of survival. Ginsburg reminds us that:

"Work being produced by indigenous people about themselves is also concerned with mediating across boundaries, but they are directed to the mediation of ruptures of time and history. They work to heal disruptions in cultural knowledge, in historical memory, and in identity between generations occasioned by the tragic but familiar litany of assaults: the taking of lands, political violence, introduced diseases, expansion of capitalist interests and tourism, and unemployment coupled with loss of traditional bases of subsistence." [Ginsburg 1995: 265]

The Bonpo Media Archive Project extends the sharing of information, as an insufficient number of trained monks exist, unable to service the population within Tibet, Nepal, Bhutan, and India. Digital media extends their ability to teach. The Project extends their culture's collective memory with visual records using the technological means available. The lamas are masters at creating meaning through ritual objects, performance and holy sites. The objects are gateways and metaphors pointing to their epistemological Truth, not the meaning or the truth itself. So too, they determined, can mediated images contribute to their symbolic representations. This project serves as a model for other refugee groups awash in the world today.

2b. The Bonpo Media Archive Project helps:

1. The only monastery with the full curricula needed to educate monks; 2. The new generation of refugee monks born outside of Tibet; 3. Solicit support from Westerners; 4. Extends the knowledge of Bon living masters.

The Archive provides a store of media available to assemble educational materials. Structurally, the monastic system served to preserve Bon teachings by housing sacred texts, ritual objects and teaching ceremony. Video is accepted as a natural tool of their work, capturing in symbolic form their icons of Truth. A student monk dedicated to the Archive Project has been trained in digital post-production. The first short video edited jointly by the monk and the professor was a biography of the Bon religious leader using video and old photographs with an English narration. The monk edited 4.5 hours of video with Tibetan narration.

2c. A Digital Cyberworld for Religion, The Promise of Interactive Non-linear Media for the Indigenous

Webcasting can be used to unite those in the Diaspora. Collecting information in remote location, the media can then be 'harvested' in a variety of ways. For theorists and researchers, like David Tomas (1993), cyberspace would be nothing more than a 'waste of space' if it did not become the site of new communities that offer significant cultural promise: The media that the Bonpo monks wish to make public will be posted on the Web to become part of this growing multicultural resource.

The Bonpo use many forms to teach - thangkhas, stuphas, music, dance, flour figures, handwritten texts, and now, computers, and video. How does form influence content? *"In a computer based education system it will no longer be a matter of information; it will be a matter of doing it. The essence will be making it as you go and changing it as you want."* [Spender 1995: xxxiii] The Archive Project has the Bon evaluate media's impact on content. It is in the potential of cyberspace that the Bonpo Media Archive Project, rich with their knowledge, keep their culture alive.

Rich Web Courses at a Pauper's Price

Daniel Despain
Northern Arizona University Office for Teaching & Learning Effectiveness
USA
Daniel.Despain@nau.edu

Abstract: Northern Arizona University Online [<http://nauonline.nau.edu>] has undertaken the development of highly interactive web based instruction that enhances the distributed learning experience for students. Working closely with experienced faculty, the design team creates engaging instructional media to ensure maximum student interaction with the course material. The design team has created over 70 completely web-based courses with enhanced activities from diverse disciplines in both undergraduate and graduate education.

Northern Arizona University [<http://www.nau.edu>] has developed an extremely cost effective system for development while maintaining a high quality and visually enticing hands-on learning environment which accommodates diverse learning styles.

NAU's system of development will be presented, along with numerous examples of interactive media from NAU courses. Attendants will be directed to online resources available to assist them in development of their own online course materials.

High Quality

Pedagogical issues are always a key faculty concern. Faculty will not embrace web-based delivery unless they see that they can provide a quality of education equal to that possible in a traditional classroom. Likewise, students demand highly interactive environments in courses delivered via the world wide web as they do in the traditional learning environment. The planning and creation of media elements is an integral part of NAU's course development. Creation of multimedia and other course content occurs simultaneously under the direction of the course instructor, ensuring high quality and seamless integration of graphics and other content.

Visually Enticing

Each web-based course developed at NAU receives a customized interface. Faculty appreciate an interface that reflects their personal taste and the essence of the course. These customized interfaces give courses a unique and expensive look for only 8-10 hours of development time. Courses within the same department share a similar style of interface, which is then customized for each course. All NAU Online courses share common elements, based on the vernacular of traditional campuses, ensuring that students only have to "learn how to learn online" once.

Hands-on Learning

Students learn by doing, and the interactive media in NAU's web-based courses ensure students are actively engaged. Whether watching film footage of racial riots from the sixties, practicing x-ray technique via shockwave movies, or viewing images of Matisse's paper cutouts or paintings by Jackson Pollock, students are exploring and interacting with the material throughout the delivery of the course.

Diverse Learning Styles

NAU Online courses reach a diverse audience worldwide. The consideration of differing learning styles is an important aspect of the development of NAU's web-based courses. Several modes of navigation have been seamlessly integrated into the courses. Students can follow a linear or hierarchical style of navigation. Hyperlinks within the course accommodate more non-linear learning – a real strength of web-based instruction. Links to external web sites bring related real world data and examples into the course and encourage students to explore additional material on the world wide web. An effort is made to include written, verbal, and image based instruction in each course. Stories and anecdotes are often presented in audio with a transcript available. A typical module of instruction might include text, audio, video, and several forms of interaction. Students are not limited to one type of presentation; they can access the same material in the format that best fits their individual preferences. The use of varying delivery methods keeps students interested and engaged while targeting multiple learning styles.

Cost Effective

The model used to develop rich and engaging web-based interactive media is extremely cost effective. Our courses are produced at a fraction of competitors' costs. Several factors allow us to create low cost engaging materials. Many graphics within the courses are created by part-time student workers hired from NAU's art programs; consequently, the students gain valuable hands-on experience in a working environment, and by using part-time workers, costs are kept low. Whenever possible, instructors assist staff in the creation of graphic materials. Often an instructor is willing to perform the basic tasks associated with graphics such as scanning images. The design team handles the more complicated steps such as retouching, colouring, or animation. Online examples and tutorials for creating media files enable interested faculty to create their own media files.

In the creation of graphics for online courses, our staff takes a modular approach. With a little forethought many scripts can be used in courses across the board. Within departments or among similar disciplines, media created for one course can be used in other courses. Sometimes the least expensive way to do something is not always the most obvious. In one case creating a QuickTimeVR™ object was \$200 cheaper than scanning dozens of x-rays.

Benefits to Faculty and Students

Faculty benefit from developing online courses. Online materials developed for the web can enhance traditional classroom lectures. Students enrolled in a traditional delivery course can use web-based materials as they study the material presented. Faculty who have developed web-based courses share their enthusiasm with other instructors in their department, thus furthering integration of technology in the classroom.

Valuable learning opportunities benefit the student workers and the students who take the courses. Student workers learn to deal with clients, determine and implement the fastest and best execution of an idea, and gain valuable web authoring skills. Students enrolled in web-based courses enjoy an active and engaging learning environment where they are co-directors in their learning. Exposure to the world wide web gives students opportunities to find, evaluate, and produce material on the web. Students can learn at their own pace in a style that they prefer.

Future Exploration and Conclusion

Improved bandwidth will make engaging and interactive media more accessible to students - particularly those in outlying regions. How will the experience of web-based learning help students upon graduation?

High quality and tightly integrated interactive media in NAU's web-based courses enhances the distributed learning process and fosters inclusion of technology in the traditional classroom. Customized interfaces give courses a unique look. NAU achieves these objectives at minimal cost by using experienced student workers, following a modular approach, and choosing appropriate technologies.

An open framework for accessing resources and engineering educational tools in a virtual university

Bich-Liên Doan, Francois Baillon

RIM Dpt, Ecole des Mines de Saint-Etienne, 158 cours Fauriel, 42 000 Saint-Etienne, France.

E-mail : (doan , baillon)@emse.fr

Abstract: With the incoming of new information technologies, including the WWW environment, more and more information resources as well as learning tools are available. The problem we address in this article is to provide content, easy access to heterogeneous resources (multimedia, multiple functions ...) and customized teaching aids.

We propose the design of a global framework which enable the integration of various components with training worth, that can be selected through structured metadata. We focused more precisely on the description of teaching aids in the environmental domain and the experience we had with a simulation program in teaching courses.

1. Introduction

The first section is dedicated to the description of pedagogical contents, the second section defines the organization of pedagogical servers thanks to structured metadata and a taxonomy of concepts, then the concepts of the virtual university and its application in several places in french universities are discussed. We conclude with the future development we expect from our new educational framework.

2. Pedagogical contents

2.1 A hydrogeology simulation program

Simulation programs are computer assisted systems which aim to train young engineers for preparing, monitoring and appraising projects. The Amise simulation program is an engineering education tool designed to acquire a first experience in underground water resources management. The simulator helps the participants, grouped in teams, to generate relevant cleaning-up scenarios to solve a real case study.

Training is based on a role playing session of five days during which the teams represent environmental consultants under contract with the city of New Brighton (Minnesota, USA). After the discovery of the municipal well contamination, the team has to identify the nature and the extend of the pollution, develop a model of the local groundwater flow (using analytic elements) and design the new water supply network (wells, treatment plant and pipelines).

The Amise simulation results are used to define environmental management rules considering the impact of modeling precision throughout the decision making process.

The simulator is structured upon three majors elements types : database, data access tools and data treatment methods.

* Database

All the information used to represent reality in the simulation is stored in databases. For example, the information relative to in force standards, financial costs and waiting periods associated to working or studying phases of the project, documents on hydro-geologic conditions or on the aquifer behavior, the possible events relative to meetings between the team and the concerned institutions.

This database contains all the information concerning the extend and the nature of the pollution, contaminant concentrations and head of the aquifer covering the area of concern (1 600 points over 110 km²).

* Database access tools

The regulation, document, and event database are organized as a WWW server(<http://helios.emse.fr/~baillon/>) available through the Internet (fig 1). The interface is written in HTML with some programs in Java.

* Data treatment methods

Data collected concerning the behavior of the aquifer as well as the extend and the nature of the pollution, need to be treated to obtain more information . This is done by using interpolation methods, and a validation of simplified models in a decision making process.

2.2 A geological hypermedia server

This WWW server is available at (<http://mure.emse.fr/TERRIMAGES>) and is composed of structured hypertext cards including images. These cards are written in a SGML format, and are accessible by various types of links. For example, the user can navigate in the geological database through hypertext links representing concepts, methodologies, or by following the hierarchy of terms given in a thesaurus or a volcanism classification. The aim of this server is to help teachers as well as students in their course preparation or training.

2.3 A sustainable development WWW server

The AGORA21 server (<http://www.agora21.org>) has been created to gather specialists, experts and environmental people in participating to virtual thematic forums and to be informed of the news in environment. It is aimed to be a place of debates, exchanges and information concerning the sustainable development.

3. Organization of multiple WWW servers

In the following, we consider that all servers we discussed previously are called documents because they provide information and other teaching programs which can be used by both teachers and learners.

We use metadata embedded within documents of the WWW servers in order to explicit the representation and the description of them.

Introducing metadata to describe the structure and content of WWW servers enable the author of the documents or experts to explicit the context. Metadata may explicit the internal and external organization of documents;

Through a common metadata shared by the WWW providers, one teacher can find and reuse reduced components from a WWW server to build a program session.

We use a taxonomy of concepts in order to classify the various learning components created by any teachers participating on the educational content production. This taxonomy is managed by a specialized server whose role is to index the structure and the content of the pedagogical WWW servers, and then to enable interactions with users, keeping the users's profile.

4. A global framework to enable access to pedagogical contents

We use a new architecture of systems to improve the management and the use of information educational on the WWW . Each taxonomic server is considered as a thematic directory which can be requested to direct the right pedagogical server. It classifies the content of servers registered in the architecture and may keep a trace of the profile of learners, in order to answer better depending on their desire and competencies.

This framework is based on thematic directories whose job is to localize the knowledges and the competencies of the declared WWW servers, and to make them participate in the overall auto-evaluation process.

This open architecture enable a cooperative work among the participants : teachers as authors and appraisers, and students or learners as participants to the online learning sessions.

5. Conclusions and perspectives

We designed this architecture in response to a virtual university project, which concerns several universities in France and USA, the Lyon University, the Alpes du Sud Universities, the Ecole Nationale des Mines de Saint-Etienne, and the New Brighton university in USA.

From now, we expect three things: one is to introduce new developments, including a better steady of users by storing their traversal of HTML links, in order to direct them towards different levels or by proposing a course recall.

Second, the evaluation of on-line trainings may be done automatically and may allow a global comparison between the students in different places. Finally we expect the extension to other universities or forums in participating in this open learning.

Expliciting structural and semantic WWW links to improve information retrieval

Bich-Liên Doan, Fernando Aguiar, Michel Beigbeder
RIM Dpt, Ecole des Mines de Saint-Etienne, 158 cours Fauriel, 42 000 Saint-Etienne, France.
E-mail : (doan , aguiar , mbeig)@emse.fr

Abstract: This paper describes the use of the document concept in order to extract the inter-document and intra-document structure and semantics. It aims to integrate the overall structure of documents into a new Information Retrieval System on the WWW. We explain how to manipulate the structure of multimedia documents at an apt level of granularity (passages, set of HTML pages, images). Finally we propose to combine the structural and textual analysis of documents to improve the performance of the system. The user is able to manipulate several abstraction levels of information, for example documents, images, chapter dealing with one particular interest domain. The structure and content of documents are described using metadata in the XML syntax.

1. Building documents

The WWW is a hypertext graph where the nodes are HTML pages and the links are text anchors which point to another page. The type of WWW links is not explicit. In this section, we classify various types of links we can find on the WWW:

Links of structure: they represent the logical structure of a document, either the inclusion or the sequencing of parts of a document.

Links of semantic association : these links reflect a semantic association between two pages, or two concepts and are very diverse because they concern of the cognitive aspects of the author. Indeed according to case's, the winter term can make think cold, season, country etc...

Links of navigation : purely functional , they are used to physically cut out a text in a set of pages limited in volume (number of bytes). They are used for navigation between the pages, for example back link, return to the home page.

Links of references : they are used to refer pages in connection with the subject, for example the bibliographical references, or the references to similar sites, personal pages.

All of these links are often chosen by the author during the building of pages, but the HTML syntax doesn't allow to explicit them. To mitigate these problems, we consider that a document is either a part of one page, for example an image, a passage, a title..., or a set of pages. A document can be defined as a semantic unit of information, autonomous in the sense that it can be given as a response against a user request. From here, we can consider now that a WWW site is a document. This WWW site can be structured into a hierarchy of documents, one HTML page is a document itself and is composed of structured elements representing either section, paragraph, image, sound, graph called documents too. Each level in the hierarchy corresponds to a different level of granularity. We choose a tree structure of nodes for our example to be understandable, but in fact, we can have a Directed Acyclic Graph (DAG) structure. For example we can have a first organization level, composed of several domains, sub-domains and so on. Each hierarchical level represents a level of granularity, the lowest level of granularity is that of the components of the pages. This concept of granularity is significant because it intervenes in all the stages of our new information retrieval system. Indeed, during the description of the documents, our formalism makes it possible to describe documents, to express the structural or semantic relations between the documents, to adapt this description to structured pages with the HTML format (META tags) or XML (the tags are defined by the author of the pages according to certain a DTD). Thus, it is possible to explicit the various types of relations between documents, between components of various natures (multi-media like its, image, video) or of various types like paragraphs, references, summaries... The semantics and the structure of documents as we precised previously may be done by the author of pages, manually, thanks to metadata. A classical hierarchical clustering algorithm can determine the hierarchy of

documents and provide the summary of each cluster. The first solution enable a precise control and the labeling of each representant of clusters by the author, but it requires human help. The second solution is full-automatic but the drawback is that the label are a list of keywords extracted from the documents and maybe the concepts are omitted. For a quality reason and to enable the author to control the indexing phase, we build the structured documents with the help of the author of documents or a librarian specialist.

2. Indexing of the documents

We define the context of a document as its metadata, including content, structure and attributes of its ancestors. Each document belongs to a context. Let's go back to the library example, and consider a page of a book. This page takes place in a section, within a page, within the book itself. Each level of organization of the book gives a context, from the highest level (root is the book) to the next level in the hierarchy up to the page level. We suggest to label each level of document with the subject and by the way to build a hierarchy of subjects. But an a-posteriori organization can be built according to a given attribute of the context, as for example organism, author, subject... In fact each metadata of a context may be static or dynamic. Static means that the metadata is local to the context, dynamic means that the metadata is forwarded along the tree of metadata.

From our model of documents, the indices of documents, WWW pages and components of WWW pages can be built a priori, i.e. all the values are propagated in the building of the index or a posteriori, i.e. the values are propagated at the request time. There is a balance between the two solutions in terms of index access time and volume storage optimization. For efficiency reasons the indices are built a priori.

3. Requesting documents

Let's assume that Docs is the corpus of the documents. We suppose that the modifications structure-induced have been taken into account in the creation, indexing and evaluation phase. In order to support the new functionalities we introduced in our paper, we defined a new query language that supports:

- dynamic granularity of the response, i.e. the granularity of the document (a chapter, a section, an image) is not expressed in the query but determined by the information retrieval system with the evaluation function at the request time,
- contextual requests, i.e. it is possible to specify in which context (referring to the definition of the context) the matter of request is required,
- combination of multi-typed requests allowing the system to manage requests against documents of various types.

We opt for an OQL-like syntax, and we give an example of a complex query, combining both multi-type, context and structure :

Query: find pages containing images like "image_input" dealing with pollution in the context of environment. Select d from d in Docs where d.type = page AND d->subject() = 'pollution' AND d -> context() about 'environment' AND image_input approx (select i from Docs where i.type = image AND i in d -> descendants() AND i ~~ image_input)

4. Conclusion

Classical information retrieval systems give responses in the pre-defined granularity of documents, often without taking into account neither the structure of a document nor its semantics and context. Here we explain how we can explicit the structure and the context of WWW pages, and we suggest a new information retrieval system that can index, search HTML pages organized into mutli-typed documents. This will enable end-user to request with a powerful semantic query language and to provide more suitable and contextual responses a several level of granularity. In the future we aim to organize the pages automatically and to evaluate the new information retrieval system.

Impact of Hosting a Virtual Conference on Online Facilitation and WBI Development Skills

Joanna C. Dunlap
School of Education
University of Colorado at Denver
U. S. A.
Joni_Dunlap@ceo.cudenver.edu

It is difficult to teach people to be good online courseware developers if they don't know what it is like to be on the receiving end of their designs -- either as a student or an instructor. In a graduate-level course on "Designing Web-based Instruction for Distance Education", students are involved in a number of design and development projects, in which they function as instructional designers hired to build a Web-based lesson, module, or course for a distance learning audience. Typically, students excel in (1) Web site and page layout and functionality and (2) the distribution of content and activity/project descriptions, but fail to address issues of social interaction, student collaboration, student motivation to return to the Web site over and over, etc. In fact, it is difficult for them to understand why it is necessary to focus on Web teaching and learning strategies in their roles as "WBI designers". Unfortunately, the class does not have access to pre-existing Web-based courses that they could be required to facilitate in order to gain experience in Web teaching and learning. Therefore, students are required to host a virtual conference. By hosting the virtual conference, students are exposed to the triumphs and frustrations of creating an interactive learning experience delivered via the Web.

Thus far, two Virtual Conferences have been hosted by two different groups of students: one in Fall 1997 and one in Fall 1998 (the 3rd Annual Virtual Conference will be held in Fall 1999). Comparing students' work prior to and after the Virtual Conference assignment revealed that WBI students/designers:

- moved from creating professional-looking "page turning" Web sites that simply delivered textual/graphical content to developing interactive, student-centered activities (such as games, case studies, and problem-based learning activities) for learners to work through; and
- utilized communication technologies differently: instead of simply posting discussion questions on an asynchronous threaded discussion forum for learners to respond to, both asynchronous and synchronous communication technologies (threaded discussions, reflective journals/forms, chat and whiteboard) were being used for debates, collaborative project/product development, peer teaching, and presentations.

The Virtual Conference assignment has been so effective as a learning experience for WBI designers/students -- as well as providing a good learning experience for the virtual conference participants -- that the Fall Virtual Conference is now an on-going staple of the Distance Education track of the Instructional Technology graduate program, with plans to host a virtual conference every Fall.

The Virtual Conference Assignment

For the Virtual Conference assignment, students collaboratively develop and deliver an online/virtual professional conference on various aspects of designing distance education for the WWW. Besides the actual conference, documentation (1) describing the strategies and tactics used to promote, organize, facilitate, evaluate, etc. the conference and (2) supporting the design decisions made based on front-end analysis data is required. Results of the conference are debriefed in class, and students are required to reflect on the overall experience and on what they learned from the process; their reflection was structured by an online assessment (see <http://www.cudenver.edu/~jdunlap/5990/conferencejournal.htm>) they helped to develop (see an example of a student's evaluation of the virtual conference experience at <http://clem.msced.edu/~woodleyx/wbi/online.htm>).

Description of Student Activities

The objective of this project is for students to collaboratively develop and deliver an online/virtual professional conference covering issues related to designing distance education on the WWW. To make this happen students have to take responsibility for a number of activities and deliverables:

- As a class, students have to select five topics that represented important issues of Web-based distance education. They then have to determine who will be responsible for which topic/s. Responsibility for topics requires students to research, prepare (includes, but is not limited to, developing a Web-based presentation and/or paper), manage, and facilitate the portion of the virtual conference related to those topics. The conference runs for four days during each Fall semester; topics, activities, and facilitators have to be scheduled by the students for each day of the virtual conference.
- As a class, students have to decide what Web-based communication technologies are needed to conduct the online conference and create or contract those technologies.
- Students need to determine what strategies and tactics should be employed to ensure conference attendee participation throughout the duration of the conference. This includes lining up “guest speakers” and/or developing presentations, debates, case studies, and other engaging activities that will keep conference participants involved.
- Students also need to develop an evaluation tool so participants can let them know what they think. Students must analyze the evaluation findings to determine “lessons learned”.
- Students develop and upload the conference site.
- Students promote the conference to classes, students, and faculty in the School of Education and any others deemed appropriate, and to outside educational and professional groups.
- Students are responsible for providing technical support throughout the conference.
- Students document in writing the decisions they make on the above issues.

1st and 2nd Annual Virtual Conferences: The Students’ Conference Sites

There have been two virtual conferences hosted by graduate students in the “Designing Web-based Instruction for Distance Education” course:

1st Annual Virtual Conference: Instructional Strategies and Delivery Issues of Web-Based Instruction – <http://carbon.cudenver.edu/~jdunlap/seminar/>

2nd Annual Virtual Conference: Beyond Page Turning and Lecture Techniques: Effective Instructional Strategies for Web-based Learning Environments – <http://web-education.net/fall98conf/>

[**Note:** For notification of future Virtual Conferences, see http://ceo.cudenver.edu/~Joni_Dunlap/AACE/virtualexamples.html]

A Web-Based Tutoring Tool for Calculating Default Logic Extensions

Uwe Egly, Michael Fink, Axel Polleres, and Hans Tompits
Abt. Wissensbasierte Systeme
Technische Universität Wien, Austria
e-mail: [uwe,michael,axel,tompits]@kr.tuwien.ac.at

Introduction and Background

In this paper, we report on the use of a tutoring program supporting an advanced university course on knowledge-based systems for students of computer science. The course is suggested to be attended at the sixth semester and deals with both practical and theoretical issues regarding knowledge-representation techniques. In previous installments of the lecture, we noticed that certain topics caused problems in understanding among students. A particular hurdle represented the calculation of extensions in Reiter's default logic [Reiter 1980]. Reasons for this difficulties can be found in the fact that (i) the notion of an extension is defined only in a *non-constructive* fashion, and (ii) in order to check whether an object represents an extension, certain skills of formal logic are required, which most students ostensibly lacked, although an undergraduate course on mathematical logic is mandatory in their curriculum. In order to tackle this situation, we had to find a way to make the complex issues easier to comprehend, and, at the same time, provide a better motivation for the students than pure class-room teaching.

Since computer-based education is growing in popularity, and students in general enjoy applying new technologies, we decided to implement a computer program which explains the problematic topic as detailed as possible. The following items were chosen as the main specification of the program:

- it must not only visualize the computation of extensions, but also explain the required steps in detail;
- it should contain examples where the characteristics of default logic are expressed; and finally
- it should require no special software and should run on any computer.

To fulfill the third requirement, we opted to use a JAVA-applet to guarantee highest possible accessibility, because all students have access to the Web and any machine which has a JAVA-capable browser can be used to execute the program. In fact, all standard browsers claim to be JAVA-compatible and are free for non-commercial use.

The Applet

Let us first briefly sketch what the tool is actually supposed to visualize.

Default logic belongs to that class of logical formalisms devoted to the study of human common-sense reasoning, i.e., the process of inferring "plausible" conclusions given less than conclusive evidence. A characteristic instance of this sort of reasoning is the frequent approach to assert a particular statement as long as there is no evidence to the contrary. In default logic, such assertions are facilitated by special kinds of inference rules, the so-called *default rules*, stating what is expected to hold under *normal* circumstances. A *default theory*, then, is a collection of default rules, together with a set of definite facts (called the *premises* of the theory).

Since the application of a default depends on both *the presence and the absence of certain knowledge*, different defaults can be mutually blocking and hence the total knowledge induced by a given default theory can give rise to several (if any!) possible "states of affairs". These sets of total beliefs are called *extensions* of the given default theory and play a vital role in default logic.

Unfortunately, the formal definition of an extension is rather tricky and involves some intricate fixed-point construction. (N.B. A *fixed-point* of an operator T is a value x such that $T(x) = x$ holds.) However, for a wide class of default theories, a concrete generate-and-test algorithm can be given which outputs all extensions of a given default theory. Our applet now has the task to visualize this algorithm. The algorithm is as follows: in the first stage, possible candidates for being an extension are generated; and in the second stage, the candidates are checked whether they represent an extension or not.

The program itself consists of several examples to choose from; *in toto* representing characteristic properties of default logic. Each example is provided with a detailed step-by-step solution, running either automatically or manually, in which case the student clicks on a button in order to proceed to the next step. In automatic mode, the speed of the simulation can be adjusted; it can be stopped at any point and also restarted if desired.

The generation of the candidates, and the checking of the candidates are presented in an own window, respectively, and the corresponding steps are given in a structured diagram at the right-hand-side of these windows. Explanations for each step can be requested by simply clicking on the respective text, which are then displayed in a small pop-up window. Help and a general description of each example can also be requested, which will appear in a new browser window.

Responses

Generally, student response was predominately favourable. The few negative reactions all centered around the inability of the respective students to execute the program. However, such situations occurred only if the student disregarded the information we provided specifying the particular versions of the browser which guarantee a trouble-free execution of the applet. For instance, some older (intermediate) versions of Netscape for Linux exhibited certain unpleasant font-related problems, which, however, have been resolved by the current release.

The most interesting question of course was whether the program fulfills our expectation of improving the students skills and examination results. Analyzing the examinations which have been carried out since the availability of the tool, there is an affirmative answer to this question. Let us discuss this in more detail.

Before we supported the students with our tool, their knowledge and ability to generate extensions of given (simple) default theories were rather disappointing. Since we knew these deficiencies, we recapitulated the topic several times during the lectures and discussed many examples. Although we stressed the importance of these examples with respect to the examination at the end of the course, less than 50% of the students got more than 50% of the possible points in those examples concerning default logic.

Since the availability of our tool, however, there is a clear improvement over the previous situation. First of all, the number of students using the tool increased quite significantly over time (from 32% to 58% of all students performing the examination). The reason is that the tool becomes more and more tested and some inevitable software glitches have been removed. Moreover, students profiting from the tool recommend its use to other students. From a performance point of view, there is a marked difference between those students which claim usage of the tool and those either claiming non-usage or giving no answer at all. Tool users received between 8% and 16% more points on the default-logic example than non-users, and 21% more points than students not answering the question about the tool usage.

Future Issues

In the current version of the applet, the examples are hard-coded. However, the program is written in such a way that additional examples can be added without much ado, and that it allows the straightforward inclusion of a simple theorem prover, enabling users to create their own examples. In fact, currently we are working on this extension of the program, and we hope that the new version will be of even greater benefit than the current one. Also, since the concepts underlying the construction of extensions in default logic are closely related to certain semantics for logic programming with negation as failure - which represent similar problems among students - we plan to develop a related visualization tool for that area as well.

Abstract : The development of Web-based courses has proceeded in an analogous fashion to the evolution of the craft industries of the 16th and 17th century. There have evolved pockets of skilled "tradesmen" who have produced isolated examples of state-of-the-art, multimedia courseware. Often, in a given department or college, there are a few faculty who are personally motivated to adopt Web-based education and to wholeheartedly investigate and develop courseware in their specific areas of educational specialty. Thus many educational programs have high quality examples of multimedia courseware which, unfortunately, are limited to a narrow field of specialized topics. Thus there are many examples of finely crafted Web-based courses but little evidence of concerted efforts to elevate an entire curriculum onto an Internet platform. In the 18th century, the Industrial Revolution began in Britain and had far-reaching consequences for the design and manufacture of mechanical products. The manufacturing age dramatically diminished the need for craftsmen who were replaced by a system involving the division of labor, part interchangeability and mass production methodologies. This paper describes the organization of a "manufacturing system" for an information technology curriculum in which a number of Web-based courses were built to a high standard of quality and regularity.

1. Introduction

The development of Web-based courses has proceeded in an analogous fashion to the evolution of the craft industries of the 16th and 17th century. There have evolved pockets of skilled "tradesmen" who have produced isolated examples of state-of-the-art, multimedia courseware. Often, in a given department or college, there are a few faculty who are personally motivated to adopt Web-based education and to wholeheartedly investigate and develop courseware in their specific areas of educational specialty. Thus many educational programs have high quality instances of multimedia courseware which are limited to specialized topics. Thus there are many examples of finely crafted Web-based courses but little evidence of concerted efforts to elevate an entire curriculum onto an Internet platform.

In the 18th century, the Industrial Revolution began in Britain and had far-reaching consequences for the design and manufacture of mechanical products. The manufacturing age dramatically diminished the need for craftsmen who were replaced by a system involving the division of labor, part interchangeability and mass production methodologies. This paper describes the organization of a "manufacturing system" for an information technology curriculum in which a number of Web-based courses have been built to a high standard of quality and regularity.

2. Organizing for "Production"

The techniques, which were developed and which were the subject of this paper, were in a response to the need to develop a new degree program, which would address the shortage of Information Technology (IT) professionals. The curriculum for the degree program was established in the summer of 1998 and consisted of twenty-five courses with computer science or IT content. It was decided that all twenty-five courses would be made available over the internet and would be established within a two-year time frame commencing with the Fall 1999 semester. Given the compressed time scale and the need for a consistent development methodology, it was decided to adopt a manufacturing model for the effort. A manufacturing system, in the common sense, involves making products on a large scale with division of labor. The latter concept relates to the specialization of function for the labor element of the system.

Any systematic approach to "mass production" first requires a product that is designed to fulfill its intended function. Once established, the product is broken down into components and a process design is created which determines which "parts" should be custom made ("in-house") and which could be acquired from vendors ("bought-in"). For each part which is custom, a production plan is established which identifies the specific technical steps that will create the functional and aesthetic features of the part. This

involves defining the specific manufacturing processes which will effect the part features and developing a sequence which will create the features in a logical order.

3.The Product

The design of the multimedia courseware was the cornerstone of the entire process. The desirable features of a typical course were established and this design then dictated the tools needed for its creation and the sequence of creation. The product specification was developed over a series of meetings by a committee which consisted of academic faculty ("content experts"), multimedia design specialists and network personnel. Based upon the discussions, the features of a multimedia course were defined as:

1. A Course Home Page which provided general course information and links to all other course features;
2. A Lessons Page that linked to the material covered in the course. This material was broken down into a number of topics, which would lie in a range between five and nine. Each topic would be self contained and would include the following components:
 1. Lecture slides, which would consist of key technical points, augmented with a video or audio presentation.
 2. Quizzes which would be used for student self-test and which could be used by the students to establish their comprehension of the lecture material. Although the quizzes would be evaluated, they would not be used for grading purposes.
 3. Lecture notes.
 4. Animations which were used to demonstrate the dynamics of, for example, a computer algorithm.
3. A Syllabus Page that would show the course content and its context.
4. A Calendar Page which provided the student with suggestions for self-paced study of the material and any externally imposed deadlines.
5. An Exercises Page which listed the coursework that had been assigned and which provided a central point of access for all quizzes.
6. A People Page which provided access to a chat room, personal web pages for all faculty and students and class and instructor e-mail.
7. A Resources Page that contained other web based material pertinent to the topic and a means by which students could submit URLs that they had discovered to a common archive.
8. A Downloads Page which would enable students to download zip files of the lectures.

This manufacturing process for the courseware is thus driven by this product specification. The creation of the courseware is dependent upon the selection of a suitable production plan which defines the tools and the production sequence. The various course pages may be likened to sub-assemblies which may be developed "from scratch" or may be existing components or may be vendor products.

Although there exists a large number of Web Course authoring tools, no single product could enable a satisfactory integration of the above product specification. It was therefore decided that a custom designed development environment would be used with the integration of existing vendor products.

4.The Manufacturing System

All manufacturing systems are designed to convert raw materials into saleable products. The essential raw material for multimedia courseware is naturally the course content. Two issues arose. The first concerned the determination of the specific topics to be covered in the courses. The second concerned the means by which the desired content was to be acquired and integrated into the courses. The first issue was addressed by creating a series of content committees who were charged with defining a consensus curriculum for each course. The acquisition of content was provided by employing "professional note-takers" or "gleaners" who would sit in specific classes and create course content from their notes. Such a system, provided support for the professors who may be too busy or insufficiently inclined to generate content independently.

A Dynamic Web-Based Help Desk Application

M. A. Espenshade

Applied Physics Lab, Johns Hopkins University, Laurel, MD, USA,

Email: MaryAnneEspenshade@jhuapl.edu

Abstract: The Telemedicine Project Help Desk Application provides a web-based interface to a centralized help desk. The Telemedicine project uses several off-the-shelf hardware/software medical records packages, integrating them on a single workstation with extensive remote communication capabilities. When something goes wrong, the user reports the problem by entering a description of it on an HTML form. The report is stored in a database, where the help desk operators can review and assign the problem and the user can check the status of the problem being corrected.

The Telemedicine Project Help Desk Application was initially written in HTML and Java in August 1997. It runs on a Windows NT 4.0 Server system using the Netscape FastTrack web server and Java CGI applications written to the jdk1.1.3 Sun Java specification. The Telemedicine project uses several off-the-shelf hardware/software packages, integrating them on a single workstation with extensive remote communication capabilities. When something goes wrong, users often don't know what part of the system has failed. Instead of having the user call in a number of vendors to identify the problem, it is instead reported through a web interface to a centralized help desk. The help desk operators have a separate set of password protected web pages for management functions. The System Incident Reports and responses are saved to a Microsoft Access database, though any database management system with a Java database API (JDBC) could be used.

A user accessing the Help Desk application begins at the top-level web page titled 'The Navy Telemedicine Technical Help Desk'. The 'HELP DESK USER' link brings up a display showing the menu of possible user actions in one frame and a blank frame for the forms that will be displayed when an action is selected. The 'HELP DESK MANAGER' link shows the menu of manager functions and is password protected. These menu frames are the only static HTML pages in the interface. All the forms and responses are generated dynamically by Java CGI programs. When a menu action link is selected, the usual response is to run a Java program that generates an initial selection form for the user's data entry or to further qualify the selection. The forms are generated rather than static HTML so that dynamic data from the help desk database can be displayed. That way, lists of sites, equipment and engineers only need to be updated in one place in the database and they will be automatically updated in all the user interface displays. Originally, a set of Microsoft Access forms was written to maintain the database locally, but the decision was made to go to a dynamic web interface so that entries could be made by users directly instead of calling a help desk operator to enter the incident report.

For example, here is the sequence for entering a new *System Incident Report* (SIR), the most common action for a general user. When the user selects the menu item 'ADD SIR', the choice box of project site names is displayed. The user picks a site from the list and clicks the 'NEXT' button. The SIR ADD form is displayed with the site name already entered and the specific equipment data for that site in a selection list, preventing invalid site and equipment entries. The user selects the equipment and SIR priority and enters their name as the person reporting the problem and the problem description. Submitting this form starts the Java program to store the entry in the database and, if the SIR is marked 'Urgent' priority, sends a page to the Help Desk Operator.

The other actions on a SIR - assigning an engineer, adding an action, adding a resolution and displaying the SIR information - all work on a common pattern. When the user selects an action link from the menu, a Java program

BEST COPY AVAILABLE

1288

generates a table of SIRs that it is appropriate to apply the selected action to, usually the unresolved ones. The user selects an individual SIR from the table by choosing the link to that SIR ID and the form for that action is generated, containing information for the SIR requested.

The sequence of Java routines to implement these actions works as follows. The 'ADD SIR' menu item is a link to 'whichloc.bat', which calls the routine to generate the list of site names in a choice box. The title and the POST method of the form generated depend on the argument passed, controlling which action is called when the SUBMIT button of the form is clicked. This case, add, is action 1, calling 'makesir.bat'. This in turn calls 'SIR_lib.NewFormViaLocation' to generate a new SIR form, with an equipment list selected from the database for the chosen location. The POST action for this form calls givesir.bat to read the data from the form, add the new record to the database and send a page if priority is 'Urgent'. The next web page displayed to the user either confirms that the SIR was stored or reports any errors. For the actions that generate a list of possible SIRs, the link for each SIR passes two arguments to a Java routine, the SIR ID number and an action code. The program reads the data for the requested SIR from the database and generates the appropriate form for the action. The POST method calls the specific routine to store the data from the action form back into the database, either updating the SIR record or adding new records to associated tables.

The main database tables that support the system are 'Sites', 'Equipment', 'Problems', 'Problems Addressed', 'Problems Resolved', 'Engineer', and 'Engineer References'. The 'Sites' and 'Equipment' tables are referenced throughout the system. The 'Sites' table contains all the site contact information, such as the address, phone number and email address. The 'Equipment' table lists all the equipment at each site, including the vendor and dates of installation and removal, for tracking purposes. There are manager forms for adding and editing the entries in these tables over the web. The values are used for dynamic selection lists on the SIR forms. The user fills in the other fields to describe the specific problem. One of the fields is 'Priority', a toggle field that defaults to 'Regular' but can be set to 'Urgent'. Urgent problems reported trigger a canned message to be sent to the text pagers used by the helpdesk operators.

The 'Engineer' and 'Engineer References' tables are used to keep a contact list of people at the vendor sites who respond to help desk problems and to assign a specific engineer to a problem. Though many people can contribute to a solution, one person is assigned to be responsible for coordinating the work and reporting the solution back to the database. Any engineer can make entries as actions are taken to address the problem.

Monthly status reports are implemented as local database reports listing all the SIRs entered for the past month and the current status. A "current unresolved problems" report and a "new problems" report can be run at any time to see where recently reported bugs are coming from.

An additional enhancement to be considered is whether to leave the user interface as generated HTML or convert it to Java controls as well. As an assignment to practice using Java GUI controls for a Java course, I experimented with rewriting the menu displays and a couple of the forms within an applet. It is much faster to switch between the forms this way than returning to the server and generating the HTML but the test didn't include any database actions. Running as an applet under Netscape (or IE), initially limited the applet code to the version of Java the browser implemented - 1.02 for both the main browsers. JDBC was only added in Java 1.1, so even if the front end were done in Java, the database access would still have to be a CGI call to run jdk1.1, as it currently functions. I also wasn't able to make the heading and buttons look much like the current version on NT. Specific line breaks can be added to label strings and are interpreted correctly on Solaris versions of Java, but are ignored when running on NT. This prevents the headings from being laid out to match the current displays in HTML and keeps all buttons to one line of text, no matter how long it gets. Rewriting the front end as applets may be useful in the future, as Java implementations of 1.1 and 1.2 spread.

sicsDAIS: A Multi-Agent Interaction System for the Internet

Fredrik Espinoza

Human Computer Interaction and Language Engineering Laboratory, Swedish Institute of Computer Science
Box 1263, SE-164 29 Kista, SWEDEN
espinoza@sics.se

Abstract: We describe the SICS Dynamic Agent Interaction System (sicsDAIS), an agent interface management application for the Internet. It provides a unified platform for users to interact with agents. It also provides the means for agents to communicate with one another and share resources and data.

Agents provide their individual user interfaces to sicsDAIS as smaller versions of themselves, and sicsDAIS coordinates and combines the presentations of these.

1. Introduction

Agents provide a new and much needed way to view and interact with complex systems. Delegation of tasks to agents that perform without supervision and exact configuration is a powerful new mode of operation. One can expect agent services to increase in number in the near future. Agents will be accessible not only on the personal desktop or from the local network, but also from sources on the Internet.

Different agents have different responsibilities and agents can make use of one another to complete complex tasks. This new method of interaction with complex systems will perhaps at some point replace the direct manipulation for some types of applications. For most agent systems, however, a combination of delegation and direct manipulation will be needed.

Agents need to be able to interact with their users. Some configuration is necessary to convey the user's intentions and the agents also require means to present the results of their work. What happens when the user interacts with agents? How will the interaction take place? Each agent will want to present itself in the best possible way, in terms of efficiency of use as in the case of ordinary desktop applications. How will agents be made available to the user? How will the user cope with a multitude of different agents providing separate interfaces? Given that we must use agents to perform some tasks, the question then becomes, how will the user-agent interaction take place?

The contribution of this work is the design and implementation of an approach to user-agent interaction. Our proposed solution is to allow the agents to present themselves and carry on the interaction with the user through a common user interface which combines all the agents but that still allows each agent its individuality.

2. The sicsDAIS Agent Interaction System

SICS Dynamic Agent Interaction System (sicsDAIS) [Espinoza 1998] provides a framework for interaction with multiple agents in one interface. In sicsDAIS it is possible for an agent to visualize itself to allow the user to configure it or to review its results. This can be achieved in many ways, ranging from advanced anthropomorphic figures to simple configuration panels.

SicsDAIS provides display resource management and coordination as well as communication and data sharing capabilities between agents created by different sources.

An agent sends its user interface to be displayed in the user's sicsDAIS in the form of a *content handler*—a small graphical component that represents the agent. The interface of the agent will be laid out according to built-in rules regarding the placement and sizing, etc.

The content handler is dynamically loaded and created in the user's sicsDAIS with accompanying data from the agent, data that specifies visual and internal properties of the content handler. At this point, the content handler may establish contact with the agent, thus becoming an extension of sorts to the agent.

After this the user can interact with the agent through the content handler. Some of the interaction will be local to the content handler if the necessary logic and data is present in the content handler. In other cases, the content handler will convey queries to the agent. There may be several agents involved in a session with the user. They may all have content handlers active in sicsDAIS and they may each have several content handlers. Some sessions may be governed by a central coordinating agent that preprocesses presentation requests of other agents before they reach sicsDAIS and the user. In this way, the central agent controls the layout and other properties of sicsDAIS. In other cases the presentations may be of a simpler nature and sicsDAIS itself may be capable of coordinating the requests of multiple agents.

The following are additional noteworthy features:

- The agent is not transferred to the client, only the agent's interface component is transferred. It is often possible for the user to interact with only the interface component thus minimizing network use.
- New agents may be introduced at any time.
- sicsDAIS is a Java based application that also runs as an applet. This in conjunction with Java based content handlers means platform independence and global access.
- A content handler may use any means of communication and modalities when communicating with its user. It may even be invisible, as in the case of some coordination content handlers that handle the affairs of several agents belonging to a common multi-agent application. This means that it is possible to build advanced multi-modal interaction systems using sicsDAIS. It is also possible to build homogeneous applications using many agents that are controlled by an invisible content handler in sicsDAIS.
- sicsDAIS provides a blackboard like data exchange facility with on-change notification. As agents cooperate they may share data that when changed by one agent triggers a response in another agent.
- There is an event-handling mechanism in sicsDAIS that handles all events and communication between content handlers. This event system may be logged which means a content handler may use this information for feedback purposes and adaptations.
- Communication and events are based on an internal scripting language. A content handler's reactions to user input is specified using a script that may be changed on the fly by the agent. This allows content handlers to be used by different agents in different contexts.

3. Summary

SicsDAIS is a platform-independent system for user interaction with agents. It is a central point for interacting with multiple diverse agents that all use content handlers for their presentations and interaction with the user. The system is open and flexible in such a way that new agents can be introduced at run-time by dynamic loading of the agents' content handler classes, the parts of the agents that handle the interaction and presentation. SicsDAIS is useful as a general interaction/presentation component in an agent-based application environment, particularly if there are high demands on flexibility and portability.

Virtual Seminars At The Virtual University – A Tutor’s View

Birgit Feldmann-Pempe, Gunter Schlageter, Oliver Schönwald,
Computer Science, University of Hagen, Feithstr. 142, D-58084 Hagen, Germany
{birgit.pempe, gunter.schlageter, oliver.schoenwald}@fernuni-hagen.de

Abstract: The Virtual University (VU) at the University of Hagen is an Internet-based learning environment which includes all aspects of an university. Part of the various teaching forms at the VU are the so called Virtual Seminars, i.e. seminars run completely in the Internet. This paper details our experiences regarding the qualifications and the work a typical tutor has to do for preparing and doing a virtual seminar in a net-based environment. Due to the offer of different internet-based technologies the tutor is able to enhance the quality of his seminar by picking up the right technology for the right task. From our experience we derive the set of typical tasks a tutor has to fulfill to run a virtual seminar, and the technical and communication skills he has to master. We then describe how a virtual learning environment should support the tutor in his work, and outline how this is realized in our VU system.

Introduction

The Virtual University (VU) [<https://vus.fernuni-hagen.de>] started as a research project with the objective to develop a technical, organizational and didactical elements to realize a university that teaches completely in the Internet. The unique feature of this VU is that it offers all functions of a university in the Internet in a integrated way. We now have two years of practical experience with 6000 students in all kinds of teaching events and types. The basic concept of the VU is to concentrate on the students view of the university. The VU integrates different teaching activities and materials, i.e. electronic courses, online exercises, practical teaching and virtual seminars. The tutors can use a set of modern internet-based technologies to rise teaching quality and success. It is also possible for the students to hold conferences between one-another, i.e. to prepare a collaborative work.

Structure of the Virtual Seminars

To understand the function of the seminar as a teaching method it is important to know some details about conventional and virtual seminars especially in distance teaching, but also in the campus university.

The typical problems of a traditional seminar are isolation of the students, discussions are time-consuming, groupwork is nearly impossible, the on-campus phase is fulfilled with presentations, less time is left for discussion. [BERK97]. The objective of a virtual seminar is similar to traditional seminars: students have to work out and to present contributions which they had to compile and prepare in a scientific manner. For this purpose, different Internet-Services were individually combined for different seminar phases. There are also mixed forms between virtual and conventional seminars, which means only certain seminar phases are assisted by Internet-based tools while those other phases are done as in the conventional seminar.

Since the beginning of the VU project about six virtual seminars have taken place.

The virtual seminars as we conduct them in our virtual teaching environment are structured in three main phases (numbering does not represent time-line, all sub-phases are parallel processes):

1. Preparation: In this phase the tutor organizes and configures any necessary resource, based on his time and organizational plan.
2. Elaboration: During this phase the participants are provided with the material and software the tutor prepared for them. Moreover, the students can use this and do their own literature research to accomplish their contributions. Meanwhile, the students and the tutor can use the provided communication mechanisms to discuss and solve problems.
3. Conclusion: The seminar ends with the public presentation and closing discussion of their contributions. The tutor acknowledges the acceptable works and presentations and prepares the certificates for successful participation at the seminar. Often, all acceptable contributions are collected in a special seminar booklet to be distributed to the participants and to be archived in the department’s library. The following functional resources

can be used in the VU: FTP-Server, NetNews-Server, Mail-Server, Videoconference-Server, Chat-Server. With these services, the tutor can establish communication channels between his students and himself, can give them his prepared material, run discussions and moderate them. The tutor has to fulfill a lot of different skills, technical and communication skills. For this a system support eases the tutors' work. The following chapter shows the way the VU supports the tutor.

System support for the Tutor

To use necessary and/or useful services for their virtual seminar, the tutor normally has to know: 1) what services are provided in the system, 2) what these services can do for, 3) how they can configure them for their own needs if possible. The success of a virtual seminar, both in the organizational and the pedagogical area, depends on the correct use of the right techniques and services. For this reason, the VU has developed a network of system support in different ways to help the tutor in his courses, especially in his virtual seminars. So, even inexperienced tutors can conduct virtual seminars and concentrate on the organizational and pedagogical issues of the seminar while reducing the technical requirements as much as possible. The main support areas are:

1. Technology: direct contact per e-mail, phone and even personally to those persons who are responsible for the configuration and administration of the communication services, especially the NetNews-Server, the Mail-Server, the Chat-Server and the Videoconferencing-Server. The tutors are given the option to administer their own service areas.
2. Tools: The system provides its own tools to create and publish content by the tutor.
3. Know How: All services and functions the VU system provides are described online. The information system provides online tutorials for every tutor, showing the use of those services by example. The system integrates its own internal news system, which is used to inform every user (especially the tutors) about changes in the system. This support element solves the problem in making the services and their usability known to the tutors.

Summary and Prospects

The experiences made with virtual seminars in the project VU are mostly positive. A users survey of participants of the VU in spring 1998 [Mitt98] showed, that the intensity of the contacts and the building of work and learning groups were rising in virtual seminars. In contrast to conventional seminars a continuing learning process is now possible, the discussions, taking place in the Internet are much more structured and disciplined than in the conventional seminars presence phase. By working out the seminar contributions in HTML it is for the first time possible to have seminar contributions as a homogenous hypertext, to avoid overlapping of topics and learn from each other's contribution. The successive publishing of the contributions enables the student to discuss continuously about certain topics, in contrast to discuss all contributions at one time. Due to the didactical approach virtual seminars follow and realize by integrating certain technological services (i.e. communication tools) the tutor's role changes from the mere teacher to a moderator and counselor for the students. To enable less experienced tutors to follow this change of role and to elaborate a virtual seminar the VU System has to implement appropriate support. What the tutor should consider: Critical for the success of a virtual seminar is the moderation process. It is necessary to look regularly in the seminar newsgroup, to read daily emails, to bundle frequently asked questions and to answer the students' questions quickly. The seminar themes should be clearly structured and the tutor should give support for the literature research and the outline of the contribution (even if the contribution should have the HTML-format). It is useful to guide from beginning on the cooperation process to have a look at the students communication styles and topics.

User Interface Requirements in Educational Multimedia

Sue Fenley
Department of Computer Science
King's College,
London, WC2R 2LS
Email :- sue@dcs.kcl.ac.uk

Introduction

The paper on the user interface requirements in educational multimedia commences with a review of the research on the use of navigational software in investigating navigational behaviour. This work has produced individual user paths in multimedia packages, recent empirical work is then detailed and related to the main previously classified types. The concept and component parts of an intelligent tutor are then developed, which includes elements which are important for the successful educational use of multimedia. Finally work on integrating this intelligent tutor into educational multimedia is outlined and some conclusions are brought together. The concept of an Interface Builder is introduced which links HCI work with results of users navigation and methods of learning in order to produce individualised learning schedules, which can be incorporated into multimedia.

Using navigational software to investigate navigational paths

Horney (1993) produced one of the most important research projects in terms of using software to interpret the navigational patterns which he investigates with hypertext users. He outlines the navigational patterns they use, details the links between these patterns and methods of constructing hypertext, and analyses their experiences. Horney finds eight hypertext authors and follows their routes through the software. He discovers that they were using five main types of navigational patterns which he terms Linear Traversal, Side Trip, Star, Extended Star and Chaotic. Mischanuk and Schwier's (1992) work on the use of audit trails in interactive hypermedia is also very helpful. Each screen that the user visits is recorded into an audit trail and these trails can then be used to investigate issues such as the number of repeat visits, how long the user spent on certain sections and their actual paths. They find four potential types of audit trails, linear, classic feedback loop branching, learner controlled parallel path branching and multimedia/ hypermedia but significantly also suggests that these are often combined by the user within each package. Canter, Rivers and Storrs (1985) use interactive databases to discover indices to characterise individual users search sequences. They then propose that these indices could be used for functions such as defining methods of searching such as browsing and scanning. Canter et al believe that users are already aware of how to navigate through concrete environments, such as a city that they are already familiar with, and in navigating data, and they explore whether or not there is an analogy in the psychological processes involved. All the users appear to follow a certain path, although as there are few choices available this is not surprising and it should be noted that true options of choice and user preferences can only be recognised if there is totally free movement within the resource. They then develop six indices (pathiness, ringiness, loopiness, spikiness, NV/NT and NV/NS. Later research by Canter (1986) investigates users navigational strategies and the implications for navigation when using different control options or front. They look at three different categories of front ends, namely command selection, menu selection and natural language techniques. They suggest that a good command of the instruction set (as in the command selection option) can allow users, especially if experienced, an ability to navigate rapidly. The results showed that once a successful method of searching the database had been discovered the user adopted this method to the exclusion of all the others. Arents and Bogaerts (1993) have been looking at intentional navigation and in particular at what kind of reader is navigating (i.e. which level), what kind of task he is performing (purpose) and what kind of information he is looking at (content).

Classification of navigation patterns from empirical work

Recent empirical work on a series of subjects revealed a distinct set of navigational patterns that each user employs. Each of the potential navigation routes e.g. linear have been investigated in turn and all the different methods of using these, recognised during the empirical work have been detailed below. The list under each of the main nine types gives an indication of whether or not it is one way or two way and how each pattern within the type differs from each other. Some of these variations or alternative ways of using the patterns were not specifically recognised from the pilot study but were potential variations which users could chose to employ and hence have been included in this list. The first two types, linear and circular are fairly self explanatory, although the early stages of the circular pattern can initially be classified as linear if sufficient of the arc or circle is complete. The star pattern in my classification implies a change in level to the next level down in the package. The hierarchical and hierarchical extra patterns can be differentiated by differences in both depth and width as the extra extension may involve more than one tree structure, while the hierarchical pattern itself is usually confined to one tree structure. The complex patterns are the most difficult to both recognise and analyse as these may be hybrid forms or simply a mixture of others or very rapid use of other patterns.

1 Linear	4 Star	7 Hierarchical - Extra
2 Linear extra	5 Star extra	8 Complex - Chaotic
3 Circular	6 Hierarchical	9 Complex - Planned

Work on intelligent tutor systems

The concept of an intelligent tutor system has been developed from the empirical work.

History - Each user, Where been, where left, relate to groups, work completed, grades link to games packages

Navigational Routes - Preferred methods, introduction and available routes, Best route, amalgamation of others, tutor's route, Perceived best route matrix, Links where to go next for student, Most successful method, Previous methods

Tutor/ teacher -Record of student achievement, Completed work/ grade

Each student's route, Most popular route links to most successful, Previous use of computers/ mm

Student level - where start/ progression, Assessment of student preferred learning methods - styles

Learning system - Problem areas/redundant/ unused - Tasks - ability levels, Where to go next

Complexity levels - higher ability/ basic level, Difficult to understand/ too easy

Individual - Portfolio/ knowledge of routes/ Problems, Specialised knowledge of own preferences

Areas that need repeating/ Strengthening exercises Extending/ higher exercises -Ways of extending/ improving coursework, Pointers to ways of improving/ gaining better assessments

Issues - Node/Screen identification, Classification of paths, Problem of dead ends, History info - separate resource, Links between users, Security - across student body, confidentiality

Creating an individualised interface

The concepts outlined in the intelligent tutor requirements above can be placed into a sequence of component parts of an adaptable interface. The interface builder requests information from the user on subjects such as their abilities and multimedia usage, novice to expert skills, previous use of computers etc. This then builds a user specific interface which can be different for each application or can retain the same major elements or appearance. This then links into the intelligent tutor with information on each student and at least some of the aspects above. The central component is the multimedia database which can be of a different composition each time or for a body of work. Other modules can also be linked in such as student databases, tutorials, user modules, levels guides etc, which can be unique or generalised.

Conclusions

Research by O'Malley (1989) states that 'the interface is the only way in which the user can operate in the represented world' and more importantly for multimedia 'if it is designed appropriately the interface becomes transparent and no longer exists for the user'. If multimedia developers are aware of how users navigate through systems and their preferred ways of learning, it is then possible to create individualised interfaces for each student. The simplicity of this system and the re-usability of its component parts should make the effort required to produce it worthwhile. Developments of this work are still being undertaken and a shell system will be constructed based on these outlines. The component parts such as the student database can then be re-used and could be applicable across a wide range of multimedia resource banks.

Going on a WebQuest with 'At Risk' Adult Learners

Lynn Fox, Ph.D

The Learning Assistance Center, Mt. San Antonio College, 1110 N. Grand Avenue, Walnut, CA. USA.

Phone: (909) 594-5611, E-mail: lynnfox@prodigy.net

Abstract: This paper describes 'At Risk' adult learners participating in a WebQuest about recent scientific cloning discoveries. Overall, participating students from two classes showed highly positive responses to the cloning WebQuest.

1. Introduction

It's the year of the clone! First we had Dolly, the original cloned sheep, then Molly (Dolly's daughter), and finally cloned cows, monkeys, and mice. Will humans be next? Cloning technology will soon touch the lives of everyone in society, very much as it enticed thirty 'At Risk' adult learners to embark on a cloning WebQuest¹.

2. Background

This WebQuest captured the imaginations of thirty reluctant readers. These readers were transformed into a group of learners who not only understood the implications of cloning, but also made appropriate inferences about how the scientific discovery could impact not only their own lives, but society as well. Although the concept of cloning was initially met with some psychological resistance, these students gradually developed a genuine curiosity and, finally, knowledge.

3. Approach

The class activities began with the question "Who knows what cloning is?" The few adults who had heard of cloning volunteered what they knew as others listened with amazement and responded with skepticism, awe, or even disdain. A barrage of comments and questions followed, e.g.,: "What does cloning have to do with pre-collegiate reading classes? There are scientific words that don't make sense! Why would anyone care? Why use the World Wide Web? Would human clones have the same personalities?" Soon this group of thirty adult learners discovered the answers to their questions.

A group journey that began with a single question, developed further with the viewing of selected segments of two award winning films, "Jurassic Park", where dinosaurs were cloned, and, perhaps more frightening, "The Boys from Brazil", a movie about Hitler clones. In addition, these students listened to, and read, news articles about cloning legislation and ethical controversies before embarking on their WebQuest.

Using the World Wide Web for research was essential. Cloning articles were available to meet the multiple learning modalities of 'At Risk' learners, such as, World Wide Web slide shows, audios, videos, and text. Government documents on ethics and theological perspectives about cloning were read and reported to the class by the students who selected their own group participation topics and teams. The WebQuest culminated with group presentations according to the class teams' selected topics. The class teams were divided into groups of four to eight students, according to the following issues: 1. Ethics of Cloning, 2. Religious Perspectives, 3. Human Health Benefits, 4. Animal research and 5. Social Issues.

¹ A WebQuest is an inquiry based activity designed for interactive World Wide Web exploration.

4. Findings

The survey results (16 items) showed an overall positive student response to the cloning WebQuest. The survey was completed anonymously, following the conclusion of the cloning teams class presentations (12/1/98). The majority of participating students surveyed from two different classes finished the project with highly positive attitudes toward using the World Wide Web, scientific research and the cloning WebQuest activities (N=23, 7 absent). These positive results not only reflected the students stated responses to the survey, but were also shown by their willingness to participate in the group activities and complete the assignments in a timely manner.

5. Conclusions

An 'At Risk' population, that some educators assume are not supposed to be motivated and are assumed to lack the requisite skills to engage in the scientific, moral or ethical debates about one of the most significant scientific discoveries of the 20th century, were enthusiastic participants. Finally, those who initially 'couldn't make sense of cloning' understood it, and those who 'shouldn't be interested' in it were.

If there is any doubt that the World Wide Web is an essential tool, or that reading about 'scientific discoveries' is appropriate for all learners, then the success of this WebQuest should help educators rediscover both. When 'At Risk' adults with developmental reading needs acquire the competency to discuss moral, ethical, social, and economic issues, then the challenges of educating them has begun, with one 'At Risk' adult learner at a time.

A Document Model for Generating Adaptable Courseware Using Background Data

Katrin Franze, Frank Wehner
University of Technology Dresden, Department of Computer Science
01062 Dresden, Germany
{kf2,fw2}@inf.tu-dresden.de

Abstract: Today's research activities in the area of computer aided teaching and learning concentrate on the realization of systems that generally satisfy the needs of people who want to take courses of advanced training. However those systems are not appropriate for an employment as a real learning environment. Mostly they offer very limited possibilities of interaction between the users and the system, of communication (in a asynchronous as well as synchronous way), of data security and protection, and of adaptation of the system to user needs, system environment and goals. Based on two approaches that include those techniques this paper describes the ideas of gathering and using background information as well as shows a solution of making documents adaptable.

JaTeK (Java Based Teleteaching Kit)

The lack of existing online learning systems - not to meet the requirements of university studies - has led to the realization of JaTeK [Schill 98]. JaTeK is a Client/Server system that consists of a database and three main modules: The JaTeK module serves as login component to the system, server and viewer for the learning documents and as gateway (server side) and frame (client side) for the JaWoS and Javal components. Besides it is responsible for the user, group and permission management. JaWoS (Java Based Workgroup Support) allows synchronous and asynchronous communication. With Javal (Java Based Evaluation System) instructors can evaluate their teaching material. Javal offers two different tools: The form generator allows to create, to show and evaluate questionnaires. The automatic evaluation tool gives a statistical overview of the learning material usage.

CHAMELEON (Cooperative Hypermedia Adaptive Multimedia LEarn Objects)

In existing courseware there is a lot of material in different formats. It is very difficult to combine it to homogeneous looking, platform-independent course material and to reuse it in other contexts. The main goal of the CHAMELEON project was to develop a set of reusable, adaptable, combinable and platform-independent components, called "Learn Components", that can be glued together to a homogeneous course material. We identified different types of learn components: content components (e.g. a picture with explanation), structuring components (e.g. containers for a chapter) and interactive components (e.g. a simulation). Dependent of the learner's level the system can switch between alternative learn paths with different levels of difficulty and levels of detail.

Document Model

Components with no interactive behavior can be structured in a document model. But it is not practicable to use existing document formats because they cannot express semantical conditions and relationships between contents parts. E.g. HTML seems to be too finegrained, blocks with higher semantics are needed. There must be three levels of information: The first level is called didactical level. Here didactical rules and models are expressed. The second level is called the psychological or design level where abstract presentation and design rules are coded. Part of the third level, the content level, are the content components. We want to use XML (eXtensible Markup Language) [Harold 98] as base for our document model. The goal is to develop a grammar for "TeachML", a markup language for courseware documents.

XML documents do not know, how to present themselves to the user. XSL (eXtensible Style Language) documents map an XML document structure to a presentation format, in the simplest case to HTML. The main ad-

BEST COPY AVAILABLE

1299

vantage is the separation of the document's content and structure from its presentation. We will develop a set of XSL styles for presenting TeachML documents in different ways, e.g. as script, or (online) presentation. In order to adapt a TeachML document to the learner it must be dynamically generated dependent on the learner's knowledge, his aims and actual success. So TeachML components are stored in an object-oriented database using DOM (Document Object Model) and dynamically glued together to a course document. A document generator selects the matching TeachML parts and creates valid courseware documents.

Background Data Model

Understanding of Background Data/Background Information (BD/BI)

Outgoing from the described document model and the Javal component it has been shown that a series of applications and tools have a constant requisition of access to so called background data or background information (BD/BI). BD/BI is data that will *not* be used for explicit presentation in a learning environment. Instead it acts directly on the process of creating the different documents. BD/BI comes from different applications and tools and can be requested from these applications whereas the requested information must not necessarily come from the same application. There are different kinds of BD/BI in learning environments, e.g. system infrastructure, course properties, application properties, precognition of the students, concrete learning progress, user behavior or concrete user actions. BD/BI can be categorized by the following criteria: *stability* (permanent, changeable permanent and dynamic), *visibility* (system-global, course-global, session-global, application specific, and user specific), and the *involved entities* (tutors, students, server and client components, network and database). BD/BI is being generated either automatically or by user input. Automatic data gathering should be produced parallel to the user's working process without annoying him with performance decreasing or other perceivable actions. This information is stored in the BD/BI repository in a applicative way. At request of an access-permitted application the needed BD/BI will be converted into a suitable format and made available.

Concrete Applications using BD/BI

At this point we demonstrate our idea by means of 3 examples of applications generating and using BD/BI:

Document Adaptation and Generation: The main application in a learning environment that should have access to BD/BI is the document generation itself. Here the document model of CHAMELEON and the background model of JaTeK will be combined.

The document generator requests BD/BI that concerns both system conditions on server, network, and client side and user information. With user information it are meant precognition, target group, aim of the learner, wishes of the learner, skills, communication goals of the content provider, and learning progress information etc. Based on this information the document will be put together to one multimedia document using the described document model. User actions on the documents are being recorded and sent to the BD/BI repository.

Evaluation of Course Material: In a real "face-to-face" learning environment the tutor has the possibility to get feedback of his demonstrations by discussing problems, getting questions and observing reactions. In computer based learning environments this has to be realized by other mechanisms, e.g. to keep track of the accesses, the access duration and the actions on the course material. Those data will be stored as background information and made available to the evaluation application.

Prefetching of Course Material is the process of loading data to the student's/tutor's computer in advance e.g. to save telecommunication costs. Thereby data can be transferred to the student's computer in cost-efficient times. E.g. in the case of a low-speed network connection to the learning server where users usually have to wait some time for the requested multimedia documents the system requests information from the BD/BI application which material is most likely to be wanted next. This one kept track of the user action and has to decide from this and other factors which data it passes to the prefetching application.

Abstract: The computer supported learning system (CSL) is a web-based teaching and learning resource administration system, developed by the Business Education On-Line Unit of the School of Business, at the University of Auckland, New Zealand. This paper describes CSL, discusses the pitfalls of multiple systems, platforms and administration. It discusses the potential and realised benefits to the user and the University of Auckland, in New Zealand.

Introduction

The need to maintain and provide ubiquitous and individualized teaching and learning support for staff and students is a growing concern for all tertiary education institutions. This paper looks at the school of Business' (University of Auckland) efforts to address these issues.

The computer supported learning system (CSL) operating at the University of Auckland, or Cecil as we call it, has been developed over a four year period by the Business Education on-line unit of the School of Business. It is a system that enables delivery of teaching assessment and class administration to occur in one environment. In the 1999 academic year Cecil will provide support for approximately 835 papers (classes) and be used by 240 general staff and academics in the School of Business alone. The take up and use of the system is becoming wide spread and it is predicted that Cecil will contain the entire enrolment of the university by the end of the year. In terms of paper (class)-enrolments it can support more than 100,000 students.

This year our web site will be one of the busiest in New Zealand. In 1999 we expect more than two million hits per week and have already serviced more than 350 hits per second. It is a 24 hours a day, 7 days a week operation professionally managed by the university's technology center. A more detailed discussion of the CSL system is described next.

What is Computer Supported Learning at Auckland University?

Cecil is primarily an instructional management and assessment system. It allows instructors to store and organize all of their teaching and research materials in one location and then assign these resources to individual papers. In this sense it becomes a personal body of knowledge (BoK) that can be shared with colleagues and with students. The architecture of Cecil is designed to replicate the BoK from the academic's desktop to the university system and then on to the student's laptop.

As an assessment system Cecil supports instruction by storing large banks of questions and then selecting from these banks, questions that meet the instructor's instructional objectives. The questions form an assessment that is presented to the student via the Internet either under supervised or non-supervised conditions. Assessments are immediately scored and the feedback is provided using a protocol established by the instructor. Cecil has been designed for computer-automated testing (CAT). CAT will adjust the difficulty of the following questions based upon the responses provided by the student.

Self-assessment activities are one of the most popular options. Students use Cecil at all hours to check their understanding of the learning materials. The fact that no academic credit might be obtained for doing a self-assessment seems irrelevant so long as the learning content is clearly mapped to the course objectives and examinations.

Cecil has enabled students to complete their studies in an efficient manner and papers to be managed in several ways. Students are able to access all course details and materials via the web either on or off campus. Announcements previously put on bulletin boards or made at the beginning of lectures are now made electronically making changes to programs or important message transfer very effective. Management of papers through Cecil is extremely flexible; academics and tutors can access the system, post announcements, upload materials and use Gradebook features from the web, therefore enhancing the overall-working environment. It has been noted that professors visiting in Europe can instantly inform all their students of the latest developments and tutors regularly mark assignments at home and post the marks via their internet connection. Gradebook has many unique features for paper management techniques and also advanced statistical summary facilities.

As well as a teaching and learning facilitation suite, CSL also has strong implications for data security, administration and data mining. These implications are discussed next.

Enterprise-wide Decision Making

From a management information systems (MIS) perspective the term "enterprise" means a perspective that includes a consideration of all of the organisational units, functions, processes and data elements (Laudon and Laudon, 1997)

A number of systems, similar to Cecil are on public offer to academics and their departments. Very few of these systems have been adopted on a School-wide basis and then exploited for their enterprise wide benefits. The installation of a stable user friendly system may facilitate more than the collation of marks and the provision of feedback to students, it enables the closer collaboration of staff at any scale within the organization.

Historically the need to provide a working solution to problems has lead individuals to purchase and administer their own systems. Often the implementation and administration of these systems have been subject to several pitfalls. Given the need to make best use of the equipment currently available software and hardware may be implemented in a non-standard fashion. Whilst the individual implementation may be sound there are increasing security risks associated with the proliferation of these systems. These risks may over time compromise the organisation's information systems security and the privacy of the client's data. Simple and essential functions such as backups and thorough administration may be unavailable luxuries for the individual's system. The short-term reliance of these systems also on one or two staff to provide maintenance will become a longer-term liability as the consequence of staff departure become apparent.

These issues can be addressed, in many universities compromise and compound systems have been forged. The inability to share and transfer data and teaching resources between administrative units and departments is, however, a major loss. This must be measured both in terms of the costs incurred in data translation and duplication and the frustrating time loss each finds at differing places of the system. A recipe for chaos and data corruption is apparent (Mensing J. R. and Adams D. A. 1991).

Given these hazards an enterprise solution has been developed. A dedicated team of developers and support staff enable the continuing success of Cecil as well as allowing assessment and resource management. But CSL gives more. CSL has the ability to facilitate the professor and administrative units to mine the statistical data stored within its database. Such data mining may be used to gauge the performance of a cohort of students, or look at the effect of changes in teaching and learning both in present and trend analysis (Dhar and Stein 1997 and Turban and Aronson 1998).

Conclusions

This paper has outlined the pitfalls of individualised solutions proliferating through out a university information system. CSL provides an enterprise solution to University problems associated with the storage, collation of teaching and learning resources, administration and student learning management. It has addressed privacy and organisational issues from the outset of its construction and now provides a stable, secure school and university wide system. Additional features that enable the collation of statistical data facilitate data mining and further in-depth examination of the way papers and students perform. With the successful manner in which this system has been utilised within the School of Business at the University of Auckland, further developments are planned to expand the range and nature of support that this system affords its users.

ABSTRACT: A *modernistic* approach to the design of concrete mixtures is presented. The weight method and the absolute volume method are standardized and detailed in the specifications of the American Concrete Institute. A new educationally innovative approach is developed to make the learning and design experience of concrete mixtures easy, enjoyable, and rewarding. The capabilities of *Internet* browsers together with the *JavaScript* scripting language are used as means toward implementing the design methods. An *Internet* site is developed where the procedure of concrete mix design is outlined in a logical form. The user can navigate through the process in an orderly fashion. Tables of data related to mix design are given. Included also are pages which allow users to enter data and to calculate the weights and/or volumes of the ingredients of concrete mixtures. The entire procedure can be done using different systems of units. The highlight of this approach is the interactive nature of the technique in addition to an interesting, graphical interface.

1. Introduction

The design of concrete mixtures is a systematic task which is outlined in the specifications of the American Concrete Institute (ACI) (1). The steps that should be followed in designing a concrete mix are simplified and presented in a modernistic form in this paper. The goal to be achieved is to make the design experience interesting and enjoyable. The proposed method takes advantage of the capabilities of *Internet* browsers and the *JavaScript* scripting language, which is used to conduct simple calculations. According to the proposed method, the designer will be able to enter data from design Tables into a form to calculate different weights and volumes.

2. Procedure

A brief description of the procedure used in concrete mix design is given in the following. The user selects the main components of a concrete mixture, and enters different factors that affect the design (2). These factors are workability, consistency, strength, water/cement (w/c) ratio, durability, density, and generation of heat (Figure 1). The user can also specify the use of pozzolanic materials and/or chemical additives. These materials are used to give the concrete special characteristics such as durability, resistance to freeze and thaw, or high strength.

Figure 2 gives the designer different options to conduct the design procedure. Based on the selection made, the design can be conducted using the weight method or the absolute volume method. It can also be conducted using either the SI system of units or the US customary units. Mixtures can also be designed for air-entrained or non-air-entrained concrete. Depending on the selection made, the computer will branch to appropriate files where design Tables and data entry can be conducted. This step is essential and cannot be skipped.

Based on the type of the structural and concrete pouring conditions, maximum and minimum values of slump are determined. The mixing water and air content are found from design Tables. This is followed by the determination of weight of coarse aggregate (using the nominal maximum size and unit weight of aggregate), and water cement ratio. The weight of cement can then be calculated. The total weight of fresh mix is determined from design Tables. The weight of fine aggregates can be computed since the total weight of the mix and the weights of other individual ingredients are all known.

If the aggregate used in making the mix is not totally dry, adjustment for moisture content in aggregate should be made. The values of free water and the degree of absorption in both coarse and fine aggregates should be entered by the user. The options of using pozzolanic material in the mix and chemical admixtures are also available.

3. Absolute Volume Method

The design procedure described above can be conducted using the absolute volume method where volumes of different ingredients are used instead of the weights of the same. The basic difference between the two methods is the volume of air (which has no weight) is incorporated in the design. This could result in more accurate results.

<p><u>Scope</u></p> <p><u>Introduction</u></p> <p><u>Basic Relationship</u></p> <p><u>Chemical Admixtures</u></p> <p><u>Background Data</u></p> <p><u>Design Parameters</u></p> <p><u>Design Procedure</u></p>	<p>BASIC RELATIONSHIP</p> <p>ACI 211.1 states: "Concrete proportions must be selected to provide workability, consistency, density, strength, and durability, for the particular application.</p> <ul style="list-style-type: none"> • Workability : The property of the concrete that determines its capacity to be placed and consolidated properly and be finished without harmful segregation. • Consistency : It is the relative mobility of the concrete mixture, and measured in terms of the slump; the greater the slump value the more mobile the mixture. • Strength : The capacity of the concrete to resist compression at the age of 28 days. • Water-cement (w/c) or water-cementitious (w/(c+p)) ratio : Defined as the ratio of weight of water to the weight of cement, or the ratio of weight of water to the weight of cement plus added pozzolan. Either of these ratios is used in mix design and considerably controls concrete strength.

In[side]out: Art in Virtual Reality, the Museum in Virtual Space

Professor Nan Goggin, Professor Joseph Squier
School of Art and Design, University of Illinois, Champaign, Illinois, 61820
Tel: 217.333.2977, Fax: 217.244.7688, E-mail: n-goggin@uiuc.edu

Abstract: The authors have created pioneering web-based and CD-ROM format electronic art since 1994. This paper describes a new artwork currently under development that will utilize virtual space in a variety of forms. The piece is titled *In[side]out* and employs a virtual hotel room as a metaphor. Viewers can navigate the room, and by doing so, explore the boundary between public and private space.

Technology is being adopted in the creation of art – the conscious use of skill and imagination to produce aesthetic work – and is resulting in new aesthetic theories and conceptions about the nature of emerging art forms. New technologies ranging from computer-mediated communications to scientific visualization and sonification are being implemented via interfaces that deliver images, sounds and other modalities of human aesthetic experience.

Emerging virtual reality technologies are particularly challenging to the contemporary art world – both practicing artists and the museum system -which is predicated on the exhibition of rare and valuable *objects*. The etiquette of engagement in the traditional museum setting, the boundaries between art and audience are in direct opposition to the inherently immersive and performative aspects of new electronic genres such as the Web, CD-ROMs, and virtual reality.

The authors have substantial experience working collaboratively to create new electronic media and have achieved considerable recognition for their work. This collaborative relationship includes the 1994 launch of *@art gallery* (www.art.uiuc.edu/@art), one of the first curated web-based art galleries to feature work produced exclusively for distribution on the World Wide Web, and the 1997 publication of *Body, Space, Memory* (BSM), the first CD-ROM artwork published by the University of Illinois Press. The *@art gallery* has since been recognized as a pioneer in the field of online artwork and BSM has since been shown at numerous prestigious venues worldwide, including the Centre Georges Pompidou in Paris. This work has been featured in *The New York Times*, the *Wall Street Journal*, *Newsweek*, and in numerous recent books on electronic art.

Our latest work, titled *In[side]out*, pushes our explorations into more immersive virtual environments. In its current form, *In[side]out* exists on CD-ROM and utilizes a navigable virtual space. Longer-range plans call for the development of a VRML version suitable for distribution via the World Wide Web and a full VR version implemented via a CAVE or a portable ImmersaDeck.

In[side]out is a parable about public and private space, using an anonymous hotel room as metaphor. It was originally conceived for publication in CD-ROM format, and is close to completion in that form. Consequently, much of the conceptual framework, content creation, and design work is firmly in place. Examples of the work in progress can be viewed at www.art.uiuc.edu/ncsa and will help to clarify the description below. We are currently seeking programming support and guidance in transforming the work into VRML format, as well as access to the CAVE.

Since the CD-ROM version utilizes a simple virtual space in the form of QuickTime movies, the move into VRML and VR is a logical extension of the work. Both of these media would afford the opportunity to explore avenues for combining sound, motion, still and video imagery, and text in new ways that far exceed what can be done with a two-dimensional representation.

In[side]out begins with viewers “checking-in” to a virtual hotel room, but what they soon discover is that it is still occupied by its previous guests. The relics of habitation are still present: clothes, book bags, used glasses, notes, and other evidence of everyday life. It becomes the viewer’s task to unravel the mystery of these two people. Who were they? What was their relationship? Why were they together in this place?

The hotel room as privacy-for-hire sits at the boundary of public and personal life. It is a curious hybrid space that is generic and public, yet it is transformed in serial fashion into a unique and private place.

When viewers of *In[side]out* “occupy” a room that is in essence not yet vacated, they unwittingly cross the threshold into a shared space. Once in the room, they can move about and touch objects; which then tell their stories, much like the ancient concept of a “memory palace”. Each object provides more information about the two former inhabitants, in the form of fragments of conversation, phone messages, personal notes, and memory vignettes.

As the story unfolds, in a different sequence for each viewer depending on their movement in the room and what they choose to interact with, the metaphor slowly shifts. Viewers come to realize that, in this space, the two former occupants were negotiating the meaning and boundaries of their own relationship. The hotel room then begins to represent the shape and limitations of that relationship. Ultimately, the audience is engaged in questions about trust, intimacy, desire, and commitment. The public/private dichotomy, which began as a question of space, is expanded to include our bodies and minds as well.

As with any work of art, regardless of era or medium, *In[side]out* engages fundamental human concerns. How is a relationship negotiated between two individuals? How do our social roles inform and inflect our many different types of relationships? How do we balance the conflicts sometimes inherent in our lives as public citizens versus our desires as private individuals? Where is the boundary between the two, and how is it established?

These kinds of human issues are particularly relevant in the late twilight of the 20th Century. Emerging digital and telecommunications technologies are themselves eroding what constitutes our private lives. Simultaneously, true public space is disappearing in some communities, with the closest approximation being the local mall. Of direct relevance is the internet itself, which exists in a gray area of its own between public and private; on the one hand a vast and nearly anonymous public space, on the other a private confessional where people sometimes feel compelled to reveal highly personal information.

In[side]out demonstrates how new technology is affecting the production of new works of art. It also points out how dramatically the delivery of artistic works by arts institutions is being altered, and how the notion of an archive is being fundamentally transfigured by changes in the physical nature of electronic art and the means by which it is displayed and stored.

Reaching Teachers Through Web-Based Distance Education

Abstract

Technology has become ubiquitous everywhere, except in schools. Although many schools are now acquiring the technology, not enough money is being set aside for professional development of teachers in the use of technology. Consequently, teachers do not feel adequately prepared to integrate technology into their daily practice. The purpose of this study was to examine the use of the World Wide Web and electronic mail as a viable option for the professional development of K-12 educators. Two classes were investigated, one delivered using the Web and another one in a face-to-face environment. Quantitative and qualitative methods were used in this investigation. The researchers concluded that distance learning is not an education of inferior quality to those university courses taught on campus, and that classes delivered on the Web provide a viable option for professional development.

Introduction

The latter part of the twentieth century has been marked by technology changes that are increasingly affecting every aspect of human life. Technology has become ubiquitous everywhere, except in schools. Although many schools are now acquiring the technology, according to a national study conducted in 1995 by the Office of Technology Assessment (OTA), not enough money is being set aside for professional development of teachers in the use of technology. There has been little attention paid by districts to professional development needs of teachers, and Colleges of Education have not modeled its use for preservice teachers (Cuban, 1998). As a consequence, teachers do not feel adequately prepared to integrate technology into their daily practice.

The design of new professional development opportunities for teachers in the K-12 classroom is a must. In doing this we must take into account that many teachers, especially in the rural areas, have very restricted access to institutions of higher education. This situation has led them to attend summer school or, in the best of situations, to continue their education during the school year using distance learning. Because of the diversity of today's learners, it will be necessary to offer many forms of education such as distance education, evening and day classes, and online classes that cater to the needs of such a diverse population (OTA, 1993). Recognizing the importance of distance education in the expansion of educational opportunities, this study investigates the feasibility for professional development of an already-existent resource in many classrooms: The World Wide Web.

Purpose

The purpose of this study was to examine the use of the Web and electronic mail (email) as a viable option for the professional development of K-12 educators. Two classes were investigated, one delivered using the Web and another one in a face-to-face environment. The uniqueness of this study is that the two classes shared the same professor, syllabus, and textbooks, but differed by the medium of delivery. By keeping the former variables reasonably constant, it was possible to look into the interaction that the students might have had with the medium of delivery. This investigation also attempted to answer some of the theoretical questions pertaining to distance education. For instance, Harasim (1990) suggested that there is a critical need for research that informs and guides future applications of the distance education field to make this promise a viable reality. Levinson (1990) stated the need to investigate and research some qualities of electronic text, such as its revisability, interactivity, duplicability, transmissibility, storage, and promotion of cognitive skills. Levin, Kim, and Riel (1990) proposed more research in the commonalities and differences of electronic networks and face-to-face interaction in the following areas: (a) group organization, (b) task organization, (c) interaction, and (d) evaluation and coordination. The results presented in this proposal shed light on the use of Internet-based telecommunications to support both professional development and life-long learning in a constructivist environment, and attempted to answer some of the questions posed by previous research studies.

Theoretical Framework

Just-In-Time Constructivist Learning: The word "constructivist" is defined as both a theory of learning and a strategy for education which involves having students work on complex projects, often in groups, and synthesize information to construct their own understanding of a content area. In this framework, students learn technology skills and concepts in the context of using them to solve a real-world problem; for example, they might create a product they can use in their classroom. These projects follow from a theory of learning that suggests that subject matter becomes meaningful, and therefore understandable, when it is used in context-rich activities (Fosnot, 1996). The course was designed to emphasize the students' own responsibility for

BEST COPY AVAILABLE

1309

learning, for figuring out their own methods of solving problems, and for assessing their own work. Teachers who learn in this way will be better able to provide such environments for their own students.

Web-Based Instruction: Online teaching is a relatively new development, but recent research has shown it to have as much rigor and educational merit as is found in face-to-face courses (Sujo de Montes, 1999). Frank Odasz states, "The promise of online teaching is both the teacher and learner can be anywhere, participating at any time, through any type of microcomputer with modem. If online instruction can demonstrate economies of delivery of distance learning, it opens the door to ongoing learning for all potential learners" (Odasz, 1994). Christopher Dede (1996) says that technology can help transform schools—but only if it is used to support new models of teaching and learning. Interactive distance learning (distributed learning) is a use of technology which supports constructivist pedagogy and school reform. It provides opportunities for faculty and students to communicate in and out of the classroom, become members of learning communities, utilize information from voice, text, and graphic sources, develop technology competencies, and construct and apply knowledge.

Methods and Data Sources

The main research question that guided this study was: Is the use of Internet-based telecommunications a viable option for university courses to address professional development practices for K-12 educators? In order to collect information and to understand how the participant (student) teachers constructed their knowledge and realities in both the online and the face-to-face classes, quantitative and qualitative methods were used. For the quantitative part, a pretest-posttest quasi-experimental design proposed to use the face-to-face class as a control group and the online class as an experimental unit. For the qualitative part of the study, three sources of data collection were used. The first data source was the Middle and End of the Semester Course Analysis, an email-delivered, open-ended questionnaire developed by Weber (1996). This questionnaire investigated the participant (student) teachers' class perceptions, and the perceived level of class satisfaction. The second data source consisted of in-depth interviews with a selected sample of participants from each class. These interviews were conducted using traditional face-to-face methods and online chat rooms. The third data source was the participant (student) teachers' electronic journals.

Conclusions

By keeping the instructional variables reasonably constant, it was possible to look into the interaction that the students might have had with the medium of delivery. The results of this study confirmed that the course taught over the Internet was at least as effective as the same course taught on campus. Distance learning was not found to be an education of inferior quality to those university courses taught on campus. However, successful face-to-face teachers do not necessarily make successful online instructors. Professional development at the university level is needed to provide distance learners with the quality that post secondary courses require and demand. Classes delivered on the Web provide a viable option for professional development, especially for those whose access to institutions of higher education is difficult or inconvenient. Additional research is necessary to compare and evaluate the viability of online synchronous interaction for in-depth interviewing.

Collaborative Learning in an Online Human Learning Course

Candace L. Gunnarsson
Assistant Professor, Department of Economics,
Xavier University, U.S.A. gunnarcl@email.uc.edu

Daniel D. Wheeler
Associate Professor, Educational Studies,
University of Cincinnati, U.S.A. Dan.Wheeler@uc.edu

Abstract: This research focused on a graduate level human learning course taught both on the web and in a traditional face-to-face format. Course materials were presented to students on the web. All participation was via email using Listserv™ mailing lists. Twenty-eight students agreed to participate, twenty-two females and six males. The distribution of age and sex matched the graduate student population of the College of Education. A questionnaire developed from the Flashlight Student Inventory and individual student interviews were conducted for the purpose of evaluating learning outcomes. The majority of the students reported favorable learning outcomes. Course evaluations from both the online and the face-to-face sections of the course were compared and differences favoring the face-to-face format were found in the area of learning and overall enjoyment.

The period of uncritical enthusiasm for web-based instruction is past. Although there are many examples of excellent web-based courses, it is now clear that much more is involved than just presenting the components of a conventional course via the internet [Kahn 1997]. Lectures are not improved by translating them into HTML and discussions do not automatically happen when students are connected to a mailing list or computer bulletin board. One of the common themes in descriptions of successful web-based courses is the use of collaborative learning activities. The theoretical underpinnings come from instructional models based on learner-centered, constructivist, and socio-cultural ideas about learning [Bonk & King 1998].

This research focused on a graduate level human learning course taught both on the web and in a traditional face-to-face format by the second author. The first author had no formal connection with the course; her contacts with the students were strictly in the role of researcher. In its original format, the class met once a week for a ten-week quarter. A chapter of the text was discussed each week. Student learning was evaluated with an exam and a term paper.

The design of the online version of the course depended on the fact that the textbook for the course was excellent; little additional material from the instructor was necessary. In order to promote student learning in the online class, collaborative projects were established. The first assignment required each student to propose an educational project to design. Part of the second assignment asked each student to rank order the projects they were interested in. Then project groups of about five students were formed of students who were interested in the same project.

Course materials were presented to students on the web. All participation was via email using Listserv™ mailing lists. A typical week's assignment required students to apply a chapter in the textbook to their project. Individual answers were sent to the mailing list for the project group and one person had the responsibility for reporting a summary to the mailing list for the whole class. The course was graded on a pass/fail basis. Participation in the group process was tracked and students who made minimal contributions to their group got reminders by email that more was expected of them.

The online version of this course is offered each spring quarter. This study is based on the third year of the course. The success of the online version led to a revision of the face-to-face course so that it now also uses collaborative project groups. Some course evaluation data from the revised face-to-face course is available for comparison.

Method

Thirty-six students registered for the class being studied. Twenty-eight students agreed to participate in the research, twenty-two females and six males. The distribution of age and sex matches the graduate student population of the College of Education.

There was a face-to-face organizational meeting prior to the beginning of the online course. At that meeting the research was explained and the informed consent form distributed. We were particularly careful to explain that the course instructor (second author) would not see and questionnaire or interview data associated with the student's name. At the end of the course, questionnaires were distributed to all participants and a sample of the students were interviewed. Additional data from the course evaluation questionnaire (require of all courses) were also utilized.

The primary questionnaire instrument was constructed from items in the Flashlight Current Student Inventory (Ehrmann and Zúñiga, 1997). This consists of a battery of nearly 500 items; only a small subset are to be used in any specific research study. The interview protocol used both items from the Flashlight Inventory and some specific questions about the human learning course.

Results

All students in the study are working on graduate degrees, either the masters degree (23) or the doctorate (5). The average quarter hours taken by the students was 13 hours. Twenty-five of the students reported being employed with an overall average workweek being 32.6 hours.

Questions taken from the Flashlight Student Inventory focused on student's attitudes and feelings toward learning online. Overall, student responses were favorable. The majority of the students were able to work on the course from either their home or office. Students reported spending less time traveling to and from campus, which made it easier to juggle school and work. Students reported spending on average 4.8 hours per week for the course. The majority of the students did not feel isolated from the instructor. Most students reported feeling that the instructor of the course was interested in what they had to say and that the instructor's comments were useful and helped facilitate learning. When students were asked if they felt isolated from other students or felt that they had missed comments made during a discussion they reported on average feeling about the same as if the course was taught in a traditional setting. Students felt about the same when it came to comfort in participating in a discussion or working in a group. When course evaluation data from the revised face-to-face section was compared to the online section, differences were found in amount of learning and overall enjoyment. Although both the online and face-to-face courses rated the collaborative learning style higher than a traditional lecture style course, the face-to-face evaluations were still significantly higher ($p < .05$) than the online section in the amount of learning and enjoyment experienced.

Conclusions

The offering of web-based courses is of tremendous benefit to some students because it frees them from constraints of time and place of participation. We are confident that are analysis demonstrates that the engagement of the students with the course material is sufficient to treat the two forms of the course as educationally equivalent. In addition, the understanding we get of participation from the students' point of view is extremely helpful for instructors who wish to design more effective web-based instruction. There are some students for whom the use of technology creates a barrier. More ways of helping those students are needed.

Abstract: For a commercial company it is very important to be able to transfer relevant information to corporate knowledge. Therefore, a new concept must support and manage the information-to-knowledge and the knowledge-to-information cycle by using trustworthy knowledge repositories and personalised retrieval systems. The xFIND system represents an approach to a future-oriented knowledge system, which supports the corporate decision-making process combined with the interaction and collaboration between employees and users outside the company. It processes Intranet and Internet sources. xFIND offers features to handle the information life cycle and fits into the concept of a knowledge management environment.

1. Introduction

The implemented prototype of an intelligent search system xFIND (Extendable Framework for Information Discovery) is based on HIKS [Dietinger et al. 99]. A very important subject was found in the field of corporate knowledge management. Informed and well-trained employees are becoming more and more important for companies and their success on the global market. By providing users with information, advice and experiences relevant for the particular situation, helps to improve their problem solving. The decision-making process is substantial to the management at any level and every part of a company. Consequently relevant and qualitative information has to be provided. To reach this goal a new concept for information gathering, distribution and managing is needed.

In [Chislenko 97] value-added services for the knowledge process may include specialised knowledge repositories, retrieval systems and semantic search engines. Furthermore, reputation broker agent certification systems and recommendation systems should be taken into account. An automated subject classification system, a quality rating system and dynamic document maintenance should offer added values. Personal needs with respect to the current problem (task specific, position specific), previous experience and references to further domain knowledge (e.g. problem base, background library and communication with experts) have to be taken into account for every employee. Not only the active demand for information has to be supported but also a optional offer of additional information should automatically be given to the users too. Problem solutions and relevant, qualitative information from users must be archived and be problem-dependably provided to other users. *"Consequently, many business activities require access to a variety of information systems both within and across organisational boundaries."* [Huang et al., 99] In the knowledge gathering process internal and external information has to be taken into account. The internal information can be located at central corporate systems (e.g. Intranet system, knowledge bases). Relevant documents may also be saved on PC stations of employees. The Internet represents an important external information source. Because of the variety of document formats and information services, an open and extendable knowledge system is required. Such a system should integrate various systems or provide an API for co-operation during the management process. In [Huang et al., 99] an

analogy to the classical marketing notation "product life cycle" is described. Here, the information life cycle "can be divided into four stages: introduction (creation), growth, maturity and decline." Bearing in mind this model, a future-oriented knowledge system should be able to manage pieces of information over the life cycle. An important feature of the retrieval process is to provide users with original information and additional information, and to consider additional information for the ranking process.

2. The Concept of xFIND (Extendable Framework for Information Discovery)

The xFIND system handles the information life cycle and fits into the concept of a knowledge management environment. Because of platform independence xFIND is implemented in Java. In order to achieve scalability xFIND is splitted into following three main parts: the Gatherer, the Indexer and the Knowledge Broker.

The **Gatherer** performs the task of visiting servers and gathering information from various sources as well as pre-processing the document data. It identifies a wide range of data like title, keywords, links, images and other embedded objects like Java applets. It also creates an electronic fingerprint of each information object. Fingerprint satisfies the need for trustworthy information in case of replication and allows detecting the origin of every piece of information. xFIND allows a wide range of configurations for pre-processing this data as well as handling meta data sets (Dublin Core [Weibel et al., 98], LOM [Hodgins et al., 98] and a special xFIND set) and their conversion to each other. Best performance and reduction of server and network load can be reached by using a local Gatherer. Local Gatherer can be configured to search for read-protected information. The Gatherer gets only a subset, original information remains protected. Furthermore, highly dynamical information can contact xFIND and external systems for information may be taken into account.

The pre-processed data can be fetched or sent compressed to one or more Indexers. Any **Indexer** may be specialised on a particular topic or can be dedicated to a work group or a department. Only authorised Indexers are allowed to operate with Gatherers. The Indexer's task is to allow the Knowledge Broker to assign words, phrases and meta data to documents, and to provide statistic data (e.g. term frequencies). It also contains descriptions of information sources (e.g. web areas) or documents, and it manages the communication with external systems (external information bases, rating systems, ACF, archiving systems, etc.). The later, if trusted, are allowed to send additional information to the xFIND system or can inform the xFIND system about new or modified pieces of information. xFIND allows replication of one Indexer to arbitrary other ones. Fingerprints (public and private keys) for all pieces of information will guarantee original documents.

The starting point for user interactions is the **Knowledge Broker**. It is also considered as the main part of the whole system and designed for a distributed concept. Knowledge Brokers distribute their search queries to a particular set of Indexers corresponding to the current problem as described below. Furthermore, past search results and user ratings may be considered to improve future search queries and the quality of information. Knowledge Brokers can be specialised on a particular topic and are able to transform the employees' problems into proper search queries. Knowledge Brokers can be individually tailored for a division, a department, a group of employees or even for a single user. This includes a specialisation of Knowledge Brokers that satisfies the needs of a particular unit (e.g. a small research group or sales division). The system also provides a Personal Knowledge Broker. Quite similar to an agent system the Personal Knowledge Broker is adaptable to user habits and their current problems. Combining it with an ordinary web browser, additional information can be provided (quality ratings, annotations, similar documents, dynamic generated links, etc.).

3. Conclusions and Future Work

The introduced xFIND system is a step to the next generation of knowledge processing and opens a way from information society to knowledge society. The systems distributed architecture leads to scalability and efficiency. First experience shows interesting application in the business (e.g. decision-making process). In the field of WBT the system introduces new paradigms of combining static and dynamic information repositories. Further development of the system deals with the usage of software agent systems and automatic classification.

TEAM 21: A Framework for the Total Enterprise

Dr. D. Charles Hair, iBASEt, San Diego, CA, USA, charles@tsiusa.com
Timothy Martin, iBASEt, San Diego, CA, USA, timothy@tsiusa.com
Dr. Yanhe Jin, iBASEt, San Diego, CA, USA, yanhe@tsiusa.com

Abstract: TEAM 21 explores a methodology for enabling computer and business experts to work together to create systems that automate the information needs of the enterprise in a framework that is faithful to the business model of the enterprise. Development is focused on rapid prototyping to quickly enable a cross-fertilization of ideas between the business and technical experts involved in development. The approach emphasizes simplicity in the sense that final systems provide the functionality that is needed, and no more. The emphasis is also on use of a transaction-based, federated architecture that results in modular systems that are scalable, modifiable, and reusable.

1. Overview

The current focus of much work in the e-commerce area is on putting in place on-line stores to sell products to customers. The appeal of that approach is that anyone, anywhere, with a Web browser can access the store and make purchases. The same benefit can be realized to institute more complete enterprise information solutions that facilitate employee transactions within the enterprise, business-to-business transactions, and division-to-division transactions. On-line approaches provide a direct means for establishing paperless business transactions. This approach leads to new ideas for restructuring business transactions so that transactions can be processed more quickly and accurately.

In order to realize the full benefits of an Internet-based approach it is necessary to go beyond simple order taking Web applications and look at a full range of transactions involving sophisticated business modeling and database needs. Technical expertise is needed to make use of the computer related capabilities available over the Internet, and at the same time business expertise is needed to faithfully model the enterprise.

2. Problems

The principal problem in using the Internet as a vehicle for complex business transactions is that the Internet protocols were not designed to support such transactions. The Web environment was designed to provide access to on-line documents. In order to support a rich commercial environment it is necessary to overcome some critical shortcomings related to the stateless environment of the Web, the lack of direct support for high level constructs, and the need for security.

A variety of new possibilities are being developed for overcoming the shortcomings of the Web environment. All of the new approaches bring some benefits, but it remains true that the goal of completely automating an enterprise's information needs is often exceedingly complex and expensive. It is not unusual to see potential enterprise solutions offered for prices beginning at \$250,000 and for installation periods beginning at six months. Moreover, problems still exist in installing actual systems both because installation experts often do not understand the real needs of the enterprise, and because the business experts do not understand the real capabilities of the available technologies.

3. Simplifying the Process

We have been exploring a methodology aimed at reducing the overall complexity involved in building and deploying enterprise level solutions for Internet-based business transactions. There are three basic thrusts of the methodology. First, there is a separation between the inputs from the business domain experts and the technical experts. This separation means that business experts can control the business aspects of the system without interfering in technical decisions, and vice versa. Second, there is an insistence on only providing the functionality

needed to perform specific business tasks rather than trying to provide all functionality that might be required for any business tasks. Third, there is an emphasis on making use of existing tools and applications rather than on replacing or replicating what already exists in the enterprise.

3.1. Separation of Business from Technical Aspects

In order to keep the business and technical inputs separate, we use an architecture in which the business experts are provided with a separate administrative tool that lets them specify the business processes. The business processes are specified through an interface that lets the user directly lay out the relationship between the activities that are supported by the system and the roles that users of the system can have. User roles are defined in terms of the set of activities associated with a particular role. Activities are defined in terms of business transactions such as entering or approving orders, generating reports, or responding to requests for data.

As the business experts work on refining the business processes, the technical experts can use that model to learn what capabilities the system needs to support. They are also then in a position to suggest and demonstrate technological possibilities the business experts may not be aware of.

3.2. Limited Functionality

TEAM 21 emphasizes a transaction based approach. Each transaction can be used in a system independently of other transactions. That modularity means that systems can be put in service incrementally as each transaction is built.

The TEAM 21 approach begins by defining the business process with a view to identifying the precise functionality that is needed. Systems are then developed to provide only that needed functionality. These systems are developed through rapid prototyping so that end users of the system can make actual use of the system as it is developed, and they can provide constant feedback as to whether their needs are met.

3.3. Use of Existing Tools

Two problems arise when existing tools are replaced. One problem is that costs go up, especially when substantial work is required to replace such tools. The second problem is that users are often required to expend substantial amounts of time learning to use the re-implemented system, when they already understood the existing system and were fully satisfied with it. The TEAM 21 methodology stresses the continued use of existing tools.

Because TEAM 21 focuses on a methodology instead of on a comprehensive new product, resulting systems can make use of whatever products are currently available to solve particular problems. The flexibility presented by this methodology means that the best available approaches can be used to solve particular needs. This flexibility is often missing in other approaches where a particular set of tools must be used as an integral part of a new application.

TEAM 21 is able to fuse a wide variety of existing tools and technologies into a loosely integrated whole because it relies on a federated architecture. The architecture is designed to loosely tie a variety of pieces together such that pieces can be used independently from the overall system, and such that each piece can be changed with little or no impact on the overall system.

4. Conclusion

The work on TEAM 21 has focused on providing a methodology that addresses some of the problems inherent in developing Internet-based solutions for automating enterprise-wide business processes. The approach we are exploring promises to provide a flexible means for providing enterprise level solutions at less cost than other current approaches. Gains are realized in part by providing a separate interface for specifying the business processes, so that business domain experts can input their expertise without needing to know about the technical details. That separation also allows the technical experts to easily make use of the business expertise. The focus in TEAM 21 is put on understanding and supporting existing business processes, rather than on building new functionality.

Demands on virtual teams and virtual leadership to support sustainable learning processes

Henrik Hansson
Viktoria Institute, Sweden
hh@handels.gu.se

Abstract: The objective of this paper is to discuss new organisations directed towards projects and teamwork, as well as how many of these functions can be enhanced, supported and, of course made better through the utilisation of Computer Supported Collaborative Work (CSCW). Thus making work and leadership less dependent on physical presence, i.e. time and space. This also increases the possibilities of global virtual teamwork, i.e. cross cultural work and management, in widespread organisations. This objective is met through research of the following functions: support of personnel, administrative tasks, taking part in the work process and strategic planning.

The outcome of the research project is ideas how the virtual team role is developed in organizing the work, how the team goes about daily routines, daily work, supports of personnel, administrative work, creation of a learning environment, as well as thinking and working strategically. This is created through the CSCW.

Background

The virtual team in its extended meaning is a rare occurrence, it is a social construction (Berger & Luckman, 1967), stemming of the possibilities with IT. In this article is however a small company presented that is coming close to what can be called the virtual team. Some work related to the proposed topic has been done within the research field of Computer Supported Collaborative Work (CSCW) (Ellis et al, 1991). The question this poses is: What are the demands on the virtual team and leader to support a sustainable learning process.

The paper is primarily argumentative, of course based on rigorous studies of teams and their relation to IT. The phenomenon competency is referred to as the ability to work together as a collective towards a task. Collective competency is conclusively the phenomenon of a group or organization of people's ability to work towards a common task in a sufficient way (Hansson, 1998). The interpersonal competence involves the relationship amongst the people in the team and the practical competence is directed towards the task of the team (Hansson, 1998). Roletaking is (Mead, 1969) in a sense the primary process of the team where the socialisation of the individual into the group. Sensemaking (Weick, 1995) is the process, which follows roletaking, and the meaning created in the sensemaking process is the basis for the action the group performs. In the different constellations we can see where the different groups were in the process of creating the joint meaning for action. Here, gestures, symbols and language are viewed as a carrier of roletaking and sensemaking (Mead, 1969), as it is through these media they are transferred.

The relation between time and space has come to be one of the more interesting aspects in that the action can always be referred to as having a place in the time-space matrix (Bergson, 1912; Mead, 1938). However, it can also be discussed in terms of temporal appearance as a process of emergence, sustaining, and diminishing (Hansson, 1998).

The methodology for studying the virtual company or virtual team elaborated in this article represents a variety of different methods, interpretative-interactionist best describe this.

The real business through virtual teamwork

The description of a small Swedish consultancy firm, is somewhat schematic although based on thorough studies of action research during a period of one and a half year. The presentation aims at giving a reference to the further discussion rather than aiming to be evidential in a stricter sense. The firm has a personnel force of five people in the core, and 3 more peripheral. What makes the firm virtual is primarily the fact that it does not have an office, one reason for calling it a virtual company. The common area for interaction is an extensive, well

utilized and official workspace where all activities are discussed, referred, developed and filed. Physical meetings do occur every other week where practical matters as well as strategic or policy discussions are brought up.

The intranet of this company is quite elaborate. The core of the intranet is a forum for discussion. Here the daily matters are discussed, posed etc. There is also a "customer space" where the more formal contacts with customers are presented. There is also an agenda of action, contacts to be made, thing to do, etc. As a basis for this work there is a structure called "webfolders" which is a database interface in the form of a file structure very similar to the personal computers own interface for file handling. The difference is that this webfolder is virtual in the sense it is connected to a server database. In spite of this it is as simple to use as the personal computer with features such as drag and drop, file hierarchies, accessible and restructurable for all.

Leadership and organizing the team

Recent studies of teamwork (Hansson, 1998) enhances the notion that amongst other things the leaders role is fundamentally different than a traditional functional leader, this becomes very obvious in the virtual team (Lipnack and Stamps, 1997). In fact the two roles of the leader represents two entirely different perspective, traditional leadership and empowering leadership. The empowering leader has come more into focus in recent organizational setting, especially when teamwork is emphasized. This type of leadership has increased the possibilities for enacting leadership in new ways, incorporating IT as a management tool to create sustainable learning processes within the organization.

The foremost principle for the virtual team is organizing. The discussion is not new, however, it was initialised by Weick as early as in 1969 (Weick, 1976). The reasoning here is grounded on the somewhat different process perspective of Bergson and Whitehead, Schutz and Mead are also involved in the discussion of organising principles of meaning and socialisation.

The thought of looking at the world from a temporal perspective is brought up i e from the perspective of asynchronous or synchronous events on the IT based learning process. Time as an organizing principle includes the practical competence being developed over time as well as the interpersonal revealing itself at a certain point in time.

A paradox has been observed in organizing groups with a proficient practical skill since they often emphasise their own development over the group's. The concluding remark of the above themes are concluded with leadership being important in organising teamwork, and can subsequently be summarised in a similar way where the leader needs to be able to be forceful on occasion, whereas in the daily process his task is to maintain the flow through support and encouragement of the process.

Design, Implementation and Operation of an Intranet-based University-Information-Management-System

Franz Haselbacher, Dipl.-Ing. (haselbacher@zid.tu-graz.ac.at)

Isidor Kamrat, Dipl.-Ing. (kamrat@zid.tu-graz.ac.at)

Andreas Passler (passler@zid.tu-graz.ac.at)

Boris Rohrbacher, Ing. (rohrbacher@zid.tu-graz.ac.at)

Computing and information services center, Graz University of Technology, Austria

Abstract: Most of the running university-information-management-systems are suffering from the lack of an up-to-date and well-designed data-model that includes all types of resources (personel, inventory, rooms, lectures, research-activities,...) and their relations between them. We have tried to set up such a data-model from scratch. As user-interface to that model we have designed an intranet-based application, that includes personal identification, the granting of functions to persons and the appointment of functions to specific program-modules that operate on different resources. This application-system can be operated without central management.

Outsourcing or not

We did an evaluation on outsourcing the whole systems design and implementation and came to the result that the costs for outsourcing are immense high. There are a only a few companies in Europe that offer commercial university-information-management-systems. There are still many constraints typical for austrian universities that cannot be parameterized in the systems and therefore have to be programmed additionally which makes the systems even more expensive. At the end we decided that the design and the implementation should be done inhouse.

The Entity-Relationship(E/R)-Model

The design of the E/R-model started from scratch. The whole E/R-model consists mainly of six sub-E/R-models with base-entities representing the base-resources, and the relations between them (see figure). The knowledge on the E/R-model gives the opportunity to act and react very flexible to requirements from the university by changing or adding entities, relations and their proper applications.

Figure 1: Entity/Relationship-model

The Application-Model

The application-model is designed in a very generic way, so it can be adapted to every universities needs. It consists of five embedded layers:

BEST COPY AVAILABLE

Figure 2: application-model

The whole model with its layers is integrated in the Entity-Relationship-model, with each layer as an entity and relations between adjacent layers. Below you get a description of the layers:

data: are entities and their relations representing the different resources.

programs: are applications that have access to the data.

roles: define privileges for programs. Each program is connected to one or more roles.

functions: define the way for an identified person to access data: identified person -> function -> role -> program -> data. A function is always connected to an organisation, that means a person gets a function only in relation to an organisation. The function called *Function-/PINcode-manager*: With this function a person gets the privilege to attach departments functions to persons, so he/she becomes the function-manager of the department.

identified persons: are real persons known to the system by unique usernames/passwords.

The proper organisation decides whether a person that belongs to that organisation gets an entry to the system or not. The Function-/PINcode-manager can grant a PIN-code to a person by Email. This Code allows the person itself to choose a unique username/password.

Abstract. This paper introduces a few WWW Hyperbooks for Teaching Electric Power Engineering produced at Tampere University of Technology. These books are the Electrical Network Book, Harmonic Book, Transformer Book and Electric Power Engineering Book. All books were programmed in HTML. The WWW hyperbooks have been used in the teaching of different courses at Electric Power Engineering.

1. Introduction

The development of WWW and multimedia based tools for teaching electric power engineering started in the 80's at Electric Power Engineering. At the beginning of the study a few multimedia and hypermedia applications were developed for teaching and learning electric power engineering.

Hypermedia programs, HyperLecture, Harmonics and TraLab96, have been developed with Asymetrix ToolBook for teaching electric power engineering. HyperLecture was designed for lecture teaching on electrical machines and transformers. HyperLecture contains four different parts: transformers, synchronous machines, asynchronous machines and direct-current machines.

The TraLab96 hypermedia program was developed after HyperLecture for teaching and learning about transformers. The program is divided into three modules: the theory module, the experiment module and the design module. The purpose of the theory module is to introduce the present curriculum on single-phase transformers by means of hypermedia. Experimental calculations can be made on interactive pages of the experimental module. The design process of the distribution transformer was also made into the form of hyperbook in the program.

Nowadays, the effect of the Internet on all information and communication increases continuously. This has meant that, more or less, the focus has moved towards Internet and WWW applications. Therefore the focus has moved to making WWW programs. For example, interactive calculation exercises are available at WWW server of Electric Power Engineering. The aim of this paper is to present new Internet based WWW hyperbooks for supporting teaching of electric power engineering at TUT.

2. WWW Hyperbooks

Electric Power Engineering has at the moment four WWW programs available at the WWW-servers of TUT. They are (in chronological order): Electrical Network Book (<http://www.tut.fi/~korpinen/ALKU.HTM>) (in Finnish), Harmonics Book (<http://svt.ee.tut.fi/harmo/eng/harmoeng.htm>) (in English and Finnish), Transformer Book (<http://svt.ee.tut.fi/transformer/>) (in English) and Electric Power Engineering Book

(<http://svt.ee.tut.fi/svtopus/pruju.html>) (in Finnish). All the WWW hyperbooks have a somewhat different structure.

The Electrical Network Book (in Finnish) was designed for supporting the course, which handles power systems. The course belongs to the subject studies of Electric Power Engineering. The course contains, e.g., calculation of transmission and distribution networks, short circuit and earth fault issues. The Electrical Network Book includes four main parts: electric networks, voltage drop, losses, and faults. The faults include calculation of three-phase short circuit and earth fault. Information structure in this book is not very suitable for self-studying. The book has been created in HTML containing 60 files.

The Harmonics Book was created based on the previous study about power system harmonics. The Harmonics Book was designed in HTML for students of electric power engineering who have a basic knowledge of electric power systems. The Harmonics Book supports the Industrial Power Systems course, which belongs to subject studies of Electric Power Engineering. The program helps to become familiar with the phenomena related to harmonics and presents methods on how to get rid of harmful harmonics.

The Transformer Book (in English) was created based on theory sections of TraLab96 hypermedia program. The Transformer Book supports the Switching and Control Devices, and Power Engineering Project Work courses, which belong to subject studies of Electric Power Engineering. The Transformer Book contains the basics of electromagnetics, distribution transformers and current transformers.

The most recent WWW hyperbook in the series, Electric Power Engineering Book, (in Finnish) contains the basics of electric power engineering. This WWW hyperbook was created based on a textbook written for the "Introduction to Power Engineering" course. All students of the department of Electric Engineering (about 200) take this course in their second year. The course includes lectures, exercises and laboratory works. Students can also use the WWW hyperbook later to revise their information when they need it.

3. Discussion

Four WWW based hyperbooks for teaching on electric power engineering have been developed at the Electric Power Engineering at Tampere University of Technology (TUT). They are Internet based applications and they were programmed in HTML. This makes them easy to access for the students. At Electric Power Engineering, TUT, the WWW hyperbooks have been used in the teaching of different courses. The experiences from new computer based teaching tools have been mainly positive.

Presently, the WWW hyperbooks are mainly hypertext books, but they can be further developed to be more interactive. For example, some kind of exercises can be used for expanding WWW hyperbooks to be more interactive. Appropriate exercises could be added in suitable places in the WWW hyperbooks.

The new teaching tools have possibly offered a variety for students and also given additional information besides traditional lecture teaching in the classroom. The WWW hyperbooks are also suitable for self-study purposes.

In addition to being used for teaching at TUT, the hyperbooks can be used in other places as well. The hyperbooks are freely accessible on the Internet. In this way they can be used for example after graduation to revise necessary information. The Internet is also a good channel for extension and continuing education.

In conclusion it can be said that based on experiences and feedback the developed teaching tools have been useful, and they are worth further developing in the future. Continuous improvement of WWW tools also promotes further development of the WWW hyperbooks.

Bleeding on the Edge II: Instructing with Live Audio, Video, and Text over the Internet

Jeffrey B. Hecht
The Technological Innovations in Educational Research Laboratory
Campus Box 5900
Illinois State University
Normal, IL 61790-5900 USA
jbhecht@tierlab.ilstu.edu

Abstract: A recent master's level delivered live audio, video and text over the Internet. This course combined two sections: one located in front of the instructor, and the other with students in several remote cities. All classes were video encoded over the Internet using RealVideo software. Remote students would point their web browser to the class site, viewing textual and graphic content in the browser while simultaneously listening to and watching the instructor using RealPlayer. Remote student questions were communicated with the instructor over a web-based chat room, and students in both sections interacted in an out of class, on-line discussion board. All classes were also videotaped, then digitized on the server for later viewing by all students. Difficulties were minor and both local and remote students reported being pleased with this method of instruction, although instructors need to be aware of the benefits and drawbacks.

Background

The Department of Educational Administration and Foundations, a graduate-level unit of the College of Education at Illinois State University, has as one of its primary missions the preparation of educational leaders in public schools. Accomplishing this mission often requires teaching courses off campus. One particular off-campus cohort draws students from a wide geographic area located loosely around the Quad Cities, approximately two and one-half hours from campus. That distance made weekly travel impractical. Intensive, multi-day weekend sessions were examined as an alternative, although certain courses do not adapt well to this delivery format. Dedicated-line compressed video is a popular options except that these off-campus students – all working professionals – were hard pressed to all have a common day or evening to meet, together with each being physically located up to two hours from the others. Asynchronous Internet-based (web) instruction has also been used in other subject areas, although there was some concern about teaching a master's level, qualitative research class (with all of the introspection and discussion that goes with such a course) solely asynchronously. Compressed two-way audio and video over the Internet using CU-SeeMe had been used in a prior semester (a paper was presented on this experimental effort at WebNet 98 titled "Bleeding on the Edge: Experiences from Teaching a Multimedia-Rich Course over the Internet" by Hecht and Schoon). Unfortunately, this method proved less than completely reliable, and required a substantial investment in hardware and software resources, and instructor and student time learning complicated software, to fully realize. *Could another Internet-based audio and video solution be found that would work better and easier?*

An investigation was begun in the Spring of 1998 to search for alternative solutions, and several different products were experimented with. By mid-summer of 1998 one approach had been chosen, and the necessary software (RealVideo and RealServer version 5) was purchased and installed at the University. The server software was loaded on a Dell Pentium-II computer having a 450Mhz processor, 192 Mb of memory, a standard monitor with 4Mb of video RAM, and two high-speed token ring connections running Windows NT version 4 (SP-3). One of the token ring cards was dedicated to providing the web (<http://>) services, while the other card was tasked with serving video ([pnm://](http://)) services. A second computer (another Dell running Windows 95) was equipped with an Osprey 100 video capture card. This machine served as the audio-video capture station, taking the feeds from the instructional classroom, encoding them as Real streams, and transmitting these streams to the server for distribution to the students. In addition, a Panasonic AG-5700 video deck was used to capture the audio and video to tape, where it was digitally encoded the next day and made available for asynchronous viewing by the students.

The first task facing the instructor was the setup, installation, and testing of the various hardware and software components. Different transmit band widths, audio and video codecs, and connection strategies were experimented with over the course of almost two months of trials. During the same time the instructor was reformatting courseware for this new model of delivery. To facilitate the evaluation of this course the instructor kept a daily diary, recording his observations and experiences. Students were encouraged to e-mail the instructor detailing their impressions, as were the technical staff assisting with the project and the graduate teaching assistant. These written records, together with records from the live chat sessions and class discussion board, were examined as the record of the course activities.

Results

The class began in mid-August of 1998 with the instructor visiting the remote students at a high-tech classroom located at a

college in the Quad Cities. During this session students were introduced to the technology of RealVideo, along with reviewing the basics of computer operations, web browser usage, and sending and receiving e-mail over the Internet. Almost all of the students were using Windows 95 systems, with only two using Macs. Student vacillated between Netscape's Navigator (version 4.xx) or Microsoft's Internet Explorer (version 4.xx) as their choice of browsers. Most utilized Eudora as their e-mail program of choice, and RealPlayer (version 5) was required to view the class sessions. These remote students also received their first hour hours of content instruction in the qualitative research course.

One week later the actual semester started. On-campus students attended each session in a high-tech, distance education classroom, fully equipped with the latest in video, graphic, computer, and projection technologies. While this room was normally used for dedicated line, compressed video instruction, it turned out to be the perfect platform for this class as well, generating a clean video signal and distortion free audio for transmission over the Internet. This facility allowed the instructor to seamlessly switch between several different camera views of either himself or the local class, to display computer generated graphics or web pages, or to use a variety of different media devices (including: a document camera, video tape player, and white board). The room also had facilities for utilizing a laptop computer, and for integrating additional A/V inputs of varying types, something the instructor made frequent use of during the semester.

Remote students had the option to participate in the class live (synchronously), or to engage in the material (asynchronously) and watch the taped class session later whenever they wanted. Work commitments and local technical difficulties only allowed approximately half of the remote students to participate in each class live. Those students would typically have three applications running on their computers at one time: a browser window pointing to the class web site containing the textual and graphic content for that class; a second browser window open to the real-time chat room; and the Real Player program receiving the live audio and video feed. These students could then interact with the instructor and campus students by typing comments or questions into the real-time chat window. Audio/video buffering and student typing speed typically resulted in between a 20 to 50 second delay from the time a remote student would hear something on the Real Player and when the instructor would receive back a comment or question on the chat.

Surprisingly, all of the classes were held without any technical difficulties! The encoding and server software performed exactly as advertised, operating for 15 full three hour class without any crashes or interruptions. Remote students occasionally reported the Real Player "locking", a condition that was easily solved by restarting the player application. Likewise, the chat software worked quite well. A graduate teaching assistance in the campus classroom handled typed communication with the remote students, verbally passing their comments and questions on to the instructor. This method proved quite effective, as the G.T.A. often was able to respond to non-content questions (e.g., technical, assignment, etc.) by typing a response back into the chat without interrupting the instructor or the flow of the class. All of the distant students, and many of the local students, reported watching one or more of the taped classes on-line after the fact, either because they were unable to participate in the live session, or (more interestingly), because they wanted to brush up on something that wasn't fully understood during the live class. This taped class feature proved to be the most popular of all the technology options to both sections of students!

Conclusions

Real Video was a relatively easy, straightforward system to set up and operate. The various components (live encoder, server, and player) all performed exactly as their specifications described. This allowed off-campus students to watch and hear a live classroom feed and to participate, though a typewritten chat window, in real time with that class. Very little computer expertise was necessary on the part of the student, although the instructor did invest a significant amount of time and energy redesigning his course for this new method of delivery. The off-campus students enjoyed not having to come to campus for their instruction, yet being able to participate in the classes from wherever they were located. The on-campus students were able to interact with their off-campus counterparts through the chat dialogue, and appreciated the on-line video tapes of class sessions for asynchronous use. While some specialized hardware (e.g., a video capture card) is necessary to conduct a class in this way, it is not nearly as expensive nor technically difficult as other means of distance education. Overall, this class demonstrated the ease with which synchronous audio and video could be delivered over the Internet. Although not appropriate for all kinds of instruction, this method is a viable means for those wishing to expand their distance education capabilities in an easy, relatively low cost way.

Web Pedagogy: Extended Seminars on the World Wide Web

Pentti Hietala
Department of Computer Science/TAUCHI Group
University of Tampere, Finland
ph@cs.uta.fi

Abstract: The new opportunities offered by computer networks require new kind of pedagogical thinking and course organization. The way to do it - web pedagogy - is still in its infancy, but what is already evident, is that learning on the World Wide Web calls for fearless re-evaluation of the current pedagogical practices. In this paper we introduce a course format where the World Wide Web turned out to be crucial for the success of the course. The new technology via a computer conferencing and groupware system brought together two groups of students from two locations geographically separated by 100 kilometers. The course organization pedagogically emphasized the synergetic features of the face-to-face and Web learning.

Web pedagogy is much more than teachers just knowing how to set up and use, for example, an IRC, FTP, or a conferencing software service. Moreover, using these technologies on the margins of serious instruction is seldom enough. Unfortunately, the Web is often only an "add-on". For example, [Althausser & Matuga 1998] report that "creating a computer conference but not requiring students to participate characterizes roughly 50% of the conferences established each year at Indiana University". Indeed, Web pedagogy comprises besides careful and conscious selection of appropriate Web tools also a lot of "know-how" in orchestrating their use in order to foster student learning. The new situation seems to call for fearless re-evaluation of the current pedagogical practices. Recently innovative ways emphasizing creative, critical and collaborative activities for the learners have been suggested [Bonk & Reynolds 1997]. However, not all that is old have to be useless in the new Internet world. Instead, "pedagogical re-engineering" of old courses is needed, e.g., in the ways outlined by [Collis 1996].

In this paper we introduce one way of "re-engineering" and extending university level seminar type courses. Face-to-face seminar discussions in computer science tend not to be very lively, and it is hard to continue them afterwards. We wanted to extend the traditional seminar sessions with special "pre-seminar" Web discussions. What made this specific course called "Internet-based learning environments" in autumn 1997 especially interesting was the fact the course at our faculty was linked to the same course given concurrently at the Teacher Education Faculty at a neighbouring town (in-service teachers extending their information technology studies). Now an idea arose to team up one in-service teacher with one student majoring in computer science. The problem here was how to get them to select their topics and facilitate them to do together the Web part and the face-to-face seminar presentation part? Our conferencing system came here to rescue [see Hietala et al. 1997].

Same number of students from these two locations was admitted to this course, altogether 36 students. The conferencing system allowed them to select the seminar topics they were interested at first-come-first-served basis. The "matching" of one in-service teacher and one computer science student was entirely carried out on the Web - we hoped that similar interests brought them together. Besides being active as a moderator (and a seminar presenter) in one topic the students were also required to select two topics to act as a designated commentator in these topics. After obtaining a partner to their work they made contact, mostly by e-mail but sometimes also by telephone, and started the work. The first thing to do was to prepare and publish their initial thoughts on their subject - in other words, to start to moderate a discussion thread within our conferencing system.

The students received guidelines how to act as a moderator: they were advised to carry out a free and open-minded discussion on their topic. The face-to-face seminar presentation, on the other hand, was required to be a more focussed. Its main purpose was to illustrate the main ideas of the topic by demonstrating one or two Web-based learning environments. The participants were encouraged to make use of the Web pre-discussions in their seminar presentations. The discussion period on the Web took five weeks and after that the face-to-face seminar sessions commenced. The in-service teachers were required to come to the computer science premises from the neighbouring town in order to give their presentation together with their partner. Many students reported this was the first time they actually saw their partner. Moreover, one session, comprising two seminar presentations, was carried out using video-conferencing facilities, the pairs presenting being 100 kilometers away from each other. These two pairs never met in real life!

In our opinion, the approach described above proved to be worth more experimenting. Credit must be given to the conferencing system. Our WWW-based discussion system that could be used anywhere through common Web browsers proved to be an easy-to-use and readily available tool also for those who used it for the first time. In addition, our system provided procedural facilitation for the discussions [see Hietala 1998]. Our course organization efforts were well received, too. The pre-discussion seemed to aptly support the actual seminar presentations, which turned out to be of good quality. As has been suggested from the theoretical point of view, the role of the lecturer changed from being the knowledge source and final solution provider to be more like a coach. The course organisation placed the students into peer teaching situations, and our students did take the responsibility. Students even wanted the discussions to be alive for a longer period than was planned, till the end of the course.

One difficult issue in the Web discussions is how to motivate the students. If discussions are not structured and no minimal participation is required, students tend to find something more important to do. Also during our course a few students “dozed off” and the lecturer had to send them private e-mail to get them back to commenting. Another problematic issue is how to grade the students. It was made clear from the beginning that both the content quality and the amount of student comments were essential for the grade. Nevertheless, one student expressed her dismay towards the activity measures (the number of comments in the Web discussions and in the seminar sessions was counted). Only the quality should be measured, both on the Web and in the classroom, she said. Indeed, we feel that the grading policy must be geared towards the quality of the comments instead of the amount of comments made. However, it is very cumbersome for the teacher to follow all the discussions close enough. Although our conferencing software provides already several monitoring tools for the teacher, we think this will be one of the major development directions in the near future.

Context-Sensitive Filtering for Browsing on Web Pages

Tsukasa Hirashima

Dept. of Artificial Intelligence, Kyushu Institute of Technology, JAPAN, tsukasa@ai.kyutech.ac.jp
Toyohiro Nomoto, Noriyuki Matsuda, Jun'ichi Toyoda
ISIR, Osaka Univ. JAPAN

Abstract: We have proposed a method to model user's shifting interest from browsing history. We call the filtering method Context-Sensitive Filtering, CSF for short. This paper describes an application of CSF to Web, that is, Web FALCON that divides a Web page into several parts with HTML tags and applies CSF to the parts. We also report experimental evaluation of Web FALCON.

1. Introduction

Information filtering is an important function whose request is high to Web users. Web provides a lot of information and a user can use it easily. However, he/she often gathers too much information to deal with all of them by him/herself. Information filtering is a function to reduce information that a user has to deal with directly.

To select information that a user has interest in, modeling of user's interest is indispensable function. Several modeling methods of user's interest have been proposed, but most of them have assumed that user's interest stable. However, browsing or surfing, which are most popular ways to gather information on Web, do not satisfy the assumption. During browsing, user's interest often shifts depending on local context of the browsing.

We have proposed a method to model user's shifting interest from browsing history. We call the filtering method Context-Sensitive Filtering, CSF for short. A filtering facility using CSF has been implemented for CD-ROM encyclopedia, and effectiveness of the facility has been confirmed by an experimental evaluation by real users [Hirashima 98].

This paper describes an application of CSF to Web. The most important issue to apply CSF to Web is modification of Web pages. Each Page in the encyclopedia has one topic and adequate volume to read through it briefly. The two characteristics are required by basic guideline to design well-formed hypertext. Effectiveness of CSF depends on these characteristics of the pages. In Web, however, one page often has several topics, or too much volume. Therefore, to modify Web pages is necessary to apply CSF to Web.

In this paper, We introduce Web FALCON that divides a Web page into several parts with HTML tags and applies CSF to the parts. We also report experimental evaluation of Web FALCON.

2. WebFALCON

2.1 Issues to apply CSF to Web pages

In user modeling of CSF, it is assumed that when a user visits a node and accepts the node, the user is interested in the content of the node. CSF is effective for CD-ROM encyclopedia because the assumption is suitable for the pages. When one node has several topics or too much volume to read it, a user often read a part of the page and does not read the rest of it. The part that the user does not read is noise for user modeling. To use CSF to WWW pages, modification of them is necessary.

In this section, we propose a division method of the pages by using HTML specification. Every Web page is written by HTML that is a subset of SGML. These are specifications to give a structure to a document. In other words, a Web page has a structure following HTML specification. Division with HTML tags is promising method to reduce noise for user modeling though it is not perfect.

2.2 Modification by HTML tags

By using HTML specification, the content of a page can be divided into several document blocks. Each Heading divides a part into several smaller parts. The lowest Heading makes the leaf document block that is semantic unity. This leaf document block is a divided page that is dealt with a page in CSF. Indexes of the divided page should be generated not only by the content, but also by the upper structure in the tree.

2.3 Interface

Interface of WebFALCON consists of four windows: Search Window, Selection Window, Page Window and User Modeling Window. First, a user can set an index as a keyword for retrieval in Search Window. A list of pages

including the index is shown in Selection Window. CSF performs for the ordering of the pages. By clicking a page in Selection Window, the content of the page is shown in Page Window. Here, when the page is a part of a Web page, the whole page is provided to the Page Window and the part is shown at the head of the window. User Modeling Window is used to acquire parts that a user reads and accepts. Current version of WebFALCON asks the user to input the sentences by dragging and copying. Figure 1 shows Search Window, Selection Window and User Modeling Window.

2.4 Experimental Evaluation

To evaluate the effect of the division of Web pages, we compare performances of WebFALCON for two types of hypertext, one is composed of divided pages and the other is composed of undivided pages. The former database includes 11,702 undivided pages and the latter database includes 50,633 divided pages. The divided pages were generated from the undivided pages by using HTML tags. Then, CSF(here, $r=0.6$ in Equation-2), was compared with other two ordering methods, (b) $r=0$ (browsing context is not considered) and (c) $r=1$ (every page has the same influence to the current user interest). We ask twelve real users to browse with WebFALCON. Each user browses every combination, that is, six times.

The results are shown in Table 1, 2, 3, and 4 (scoring procedure is the same one referred in [Hirashima 98]). CSF for undivided pages, is not significantly better than other methods, but for divided pages significantly better. These results mean that CSF is effective for divided Web pages by using HTML tags, although it is not effective to raw Web pages.

3. Conclusion Remarks

This paper described a project to apply CSF for browsing in Web pages. CSF is based on well-formed hypertext, such as CD-ROM encyclopedia. To realize CSF for Web pages, modification of Web pages is required. We confirmed that CSF performed effectively by dividing Web pages with HTML tags. Improvement of division methods and large-scale experiment of WebFALCON are our future works.

Experiences with Real-time Streaming Audio/video in Delivering Web-based Courses

Thomas I. M. Ho
Department of Computer Technology
<http://www.engr.iupui.edu/cpt/>
Indiana University Purdue University Indianapolis
USA
tho@iupui.edu

Abstract: Over two years of experience with the application of real-time streaming audio and video (RealAudio/Video) to Web-based courses has yielded a wealth of experience in synchronous delivery of live instructional content and asynchronous delivery of archived content. Outcomes include:

1. Live broadcast
 - a. Audio/video lecture content
 - b. Visual aids "pushed" to remote viewers
 - c. Chat feature for remote audience participation
2. Archived lectures with the soundtrack synchronized with the Web pages displayed during the live lecture (Synchronized Multimedia)
3. Multimedia annotations of Web page links including:
 - a. Explanation of examination questions and answers
 - b. Motivational messages to explain Web pages
 - c. Oral instructions for assignments

An example of a course with these features can be found at: <http://oncourse.iu.edu/in/> (select semester Fall 1999, enter "B684" for "Find a course" and log in as guest)

Products of this experimentation include:

1. User interfaces for:
 - a. live broadcast
 - b. archived lectures
2. Productivity tools for:
 - a. constructing Synchronized Multimedia content
 - b. creating voice annotations
 - c. Economical classroom premise equipment for originating live broadcast and encoding archived lecture

What is RealAudio/Video?

The RealNetworks Basic Server, RealEncoder, and RealPlayer comprise the RealMedia System created by RealNetworks (1997). The RealNetworks Basic Server streams files created with the RealEncoder to *free* RealPlayers on sound card-equipped personal computers, which continuously decompress the audio and play it in real time without download delays, even over 14.4 Kbps modems.

RealAudio has been widely deployed on the World Wide Web especially to distribute news and music as described at the RealGuide (1998) site guide. More recently, RealVideo has added video capability to RealAudio within the RealMedia architecture. Educational applications have become more common and examples can be found at RealNetworks' (1998) education page.

Experiments with RealAudio

Beginning in September 1996, Introduction to Data Processing (CPT 115) broadcast lectures *live* from Indiana University Purdue University Indianapolis (1996) via RealAudio. In addition, the lectures were archived on the Web site. As a result of this audio content being available, the Web site was significantly enhanced by the addition of voice annotations and oral instructions for assignments. Voice annotations were used to provide motivational messages to explain Web pages such as the one at: <http://www.engr.iupui.edu/cpt/courses/cpt299/1997fa/itaitads.html>

During the Spring and Fall 1997 semesters, Internet Skills (CPT 299) at Indiana University Purdue University Indianapolis (1997) continued the experiment by using Synchronized Multimedia to synchronize the lectures with visual aids on Web pages. Most of the lectures on: <http://www.engr.iupui.edu/cpt/courses/cpt299/1997fa/tcs.html> have been synchronized. An example of Synchronized Multimedia by Thomas I. M. Ho (1997) explains this experiment in greater detail. To *experience* it, one will need:

- A personal computer with sound card
- An Internet connection with a speed of 14.4 Kbps or better
- RealPlayer 5.0 (free to download from the RealNetworks Web site at www.real.com)

In addition, voice annotations were used to explain examination questions and answers on: <http://www.engr.iupui.edu/cpt/courses/cpt299/1997fa/tcs.html>

BEST COPY AVAILABLE

Experiments with RealVideo

Beginning in January 1998, Electronic Commerce (CPT 423) broadcast lectures *live* from Indiana University Purdue University Indianapolis (1999) via RealVideo. Origination of live broadcast and archiving were accomplished via the ClassCast project developed by the CyberLab (1997). In addition, the archived lectures were significantly enhanced by the addition of "highlighting" which draws the students' attention to lecture segments that the instructor emphasizes because they are important and likely to be tested in examinations. A red bar that appears above the visual aids that are synchronized to the sound track indicates highlighting. As a by-product of these "highlighting" events, the important segments are indexed in the archived lectures so that these segments are then subsequently hyperlinked to the correct responses in the examination key so that the student can play back the video clips in which the answer to the corresponding examination question was given. RealVideo requires an Internet connection with a speed of 28.8 Kbps or better.

Results of experiments

Products

The major products of this experiment include:

- User interfaces
- Productivity tools

User interface for archived playback

The primary user interface has been developed for playing back archived lectures synchronized to the Web pages displayed during the live lecture. An example at:

<http://weblab.iupui.edu/cpt/archive/archive.asp?course=499&sem=fall1998&sec=B554&date=0923&start=1:0:0&end=01:19:0.0>

demonstrates the controls for the video/soundtrack with a frame for displaying the synchronized Web pages and another frame for displaying the highlighting visual cue.

User interface for originating live broadcast

The live lecture is broadcast to remote viewers via the ClassCast user interface [Williamson, 1999] with the following capabilities:

- Delivery of audio/video content
- "Pushing" Web pages displayed to students in the classroom
- Chat to enable remote viewers to ask questions and to participate in classroom "discussions"

A notable contribution of the ClassCast user interface for the instructor is its ability to "time-stamp" each mouse click while "pushing" Web pages to remote listeners. This capability has greatly facilitated the creation of event files for producing Synchronized Multimedia versions of the lectures for archived playback!

Another notable outcome is the fact that an ordinary classroom was equipped with the ClassCast originating equipment for *only* about \$20,000! For this modest amount, this classroom can serve a *global* audience!

Another capability developed by the CyberLab (1998) is NetCast which enables RealAudio content to be originated (broadcast live and archived) from *anywhere* via telephone. This capability is convenient for originating lectures from home when the instructor is ill or even for delivering conference presentations at remote locations without traveling to the conference venue. Although NetCast is conceptually similar to the original RealAudio origination capability, NetCast has the additional capability of scheduling the encoder via the World Wide Web as well as equipping the encoder with "auto answer" rather than requiring human intervention to answer the phone when initially connecting to the encoder.

Experiences

This experiment has demonstrated that significant instructional content can be delivered via real-time streaming audio and video that can be received by a modest computing platform with no more than a 28.8 Kbps dial-up connection to the Internet.

An anecdote serves to remind us why it is so important for us to experiment! Our experiments with RealVideo have led us to consider whether RealVideo can be used practically to broadcast signing to reach deaf students. Remember that we first experimented with real-time streaming *audio* to enable us to reach students who could hear!

Innovative use of IT to support Competency Based Learning Paradigm – The Ngee Ann's Perspectives

TAN Hock-Guan(thg@np.edu.sg) & LUA Seu-Kea(lsk1@np.edu.sg),
Computer Based Learning Centre, Ngee Ann Polytechnic, Singapore

Abstract

Through the years, Ngee Ann Polytechnic, Singapore, has embarked, experimented and implemented several strategic initiatives to take advantage of the sophistication and advancement in Information Technology (IT) to enhance the teaching and learning environment on the campus. The lessons learned thus far have propelled the polytechnic into establishing innovative learning environment to support changes in education paradigm. This paper presents the Competency Based Learning paradigm and addresses how IT has been integrated to support the teaching and learning activities in a pervasive manner at the polytechnic. The conceptual model and framework for the implementation of the mentioned paradigm that make innovative use of IT will be presented. Key initiatives such as the use of Smart Lecture Theatres, Smart Laboratories, Computerized Tutorial and Assessment Classrooms, Multimedia Digital Repository, and Notebook Computing infrastructure will be discussed. The talk will report the findings on the impact of these infrastructures and their implications. The talk will also discuss and highlight the various problems encountered.

Introduction

The management of Ngee Ann Polytechnic advocated the notion of competency based learning paradigm to improve students' learning and instruction. The revolutionary approach aims to increase passing rate and to achieve a near zero or zero defects student population in the next millenium. Programme involved the use of IT has been put in place since April 1997 and there have been much encouraging results.

The Model

In the new education paradigm, all students must achieve a criterion set of competencies in the under-study module prior to the examination. By attaining the pre-specified criterion they would deem to have passed the module. This will then be served as a pre-qualification for them to take the final examination in the module, which would be used for grading purpose. In practice, this criterion set is generally translated into marks scored by the students based on their performance on project works, assignments, laboratory works, tutorials and/or tests. The percentage distribution of marks for the criterion would differ from one module to another.

Given that if all modules have been reviewed and re-designed to address the above and implemented accordingly, it is envisaged that the shift in paradigm towards competency based learning would improve passing rates and eventually contributes towards the objectives of achieving a near-zero attrition rate. This also implies minimizing the number of repeating students for any single module. In principle, it is understood that majority of students who have studied, completed their tutorials and all other course works progressively would do well in the

module. This is based on the assumption that, during the process, learning takes place and that the students master what they have learned, develops the necessary skills and are able to apply them whenever necessary.

Information Technology Infrastructure

Key Information technology infrastructures such as Smart Lecture Theatres, Smart Laboratories, Computerized Tutorial and Assessment Classrooms, Multimedia Digital Repository, and Notebook Computing have been amalgamated into supporting the campus wide implementation of the new education paradigm.

The Smart Lecture Theatres enhance lecturers' presentation through the use of multimedia, gauge and pace their teaching to large groups through simultaneous feedback in real-time. The added benefit of this student-teacher interaction, mediated through the computer, is that students are less inhibited and more involved in the learning process. The Smart Laboratories or virtual laboratories provide students with the convenience of carrying out an experiment numerous times with varying parameters. Less time is spent taking measurement and calculating and leaving more time to focus on results and key concepts. The Computerized Tutorial and Assessment Classrooms are outfitted with powerful software systems enabling students to do their tutorials and assessments interactively. Students are not restricted to working on tutorials in the new classrooms but are able to access "electronic" tutorials from home or other remote sites. The Multimedia Digital Repository is a one-stop web site in which teaching staff could have access to shared multimedia components for developing their instructional materials. Likewise students could also access to them for their project works. To date, our classrooms have already fitted with network points and/or wireless point to support Mobile Computing communities on the campus. Such classrooms of the future could be located in such diverse places as a corner in a canteen or the library, as well as any other virtual environment that students and lecturers might gather.

Summary

The above summarized our competency based learning paradigm and provided a representative view on how IT has been adopted to support the implementation at our polytechnic.

Where To Build A Tide Power Plant?- Cooperative Learning On The Web

Ying-Shao Hsu, Department of Earth Sciences, National Taiwan Normal University, Taiwan, yshsu@cc.ntnu.edu.tw

Hung-Jean Wu, Department of Earth Sciences, National Taiwan Normal University, Taiwan, s44217@cc.ntnu.edu.tw

Chi-Chuan Chen, ARGIS Company, U.S.A. cchen@argis.com

Abstract

The article presents the implementation process of developing web-based courseware which was used to cultivate high school students' problem-solving and communication skills through cooperative learning. Students completed some exercises which help them learn the relative concepts of "tide" before they were grouped to solve a problem which presented energy crisis and required them to choose a place to build a tide power plant in Taiwan. Learning activities were delivered through web, and students' learning processes were tracked using network technology. Analysis of students' learning paths and communication protocols shed a light on how students sought and shared information in order to solve a problem.

Introduction

We are living in an era in which information virtually grows fast every day, work requires higher and higher information skills O'Leary, 1998 . Learning and teaching cannot come from books alone. The needs of learning include the ability to process information systematically, to read complicated diagrams, to solve problems effectively, and to communicate with others conveniently. To create a learning environment for these needs, a cooperative learning method needs to be embedded in a web-based courseware.

Three general cooperative methods are used in many research fields and adaptable to most subjects and grade levels: Student Teams-Achievement Divisions (STAD), Teams-Games-Tournaments (TGT) and Jigsaw II (Slavin, 1996). STAD is used in this study to promote effective learning. According to STAD, students need to help their teammates in order to make their teams succeed. The only way for the success of the team is for all teammates to master what they are learning. Students' achievement scores are added by individuals' scores and team score based on students' improvement over their own past records.

STAD was embedded in the web-based courseware. Although individuals' cognition, social contexts of learning tasks and cultural contexts affect individuals' learning (Bronfenbrenner, 1993), researchers can focus their studies on one or more levels at a time (Marshall, 1996). This study serves as a preliminary investigation of one Internet-accessible lesson based on a model of cooperative learning. The purpose of the study was to address how individuals' immediate social context impacts on their problem-solving processes.

Learning Activities

Once the conceptualization of learning is as a simple case of knowledge transmission from expert to novice. With a paradigm shift, the rationale for learning emphasizes the social construction of knowledge (Vygotsky, 1978). Cooperative learning increases dialogue among students and potentially promote students' comprehension and knowledge. Networks can provide a powerful means to surmount the barriers that make shy or slow students fail to communicate with others. A web-based lesson, named "Where to build a tide power plant?", has been developed to support cooperative learning. This lesson allows students to explore the relative concepts about tide using raw data and animations. After complement of several exercises, students work on a project cooperatively using tide data and geological information of several locations in order to make a decision where is the best place to build a tide power plant in Taiwan. Since there is no fixed answer for this problem, students' tasks are to provide enough reasons and explanations about their final decision. Learning activities were delivered through web, and students' learning processes were tracked using network technology. The records of students' learning paths and communication protocols help researchers understand how students sought and shared information in the problem solving process.

Conclusion

The strength of this study is to design a cooperative learning environment using network techniques in order to cultivate students' problem-solving and communication skills. Higher ability students can help other students work on a project. The success of cooperative learning requires all members in a group to contribute their efforts. STAD counts the success of a team using the score based on students' improvement over their own past records. This motivates higher ability students to assist other group-mates master learning materials and reduces lower ability or passive students' frustration when they work on a complex problem alone. In order to keep engagement and motivation, a reward should be announced when students just starts their learning activity. Students who are not familiar with cooperative learning methods will not get optimal benefits from this setting. The training of communication skills and cooperative learning methods are needed before students use this lesson.

Modulo: Development and Evaluation of an Interactive Multimedia Education Concept for the Subject "Fundamentals of Computer Science"

AXEL HUNGER, STEFAN WERNER and FRANK SCHWARZ
Gerhard-Mercator University of Duisburg, Department of Data Processing, Germany
schwarz@uni-duisburg.de

Abstract: It is often criticized that university education is too inflexible and does not go enough into the needs of individual students. As part of the restructuring process of university education which includes using the new forms of media, a new education concept for the vocational teaching profession "Computer Science" is presently being developed at the Gerhard-Mercator University of Duisburg. The aim of the MODULO Project is to create new possibilities of differentiated and decentralized learning. The new didactical concept of this course should take the different learning needs of the students into account. Therefore a teaching concept has to be developed which considers the heterogeneous educational background of the students and also offers students different degrees of preparation, accompaniment and practice. Finally the new didactical concept should promote a media competence for the to-be teachers, which is based on multimedia related learning and teaching methods, so that these contribute in their later practice to new teaching and learning forms.

Introduction

The subject "Fundamentals of Computer Science" at the Gerhard-Mercator University of Duisburg is an important basic offer for different degree courses, for example the German "Diplom Ingenieur" course "Electrical Engineering", the vocational teaching profession "Computer Science" as well as the new Master of Science degree course "Computer Science and Communication Engineering" which was introduced in the winter-semester 1997/1998.

Since every student has his own learning needs, the basic knowledge of computer science varies dependent on the students background. The vocational teaching profession especially deals with students of different background. The professional field "Computer Science" can be chosen as a secondary or specialized professional field with the combination of different main professional fields, for example mechanical engineering, chemical engineering or professional fields like textile and clothing engineering. Likewise students who are enrolled at another university have the possibility to take their secondary professional field at the Gerhard-Mercator University of Duisburg.

Taking this facts into account, a teaching concept has to be developed, which

- considers the heterogeneous educational background of the students,
- offers students different degrees of preparation, accompaniment and practice
- and gives students who are not enrolled at the Gerhard-Mercator University of Duisburg the chance to follow the courses at home, and thus reduce the need of travelling to a minimum.

Students following technical courses and especially those who are following a teaching profession, need to deal with multimedia teaching and learning methods. Furthermore, it is expected these to-be teachers have already acquired a media competence during their university education, so that they are able to handle new teaching and learning methods using the new media.

Concept and Structure

The concept of the interactive multimedia teaching and learning software is built up in such a way that the different learning methods of the students are taken into account. It is build in a modular way in order to obtain the possibility to adapt it to new needs. This concept follows a general set up, implementing the subject

structure or script of the lecture "Fundamentals of Computer Science". Here the theories and methods are imparted, for example switching algebra, finite state machines or micro-programming. Starting with some basics the topics are presented in a linear way. There are also links between all topics, but this is more or less a linear structure. Every topic holds some graphics and interactive animations for explaining and illustrating the contents. Multimedia based animations can explain technical things often better than a textual description. This is the traditional way of developing multimedia based teaching software. In addition this concept contains an exercise module, where students have the possibility to test and apply the learned methods. So the students also have a self-control. The exercise module is directly linked up with the script module.

The innovation of this concept is the third module, which represents a second starting point of the learning software. This so-called scenario enables a learning goal oriented or rather problem based learning by offering a structure which is based on an example taken from a real life development. Here, for example the development of a production robot is given as a task. The scenario is linked again to the exercises, but not in a linear way like in the script, but based on the problem given through the task. This form of learning should provoke curiosity and activates the educational background of the students. It is again possible to switch from the exercise to the script module in order to look up necessary information. For each main professional field a scenario will be developed, so that the students can identify themselves with it.

In addition to this concept, an information system is developed, which is supposed to deepen and strengthen the knowledge concerning the already mentioned emphasis. It includes a glossary of the most important technical terms, some data sheets as well as pictures and videos of the production and use of IT-components.

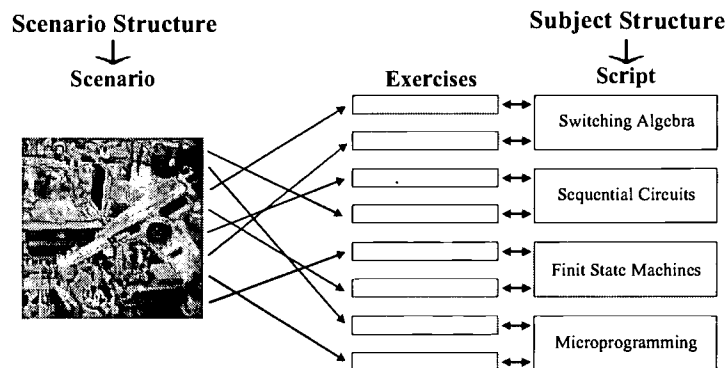

Figure 1: Structure of the MODULO Concept

Students are used to work with heterogeneous platforms like Windows 95/98, Windows NT, Apple Macintosh or Linux. That's why the implementation of the software is done by HTML in combination with JavaScript and Macromedia Director. This ensures platform-independence and enables the access via the internet. The user just needs a Java Script-able browser like Netscape or Internet Explorer Version 4 or higher with an installed Shockwave plug-in.

Conclusion and Prospect

In this paper a new concept for the support in the teaching of the subject "Fundamentals of Computer Science" was presented. The aim of this concept is the media technical processing of the course, the development of suitable scenarios and the development and implementation of a WEB-Database with dynamic access. This concept allows, thanks to its modular design, to go in on the individual requirements, states of knowledge and learning methods of the students. It allows a self-controlled learning, promotes media competence and offers comprehensive possibilities of acting. The modules can be adapted easily to respective requirements. The scenario is exchangeable and can be adapted for each professional field. A first development phase accompanying evaluation leads to positive results and constructive criticism. The complete system should be ready by September 1999 so that an extensive evaluation can begin during the winter-semester of 1999/2000.

Creating a Web-Based Learning Community: CalState TEACH

Abstract: Governor Gray Davis and CSU Chancellor Charles B. Reed unveiled CalState TEACH April 28 in Sacramento. CalStateTEACH offers a new approach to earning a California teaching credential by addressing the needs of the 15,000 California elementary teachers now working with emergency permits. Tailored to meet the problems of working teachers with scheduling difficulties, family commitments and limited time, this visionary program combines print material, tapes (audio and video), email and the Internet and periodic Saturday seminars with field-based learning in elementary classrooms with support from CSU faculty. Modeled after the successful British Open University, the CalState TEACH curriculum was designed by a team of 30 CSU faculty members from virtually all CSU campuses to prepare working teachers to meet California teaching standards. This paper highlights the collaborative efforts of the technology team to infuse technology throughout the curriculum and assure compliance with state and national technology competencies for teacher candidates.

Increases in elementary school enrollment along with class-size reduction and teacher retirements have multiplied the demand for teachers. The chronic shortage of teachers in California is especially acute in urban districts. California's urban districts have the largest proportion of emergency permit teachers with Los Angeles Unified School District facing the most serious shortfall of credentialed teachers. Designed to meet the immediate need for qualified teachers, CalState TEACH combines independent study at home via the Internet with personalized supervision by school-based mentors and visiting specialists from the CSU campuses. Offered in four stages over an 18-month period, CalState TEACH recognizes that a working teacher has little time to commute to his or her closest CSU campus. Unlike traditional campus-based courses, CalState TEACH is centered at its five regional centers throughout the state. Beginning teachers are supervised by CSU faculty members who provide advice and support as they observe them in action. Partnering with school districts throughout California, veteran teachers from the credential candidate's own districts serve as mentor.

CalState TEACH supports independent learning, where students can study at their own place and time, without the need for class attendance. Using email and the Internet students can receive and submit assignments, question professors and discuss the program in special chat rooms. Although the delivery technique is innovative, the rigorous nature of the credentialing process is not. Assignments due dates and testing are all elements of CalState TEACH. Applicants are expected to commit at least 12 hours per week to complete the program successfully.

Assembly Bill 1023 (Mazzoni, Chapter 404, Statutes of 1997) requires that California credential candidates meet certain preliminary minimum standards relative to the effective use of computer-based technology in the classroom prior to receiving a *Preliminary* Multiple Teaching Credential. Additional standards must be met before receiving the *Professional* Multiple Subject Teaching Credential. The full report containing the recommendations of the Commission's Computer Education Advisory Panel for the implementation of AB 1023 can be found at: <http://www.ctc.ca.gov/aboutctc/agendas/December%201998/prep/prep2.html#TOC>

A team of educational technology specialists was selected to assure CalStateTEACH compliance with these technology standards. Each specialist was assigned to one of the four curriculum content teams with the task of infusing technology throughout the curriculum. The technology team met regularly to gather, preview, discuss and select relevant software materials and WWW sites. The appropriate and efficient use of software applications and

related media to access and evaluate information, analyze and solve problems, and communicate ideas was considered essential to maximizing the instructional process for the interns. Such use of technology supports teaching and learning regardless of individual learning style, socio-economic background, culture, ethnicity, or geographic location.

To help candidates become fluent, critical users of technology and to help them develop the technology skills necessary to succeed in the program, a CalStateTEACH Technology Guide was created. It provides essential resources to help candidates develop the confidence and ability to use technology effectively in their teaching. Most importantly, it inspires candidates to continue using and exploring technology to facilitate their own learning, to increase professional productivity, and to expand their own capacity to use technology for creative growth.

The education, techniques and feedback that the CalStateTEACH credential program offers can tip the balance between success and failure, staying in the profession of teaching or leaving it. A field-based credential program firmly grounds the novice teacher in the mechanics of learning the hows and whys, what works and what doesn't. The pervasiveness of incorporating computer-based technology regularly through out the 18 month learning experience has educational implications. Since quality teaching is the most important predictor of a child's educational success, helping teachers succeed by earning a teaching credential benefits the teacher, students, and the school. The CalStateTEACH program is the equivalent of 39 semester units. Participants who complete the program will receive a Multiple Subject teaching credential (elementary) with an emphasis in Crosscultural, Language and Academic Development (CLAD), as well as immersion in a technology-rich learning environment.

Abstract : Forums are frequently used in distance learning platforms in order to make easier the exchange of ideas between students and tutors. But, frequently, the huge number of available contribution limits the use of newsgroups as real work groups. This communication introduces a work, in progress, which aims at making contacts easier in a distance learning newsgroup, by the integration of tools which collect contributions in the form of cases and which are able to evaluate similarity between cases.

1 Introduction

The aim of this paper is to describe a work in progress, about an interactive communication forum dedicated to Distance Learning. On the web, newsgroups constitute a privileged way to confront experiences, in spite of a still weak interactivity [Dessus, et al., 97]. Thus, when a user wants to make an intervention in a forum, the main problem he can find is the number of questions raised and their heterogeneity. In the context of an asynchronous forum, a majority of participants adopt the solution to give themselves a contribution, instead of trying to make contact with somebody who has previously related a similar experience. These reasons justify the interest of a functionality allowing to structure the expressed knowledge and to help drawing links between students who have similar experiences.

In the context of a distance learning action, the integration of this kind of forum constitutes an additional value that allows students to interact with the tutor and with other students. Such a forum can, for example, take all its interest in the context of the medical lifelong learning. In fact, for this kind of training, discussion workshops arise, in which significant experiences are mentioned. The site of "Arrakis Formation Medicale Continue", managed by Dr. Tusseau [Tusseau, 98], presents some examples of this kind of meetings and reports about previous meetings. Regular work sessions on interactive discussion forums could tend toward the functions of these real meetings, with the advantage that some of the participants of the virtual group could not have the opportunity to take part in a real one. This situation, obviously applies in a great lot of domains. This approach draw its inspiration from both the concept of communication GroupWare [Dillembourg et al., 96] and the notion of collaborative learning ([Grudin, Poltrok, 96]).

The next chapter presents the actual work about the communication system and describes tools which are necessary to build it. We then conclude with the technical advancement perspectives and on the methods designed for the evaluation of this forum.

2 An interactive communication environment...

This section describes the proposed interactive communication forum and its main interactions. The

presentation of the tool dedicated to collect different experiences and to emphasize similarities between them gives then an idea of the implementation approach.

This system is an application of the Case Based Simulation model elaborated by D. Lecllet and G. Weidenfeld ([Lecllet, Weidenfeld, 96] [Lecllet, 98]), which is inspired by Case Based Reasoning methods ([Koldener, 93] [Schunk, 82]). This model considers a *case* as a scenario, an experience illustrating a precise pedagogical objective. The case description lean to a lower model layer in which all the entities, acting in the case, are represented by an object formalism. A particular structuring of the case base allows the constitution of interactive environments, based on similarity between cases.

A distance learning student contribution in a forum is considered as a case that this student will be able to annotate and to structure, using an adapted representation of the domain and of the activity. To collect the contribution, a design and implantation work of a generator has been put in place. It is a matter both to build an intuitive and supple environment in which experts will be able to describe their experiences and equally to give to this tool some structuring means of the obtained case base. This tool will be used, at first, by experts in order to formalise the domain and, later, everyday by students in order to relate their own experiences in their activity practice. The tool will then be considered as the heart of the interactive communication system devoted to the distance learning community.

So, the interactive communication forum general architecture is centred around an case base tailored for the collection of different related experiences. At the beginning, the initial case base is established by a domain expert group. Once this base is constituted and structured, it gives to each forum participant the possibility to relate a new case under a standardised formalism. This will help other participants, among which the tutor, to make connections between experiences having some kind of similarities. Parallels may be relative to the comparison of new experiences with initial experiences, or between new experiences. Once a relevant parallel is realised, the system informs the students which are involved.

The following paragraph concludes over the development perspectives and on the means considered to estimate and validate performances of this kind of forum on a distance learning platform.

3 Conclusion and perspective

This paper present a new application of the "Case Based Simulation" model, applied to the design of an interactive distance learning forum. The need of improving forum interaction in the context of distance learning is patent, thus the first perspective for the present work will be experimentation in effective contexts. These actions will allow, in fact, to obtain important returns of information on behalf of authors, tutors and users. The analysis of these information will enable new specifications and hence a new tool version and a solid similarity assessment method. Afterwards, the pedagogical validity of this forum will must be established by confrontation with different student groups, by the comparison of interactivity in sessions both in place and at distance, and after all by statistical calculus of a satisfaction clue established with a questionnaire given to each speaker. The combined analysis of the obtained results will allow to assess the pedagogical interest of this kind of forum and the interaction validity between all the forum actors.

Abstract: By comparing different cultural values through e-mail Correspondence, classroom connections and discussion, direct interviewing, and playing the web-net game called VESAX to discover where they stand on a culturally different value scale which compares a common westerner with a common Japanese, students learn to communicate better, while removing some of their prejudice and invalid assumptions□to view themselves and their own culture objectively, and to internalize global values through discovery-learning and enlightenment.

Two of our seminar students, who had joined a home-stay program in California State, mentioned that the family they stayed with often made use of fast foods as a main part of their meals. They generalized that most American people have such an eating habit. They felt that making use of fast foods was the typical American style. The writer responded that they should not jump to such a conclusion. Later they found that none of the family members they stayed with were college graduates. Does an eating habit have to do with higher education among the people of the United States? What about Japanese people? These questions were not such a great discovery for them after their home-stay experiences, but they became the beginning of their quest activity for the writer's seminar class on "Culturally Different Criteria for Decision-making."

Through the students' survey between Himeji Dokkyo University in Japan and S. University in the United States, they discovered that Japanese students would make use of fast foods more than American students in a given situation. They also learned from the newspaper that an organically grown vegetable garden in the grounds of a public junior high school in the suburbs of San Francisco, which used to be a "blackboard jungle," positively influenced both the children's physical health and their mental health. With Alice Water's comment on a definite relationship between a vegetable garden and calm minds□they also learned that there are now similar vegetable gardens in more than 1,000 public junior high schools in California (1998). They realized that some of the assumptions they make about overseas people could be mere prejudice and that they should not make a judgement unless they do some research on what they are discussing.

In the seminar class each student first thinks up a specific situation with two or three ways that an individual might react in the situation. Second, he or she collects data by asking two groups of students. The subjects of the first group, Japanese students, are from Himeji Dokkyo University, and the subjects of the second group, overseas students, are found through e-mail either from the world Pen Pal lists or e-mail classroom connections. Third, they analyze the data to find out whether the two groups have culturally different criteria for decision-making, using the chi-square table. Fourth, they put their results up on the web site under Culturally Different Criteria for Decision-making. Fifth, they discuss the results with overseas students through e-mail corresponding or sometimes by interviewing overseas students. And finally they make presentations in class, demonstrating the English communicative skills they have gained as a byproduct. The survey results have turned out to be so interesting that we have made a simulation game (VESAX□Virtual Edutainment Systems using Active-X) to show that if what they discover is so fascinating, their enthusiasm will go up, too.

BEST COPY AVAILABLE

These seminar classes are not enough to show the efficiency of the classroom activities empirically, but as case studies they seem to be sufficient enough to show that the class projects are highly motivating as well as instructive for the students. After gaining some confidence in English communication through e-mail corresponding, some of the students actually went to overseas countries and interviewed some students there, which really enlightened their thoughts. They were surprised to find out that the overseas students were very interested in the project and felt happy responding to their interview after seminar students explained why they were doing this project. As e-mail classroom connections, the seminar classes could contact some intercultural classes and cultural Psychology classes in the United States. The teachers in charge of these classes and the class leaders of those classes were happy to send the responses and comments of their students since the project mutually benefits both sides.

In the VESAX, one can realize a common Japanese and a common westerner's decision-making tendency the outcome by the size and shape of the globe which appears every time you click the result icon box. One can also realize where he or she stands in comparison with both common Japanese and common westerner decision-making after responding to the questions, or checking A or B or sometimes C in every three questions under six criteria: (1) Growth of the Enterprise in terms of the People's Work, (2) Individual Care in the Enterprise and the Society, (3) Various Aspects of Development throughout the Society, (4) Fair Opportunities for Business and Employment, (5) Satisfaction of Family Members in terms of Having a Good Life Together, and (6) Growth of the Enterprise and Society in terms of Information Flow with the People's Understanding. The VESAX shows that if you are a common Japanese, you may be working very hard and taking good care of only those who are really close to yourself due to so-called personal connections, but that you do not grow in various aspects much. The result is an uninteresting society, only a few chances for good business and good employment, sacrificing your time more for work instead of having more fun time with your family, and trying to do your best to conceal something obnoxious for face value. The end result is that the globe crashes as if you felt completely frustrated and your life became extremely uncomfortable and unhappy. Through the VESAX one can realize that common Japanese decision-making does not lead to creating a wholesome society. Of course, there are some negative sides in almost all cultures. But realizing them in one's own culture and trying to improve them as an individual through personal decision-making means a great deal to any Japanese individual who plays this game. The goal for the VESAX is not to reject all Japanese cultural decision-making elements but to enable each student to see things more with international views and more with global values as a result of discovery-learning and enlightenment comparing value systems of several cultures.

The VESAX is the tool for students to see cultural differences while looking at the shape and size of the globe. Since it is difficult to look at yourself and your decision-making objectively, if you are inside the box of a particular culture, this simulation game helps you.

Throughout the seminar course on Culturally Different Criteria for Decision-making, as a whole, the students did gain enthusiasm in aggressive English communication. Also the web-net game called VESAX has enabled the players to understand cultural differences without going to overseas countries and has provided them with the chance to reconsider their priorities and values. Not only the seminar class students have grown enthusiasm in developing their research on the theme, Culturally Different Criteria for Decision-making; also overseas students found it quite exciting to discuss the contents of the web sites, (<http://www2.gol.com/users/arise0mk/>) and (<http://www.sys.wakayama-u.ac.jp/~shima/call/>), and to discuss them through e-mail correspondence. This study certainly demonstrates how the students developed aggressive English communication for discovery, enlightenment, and global values by comparing culturally different values for decision-making through the inter-net.

Formative Evaluation of an Evolving Web-Based Digital Archival System

Ed Kazlauskas, Rossier School of Education, University of Southern California, USA, kazlausk@usc.edu

Abstract: ISLA (Information System on Los Angeles) allows access to a wide variety of archival information of a geographic region in multiple formats (textual, qualitative, photographic, spatial, audiovisual) from all historical periods. A number of issues have been raised in the project's implementation which call attention to the need for a formative evaluation of the evolving web-based digital archival system. In this formative evaluation phase, several parallel systems with different interfaces and search capabilities, but with the same core of archival materials, are operating. These systems are being evaluated in terms of user-oriented dimensions using standard web evaluation criteria, and by measuring learner outcomes, attitudes, and employed teaching and learning strategies.

Introduction

Much information is gathered about metropolitan regions but access to and interpretation of these data is difficult due to the fact that the data are segmented into discrete entities. A group of interdisciplinary researchers, in collaboration with area institutions and community groups and various funding sources, have been developing a web-based digital archive system to allow a more robust analysis of a metropolitan geographic region. The basic concept behind this system is to allow access to a wide variety of archival information from all historical periods of a geographic region, linked by spatial and temporal coordinates. The primary, long-term goal is to create a system that will enable all kinds of users, from elementary school children to advanced researchers, to search and access a rich and diverse range of digital archival research materials in multiple format (textual, qualitative, photographic, spatial, audiovisual).

It has been noted that digital libraries can be considered some of the most complex and advanced forms of information systems due to the myriad of complexities involved (Fox & Marchionini, 1998). This has been the case with this digital archival system. A number of issues have been raised, including the fragility of a system which is "leading" the technology, and the fact that users, such as students and non-researchers, may not have the capability to access a system with high-end computing requirements. There was the need for a formative evaluation of the evolving web-based digital archival system. The following describes the present system (ISLA), an alternative to this system (The Digital Library System), and the methods of gathering input from users on these systems. The overall purpose of this effort is to help refine the direction of the overall digital archive project.

ISLA

ISLA has two main components: 1) the user interface, an advanced Web application and known as IDA, or Integrated Digital Archive; and 2) a large database of materials, or ISLA. The system allows for space/time/fulltext/format indexing to search for and retrieve materials and, in addition, has the conventional indices of author, title, subject, and other cataloging fields. The materials/resources in ISLA include photographs, newspaper texts, aerial and satellite images, digital spatial data made available from Thomas Bros. Map Company and the Bureau of Engineering of the City of Los Angeles, and data from the 1939 WPA (U.S. Work Project Administration) and land use maps (Kazlauskas et al. 1997).

The Digital Library System (DL)

On a broader front, the university library has undertaken a more conventional (although not to mean less complicated and less useful) digital library initiative based on the IBM Digital Library Software. This is a more traditional library of digital objects that can be searched by keywords that are in the structured description of the item. This development is in the mainstream of digital library developments worldwide, such as being developed as UC Berkeley (<http://www.storage.ibm.com/storage/customer/berkeley.htm>) and the Russian State Hermitage Museum (<http://www.ibm.com/ibm/ibmgives/hermitage.htm>). In the meantime, another initiative using the University's WebCat interface is anticipated.

The Current Evaluation Project

Evaluation has always been a central component of this project. In this formative evaluation phase, we are operating and examining parallel systems with different interfaces and search capabilities, but with the same core of archival materials. The ISLA objects have metadata in their own format which contains keyword search fields but also the GIS information for the spatial and time searches. These items have been exported out of the ISLA library and imported into the digital library system (DL).

At present, we are conducting training sessions that present both systems to the 'trainees.' Upon completion of the training sessions, the trainees have the task of developing a curriculum lesson plan using the ISLA digital archival resources. Individuals included in this formative evaluation include master's degree students in instructional technology representing both the corporate and educational sectors, graduate students in education, and practicing K-12 teachers. Evaluation of the two systems is being conducted through the analysis of data generated from the investigation of the two major areas of interest to us: user-oriented dimensions, and student learning and student outcomes. The effort includes the use of a variety of data gathering techniques, including observations of learners, unstructured and structured interviews, and examination of student work.

We are basing our evaluation of user-oriented dimensions on standard web evaluation criteria, such as on framework for evaluating multimedia packages by Reeves and Harmon (1993) and that found at the Web-based Training Information Center (<http://www.filename.com/wbt/index.html>). Some of the dimensions we are addressing include: ease of use, navigation, cognitive load, screen design, and content.

Evaluation of students is being accomplished by measuring learner outcomes, attitudes, and employed teaching and learning strategies. In addition, we are concerned with the motivating and engagement factors of the two systems, and the ability to link these systems to curriculum standards, such as the California Curriculum Frameworks and the national geography standards.

ABSTRACT: Telecommunication companies and video/audio codec makers are actively participating in the standardization activities of multimedia conference over packet based network such as the recommendations of H.323 series. Development of some standards of multimedia conference is completed. Multimedia conference services for closed user groups like distance learning and company wide conferencing are provided.

In this paper, an implementation example of multimedia chatting service is described. A multimedia chatting service is developed in order to increase the popularity of multimedia service. A chatting participant of the system can simultaneously watch documents with remote people and change the content of the documents.

1. Introduction

Telecommunication and video conference related companies such as NTT, AT&T, Intel, and Lucent have given active contribution to standardization of multimedia conference. Multimedia conference standardization over ISDN is completed. Standardization over packet based network is being done with the active contribution by many companies. H.323 v1 and v2 were published as recommendations and H.323 v3 is being developed. Standards of multimedia conference is implemented and tested in IMTC. It is required to provide general multimedia conference service in order to increase the popularity for multimedia service.

Chatting service is a commonly well-known service. Features of multimedia conference like video/audio/data signal transmission can be adopted to current text based chatting service. Additional system component is needed to add new type of media stream other than text signal.

In this paper, an example of multimedia chatting service is described. Using multimedia chatting service, chatting participants dynamically make the chatting rooms, enter the rooms and do chat. Multimedia chatting system is comprised of a MCU(Multipoint Control Unit), MCU operation server, a chatting service server, a gateway and terminals. System configuration of Multipoint Multimedia Chatting service is shown in Fig1.

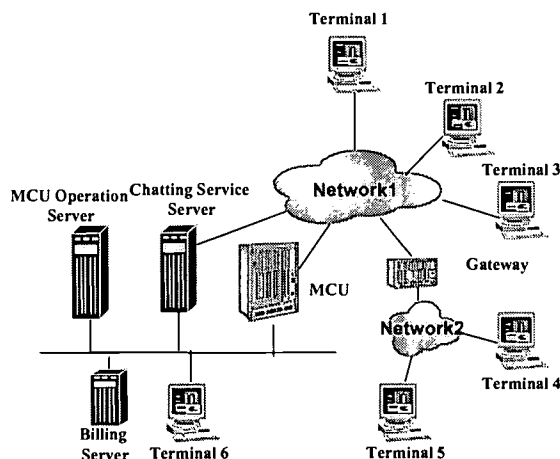

Fig1. Elements of Multipoint Multimedia Chatting System

Fig2. The State Transition Diagram of a Main Control Class

2. Multimedia Chatting and Collaboration System

Terminal : A chatting terminal is a multimedia conference terminal that can communicate with a chatting service server and provide for real-time, two-way communications with other terminal. A chatting terminal establishes one connection with the chatting service server or MCU at a time or simultaneously builds two connections with both of them. A terminal asks the chatting service server to arrange a chatting room. After the chatting service server creates a chatting room, it notifies the terminal that a room is successfully created. When the terminal receives a message of room-created, it tries to make a connection to a MCU. The terminal can disconnect the connection to the chatting service server in order to use all bandwidth of the line in the connection to the MCU.

MCU(Multipoint Control Unit) : The MCU provides the capability for several terminals to do multipoint

chatting. The MCU sets up a point-to-point connection with each chatting participant. The MCU receives video/audio/data streams and processes them according to the type of conference. Then it distributes the stream to all terminals. It simultaneously shows several participants on a screen. The MCU consists of a mandatory multipoint controller and optional multipoint processors for audio/video/data stream. The multipoint controller(MC) controls terminals that participate in a chatting and provides for capability negotiation among terminals in order to determine common mode of conference. The multipoint processor provides for media stream mixing, switching.

Chatting Service Server: It manages the connections from terminals. It receives terminal-transmitted commands and processes them to manage chatting rooms. It also provides the directory service to send to each chatting participant the information of currently connected user. It has a registered user database and identifies the chatting service users.

MCU Operation Server: The MCU operation server controls the behavior of the MCU. It receives chatting room related commands from chatting service server. Chatting service users also can provide the preference for a conference like call setup method(call in/call out), video presence(video switching/continuous presence/transcoding).

Gateway : The gateway is connected to two different networks. It allows terminals that are connected to different networks to communicate. The gateway translates transmission format and communication procedure. It also translates video/audio/data formats into appropriate ones. But if media formats that are used in a conference are same, translation is not required.

Billing Server : A billing server retrieves log information called CDR from MCU and chatting service server.

3. Operation Modes of Chatting System

There are two operation mode, i.e. dual connection mode and single connection mode. In dual connection mode, a terminal simultaneously has two connections. One is to a chatting service server and the other to a MCU. A terminal can see how many chatting participants and chatting rooms there are.

In single connection mode, a terminal makes one connection at a time. Firstly, the terminal builds a connection to a chatting service server and asks a chatting service server to join/make a room. If a terminal is informed that joining/making a chatting room is allowed, the terminal disconnects from the chatting server and makes a new connection to MCU and do chatting. In this mode, the terminal can do document share. A chatting service server maintains the chatting participant list.

4. Development of the Service

In the case of developing several systems sharing similar functions, the formalized software development technique makes developer easily reuse the analysis and design result as well as source code of the system. Several multimedia conference applications are being developed. In this section, an example of multimedia chatting terminal is explained in which object oriented software analysis and design method is adopted.

In the iterating software development phases of design, analysis, implementation and maintenance, the relation of objects that compose a system is described by object model and the life cycle of the objects is represented by dynamic model.

Main control class of the chatting terminal software manages calls to MCU and Chatting Service Server. It has eleven states including 3 substates. A state 'ST_INITIALIZING' is initial state. When initialization of all controls including video/audio/data controls are completed, the state is changed to ST_ALL_READY. When a participant tries to connect to a chatting service server, the state becomes ST_CSS_CONNECTING. After 'CSS_ConnectionRejected' event is received, the state goes back to ST_ALL_READY. The state ST_CSS_CONNECTED indicates that connection is successfully completed. State change from ST_CSS_CONNECTING to ST_CSS_CONNECTED is occurred when CSS_Connected event is received.

When the 'join' command is transmitted from a participant, state is changed to ST_CSS_ROOMCREATING. When 'CreateRoomSucceed' event is transmitted by the chatting service server, the terminal tries to establish a call to MCU and the state is changed ST_OP_CONNECTING. The state ST_OP_CONNECTED means the connection to a MCU is completed. When a chatting participant tries to hang up the connection, the state is changed from ST_OP_CONNECTED to ST_CSS_CONNECTED.

5. Conclusion

In this paper, an implementation example of multimedia chatting and collaboration service is showed. This system is designed to increase the popularity of multimedia service. A user of the system can simultaneously watch documents with remote people and change the content of the documents. In the development process, a methodological software development technique like object modeling technique is adopted to reuse the analysis and design result. The design result can be used in building another multimedia conference applications

Creating Poetry For Cyberspace: A 3-D Haiku Experience

Michael A. Kolitsky, Ph.D.
Instructional Technology
Rowan University
Glassboro, NJ 08028
United States of America
kolitsky@rowan.edu

Abstract: Poetry is no longer limited to the 2-D flatland of a page. With the emergence of VRML, it is possible today to write poetry for cyberspace. This idea was tested by writing four Haiku with the same middle line which were then arranged in 3-D space using VRML so that a cube of poetry was created. The Cosmo Player dashboard tool was used to rotate the cube for Haiku reading. The first and third lines of each Haiku form each poetic cube edge and can also be written to have meaning. Images can be placed as backgrounds behind the poetic matrix, music can be added which can affect the Haiku reading. Other Haiku poetic cubes can also be positioned in the 3-D world to form a "constellation" of Haiku cubes each with different student authorship. Haiku, multimedia and VRML combine for a novel type of interactive poetic experience.

Throughout the ages, poetry has been written to fit the two-dimensional space provided by the area we have come to know as the page. But, with the emergence of VRML (Virtual Reality Modeling Language) and the capability to create interactive, explorable worlds in three dimensions, it is now possible for the first time to write poetry to take advantage of the "extra" third dimension provided by the creation of virtual worlds in cyberspace.

In order to simplify the first exploration of using virtual space as a way of presenting written poetry, the Japanese form of poetry, the Haiku, was chosen as the first type of poetry to be placed in a cyberspace environment. The traditional Haiku is composed of three lines, with the first and last line containing five syllables and a middle line composed of seven syllables. Four Haiku were written with the same middle line so that these four Haiku could all be arranged in three dimensional space around that middle line.

What is produced from this arrangement is a visually appealing poetic matrix that is in the shape of a cube with the center line of the cube shared by all four Haiku. In addition to being able to read the Haiku in their traditional line order, i.e., five syllable line first, seven syllable line second and then a five syllable line, one discovers that when in a poetic cube arrangement, the first and third lines which form the outer edges of the cube, can also be written as poems albeit not Haiku since all the edge lines have only five syllables. This adds another element of complexity in writing Haiku for the three dimensional world because now one must be aware that the "edges" of the completed poetic cube can have meaning and must be taken into account in the initial writing of Haiku for inclusion in a cube of poetry.

VRML scripts were written so that novice or experienced creators of Haiku could place their own work in a virtual world so that they could be accessed via the web with a VRML-smart browser. Cosmo Player 2.1 from Silicon Graphics, Inc. and Netscape Communicator 4.06 were used for this study. Cosmo Player 2.1 has full Java support and can accept the inclusion of other scripting languages such as Javascript for the production of buttons and objects which can respond to mouse clicks for a greater degree of interactivity.

VRML has the built-in capability to write text in a three dimensional space with control of its placement along an X, Y and Z axis. One may also choose a font type, size, style and color. In order to provide some help in determining how Haiku should be read when arranged in a poetic matrix, the first and last line of each Haiku were given a color which would differentiate it from any of the other Haiku in that cube of poetry. The middle line which is being shared by all four Haiku in the cubic arrangement was made to animate in color sequence changing color continuously to cycle through each of the colors assigned to the four Haiku. In this way, it made easier to understand the notion that the first five syllable line colored red in the upper right corner of the cube was written to go with the five syllable line colored red in the lower left corner. As the middle line containing seven syllables cycled through its colors, it became red at one point in its cycle to reinforce the reading of this diagonally arranged Haiku from the upper right of the cube to the lower left corner. The opposite left corner

BEST COPY AVAILABLE

1347

contained the first five syllable line of another Haiku and was colored green and was linked to the last line of this Haiku located in the lower right corner of the cube which was green also. Again, the middle line during its color cycling became green at one point indicating that the reading of this Haiku began in the upper left corner and proceeded on the diagonal through the middle line to the last line in the lower right corner. The other two Haiku were arranged in a vertical and horizontal direction both sharing the same middle line but differing in color from each other as well as the two Haiku on the diagonals.

By using the "rotate" tool found on the Cosmo Player dashboard, the cubic arrangement of the four Haiku could be rotated around a central axis to explore how the Haiku are arranged in the 3D space of the VRML world. In a frontal view of the poetic cube, it is difficult to read the poetry because the text for all the Haiku is layered three lines deep along the Z axis. In order to read the individual Haiku, the poetic cube should be rotated and twisted slightly to the right or the left. This creates the proper perspective of three dimensionality and makes it easier to visualize the directionality of each of the four Haiku.

The "rotate" tool also must be employed to read the lines forming the edges of the cube. The Haiku poetic cube has four faces that contain three lines of five syllables each. It is challenging to write four Haiku with the same middle line and this process becomes even more complex when the first and last lines of different Haiku are written to have meaning when arranged together on one of the edges of the cube. The writing and positioning of poetry for 3D display calls upon both right brain and left brain functions as one first captures ideas and thoughts in text and then secondly must work with that text for its ideal arrangement in the very visual world of the 3D environment.

The VRML world may also be designed to have a sky, horizon and landscape in a background which creates some visible landmarks that also move with changed perspective as the Haiku cube is rotated. Images may also be mapped as a texture onto a flat, thin rectangular shape. This rectangle can then be positioned as a wall along the Z axis so that it is now located behind the poetic matrix and is viewed by looking through the Haiku text. The images can be obtained locally from one's own server or hard drive but VRML also provides the option to designate URL's at other sites anywhere on the web as sources for background images or for use as a texture to map onto a flat, thin rectangular shape which can now be observed behind the text as one reads a particular Haiku.

Images can be placed as backgrounds on all six walls of the virtual world in which the Haiku now exist and these images can be chosen to create different meanings from the reading of the Haiku as one observes the image while reading the Haiku. Musical clips may also be activated while reading the Haiku and these clips also can be chosen for their emotional impact while reading the Haiku. In this way, Haiku placed in virtual space can combine with images and sound for an interactive multimedia experience.

The ability to write Haiku and arrange them in a three dimensional array offers a new perspective on the writing of poetry. It may offer students the opportunity to take a greater interest in writing poetry and it challenges the more experienced poet to be a wordsmith as well as a designer of spatial poetics. The three dimensional spaces or worlds offered by VRML can be quite large and there is no reason why many poetic cubes cannot be placed throughout that world. One might imagine many cubes of poetry located both near and far away from the opening viewpoint. When one has many Haiku poetic cubes arranged throughout a virtual world, it is possible to script in VRML a number of viewpoints which can then be selected from the Cosmo Player dashboard for easy travel through the virtual space to that particular Haiku. One might liken this world to a constellation of poetic cubes waiting to be traveled to and explored by the skillful use of the tools provided by the VRML player of your choice. A VRML-based web world can also be created for the placement of poetic cubes constructed from the contributions of many poets. Visitors to this page would be invited to travel as cybersnauts from one Haiku island to another.

The web site located at <http://users.rowan.edu/~kolitsky> may be accessed to demonstrate how Haiku can be placed in a virtual world to form a poetic cube. Also, a world containing many poetic cubes may be visited at this site to further underscore how this method of writing Haiku for cyberspace can be used as a tool to encourage students to write Haiku and place them in cyberspace for viewing anywhere in the real world.

Examination Registration and Course Feedback System for Students in the Intranet

Abstract. The aim of the study was to develop a WWW based examination registration and course feedback system that covers the whole Tampere University of Technology (TUT), serving students, as well as teachers and other personnel. The examination registration system makes it possible for a student to register himself or herself in any available examination arranged at TUT. While registering the student can also give feedback. The course feedback system includes the generation and analysis of course feedback pages, giving feedback and the creation of a summary. The system has been in test use by students of the Department of Mechanical Engineering (about 900 students) since November 1998. The personnel of the same department has used the system since January 1999.

1. Introduction

The effect of the Internet on all information and communication increases continuously. WWW education has been developed at Tampere University of Technology (TUT) for a few years. Active institutes in this field have been, e.g., Electric Power Engineering, and Hypermedia Laboratory at the Department of Mathematics.

The existing Unix based (non-web) program (OINFO) was the basis for developing the new web system. OINFO is a large system which includes, e.g., registration for courses (about 800) and examinations, as well as a feedback system. The development of a new web system (for Microsoft NT 4.0 environment) was started by creating a new course feedback system that covered first one department (demo version), and then continued to cover the whole university (test version). The examination registration system was being developed at the same time. After a password protection was created (autumn 1998), both systems, examination registration and course feedback system, were linked together. However, for the time being, the old WWW based course feedback system (without password protection) was left in daily use at TUT.

The aim of the study is to develop a WWW based examination registration and course feedback system to serve university students and teachers. The functionality and usability of the system has also been tested. The results are presented in this paper.

2. Description of the system

The examination registration system contains two main parts: an examination registration part for students and an administrative part for personnel. The course feedback system consists of three main parts: generation and analysis of course feedback pages for personnel, entering course feedback for students, and summary of course feedback for everyone. In addition, the system includes a lottery for students, which works as an incentive for giving course feedback.

Each user has a personal user ID and a password for logging into the system. Students and personnel log into the system using different URLs. The system allows navigating only through fixed paths. The user information is in memory until a user logs out. There are different time limits set for using the system. Logging into the

system must take place within one minute. The system allows five minutes for staying on each page. If the time is exceeded, the system logs the user out. After the user has logged in the system, she or he can select a different number of examinations from the examination lists of different units of TUT. As the selections have been made, the registration can be done.

Figure 1: Example pages for the selecting examination dates in the registration system

The web system was programmed in Perl 5 language, but plain html based coding was also used. The examination registration system includes 223 Perl scripts and 78 html files, and the course feedback system contains 107 Perl scripts and 747 html files. The program runs in different browsers (e.g., in Netscape 3.01 and Internet Explorer 3.0).

3. Testing of the system

In the first phase step, the examination and registration system was tested by the programmers. All links were tested, and calculation results were checked. In August 1999, the system was demonstrated to all departments of TUT. The Department of Mechanical Engineering was selected as a test department. In October 1998, userIDs, passwords and instructions for the system were e-mailed to all students of mechanical engineering. After that the students could register in the system. Training demonstrations for department secretaries were arranged in January 1999. They have begun to use the system with other personnel of the Department of Mechanical Engineering. The old UNIX based (non-web) program is used by other departments of TUT.

Generally the system has been working well. The system has not collapsed even once. By the end of January 1999, the administrators of the system have received 49 comments about the system by e-mail. The problems have mainly been related to logging in the system for the first time. Some students have used a wrong password, because they did not read instructions carefully enough. Feedback from the system is received by email. The feedback has mainly been positive. The system is being developed further.

How the Hypermodern Technology Assemblage Bites Back

Abstract: Institutions of higher education have been rapidly moving toward ever-more non-traditional methods of producing and distributing knowledge, joining what Wise (1997) called the “hypertechnology assemblage”. The terms hypermodern technology (or hypertechnology) refer to “...not just one piece of equipment, but the entire globally interconnected assemblage of new communication, transmission, and information technologies...which share a formal resonance or common episteme” (Wise, p xvi).

1. Introduction

The authors consider a broad range of possible pitfalls that this international assemblage can have for higher education, particularly considering the interposing of technology between teacher and student. If faculty are not careful, they will find themselves short changing their students in the use of “post-it-note” transmissions using voice mail, e-mail, list-serves and other hypermodern communication methods. The authors have found, for example, that while term papers contain fewer spelling errors, students are not better spellers, and they may be worse spellers than their predecessors, who were non-users.

2. The Problem

Traditional education was characterized by relatively closed classrooms, with instruction contained solely within bounded physical space where it utilized locally available resources. These practices paralleled the larger social and economic organization of the surrounding community. But the post-industrial period has witnessed a transformation of the surrounding organizational field from an industrial to an information-based environment, and educational institutions are rushing to catch up.

The use of one-way and semi-synchronous television instruction has created a host of potential pitfalls for educators. Unlike face-to-face interaction in conventional classrooms where both professor and student shared in the creation and execution of the learning process, hypermodern technology has instead restricted the instructor’s knowledge of students to available photographic images or textual representations. Likewise students experience flattened and truncated two dimensional views of their professors. According to Dede (1991) “The teacher faces the challenge of building an intellectually and emotionally attractive telepresence, like that of Bill Cosby, Captain Kangaroo, and Mr. Rogers ...having psychosocial consequences which are not well understood.” (Dede, p. 149).

There are numerous problems associated with the current push to acquire and upgrade hypertechnologies. Sassone, (1992), for example, has found that highly trained educational professionals are spending more of their energy engaging hypertechnological activities that amount to secretarial and clerical projects. While Birkerts, (1996), argues that even though computer networks may be seductive places to work, play, and educate, they remove professionals from the ebb and flow of the natural networks found outside the classroom. Textual messages can be sent across a computer net in a few milliseconds, but conversations and other meaningful life experiences, so critical for role modeling, require much longer periods of time to unfold.

Communication oriented hardware and software, so important to distance learning and the electronic campus, promise to link students and faculty together, they actually promote social distancing through the exchanging of time-staggered messages. Faculty report that hypermodern communication methods are “easier” or “more convenient”, but they may also

find that personal relationships central to educational communication are being avoided, not encouraged. Such electronic post-it-note communication does not always favorably compare to the all important sharing of streams of consciousness available in face-to-face interaction in traditional higher education, especially in mentoring relationships.

Until better data are available, we hold that technology should be viewed solely as an ancillary tool to support the production and distribution of knowledge, the development of skills, and the examination of the value bases of our profession. We need much better data to assess how students adapt to temporal and spatial distance, how they relate to the emerging physical and spatial aspects of learning off site, how they manage access to sometimes costly equipment, and how they adapt to individual differences in reception of electronic messages. This is especially important when the agents of transmission (electronic devices) were originally designed to mass communicate to essentially passive non-adult audiences.

We are not arguing that technology harms directly, but rather that it is being misused when employed to mediate interpersonal relationships and when it serves to satiate market commodity fetishes without regard to effectiveness. We hold a corresponding view of the dynamic involved in critical learning environment, especially for non-traditional learners. Gadgets and mechanical objects cannot substitute for human pedagogy. Technology bites back, especially in regard to the lost opportunity costs. We offer the following recommendations We need to advocate for low cost or free access to the Internet as a form of public admission to the international assemblage.

3. Summary

We need to be mindful of the impact of hypertechnology on the environment, especially in the Third World. We need to be mindful that hypertechnology often requires the use of language which differs from ordinary everyday vernacular. The use of novel terms and specialized meanings may have the effect of leaving students or clients behind, (Karger & Kreuger 1988). More and more challenging research into the beneficial effects and what may turn out to be unwelcome iatrogenic effects of technology in social work practice and education for practice. We need new paradigms which help us think through as a profession the issue of hypertechnology in terms of it's socioeconomic and political consequences. Core values important to social work and moral issues on human subjects and human rights need to be considered, including the code of ethics. Wholesale application of specific technologies involved in distance learning and the electronic campus and carefully crafted empirical evaluation on outcomes and long term impacts on professional training;

A MODEL FOR WEB-BASED COLLABORATIVE PROJECT - LEARNING LANGUAGES AT WORK

Leena Kuure, Department of Teacher Education, University of Oulu, Finland, lkuure@ktk.oulu.fi
Maarit Saarenkunnas, Faculty of Education, University of Oulu, Finland, msaarenk@ktk.oulu.fi
Peppi Taałas, Centre for Applied Language Studies, University of Jyväskylä, Finland,
peppi@cc.jyu.fi

Abstract

In this paper we will discuss a model for organizational training in the area of languages. The recent technological developments have led us to an illusion that staff development programs are easy and cost-effective to pull through. This is partly true but it is in no way sufficient to offer employees access to a multitude of information and courses. There still is a need for expert guidance in finding the suitable solutions for the individual learner in the maze of possibilities. Largely because learning outside formal schooling differs from the ways in which most adult learners remember on the basis of their own experience from their years in school. We need to expand the old concept of learning to include a dynamic idea of knowledge, shared cognition, collaborative learning and the changing roles of learners and teachers.

We have quite a lot of well-designed technology available and a lot of effort is put to improving the old and developing new technological aids for learning. What is lacking, however, are functional pedagogical models, which would allow those who work in these environments, both the learners and their teachers, to control their learning processes so as to get a feeling of "really learning". By combining aspects from the existing resources - pedagogical and technological - we aim at designing a flexible framework, which would lend itself to versatile uses/users. It is not uncommon that people who have received a considerable amount of formal schooling in languages, for one reason or another fail to use the language in real life situations.

The aim of this approach is to provide a model for learning languages at work. This model offers a shared space and built-in guidelines for the learning process. One of the central points is that the contents are not determined externally, but instead they are produced together with the people involved in the process, the employer and the employee. Even though the employer is the funder of the training in most cases, successful learning outcomes cannot be achieved unless the employees themselves are involved in the planning of the learning content, process and goals.

The underlying factors of every individual learner should not be overlooked when planning and carrying out the training. The learners come from very different backgrounds, have varying grades of motivation, different learning goals, different entry levels and also varying amount of time and energy to invest. As for the employer, the training has to react to the rapidly changing contents of work, and the diversified groups of trainees (time/length, depth).

There are three main building blocks involved:

- Analysis of the participants' language abilities and the language needs in their work
 - using a web-based diagnostic self-assessment tool (DIALANG, <http://www.jyu.fi/DIALANG>) to set an so called entry-level for the learner

- Planning for the collaborative process (tools for student learning/evaluation)
 - support questions and an transparent and transforming structure
 - various collaborative approaches for producing the learning content
 - various web-based tools (ProjectTools, COW) as the shared meeting place
- Launching the learning process
 - the goal is to support learners' language awareness and autonomy and to offer learning task which offer enough challenge as well as support to the learner

We will briefly describe the previous experiences of the reseach group on which the current model builds on. These include projects in which focus has been on improved interaction in web-based learning environments and also staff development programs where technology has been incorporated into the process of doing learning.

ABSTRACT

In this paper we describe the approach to merge a hypermedia authoring system (MEDIT) with an adaptive tutoring system (CAMELEON), in order to build a complete teaching and learning environment on the WWW. The aim is to support the use of the WWW in education such as a cognitive tool, for the improvement of learning effectiveness.

KEYWORDS: Web Based Training, Hypermedia Authoring System, Adaptive Hypermedia

INTRODUCTION

Every distance education system addresses both actors concerned, teachers and students, offering them the corresponding working environment: an authoring system and a tutoring system. However, as far as we know, no existing research projects deeply investigate both aspects. In an educational hypermedia environment we often take care of the student which is the final user. The vast majority of existing systems adapt their interface to the student using information represented in a user model [3], such as knowledge level, gender, age, background etc. Nevertheless authoring systems are also an important part of the whole environment allowing teachers to introduce and manage the course content without dealing with technological drawbacks. For this reason we believe that offering a tailored hypermedia authoring system for teachers, coupled with an adaptive tutoring system for students could be the best way to assure an increased effectiveness. That's why we merge MEDIT (Multimedia Environment for Distributed Interactive Teaching) with CAMELEON (Computer Aided Medium for Learning On Networks), to give a complete teaching and learning web based environment, who inherits the advantages of each system and throws out the hindrances of each isolated one. In the first two parts of this paper we describe in more details both MEDIT and CAMELEON, in the third part we illustrate how we build a complete environment from the two systems.

MEDIT

MEDIT [2] (Multimedia Environment for Distributed Interactive Teaching) is Web Based Teaching environment for the creation, management and delivering of a university course on the Web. The main goal of MEDIT was to build Hypermedia Authoring Systems suitable for WBT, allowing users to manage the whole course components without facing with technical problems. Unlike other WBT authoring systems, MEDIT management of the course content is suitable for different level of HTML knowledge. Moreover MEDIT has been conceived to increase the pedagogical effectiveness of teaching in order to use the WWW such a cognitive tool to support problem solving, collaboration, coaching and authentic tasks. In fact the environment supports all teaching and learning processes experienced by the students and carried on during the educational activity [4]. All these process components are grouped in MEDIT in three main activities corresponding to three working spaces: Course, Exercise and Discussion.

CAMELEON

CAMELEON is the English acronym of Computer Adaptive Medium for Learning On Networks, It is a system running across the Internet/Intranet, allowing student to access the course content via an adaptive interface.

CAMELEON offers adaptive systems that can compare the student's model and the domain model and thus automatically change its teaching style [7].

Most of the approaches dealing with student modeling involve a rather simplistic model of the learning process and don't take into account of the wide range of learning styles and capabilities. Moreover, neither the student nor the teacher can infer with the student model to adapt it to specific learning styles.

The CAMELEON student model is mainly based on the learning style model proposed by Felder. This model is a fine-grained model for deciding which type of media to display (Text, Images, Simulation, etc.) and works as a coarse grain model to reflect whether the student has or has not mastered the course material presented. The model keeps records of a tutoring session and uses this information to update the teaching strategy for the particular need of the student. All this information can be used as a feedback from learners while they work to master a subject they acquire or improve knowledge and skills. This can be mapped into the student model.

MERGING THE AUTHORING AND THE TUTORING SYSTEMS

MEDIT environment is based on a the conception of working spaces according to the needs of traditional course components: Course, Exercises, Discussion; each of them is then further divided into sub spaces and includes the proper authoring services. Each service realized is a Hypermedia Authoring System, based on structured document approach and on documents reuse features [1].

In MEDIT we developed authoring systems with the goal to take care of pedagogical issues. For this purpose we exploited the possibility for students to personalize documents within a course depending on specific learning styles [6], [5] giving them a Private Working Space. In this space, students can create their own course on the basis of the elements (texts, images, formulas, etc.) of the course content, proposed by the teacher in the Course space. These elements can be selected and automatically copied in the student space. The shared goal of the collaboration is to use MEDIT as an authoring tool for teachers, and CAMELEON as a tutoring tool for learners in order to build a complete and effective educational environment. Teachers will use the authoring environment to introduce the course content (course, exercises, discussions, etc.) including different media such as text, audio, video, simulation, graphics, charts, etc. When the student access the learning environment organized in working spaces, CAMELEON tutoring system intervenes on the display of Course material to present the content in an

adaptive mode. From the data base of the system is able to generate the adaptive interface for the web course using requests according to the user's model (profile, knowledge level and learning strategy). The student will use the Private Space authoring system, to build his/her own course view. This information will also be used as a parameter to update the learner's model. The Discussion and Exercise spaces are not presented adaptively because in our opinion students have to be trained and acquainted with every kind of tests and exams during their study's life.

FUTURE WORKS AND CONCLUSION

In this paper we described the integration of the projects MEDIT and CAMELEON in order to build a complete adaptive and effective learning and teaching environment on the WWW. Our first goal is to create and test a prototype on case study courses in Tunisia and in Switzerland in order to carry on a formative evaluation and improve the system. Future development of the collaboration include the customized management of the physical aspects of the interface (backgrounds, fonts, size, colors etc). It also includes the creation of game space allowing teachers introducing educative games and helping learners to resolve those exercises.

lawhead@cs.olemiss.edu

Abstract: What sorts of Web-based course supplements would students find to be most useful and least useful? Is there a difference in what students in computer science courses would prefer and what students in a humanities course would prefer? Answers to these questions were sought by surveying students in both computer science and philosophy courses. Briefly, we found that there was a core of materials that both groups of students would find helpful. There was also a high degree of agreement concerning what they would find least helpful. Finally, there were some interesting differences on some of the items between computer science students and philosophy students.

This paper presents a study that was done on the use of Web-based course supplements in an otherwise traditional classroom college course. Most of the articles on Web-based instruction discuss such matters as the design of Web pages and the correlation of Web-based materials with instructional objectives. The problem is that the majority of these discussions are based on the operating assumption: "If you build it they will come." However, our study suggests that the safest assumption to work with in providing Web-based instructional materials is: "If you build it they will come—maybe." This assumption raises a number of questions. Do students think that Web-based course supplements would be useful? Or is the work involved in creating them wasted effort? What sorts of supplements would they find most useful and least useful? Is there a difference in what students in computer science courses would prefer and what students in a humanities course would prefer? Do male and female students have different preferences on this issue?

Answers to these questions were sought by surveying students in both computer science and philosophy courses. The responses of approximately 120 students in computer science classes were compared with roughly the same number in philosophy classes. The philosophy classes were several sections of introduction to philosophy. However, to balance the number of responses, the computer science surveys included both entry-level programming sections as well as several smaller advanced classes. The survey was composed of 17 items gathered from a review of materials that are commonly posted on the Web for a wide-range of courses. There were five responses available ranging from "very useful" to "would not use." The two positive responses and two negative responses were separated by a fifth alternative labeled "neutral."

Briefly, we found that there was a core of materials that both groups of students would find helpful. There was also a high degree of agreement concerning what they would find least helpful. Finally, there were some interesting differences on some of the items between computer science students (hereafter, designated as CS) and philosophy students (hereafter, designated as P). The survey that was used, as well as an item by item tally of percentages for each response separated according to the two types of courses are posted at the following URL: <http://www.cs.olemiss.edu/webnet/surveyin.html>.

The ranking and comparisons of the various items were carried out by combining the two positive responses of "very useful" and "somewhat useful" into one, combined score. The percentages listed below reflect this combined, positive score for each item. For both sets of students, several items received an equal number of percentage points. Consequently, the 17 survey items fell into 14 levels of preference in both cases. Those that ranked 1 or close to it were the most preferred items and those that were closer to 14 were perceived as the least

useful.

The items that received the most positive responses (they ranked within the top five) for both CS and P were: (1) syllabus, (2) study questions, and (3) announcements, reminders, and calendar of events. The items that were equally ranked least useful by both sets of students were "on-line chat spaces" and "suggested reading list." Both sets of students also ranked "anonymous feedback to instructor as the course progresses" as fifth from the bottom. It is likely that these items were perceived to have the least direct impact on one's ability to master the material and get a good grade.

There were also a number of interesting differences between the responses of the two groups of students. CS ranked "homework assignments" 2 (91%), but P ranked it 9 (76%). One can only conjecture as to the reasons for this difference. Because philosophy assignments tend to be essays, there are fewer of them. Furthermore, they tend to take the form of a single, simple question or topic. On the other hand, there tend to be more CS assignments and programs to write and the technical details tend to be more complex. These differences may be why CS would like to keep track of the assignments on-line. For P, "lecture notes" received the second highest score (91%), but ranked 8 for CS (81%). This may be because philosophy lectures are harder to follow or it may be because CS instructors tend to use more outlines and handouts when lecturing.

CS ranked "interactive exercises" 6 (85%), but P ranked it third from the bottom at 12 (61%). Perhaps, this is because there are more possibilities for helpful CS interactive exercises. The philosophy students may have perceived that it would be hard to design interactive exercises in philosophy that would help them master the conceptual material. In philosophy logic classes, however, there are a number of interactive tutorials available. Although this was not studied, it would be reasonable to expect that "interactive exercises" would have gotten a higher ranking in logic classes.

The item "links to web sites relevant to the class" ranked 6 (85%) for CS, but ranked 11 (70%) for P. While the majority of P thought it would be helpful, CS may be more practiced in seeking resources on the Web than humanities students and, therefore, ranked it higher.

Interestingly, concerning the item labeled "class members e-mail addresses and links to their web pages," P ranked it 8 (77%), while CS ranked it lower at 12 (66%). Any proposed reason for this difference would only be speculative. Perhaps this form of communication is rather routine for CS students, so they took it for granted. On the other hand, this may be more of a novelty and an exciting idea for humanities students. However, this seems to be inconsistent with the fact that P ranked "chat spaces" the lowest. One would think that in a philosophy course, they would welcome the opportunity to continue the class debates in this way.

Since there did not seem to be any significant differences between the responses of males and females, these statistics have not been included in this report. Likewise, categorizing the responses by age or year in school (freshman to graduate student) did not seem to yield any interesting results. Initially, it was hypothesized that females would be more oriented toward collaborative endeavors and sharing opportunities. However, the male and female responses (the percentages of both the positive and negative responses) on the e-mail and chat space items seemed to be about the same. Even if female students tend to be more oriented toward collaborative group experiences (as psychological studies suggest), they may also be more reluctant to communicate with fellow students who are more or less strangers. Also, the female students (and males as well) may have perceived that this faceless, detached, distant form of electronic communication was not one that would enhance their class experience. It was also hypothesized that CS would consistently rank most of the items very high, while P would be less enthusiastic about Web-based instructional materials. However, while they did register some differences in preferences, the P group seemed to be equally enthusiastic as the CS group about on-line, instructional resources.

In conclusion, both computer science and humanities students believe they would benefit from Web-based course materials. However, which ones should be used will vary with the nature of the class. Furthermore, it was found that it is difficult to anticipate what students will find helpful. Surveys of this sort, both at the beginning of the semester and at the end, will be helpful in discovering what students initially perceive they will need and, after more experience, what they have actually found to be helpful. A further study that would be revealing would be to incorporate some of the items that received the lowest scores into a course. Then one could see whether or not the students ranked them higher at the end of the course once they have had experience with using them. This is particularly true since many of the students surveyed had not had the opportunity to try out some of these items (such as on-line chat sessions) and therefore were simply going by how useful they imagined or guessed these items might be. These sorts of considerations will guarantee that if you build it, they will indeed come.

New Technology In Information And Communication : A French Experience

Dominique Lecllet

University of Picardy - New Educational Technology Research Group - IUP Miage - BP 2716 - 80027 Amiens
Cedex 1 - Dominique.Lecllet@u-picardie.fr

ABSTRACT: The article presents an experience in the domain of New Technologies of Information and Communication. The training strategy adapted gives a great importance to the realisation of computer multimedia applications by students. This is done in co-operation with companies and this five year activity yielded three main extensions. The setting of an apprenticeship organisation which enables the student to work inside companies with the methodological support of university staff. The setting of distance learning activities contribute to life long training. The synergy between those actions provides an example which may be extended to other sections.

1 Introduction

One of the changes induced by the information society which is constituting itself before our eyes regards is the fact that sources of knowledge are more and more diversified. This affects the traditional function of transmission held by universities [Berger, Levraux,96]. In our opinion, a way to face it is to use new technologies of information and communication for knowledge transmission, as much as possible and to put much human contact and efforts to help students acquire know-how. Of course, know-how are related to precise activities, and this brings up right away the problem of relations between companies and universities. The following article is a synthesis of experiences on these topics held by the author.

The first input is related to the effect of this evolution to the teaching strategies in the context of a course : the DESS SIM (Multimedia Information System) is a one year postgraduate training to multimedia. This course is intended to form future professionals, and devote a lot of time to the development of computer or multimedia projects. Most often, these projects lead on to an effective realisation of products or make ups of real applications. They always imply three partners : the student, a company, or an end user and a member of the university staff. This latter plays the part of project manager. In this part he puts an accent on methodology training, behavioural training, and has also a part as of mediator between the cultures of university and companies. This role led quite naturally to put accent to methodologies and more specifically to those needed to drive multimedia projects. An other axis of development is the organisation of distance training: it enables to link the training capabilities of the University with a lifelong learning demand [Levraux, 96].

2 A privileged environment

2.1 The practice of alternation between company and university

Dess SIM is a post graduate diploma which provides a 800 hours specialised course in multimedia to people having an initial competency in computer technology. The program aims at making students able to design and realise multimedia applications for business: communication, advertising, co-operative activities, training, etc... The main competencies addressed are ability to analyse a system of information and communication, knowledge of multimedia applications and development systems, mastery of sound and video processing, ability to structure and manage multimedia information. Practical projects consist on the design and realisation of a multimedia mock up.

In this course, the organisation of the training is divided in formal teaching and practical projects development. Projects are very important: they takes about 50 % of the time and is equally important at the examination. It is a way of learning by doing information technology and multimedia. Students, University staff and external experts meet together for these projects.

The development of apprenticeship in higher education registers itself in the continuity of state laws which have made the apprenticeship juridical bounds more flexible in order to favour men extension to new professions and to higher qualification levels. It thus seemed important to lead this action within the DESS SIM through the development by each student, alternatively, of professional projects. The apprentices are entrusted, within the scope of the prepared professions, to professional activities where the progression is organised by the companies after a dialogue with the university. This activity in the firm, accompanies at the best the progression of the education, and favours an alternating pedagogy.

2.2 A distance education platform

A distance learning action, related to the DESS SIM, has been launched at the University with support of the French Ministry of Education, Regional. In order to put into place the distant training plan, various stages have been considered:

1. At first, the writing of a book: "*Technical basis for the multimedia*" [Weidenfeld, Lecllet, 97] have been made as paper class support.
2. Secondly, the making of hypermedia books has been taken into consideration. This work of bringing into hypermedia form this book is nearly finish. Compared to the paper version, this hypermedia have two major plus: *indexing* (a pre-eminent work about the contents allows to constitute an index organised according to a predefined frame : "biographies", "technical aspects", "methodological aspects", "professional activity", ..., [Bayrou, 97]) ; a *complementary browsing method* is provided by an additional "linguistic" work on the index. A collaborative definition of synonymies, antinomies, proximity's, etc enables to build a thesaurus. This thesaurus enables, in return, to create links quite automatically [Fauroux, 96].
3. At last, the use of interactive simulations for some of the previous activities. It is possible to associate an interaction, achieved through a computerised program, to the part of the hypermedia which will illustrate the illustrated notion. We shall call such a program an *interactive simulation*.

An initial interview (with the possible help of a screening system) allows the elaboration for each person of an individual degree course. This elaboration takes into account the acquisitions and the objectives of each one. In the end, it comes to the global suggestion of modules and/or to the suggestion of supports to be studied, as well as an evolution within this study.

Moreover, for each of the modules, there will be an allocation of individual tutoring during two hours. This tutoring allows the correction of the applications and activities offered in this module and the settlement of a regular communication, through e-mail, between the tutor and the learner. This e-mail (with *mail* and *talk* facilities relies upon the installation of a server accessible from the university servers). Besides the individualised help given to the learners, this e-mail will make the updating of so-constituted knowledge, easier. Therefore, the messages exchange format will include such elements as: the information, by the learner, about the reference of the chapter(s) regarding his question or the information, by the tutor, of the general interest "level" of his answer (circumstances or deepening compared to the existing contents).

3 Conclusion

This various activities developed are in the scope of the future university model. The alternating organisation enables to develop a rich partnership between the University and companies. One of the key factors to the success of this partnership is the visibility of the training paths. The evolution of New Technologies of Information and Communication leads quite naturally to open and distance learning organisations. It is one of the devices, which enables long life training.

Web-based Instruction: A Study of the Effects of Self-Efficacy and Task Values on Students' Commitment and Achievement

Chia-Jung Maigo Lin, Journalism and Communications, Shih Hsin University, Taiwan, maigo_lin@hotmail.com

Edward Kazlauskas, Rossier School of Education, University of Southern California, USA, kazlausk@usc.edu

Nay-Ching Nancy Tyan, National Taipei Teachers' College, Taiwan, ntyan@tea.ntptc.edu.tw

Abstract: This study explored whether students' task value and self-efficacy would enhance their commitment and achievement in a WBI class in Taiwan. This study compared students' commitment, achievement, self-efficacy, and task value with and without a training workshop that was designed to increase students' commitment and achievement. The results of this study included: (a) the higher task value students' perceived, the stronger commitment they made; (b) The higher self-efficacy students held, the easier the task was perceived; (c) The training workshop had positive impacts on students' perceived self-efficacy, interest, and importance.

Introduction

Web-based instruction (WBI) class pages have been used not only in fully distance programs but also in supporting the face-to-face traditional classroom for the purpose of increasing class interactions. Researchers, such as Jonassen (1995), have suggested that the use of WBI class pages can create an effective learning environment by creating asynchronous communications, collaborative learning, and case-based instruction. It is expected that students can self-motivate and can perform higher order thinking by actively participating in meaningful discussion with their peers. The self-pacing benefit of asynchronous learning on the WBI class page becomes a disadvantage when learners are unwilling or unable to be self-motivating or self-regulating. When learners lack required skills or task value they may not adequately direct their own learning. Learners who have lower self-efficacy tend to achieve less successfully than those who have higher self-efficacy (Bandura, 1997). Those with higher task value tend to devote more effort in the use of learning strategies resulting in better performance. Task value has indirect impact on Taiwanese students academic achievement through influencing effort (Wang, 1997).

The Problem and Study Purpose

In most Taiwanese classrooms, students are passive and quite listeners and they record class notes and memorize factual information. It is rare to see meaningful discussion between teachers and students (Tyan, 1998). In Spring 1998, a professor at National Taipei Teachers' College adopted WBI to support classroom instruction. Case studies were used as the major instruction method with 4-6 open-ended questions posted for each case on the WBI class page. Students were required to post their responses as essays, read others responses, and provide feedback to others. The goal of the class was to increase student interactions, and to construct meaningful discussions through collaborative learning. At the beginning of the semester, students showed a very high interest in online discussions. However, by the end of the semester, the number of responses decreased. The goal of commitment of increasing discussion interactions decreased. After interviewing the professor and the students, it was noted that since this was a new learning approach, students did not recognize the task value of cased-based discussions. Most of students were not confident with this new learning approach. Student self-efficacy in conducting a meaningful discussion was low.

Methodology

Thirty students at a teacher education institution who were enrolled in a WBI class in educational technology were randomly assigned to a treatment and control group. None of them had experience in performing online case-based discussions. The research design for the study consisted of: (1) Control-treatment comparison of subjects' achievement, level of self-efficacy, task value, and commitment; (2) Investigation of the correlation relationship among subjects' self-efficacy, task value, commitment, and achievement; (3) Interviews and observations of subjects. A pre-intervention survey was distributed at the beginning of the semester and a six-hour workshop was presented before conducting the first case study for the treatment group. The objectives of this workshop were to (1) increase students' positive task value and (2) increase their self-efficacy by teaching them necessary strategies with practice for improving their performance. Two useful job aids were presented for helping students assess their commitment problem and for improving their performance on case studies. This workshop included a considerable amount of student interaction, practice, and in-class discussion. An evaluation survey was distributed immediately after the workshop. In the following three weeks, students posted their responses with an essay format in answering open-ended questions for case one. At the end of this period, a post-intervention survey was distributed and a grading rubric utilized to measure students' achievement in case one. The study compared subjects on scores of the first case study, their perceived self-efficacy, task values, and numbers of posted responses, and investigated the relationship among students' task values, self-efficacy, students' numbers of online responses (refer as commitment), and scores of the case study (refer as achievement).

Results and Conclusions

The results from the study revealed students' task value had significant correlation on their commitment in a WBI class. The higher self-efficacy students held, the easier the task was perceived. In addition, teaching students necessary learning strategies and providing them more practice would increase their self-efficacy. This finding supported the previous research, such as Bandura (1997), that individual's level of self-efficacy is not stable and can also be affected by many factors such as providing necessary training to improve skills or knowledge and giving them more practices so that these positive learning experiences will become another entry characteristic to increase self-efficacy. This study found that emphasizing the importance of the task and connecting it to students' personal relevance would increase students' task value. This finding also supported the previous research studies, such as Schiefele (1991), that discovering the task's features by relating its importance or personal relevance stimulates students' task value. However, the self-efficacy did not demonstrate its effects on students' commitment and achievement. Four implications of the study include the following. 1) Teaching students necessary learning strategies and providing them more practices may increase their self-efficacy. 2) Emphasizing the importance of the task and making it relevant to students may increase students' task value. 3) Considering the effect of students' task values on their commitment should be a part of WBI course planning. 4) Training workshop can be one example for instructors who try to increase students' task values and self-efficacy in WBI.

Abstract. This paper addresses the problem of image transmission over the Internet. Work-in-progress with an IIP-compliant image delivery and management platform, Hewlett Packard's OpenPix Image Igniter, in an art education context is discussed.

1. Introduction

This work_in_progress addresses the problem of image transmission over the Internet. High quality image files are slow to download over the Internet. Rather than wait for such images to arrive, users will drop a connection and move to another site. This problem has inhibited the development of image intensive WWW based applications and restricted the quality of the work displayed in on-line museums and art galleries. To resolve such problems, a multi-purpose, information rich image format is required which would provide bandwidth efficient web viewing by allowing an image to be downloaded over the Internet at a resolution appropriate to a user's purpose and device capability. Two Internet imaging open industry-standards have emerged to meet this requirement: the Internet Imaging Protocol (IIP) and the FPX file format. In this paper we report our work with an IIP-compliant image delivery and management platform, H.P.'s OpenPix Image Igniter.

2. Technical Background

The IIP is an image-transport protocol that provides a standard method for sending "tiled" images and other related information over networks. It is designed to work within HTTP or under a dedicated socket connection. The FPX file format is a tiled-image file format that can support multiple versions of the same image at different resolutions. Each FPX file format image consists of several resolutions of tiled image data, represented in independent 64 x 64 pixel tiles. For example, a 640 x 640 pixel image would consist of 100 tiles. Each resolution is four times that of the previous one. The entire resolution pyramid is stored on the image server, making the overall size of a FPX file format 33% larger than a comparable flat JPEG file. The gain is in efficiency of use of network resources and in download time. When a user zooms-in on an image, only a small portion of the complete file - the tile set defining that part of the image the user wishes to magnify at the next higher resolution - is transmitted over the network. Further, all image transformations are applied by the server before image transmission. This obviates the need for a sophisticated client application in order to view an information rich image. Users can also preview images at a low resolution before requesting the appropriate data for high-resolution printing. Unnecessary network traffic is thus reduced. Only the tile sets and metadata (stored textual information associated with the image such as image description, keywords, author) required to meet a particular need are transmitted over the network. Access to images can also be restricted as IIP provides image security at the tile level. Finally, consistency in the colour of images when delivered to different applications/systems is ensured through the FPX file format's support of sRGB (<http://www.color.org/>).

The OpenPix Image Igniter software suite consists of three core components: - a IIP-compliant image server which runs as a CGI, FASTCGI, NSAPI or ISAPI program within a standard WWW server; a set of four OpenPix viewers - a Java applet, an ActiveX component, a Netscape plug-in or a flat JPEG image delivery - and an OpenPix Authoring environment which allows developers to integrate OpenPix authoring extensions within a standard Web page. ImageIgniter permits access to FPX file format, JPEG and uncompressed RGB files. Multi-resolution tiled support for the latter two file formats is provided through the OpenPix Transcoder API which performs tile extraction, scaling and compression on the fly in response to a Web client request.

3. Educational application of the technology

Our primary purpose in using the technology is to enhance the presentation of the Pre-Raphaelite section of the newly designed National Museums and Galleries of Merseyside WWW Site (<http://www.nmgm.org.uk/>). Fig

1 shows an example of our work. On the left of Fig 1 is a conventional WWW page with the OpenPix enabled image presented inline. When this image is clicked, an OpenPix viewer appropriate to the platform -in this example a Java applet - is automatically downloaded complete with controls which permit the user to select area of the image for exploration in detail, zoom in and out, pan etc. This is illustrated on the right-hand side of Fig 1.

Figure 1: A OpenPix ignited painting

The user is able to actively explore a painting without incurring the high overheads of a complete download of the image on first exposure to it. Museum management can monitor access to and interest in the pictures through the OpenPix ImageReporter facility. The latter permits the construction of visual histograms indicating which pictures and parts thereof in a collection are most frequently accessed. Non-image data such as textual and audio information can be embedded in the FPX file format. In the above example, the only associated 'metadata' is the painting caption and the painter's name. It would, however, be possible to embed more didactic content if, for example, the technology was being used as part of an art history tutorial and music, characteristic of the period, could be embedded. The technology also has the potential to support novel forms of art exhibitions in both an Internet and Intranet contexts. For example, within an Art Gallery one could display OpenPix enabled digital images of exhibits in a flat panel format ideally with a touch screen interface. Children and adults alike could actively explore these images without damage to the paintings either prior or subsequent to viewing these images conventionally. Likewise one could image 'preview area' for an especially popular exhibition that allowed users to interact with the digital images of paintings prior to gaining access to the latter. Coffee tables with embedded flat panel displays of the digital images could be constructed. There are also many other contexts in which the ability to readily refine the detail with which an image is presented is important. Hewlett Packard has emphasised application of the technology in Electronic Commerce - to enhance the display capabilities of on-line catalogues (<http://www.image.hp.com/>). The higher the quality of the photographic image displayed in an on-line catalogue, the greater the probability that the image can convey features of an object such as its tactile quality and the more opportunity the user has to explore features of a garment - such as logo design - in detail. Telemedicine and geographic exploration are other obvious application areas.

The main issues arising from the deployment of the technology are :- the adequacy of the proposed technical solution to the delays associated with image transmission over the Internet; the support provided for non-programmers in use of the technology, particularly within the authoring environment, and users' reactions to the technology. Other solutions to the problem of image transmission are considered e.g. the Zoom project at the University of Berkeley (<http://now.cs.berkeley.edu/Td/zoom.html>) and the Viseum project at the University of Southampton (<http://www.ecs.soton.ac.uk/~km/projs/viseum/>). Both of these also employ tiled image formats. The Zoom project utilises the GridPix format. Because it is based on server scripts the implementation is entirely in HTML and can be supported by any graphical WWW browser without need of a special viewer.

Web Based Instruction: Intellectual Property, Compensation, and Redefining Faculty Work

Dr. William Lynch, Center for Distance and Mediated Learning,
The George Washington University, U.S.A. (blynch@gwu.edu)

Dr. Michael Corry, Educational Technology Leadership Program,
The George Washington University, U.S.A. (mccorry@gwu.edu)

Abstract: The rapid rise in popularity of web based learning materials has accelerated discussion and debate on the changing roles of faculty in institutions of higher learning. The accessibility of the world wide web and the relative ease with which one can create materials for distribution and facilitate communications for learning have challenged the traditional relationship between faculty and institutional employer. What was once assumed as a normal part of a faculty member's contractual activities can no longer be take for granted. This paper examines two high profile issues in redefining those expectations of faculty work relative to web based instruction; intellectual property and compensation.

Introduction

It is becoming increasingly clear that the sanctity of the college classroom and the dynamic nature of college teaching has been challenged by the creation of semi-permanent collections of mediated materials designed to replace at least some of the need for the physical presence of the instructor. The challenge comes in the form of defining reasonable expectations and conditions for faculty work and productivity.

Complicating the development of strategies to address these issues is the fact that current intellectual property and compensation policies at institutions of higher learning vary depending on type of institution, orientation toward research productivity, geographic location, source of funding, mission, and tradition. In addition to the variability between institutions of higher learning; there are other units that compete with traditional college and university programs including divisions of external education, for profit training and education companies, individual courseware creators, and corporate training divisions which can compete for the instructional talent of able faculty. It is reasonable to assert that faculty personnel policies will have to be aggressively competitive, but institutions of higher learning are struggling with the implications of new compensation policies appropriate to web base instruction because of the implications for traditional faculty .

Intellectual Property

Traditionally, most institutions of higher learning recognized that work directly attributable to the personal creative and intellectual effort of faculty belonged to faculty alone, unless the creative effort was the result of a project sponsored by the university or other sponsor. In the latter case, ownership might reside strictly with the sponsor or be jointly owned by the sponsor and the creator. There are, of course, many shades of gray in determining what constitutes personal effort and what constitutes sponsorship, but institutions have tended to favor the individual.

As mediated learning products gain market value, institutions have been reexamining policies that control intellectual products. Mediated learning materials such as web based course materials have generated

much debate and concern on the part of faculty and institutional administrators precisely because of their market value and the investment required to create these materials. The central issue is one of control.

In the case of web based materials, neither the institution nor the faculty developer can wisely be left in total control of these products. New web based materials cannot be developed quickly enough to replace a course which a faculty developer refuses to offer at the last minute. Similarly, a faculty developer's professional reputation is at risk if a course is offered after its accuracy has expired or if it is managed by unqualified personnel simply to improve the economic return to the institution. Additional issues are raised if the institution wishes to sell or lease the materials to another institutional client or if the faculty developer wants to transport the materials to a different institution.

The only reasonable solution to these potential problems is clear ownership policies and special circumstance negotiations. An agreement can be reached through a standard contract that provides a range of options for the faculty developer and the institution. For example, a faculty developer may request a lump sum payment for course materials upon delivery and release all rights to the product, or the institution may offer a percentage of the return on all future use of the materials with little or no initial payment. The variations on these themes are many.

There are ample precedents for this type of negotiation in other industries, especially entertainment. The assumption is that ownership rights of intellectual and creative products belong to the creator, however, these rights can be limited by special conditions or compensation agreements.

Faculty Compensation

Compensating faculty is and will continue to be a complex problem. There is no question that on a course to course comparison with the same number and same quality of students, a course formatted for web based delivery typically requires more time, thought, creativity, and effort on the part of faculty than a similar classroom based course. Issues of equity, measurement, quality, cost and revenue all come into play.

There appear to be three basic institutional responses to the question of how to appropriately compensate faculty for distance learning responsibilities. One model is to offer distance education through a division or school of continuing studies with a independent faculty or separate compensation structure,; a second model is to pay faculty overload salaries,; while a third approach offers faculty a percentage of the revenue generated from the courses. Each response has strengths and weaknesses dependent on the institutional context in which they are implemented.

While aspects of these three models may work well for individual institutions, the position offered here is that of a differentiated staffing model. This simply means that an individual faculty member would become part of an instructional team comprised of specialists in different aspects of the distance education provider responsibilities. Each of these team members, (e.g. subject matter expert, course manager, video producer, instructional designer, evaluation designer, administrative and technical support personnel) would negotiate compensation based on their contribution to the project. Part of the negotiation on the part of the faculty would be a decision as to whether the tasks were part of their basic teaching load, an overload, or a form of service for which supplemental compensation could be provided. The team approach guarantees multiple inputs into the development process, does not infringe on academic freedom, reduces the burden of distance learning on the individual faculty, and creates a common practice from which a standard design quality emerges without inhibiting creativity.

Abstract:

We created a web site to support a sophomore/junior level class (ANSC/FREC/PLSC 270) on the Science and Socio-economic Issues of Biotechnology. The primary objective of this course was to increase and expand the knowledge of biotechnology in agriculture. The course used an interactive website to team distance students with traditional "in-class" students to complete case studies in a problem based learning approach to the material. By working together, traditional and distance students gained the benefits of problem based learning, experienced a team approach to the material and generated insightful discussions on the various scientific, ethical, and economic issues raised in the class.

Students are more likely to retain and apply knowledge appropriately when concepts are coupled with applications (Boud and Feletti, 1991; Dunkbase and Penick, 1990). Our goal was to provide an enhanced learning experience for both distance and traditional students taking Biotechnology: Science and Socioeconomic Issue.

The class used problem based learning (PBL) case studies. Students work on case studies, in groups that include both traditional and distance (geographically dispersed) students. The course is taught to traditional students in the classroom and to distance students via videotaped lectures. A USDA Challenge Grant funded this course's design and implementation. The major challenge of the course was to teach a PBL course to distance *and* traditional students working together. The web site facilitates the interaction between traditional and distance students and successfully combines the use of PBL and distance learning in the class.

The web site (<http://bluehen.ags.udel.edu/biotech>) includes the syllabus, all lectures, homework assignments, hundreds of links to sources of information on biotechnology, case studies and technical computer support pages. The website's "message center" (modified discussion board) is the primary mode of communication for the groups on the web site. The message center had to meet several criteria to be effective. It had to be automated, provide security without requiring user accounts on the server, be easily accessible and easy to use.

The course was taught as a series of lectures, each given by a different expert. The instructors gave their presentations in PowerPoint. The presentations were videotaped for the distance students and the PowerPoint presentations were converted to html and made available on the website. The lecture section of the web site was restricted (by password) to registered students.

Links to sources of information were divided into several sections including journals, research centers, genomic databases, jobs, software, transgenic plants and animals, EST, cloning and many others. We hired an honors student to search the web for biotechnology links, evaluate them and write a short description. This section of the web site is accessible to everyone.

The message center is divided into 6 sections, one for each group. Members may only read the discussion and post to their group's message center. Users were assigned user names and passwords to restrict access to the message center. We chose not to provide students with accounts on the server because it is also a file server for the school's administrators. We felt that

granting students accounts on this machine would be an unnecessary risk. Security was implemented with basic HTTP authentication. This protocol allowed us to create groups and grant access to sections of the site based on membership in those groups.

We chose HTTP authentication over Java or Javascript because HTTP authentication is supported by the vast majority of browsers. We don't know what computers or browsers students are using so we chose the most widely supported method.

The message center is extremely easy to use. Students simply access the page, click on the message center and enter their username and password. At that point they can read other users' messages and post their own. For students that are not familiar with computers and the Internet we provide extensive technical help including sections on connecting with ISPs like AOL and Erols.

Students in an honors section of the course were trained to facilitate the on-line discussions. These students "broke the ice" for the other students in the group and encouraged participation. Honor students indicated that the primary obstacle to other student's use of the site was technical inexperience. We found that once a group member began posting messages, the other members quickly followed with their own messages.

Students completed a survey *Attitudes about Biotechnology* and the *Kolb Learning Style Inventory* before taking the course. They completed the same survey after taking the course. The questions on the survey probed both perceptions of biotechnology and knowledge of biotechnology. The results of the surveys from the past 3 years indicate that students' understanding of the scientific material increased after taking the course, but many students still harbored concerns about the risks and ethical issues involved in many applications of biotechnology.

Preliminary results also show that distance students had more contact with the instructors and classmates than they would otherwise have had and all students had a more active learning experience.

Abstract: This paper gives an introduction to modeling of hypermedia composites used for structuring of web-materials. In the introductory part we explain the need for a data structure such as hypermedia composite in order to provide better characterization and construction of hypermedia-materials. In the second chapter we bring a description of hypermedia composite model. Third chapter tells how to create such a composite and how can it be used. The conclusion chapter brings a short comparison of our approach to authoring web applications and other tools used for the same purpose.

1. Introduction

The requests on web applications today are growing fast: the idea is to give the end user a possibility to understand a presentation easily and quickly, prevent the user from "getting lost in hyperspace", and at the same time the application should allow the author to easily reuse presented (created) material, create new web-materials and produce a new application [Maglajlic et al. 1998].

In order to create a hypermedia application running on the web the author of a such application has to define and compose some building blocks which can contain a lot of actual multimedia documents (units containing hypertext and multimedia materials together). For that purpose we propose here a usage of hypermedia composites.

2. Hypermedia Composites

Hypermedia composite can be seen as a basic building block of a hypermedia application. An author has a number of primitive multimedia/hypermedia documents which he/she combines into a hypermedia composite. The created composite can be further combined with other documents and/or other hypermedia composites to produce a more complex hypermedia composites. Each hypermedia composite has its own internal structuring mechanism, which defines, for example, the number of documents that can be members of this composite, can other composites be added as elements, how the elements of this composite are interrelated in means of computer-navigable links, which operations can be applied to this composite and its elements (open, save, delete, etc.) and a number of other attributes which can be used to describe the composite. Moreover, we should understand hypermedia composite as an instance of a well-defined data type. The data type

definition indicates types of the elements of a hypermedia composite and operations that may be performed on the composite and/or its elements. Thus, we can say that we have different types of hypermedia composites which characteristics and the behavior are predefined in some way and that we have instances of these types that actually hold the data, as much similar as we can speak about classes and objects (instances of these classes) in object-oriented programming languages.

After a creation of some number of such composites it is not hard to combine them into a structure recognized by a hypermedia system (e.g. an information server based on a hypermedia technology).

3. Creation Procedure

A creation procedure of a hypermedia application using hypermedia composites can be seen as a three stage process. First we define a single composite using a particular application for data definition, an application which allows specifying the attributes of the composite and operations that can be applied to its units. For example, we can say that our composite has an attribute which tells it is a teaching course, corresponding units which actually make this composite are title, short introduction, chapters overview and chapters repository.

Let us say that a unit characterized through a particular attribute as a chapter repository has as its contents chapters - which are again hypermedia composites with particular units, e.g. a title, an abstract and contents. Because chapter repository unit can have several objects as its content, the particular operation applied to this unit should than an "add" operation -it means, we allow adding more documents to this repository.

After the composite definition process, as a second phase, the author can supply the composites with an actual contents using an application which recognizes the composite as its template and has an access to a multimedia documents resource directory which can be a local hard-drive or an information server.

The third step in this approach is specifying a visualization procedure for defined hypermedia/web materials. The author can use again the special application which makes it possible to design a final outlook of a hypermedia application and specify the linking structure between different composites. A produced structure can be mapped e.g. to HTML or XML, and special created Java-applets, JavaScript or XML can be used for navigation through and between the composites.

4. Conclusion

Using this approach we can achieve the aim of giving an user a web application which is strictly context-oriented. With predefined visualization structure of composites it is hard to "get lost in the hyperspace". On the other hand, the author can use once defined composites to combine them into a new one and create a new hypermedia application. Usage of specially defined application for composite creation and visualization gives the author freedom to functionally define a hypermedia/web material (using operations on the composite units) and to characterize it through the usage of composite attributes.

Overview Of Groupware And The Groupware Market

Julie R. Mariga

Computer Information Systems and Technology, Purdue University
1421 Knoy Hall Room 242, West Lafayette, IN 47907-1421 USA
jmariga@tech.purdue.edu

Abstract: Groupware is a collection of different electronic technologies that supports communication, coordination, and collaboration among two or more people. Groupware seeks to take advantage of the fact that workers are connected together electronically. As client server architectures have evolved, groupware technologies have matured and expanded. Two of the most commonly used synonyms for groupware are collaborative computing and work group computing. This paper discusses what groupware is, lists the major components, the benefits and disadvantages of using it, where it makes sense to be installed, and lists the major vendors in the groupware area.

1. What is Groupware?

Groupware can be defined as technologies that allow people to work together electronically to become more productive and increase communication regardless of physical location or time. Groupware products are collaborative products that allow people to work together and share information in a variety of ways. Since groupware technologies have an impact on the way people work, before a company evaluates and implements any type of groupware technologies it is essential to ask users for their input. People do not like being told what to do or how to do it. In order to assure a successful implementation it is essential to get the users involved. It is important to help users understand the benefits that groupware technology can provide them. It is also important not only to get users' input but also to provide them with training on how to use the new technology effectively so that they will use it and see the benefit first hand.

There are five fundamental technologies that groupware builds on:

- Electronic mail
- Calendaring and scheduling
- Workflow
- Real time and non-real time conferencing
- Electronic meetings

No single groupware product incorporates all of the above technologies but products are becoming more advanced and are incorporating new technologies while improving the technologies already included. The three main vendors and products in the groupware area are:

- Lotus Notes and Domino Server
- Microsoft Exchange Server, Outlook, and NetMeeting
- Novell Groupwise

What are the benefits and problems of using Groupware?

There are several benefits to implementing groupware technologies into a company. The benefits are: increased information access, eliminates redundant information, improves business processes, automates routine processes, improves decision making, and increases organizational learning. Along with the benefits of any new technology there are also some problems that can be encountered. Some of the potential problems are: not enough properly trained people, lack of upper management support, no clear business objective, lack of understanding of what groupware is and what it can do, and lack of standards.

Where should Groupware be employed?

Industry analysts are predicting that the groupware market will become a multi-billion dollar industry by the end of this century. This leads to the questions: Where should groupware be implemented? and Who should implement groupware? The answer is generally the typical IT answer: it depends. Many companies have already started pilot projects and some have fully implemented groupware technologies in their companies. Some companies have decided to use Lotus Notes and Domino Server as their groupware choice.

A few examples follow:

1371

- NYNEX decided to implement Lotus Notes to bring the data warehouse to the desktop. According to Carl Fiore, managing director of NYNEX's Marketing Information Systems division, by providing access to the data they were able to empower the marketing departments to make faster, better, and easier decisions.
- Prudential Insurance Company upgraded its worldwide messaging infrastructure from IBM Mainframe-based PROFS to Notes. Not all companies select Lotus Notes and Domino Server.

These are just a few examples of companies that have implemented some type of groupware technologies and achieved measurable benefits thanks to careful planning and a clear understanding of how the technology would support business processes. These are some tips to follow to ensure success in implementing groupware:

1. Get top management involved.
2. Implement the groupware technology during a pilot program in one area of a department, not the entire organization at once.
3. Get users involved so that they are more willing to accept the change. Remember, users are very resistant to change. Have open communication and be prepared for resistance.

2. Major Players

There are currently three main players in the groupware market: Lotus Development Corporation, Microsoft Corporation, and Novell Inc. According to industry research at the end of 1997, Lotus Notes had 15 million users, Novell Groupwise had 8 million users, and Microsoft Exchange Server had 7 million. Industry experts are predicting that by the year 2000, Lotus and Microsoft will have equal market share. Needless to say it is expected that the groupware market will go through continuous change for the next few years.

3. Conclusion

Having gone through corporate downsizing in the early nineties, many companies still had the same amount of work or even more work to accomplish but with fewer people. So how were companies going to do this? Many companies turned to their information technology architectures as the answer. Many companies started to move from a mainframe architecture to a client server architecture. As client server architectures have developed and matured companies have been provided with a great deal of flexibility, have empowered employees to meet a lot of their own information needs, and have allowed for employees to communicate and collaborate in ways that were not possible before. One new area of computing that grew out of client server computing is groupware. As educators in the Information Technology field we must stay current on what is happening within industry so that we can develop new courses and provide the best and most current education to our students.

Interactive Courseware Quiz Creator: An Adaptive Zero-Programming Content Development Tool for Students Learning and Testing via Intra/Internet

Abstract: We should be prepared for the rapid progress of multimedia technologies in terms of extending the life span of both developed programs themselves and the products created by these programs. Otherwise, our hard-won achievements may become rapidly obsolescent, due to rapid changes in technology, before we are able to put the programs and/or the products to practical use. This paper describes the "Interactive Courseware Quiz Creator," which allows teachers to create and publish several types of quizzes to the intra/internet, without prior programming knowledge. As well, the program's ability to adapt itself to rapid technological change is presented in detail.

1. Background

The rapid progress of multimedia technologies may make computer programmers' hard-won achievements rapidly obsolete. Computer programmers may be forced to become compliant with new technologies before they are able to put their products to practical use. Our Interactive Courseware Quiz Creator (ICQC) enables teachers to design their own educational software with zero-programming knowledge: no specialized computer programming skill is required on the part of teachers [Matsuno, Tsutsumi & Ushijima, 1999]. Additionally, in order to counterbalance rapid changes in technology, we are developing the Web-based ICQC to adapt to multimedia technology innovations. This conceptual design feature should extend the life span of both ICQC and coursewares created using ICQC.

2. Description

As shown in Figure 1, ICQC consists of several programming parts and a "Programming Quiz Module Database"(PQMD). Programming parts are divided into a "CORE-PROGRAM" and several programming quiz modules (PQM1,...,PQMn). The "CORE-PROGRAM" includes several common sub-programs for each quiz module (PQM). We have designed five types of quizzes: 1) Multiple choice, 2) Fill-in blanks, 3) Sequencing (arrange -n mixed up items into proper order), 4) Connect -n to -n items, and 5) Check true/false. Each type has its own quiz module, which helps teachers to create new quizzes of each type, maintains the PQMD, and generates Web-based quizzes with DHTML and JavaScript. In Figure 1, for example, PQM1 illustrates the "Multiple Choice" type quiz. When a teacher tries to create this quiz, the notice in the box named "QM1:" at the top of Figure 1, will be extracted from the PQMD. In this case, the extracted notice shows that a)QM1 is a "Multiple Choice" type quiz, b)The number of necessary data entries for creating this type of quiz (four), c) The allowable media types for the questions are: "Text," "Sound," and "Video," and so on. Additionally, the PQMD stores media attributes and associated object modules, such as an object module for QuickTime movies. By adopting this modular organizational method, it will be easy for users to adapt to new technology, if (as in a typical case), they are adding new attributes within program modules associated to the PQMD, as new multimedia technologies appear. Over and above that, since each quiz module is independent of the other modules, it will be easy for a programmer to add/update a module if a teacher asks the programmer to add a new quiz -type module, or requests software upgrades.

3. Generating Web-based Quizzes

As far as generating web-based quizzes is concerned, ICQC is divided into two phases (see Figure 2). In the first phase, a teacher has to create new quizzes and store them in the Teacher's Quiz Database. In the second phase, the teacher has to choose the number of questions he/she wants on his/her quiz, from the database. Then, ICQC automatically creates the Web pages. We will next show the process in detail.

a) Phase 1: Creating New Quizzes

In order to create new quizzes, as shown in Figure 2, a teacher has to first choose a quiz type. Then ICQC will prompt the teacher to input the necessary data. When a teacher chooses "Multiple Choice," for example, ICQC will show the teacher an "input form," which prompts for four groups of data: 1)The questions, 2)The number of correct answers to be chosen, 3)The correct answers, and 4)The wrong answers. Since ICQC provides teachers with a simple text editor and a sound recorder, they can both input text and record sound clips. Of course, they can use any type of media they have already prepared in advance. By clicking the "Add" button, after inputting the necessary data, the teacher can add the new quiz to the Quiz Database.

b)Phase 2: Generating Web-based Quizzes

The right side of Figure 2 shows the method of publishing Web-based quizzes. First, a teacher has to choose a quiz type, and then ICQC will show the contents of the Quiz Database. Second, by clicking on database entries, the teacher can add quizzes to the quiz list. Finally, the teacher can publish Web-based quizzes with DHTML and JavaScript by clicking the "Web" button. For example, if a quiz type is "Multiple Choice," ICQC will shuffle the correct answers and wrong answers each time it creates Web pages. This feature is useful in preventing students from memorizing answer locations in successive quizzes. Additionally, ICQC provides teachers with several features, such as making 'blanks' in "Fill-in blanks" type quizzes, and allowing teachers to publish quizzes in a "Practice Mode" or "Test Mode."

4. Discussion

As we mentioned above, we are developing ICQC with two overall themes: one is to give an adaptive function to allow for the rapid change of multimedia technologies, and the other is to allow teachers to create their own Web-based quizzes with zero-programming. At present, we have developed the "Fill-in blanks" section and "Multiple Choice" section. If we adopt the CGI design, we can provide more useful features, including students' study histories. Although there are administration and security issues associated with CGI implementation, if a significant number of teachers wish to use CGI to manage their students, we are preparing to build this function into ICQC.

Abstract: The Information Environment for School Leader Preparation (IESLP) is a web-delivered information environment and problem-based instructional system. IESLP provides users with access to an extended set of data from actual community and school environments that serve as a realistic backdrop in front of which a wide variety of problem-based learning activities can take place. IESLP problem exercises encourage self-directed learning and skill building responsive to the real world tasks and genuine problems administrators are faced with in contemporary schools. The system fosters the use of web resources and other information technologies in the identification and framing of problems, and the generation of proactive and collegial approaches to intervention. Thinking and acting in the real and imperfect environments provided by IESLP parallels the limitations and stresses of work in the real world and prepares future school leaders to deal with all types of situations in which they might eventually find themselves.

As in other realms of education, a need has been identified to reconstruct the professional preparation of educational administrators so that it is more closely tied to the complex problems facing practitioners [1]. In response to this need, the University of Missouri-Columbia Center for Technology Innovations in Education has developed a web-delivered information environment and problem-based instructional system that uses the tools of modern technology to place educational leaders in the virtual halls, classrooms, and boardrooms of actual public schools. It draws practitioners and would-be educational leaders into ways of thinking that incorporate the use of technological resources, tools, information, theory, and research. It creates a demand for the capacity to use information technology to make reflective, information-based decisions and engage in collegial problem finding and intervention. It is an authentic approach to acquiring knowledge, skills, and dispositions appropriate for leadership in contemporary educational organizations. The IESLP project was conceived by the University Council for Educational Administration (UCEA) to stimulate a revolutionary departure from predominant patterns of administrator preparation using authentic avenues for teaching and learning school leadership and to encourage the use of information technology in the practice of school leadership.

Problem-based learning is a pedagogical approach for posing significant problems in the context of real world situations and providing resources, guidance and instruction to learners as they build content knowledge and problem solving skills and strive to devise viable solutions. IESLP fosters the use of web and other information technologies to build skill in identifying problems and opportunities, generating proactive solutions, encouraging collegial approaches to intervention and the acquisition of knowledge, skills, and dispositions appropriate for leadership in contemporary educational organizations. The IESLP approach challenges learners to use technological resources to solve problems and demonstrate learning through varied authentic activities.

IESLP is not a computer simulation. Computing technology is an integral part of using IESLP; however, instead of acting on problem exercises in a simulated computer environment, IESLP exercises are worked on by people in face-to-face groupings, using technology like they do or will in their actual work-lives. That is, students use technology as a tool to retrieve information and data, analyze data, communicate, and produce products. However, unlike a simulation, in IESLP this is done in the context of human work groups, subject to the uncertainties and limitations of those groups, just as teams of administrators do in real educational settings. IESLP, therefore, is much more than a traditional simulation could be. It is a comprehensive information learning environment that brings to learners and instructors the genuine complexity of contemporary schools. While older style simulation systems tended to define school administration in terms of coping with problems that find administrators, the IESLP system is based on another idea: *that the most critical skills administrators can develop are those having to do with problem identification, problem framing, problem intervention, and problem prevention.*

IESLP's information and learning environment creates a realistic backdrop in front of which a wide variety of problem-based learning activities can take place. Three essential components constitute the strength and uniqueness of the IESLP information environment: the problem exercises, the community and school environments, and the tools and resources.

IESLP learning begins with authentic problems of professional practice surrounding K-16 education with a particular K-12 emphasis. Problems in educational administration are often ill structured: there are no clear-cut right or wrong answers. Ill-structured problems are those that involve several simultaneous conceptual structures and are irregular across cases. IESLP problem exercises vary along a continuum from virtually unconstrained problem identification to highly constrained problems. In problem finding exercises learners are asked to define and shape the problem with little direction. Thus, these problem exercises take the form of very general and ill-structured charges. These ill-structured assignments are unconstrained such that the problems as well as the solution are to be discovered. In contrast, problem presented exercises provide learners with more information, more constraint, and create rather specific expectations about products required of individuals and learner groups.

IESLP provides users with access to an extended set of data from actual community and school settings that serve as a backdrop for problem/opportunity discovery, examination of relevant research and best practice knowledge, and group negotiation of decisions about appropriate interventions. The information provided in the community and school environments is comprehensive and provides context in which students can engage in problems of practice. The environments are fictitious community and school web sites constructed with authentic information collected from actual schools and their surrounding communities, including community demographics, district information, school characteristics, and information on facilities, budget, students, parents, and teachers. The data in the environments are real, but modified to protect identities. The IESLP community and school environments vary by educational level and community type. Data contained in the first environment included in the IESLP system were collected in a rural Oklahoma public school district. Future environments currently under development will include urban and suburban public school districts and the communities they are each situated in.

IESLP includes links to the appropriate analytical tools and research in education and the social sciences, and fosters the routine and intelligent use of both. Consistent with the notion of providing rich, authentic learning experiences that include skill learning objectives, IESLP exercises incorporate information management, data analysis, decision-making, presentation, etc. Many of the tools required to complete tasks are available on the web, and a number of them at the *Planet Innovation* web site. Also developed at the Center for Technology Innovations in Education, Planet Innovation provides tools that support decision-makers as they plan, implement, and evaluate programs, particularly K-12 technology planning, by supporting communication and informed choice making. To facilitate this process, Planet Innovation developed an on-demand web environment through which individuals could choose web solutions based on their needs and, if desired, form groups to work in a distributed environment.

Thinking and acting in the real and imperfect environments provided by IESLP parallels the limitations, stresses and processes of work in the real world and prepares future school leaders to deal with all types of situations in which they might eventually find themselves.

ENiSpace: Evaluating Navigation in Information Spaces

Rod McCall, David Benyon
School of Computing Napier University, Edinburgh, UK, EH14 1DJ
Tel: +44 131 455 4675 Fax: +44 131 455 4552
EMAIL: {mccall,dbenyon}@dcs.napier.ac.uk

1. Introduction

Traditional methods of evaluating usability such as heuristic evaluation and cognitive walkthrough do not address all issues relating to navigation. This is despite the fact that designing effective navigation within electronic spaces is now considered an important issue.

The research presented here describes the development of the ENiSpace system which is a software package aimed at allowing people to evaluate the navigational properties of electronic spaces. The software includes reporting features and supporting documentation and is based on a checklist. ENiSpace is also intended to be used to inform the design of electronic spaces.

2. Disorientation within Electronic Spaces

The increasing use of the web as a means of mass information storage and retrieval has led to a number of studies of the navigational problems encountered by users. The three main problems are: *not knowing where to go next, knowing where to go but not how to get there and not knowing the current position relative to the overall hypertext structure.*

One study [Foss 1989] indicated that there are three observable symptoms of becoming disorientated within electronic spaces: *navigational Disorientation* (a person can be seen looping or taking inefficient paths), *embedded digression problem* (the screen may become disorganised and cluttered) and finally the *art museum problem* (the person does not study any part of the environment for a period of time. Instead they are observed merely scanning it).

Taking this further it is possible to see that (as an example) the overuse of the back button may be a result of people looping and taking in efficient paths, even when other navigational aids are provided on page. Therefore in order to combat this and other navigational problems, we need to provide navigational cues at appropriate times.

3. ENiSpace

ENiSpace seeks to cover the three main aspects of navigation: *object identification*: where people gain an understanding of the space and objects within it [Benyon et.al. 1997], *wayfinding*: orientating towards a specific point [Downs et. al. 1973] and exploration: where no specific destination is required. Therefore when designing an electronic space we must be aware not only of supporting task specific activities (wayfinding) but also the ability of people to explore the environment and identify objects. In addition we must also look at ways of supporting all three at any given time during the navigational process. The framework [Spence 1998] highlights four parts which encompass object identification, exploration and wayfinding. The components are *browsing* (this is similar to exploration however the person has an imprecise goal), *context modelling* (the creation of a mental map of the environment), *gradient perception* (the weighing up of various route options) and finally strategy formulation (this is the formulation of strategy used by the person when browsing).

In addition to supporting the models of navigation ENiSpace also seeks to build upon the research into the environmental knowledge which people have. Therefore ENiSpace seeks to support the three types of environmental knowledge [Siegel et. al. 1975] *landmark* where users navigate by landmarks, *route*: where they use a set procedure, and *survey*: where they use mental maps of the environment.

ENiSpace covers four main areas which attempt to inform the designer on how to avoid potential navigational problems. For example the section *signs within the environment* specifically covers the provision of information signs (to aid in object identification). In addition it also covers directional signs where the aim is to provide route and other information which will prevent the problems highlighted earlier, as well as warning and reassurance signs. In another section *conceptual and physical structure* the method looks at the ability of the environment to convey content and structure through the way the objects are distributed as well as the use of landmarks. One particular departure from existing methods is the examination of the dynamic aspects of the environment. The third section *users in the space* deals with enjoyment and also how they interact with other agents within the space (also known as social navigation). The final section *navigational methods and aids*, examines the issues relating to shortcuts, maps and overview structures. In addition within all these sections issues relating to metaphor, imagery, analogy and sound are discussed. Further to this each section covers how the cues will effect the users current navigational mode, knowledge of the environment and ability to remain orientated.

As can be seen the method marks a stark change to the traditional method of usability as it examines the impact of specific cues on the users in particular the use of social navigation techniques [Munro et. al. 1999]. The aim being that by incorporating aspects of social navigation the navigational process will be easier and become more natural.

4. Conclusion and Future Directions

ENiSpace offers the designers of electronic spaces a method which can be used to inform as well as evaluate design. In addition its rich set of questions, structure and supporting documentation provides a highly focussed method which also can provide possible suggestions for improvement. At the time of writing it had been tested on a number of 2D and 3D environments.

Abstract

This paper describes how an area of learning theory, specifically learning styles, is used to evaluate the learning outcomes of a web based course. The Kolb (1985) Learning Style Inventory was administered to a group of 70 accounting students who had no prior experience with web based learning. Results are tentative, however it appears that there are learning style differences with respect to preference for asynchronous web based courses and there are improvements in overall student grades for some learning styles when using such courses. If replicated this study has an implication for university educators and their corporate counterparts due to the range of different dominant student learning style preferences across faculties.

Results

The results of the study are presented in Tables 1 - 5:

The first table shows students results in the unit AFM 272; Accounting Information Systems grouped by each of the four learning styles. Results are presented as letter classifications with numerical ranges shown.

	Accommodator	Diverger	Converger	Assimilator
High Distinction 85+	0	0	0	19%
Distinction 75 -84	20%	35%	22%	10%
Credit 65 -74	54%	35%	55%	24%
Pass 50 -64	13%	17%	12%	28%
Fail <50	13%	4%	11%	19%
Withdrawn	0	9%	0	0
	100%	100%	100%	100%
Average	Credit	Credit	Credit	Pass
N = 70	N = 15	N = 25	N = 9	N = 21

Table 1 Results in AFM 272 Accounting Information Systems

A grade average for each learning style based on past results in all courses was then computed. This information is shown in Table 2. Data from Table 2 is used as basis for comparison with various components of web based learning as shown below in Tables 3 -5

	Accommodator	Diverger	Converger	Assimilator
High Distinction	0%	0%	0%	5%
Distinction	13%	36%	22%	14%
Credit	20%	24%	56%	28%
Pass	54%	34%	11%	48%
Fail	13%	4%	11%	5%

Withdrawn		2%		
	100%	100%	100%	100%
Average	Pass	Credit	Credit	Pass
N = 70	N = 15	N = 25	N = 9	N = 21

Table 2 Average results for all other courses

Table 3 shows student use of the web based course by learning style and average number of hits.

Table 3	Average Number of Hits			
	Accommodator	Diverger	Converger	Assimilator
Average no of hits	347	458	353	288

Table 3 Average Number of Hits by Learning Style

Table 4 presents a synthesis of student use of the asynchronous web based material by learning style, results and number of hits.

	Accommodator	Diverger	Converger	Assimilator
High Distinction	0	0	0	186
Distinction	872	678	242	611
Credit	205	282	131	132
Pass	318	382	142	367
Fail	280	69	143	266
Withdrawn				

Table 4 Learning Style, average number of hits and associated grades

Table 5 presents a comparison between the number of hits; differences in results gained and learning style.

	Accommodator	Diverger	Converger	Assimilator
High Distinction	0%	0%	0%	14%
Distinction	7%	-1%	0%	-4%
Credit	34%	11%	-1%	-4%
Pass	-41%	-17%	1%	20%
Fail	0%	0%	0%	-14%
Withdrawn		7%		

Table 5 Student Performance Differences between AFM 272 and Average Grade by Learning Style

Conclusion

Early results suggest that there *are* learning style differences in student use of asynchronous web based material and that there is a relationship between use and enhanced performance. It is acknowledged that conclusions can only be tentative, given the sample sizes in each group. Nevertheless, if replicated with a larger sample size the results would have implications for accounting educators where studies have shown dominant student categories are Converger (Lillie 1990) and Accommodator (Willcoxon 1996, Kolb 1976). There is also relevance for educators in the arts where the dominant student category is Diverger and economic/sciences where the dominant learning style is Assimilator.

The drive by universities world wide to develop flexible learning programs which are both educationally effective and time and cost efficient means that the potential for research, in the relatively new area of web based teaching, are numerous. It is important that there is continuing evaluation of all aspects of web based teaching and learning if the promise of web based instruction is to be fulfilled.

PsychExps: A Web-based Cognitive Psychology Laboratory

Kenneth O. McGraw and John E. Williams, Department of Psychology
Mark D. Tew, Department of Electrical Engineering
University of Mississippi, USA
psychexps@olemiss.edu

Abstract: PsychExps is a public, on-line cognitive psychology laboratory that has been developed to address problems of cost and periodic obsolescence of both equipment and software in department-maintained undergraduate psychology labs. Located at <http://www.olemiss.edu/projects/PsychExps>, the laboratory is being developed using Authorware®, a relatively easy-to-learn multimedia authoring tool, and Shockwave, a free technology that makes interactive Authorware® programs deliverable over the Internet to both PC and Mac users.

The PsychExps Site

The PsychExps project to establish a public, on-line psychology laboratory for use in collecting data from interactive psychology experiments began in 1997 and the site became operational in Fall, 1998. By May 1999, 45 classes at 39 different institutions had registered as users and students in these classes had generated 1464 data records.

The lab features a set of experiments appropriate for use in psychology laboratory classes. Included among them are experiments involving visual illusions, mental rotation, face recognition, pitch memory, and word recognition. Participants conduct the experiment of their choice on-line then submit their data to the data archive where it is appended to the data already collected for that experiment. Any portion of the data archive can be downloaded as a text file for analysis--the whole archive, an individual data record, the records for an entire class, or the data for a particular semester in a particular year. This filtering is performed using an ASP page that assembles the data from an Access database.

In addition to the data downloads, PsychExps offers Excel macros that are designed both for those who want one-click data processing and for those who want to create a tab-delimited data file that can be submitted to a standard statistical package. The product of the macros is a workbook with sheets for each research participant and one overall summary sheet. The individual data sheets give raw data for each participant along with individual summaries. The overall summary sheet lists summary results for each participant along with descriptive statistics for each experimental condition.

Authoring Tool

Whereas Web delivery of interactive experiments could be created using Java, JavaScript, or Visual Basic Script, we have elected to use Authorware a multimedia programming tool from Macromedia that we have found to be ideal for developing psychology experiments. The experiments are executed using a free plug-in known as the Authorware Web player, which is best obtained by linking from our site. The plug-in has been under constant development since first being introduced as "Shockwave for Authorware" but Macromedia now offers automatic updating so that new improvements will be obtained automatically once the WebPlayer is installed.

Can You Trust the Data?

Skepticism regarding the feasibility of delivering experiments via the Web focuses on the absence of control over both the research context and the research equipment. In addition there is concern about the

capacity for computers to deliver and record the experimental events as planned, particularly with regard to tachistoscopic displays and response time measures. Our experience indicates that the skepticism is unwarranted in that the data from our Web-delivered experiments mirror lab-based findings, even for experiments that require precise timing of displays and responses. Textbook results are obtained not just for within subject effects but for between subject effects as well. These results suggest that existing technology is adequate to permit Web-delivery of many cognitive and social psychological experiments and that the added noise created by having participants in different settings using different computers is easily compensated by the sample sizes achievable with Web delivery.

Development Plan

A primary reason for choosing Authorware over other programming tools is that its icon-based interface makes it relatively easy for non-programmers to either make changes in existing programs or create their own. Ease of learning was important to us because our goal is that PsychExps become a communally owned and developed site. Toward that end, we permit users to download the Authorware code for existing experiments in hopes that some will take our experiments, modify them to their needs, and resubmit them to the site as novel experiments. In addition, we have begun training faculty from other institutions to use Authorware to develop experiments they would like to place at the site. By the end of Summer 2000 40 faculty will have been formally trained in workshops we conduct and we are actively seeking other means (e.g., off-site training, CD-ROM and text materials, as well as the development of experiment wizards) of giving psychology instructors the tools they need to develop their own ideas for experiments.

Our commitment to the communal development model for PsychExps is based on the belief that communal site development is essential to long term viability. The intense efforts required to develop and maintain websites can produce burnout in the initial developers. Obsolescence will ensue unless there is a way to pass on the site to others, but for sites developed on a proprietary rather than a communal model, this may not be possible.

At PsychExps we hope to avoid obsolescence by enlarging the development team to a community of individuals with a vested interest in the site. In this way the site can have the longevity of journals, which are sustained and made continually relevant through the joint efforts of contributors, reviewers, and editors all of have a mutual interest in the journal's well-being.

Acknowledgements

PsychExps has been made possible through funding from the U.S. Department of Education's Fund for the Improvement of Post-Secondary Education and the University of Mississippi.

A Web-based System to Coordinate Examination Processing

David McIntyre, Department of Mathematics, University of Auckland, New Zealand

E-mail: mcintyre@math.auckland.ac.nz

Abstract: The Department of Mathematics at the University of Auckland teaches about forty undergraduate papers at three stages. After marking examinations, the examination marks are combined with coursework marks, and overall grades are calculated. However, it is often necessary to apply a certain amount of scaling or variation of grade boundaries to ensure that pass rates are appropriate or that grades are reasonably consistent between papers. In this paper we describe a Web-based system we have developed to coordinate this process.

The Department of Mathematics at the University of Auckland teaches about forty undergraduate papers at three stages. After marking examinations, the examination marks are combined with coursework marks, and overall grades are calculated. However, it is often necessary to apply a certain amount of scaling or variation of grade boundaries to ensure that pass rates are appropriate or that grades are reasonably consistent between papers.

Until recently this processing was done more or less “manually”: of course the calculations were done by computer (using the statistical package SAS), but the SAS scripts were edited by hand, and essentially one person was doing all the work. In some other departments, each examiner processes their own paper, doing their scaling using a spreadsheet program such as Excel. Both of these approaches have severe drawbacks: in the first, there is a significant bottleneck in the process, which could mean accepting results simply because there is not enough time to reconsider scaling. In the second approach, each examiner is working in isolation. While it is easy enough to ensure that pass rates meet quotas, it is hard to justify the scaling in terms of maintaining standards: is the pass rate low in a particular paper simply because a greater proportion of weaker students enrolled in it?

We have avoided both of these problems by adopting a system in which all the results are in a central database, which each examiner can access and manipulate using a Web-based interface. The interface consists of a number of CGI scripts. One advantage of using a Web interface in this way is that it avoids compatibility problems. Our department has a mixture of old and new Macintosh computers, Unix workstations and X-terminals, and a few PCs: all of these are capable of running at least some version of a browser such as Netscape. So long as the scripts produce reasonable HTML output, Netscape can take care of any compatibility issues. Another advantage is that the results lists are hypertext documents, and as such can have links to useful queries of the database. For example, each student’s name in a results list is a link to a full history of that student’s results in current and previous mathematics papers.

A brief overview of the system

There are essentially five parts to the process of generating examination results:

- getting (raw) marks into the system;
- combining the marks from various components to get an overall mark;
- listing the results, in full or in summary;
- comparing results with other papers; and
- scaling marks and/or varying the grade boundaries.

The first three parts are reasonably straightforward. Marks are either entered in an HTML form, or are entered in a spreadsheet which is then saved as a text file and uploaded. Once this has been done, and information such as the weighting given to the coursework and final exam have been supplied, results lists can be generated. These might be a full list of results by name, or a summary showing the number and percentage of students getting each grade.

Comparisons between papers

Of course, one form of comparison between papers is to look at the percentages of students who pass, or who get A grades, using the summaries mentioned above. However, a more useful comparison can be obtained by generating a scatter plot of all the students' marks in both papers, such as that shown in Figure 1 below

Figure 1: a scatter plot comparing performance in two papers

This plot shows a comparison between the performance in paper 445.225 with that in 445.251. Each + symbol represents a student taking both of these papers in the current semester, while the × symbols represent student who took 445.251 in a previous semester (this plot would be generated while considering the appropriate scaling for 445.225: thus it is not necessary to consider marks for 445.225 in previous semesters). This plot is a clickable image: if a user points their mouse at one of the + or × symbols and clicks, they will be shown the name of that student, together with a list of their marks in all mathematics papers in this and previous semesters.

Scaling

Examiners are able to adjust the results using any or all of the following:

- scaling the marks for an individual component of the examination mark (short answers, multiple-choice questions etc;
- scaling the total examination marks;
- scaling the overall marks; and
- changing the grade boundaries.

The use of CGI scripts rather than spreadsheets or hand-edited SAS scripts has another advantage here, in that it allows “sanity checks”: marks cannot be scaled outside their range, the scaling function must be monotonically increasing, and grade boundaries must be increasing.

Availability

Interested readers can explore the system by going to the URL <http://exams.math.auckland.ac.nz/guest> .

The system was originally written specifically for the Department of Mathematics at the University of Auckland, but it is written in the freely-available scripting language Perl, so it should be possible to edit it to run at any other university with a similar examination system and a reasonably standard web server. Anyone interested in obtaining a copy of the scripts should contact the author.

Conclusions

Using a World Wide Web interface to the processing of examination marks has made a significant improvement on the convenience of the processing. Although the initial impetus for this system was to streamline the process, it has also opened up a number of possibilities for the analysis of examination results which were previously too awkward to achieve. Thus, what started as principally an administrative development has also had an impact on the teaching offered by the Department.

A Nexus of Resources, Tools and Content: Using 3-D Animation and a Digital Image Library

**Steve McNeil, Lecturer SOE
Landscape Architecture Program
Department of Environmental Design
University of California, Davis, USA**

Abstract: The creation of educational multimedia is an arduous task for an instructor. In order for development to proceed, a nexus of skills, tools and infrastructure must be present. The experiment described here revealed that an investment in resource libraries, 3-D modeling and sequencing software can result in useful and well received educational tutorials, lectures and study aids. Availability of the proper mix of resources makes the task much less stressful for the individual instructor and can improve the quality of the product and reduce development time.

The mix of tools and capabilities described resulted from the author's efforts to produce educational materials for his large lecture courses in landscape architecture, a professional discipline strongly tied to visual and animated media for instruction. The successes and lessons learned are applicable to a wide variety of visually oriented disciplines and should be of interest to anyone involved in or contemplating the development of graphically rich educational media. Examples of image libraries, sound tracts, interfaces and the final tutorials, as well as student responses will be shared during the presentation.

This project began with my desire to incorporate 3-dimensional graphics into my classroom lectures and to provide student access to a variety of photographic images of real places. My motivation was heightened by a need to serve a class that I taught once a year in a room with 318 desks but with 600 students signing up. This level of demand can motivate any educator to seriously consider alternative methods to the usual fare of chalk board scribbling and slides. Something more efficient and more dynamic was needed.

The content I needed to convey included how the design of the physical aspects of human settlements responded to the natural environment and the social constructs of each culture covered in the course, throughout time. These relatively large units of analysis were unfamiliar to most students and they had difficulty comprehending the structure of a city from 2-dimensional images alone. Cities are decidedly 3-dimensional constructs in the real world and we experience them best by moving through them. While we rarely comprehend them as complete architectural entities while standing on the ground, as we move to a birds-eye perspective or an animated virtual fly-through, a completely different set of understandings becomes possible.

3-Dimensional Animations and Stills

What I needed was a way to reconstruct ancient cities and historic landscapes as 3-dimensional block models to help students understand the spatial organization and morphological patterns that evolved over time. The solution was to develop an on-line image library of still images of real places and link these images to dynamic, 3-dimensional block models that served both as an overview and an interface for accessing additional imagery and information about particular parts or aspects of a place's history.

The solution to how to present communities as 3-dimensional spaces came in the form of a nexus of evolving technology, tools and my own rising skill level. As a research team, we explored a variety of software applications to see which were the most intuitive and efficient for modeling cities and landscapes. Eventually we settled on several moderately priced modeling applications including MiniCAD™, Modelshop™, Infini-D™ and Bryce 3-D™. We found each of these applications to be best suited to a particular type of modeling, though all were fully capable systems on their own. We developed favorites. For example, MiniCAD™ (now Vectorworks™) produced the most accurate architectural models while Infini-D™ was especially good at animating and rendering and Bryce™ was by far the best at producing believable landscapes and backgrounds.

Web Based Digital Image Library

One of the more significant pieces of the digital resource puzzle was the development of a web based image library to provide the bulk of the factual visual content to the teaching and learning process. It was designed to be used with a video projector to deliver slides during lectures, and to be accessed by students for use as a resource for the papers they were required to write and illustrate, and for studying for exams.

Started in 1995-96, I continued building a digital image library in 1997-99 through my participation in a USDA National Education Challenge Grant project that included construction of an on-line slide library for holding and retrieving teaching slides for landscape subjects. The slides for the Landscape Architecture Image Resource (LAIR)* were contributed by faculty from the six American universities included in the research project (U. of Maryland, U. of California - Davis, U of Oregon, U. of Georgia, Cornell and Virginia Tech. at Blacksburg).

The image library built by this consortium has greatly increased individual faculty member's access to current and historic images of places they are likely to use in lectures. It has also provided an important resource for students and practitioners of landscape architecture as well. The library, served from the University of Maryland computer, has a custom CGI and search engine that allows any Boolean combination of the fields and keywords in the database to be used as search criteria. A table of labeled thumb nail index images is returned in a search, and information about each slide is available in summary or long form. These images can be accessed in real time or downloaded onto the instructor's hard disk for sequencing and playback in the lecture hall. For student access, the professor merely posts a list of URLs for the students to review or they can access images from their own computers or at school using the one-line search engine.

Though not as dynamic or explanatory as 3-dimensional animations, the capabilities of the on-line slide library offers a different kind of informational depth, and it's inherent flexibility and speed, compared to animated media, makes it the core of an effective and adaptable system of content delivery. Slide show software such as Power Point™, Director™ GoLive™ or Flash™ can provide easy assembly of sequences, complete with timing, titles and sound tracts for live delivery, CD ROM, DVD or distribution on the web.

Student Evaluations

During this project several successive years of student evaluations provided continual direction and feedback and revealed a high level of consensus concerning the educational value of our experiments. Moreover, in open-ended comments the students expressed enthusiastic support for our efforts and a expressed a desire to see more.

Because of student feedback, a sound tract was added to the tutorial and a Spanish version is planned for future production. I found that learning to create sound tracts is almost as obscure and deep as learning 3-D graphics, but in the end, we were able to record, mix and synchronize sound to add another dimension to the information offered in the tutorials. Again, we used affordable software to create the soundtracks, relying on SoundEdit 16™ on the Mac and Sound Forge™ on the PC.

Multimedia technologies are a moving target, with current capabilities exceeding my wildest dreams of just four years ago. My work has proven to me that it is not only possible but also practical to provide 3-D animations and interactive web-delivered media to students in a variety of formats, to enhance and augment their classroom learning. Their course evaluations provide a distinct picture of their enthusiasm, acceptance and perception of learning effectiveness of these beginning efforts. As always, the trick is to firmly establish the content and pedagogy and match the software tools and hardware to ones skill level and budget.

A Conceptual Model For Utilizing The Internet For Social Development Research In Third World Countries

Dr. Goutham Menon

College of Social Work, University of South Carolina, Columbia. SC 29208. USA.

Tel: (803) 777-4313, Fax: (803) 777-3498, E-mail: goutham.menon@sc.edu

Abstract: The vast inequity between info-rich and info-poor countries in the creation and dissemination of knowledge using technology is increasing by the minute. This paper looks at some issues that confront us as academicians in the sharing of info-wealth with colleagues in developing countries. It provides a model to create world wide web pages to facilitate the growth of professions.

1. Introduction

This paper describes a conceptual model to be adopted by various helping professions in creating relevant world wide web sites which will help bridge the divide between info-rich and info-poor nations. It looks at the area of information dissemination using communication technologies, with specific reference to the utilization of the Internet. One of the major needs for practitioners and researchers in the developing world is to have easy and cost effective access to educational material. Given the prohibitive costs in getting journals and books in their countries, these professionals are often struggling to get much needed information to improve the lives of the people they are dealing with.

We are entering the new millennium in the midst of an historical transformation wherein traditional communication mediums are being replaced by the products of the seemingly unstoppable digital revolution. The latter part of this century has opened the floodgates, and with that the unending possibilities, in the utilization of new information and communication technologies. Living through these changes, we are often challenged by opposing viewpoints on the social impacts of the technology revolution (Castells, 1998).

2. Background

The proponents of the new mediums hail all development as answers for the milieu of problems that exist in today's society. In their opinion, advances made in the digital age will benefit millions of people, through the early dissemination of information to prevent catastrophes, or simply just making one's jobs easier to handle. On the other hand, those opposing the unfettered growth of the new medium view these changes in disdain. For them, "information technology is a tool for renewed exploitation, destruction of jobs, environmental degradation, and invasion of privacy" (Castells, 1998, p.2).

The social contexts within which new information and communication technologies are developed need to be understood more fully. According to Castells, "social development today is determined by the ability to establish synergistic interaction between technological innovation and human values ... in a new model of development that could be socially and environmentally sustainable" (p.2). Just the development of technology will not solve social problems but its availability and use are a pre-requisite for the economic and social development in our world (Dosi et al, 1988; Hirst & Thompson, 1992).

This area is new to the area of social development. It is only recently that the United Nations has recognized the need to assess and develop appropriate technology for use in the area of sustainable development. With the creation of a program in Information Technologies for Social Development within the United Nations Research Institute for Social Development, it hopes to respond to the need for multidisciplinary research and international networking in order to identify appropriate strategies for the adaptation of new technologies in developing countries and countries in transition (Uimonen, 1997).

3. Pages of the Profession (POP)

While the majority of strides being seen in the development of web sites currently dwell in the area of e-commerce, the relative under development in the area of educational sites are alarming. Yes, there are sites stemming out of various universities and research centers which focus their attention in "selling" their product, namely a course or a program, the creation of pure educational sites are often frowned upon since there is no money to be made, especially in the area of the helping professions.

The POP model strives to provide a balance in both the creation of effective one-stop-site for the helping professions and at the same time generate money for the expansion of such endeavors. The model is envisaged as a constellation of sites dealing with the helping professions all with their own unique domain names, like socialworkeducation.com, nursingeducation.com, socialdevelopmenteducation.com, and so on.

To describe one such site's content, let's look at socialworkeducation.com. The site will be organized using the professions major fields of study, which includes Human behavior, Practice, Field education, Policy, and Research. Under each hierarchy there will be links developed to help the surfer to get all the information one needs to help understand the profession. It will also have additional categories for jobs in the profession, chat rooms for discussing issues, syllabi for various courses, e-journals etc.. In short, it will be a unique source of information for every college of social work in the country and abroad to use as part of their distance education program.

The financial aspects of such a site will depend on banner advertisements sold to universities, book publishers and others related to the field, like hospitals, agencies and so on. This will prove to be an effective medium of advertising since they have a captive audience in those interested in that particular profession.

4. Conclusions

The POP model will be an interesting blend of education and commerce which the distance education community will be quick to embrace. It will break the barriers of communication across world boundaries and will be in a position to share the experience of learning with all in question.

1. Abstract

This paper describes an experimental Java client-server system using the Amateur Radio Service over the World Wide Web (WWW). This system allows a mobile user to receive maps of his present location as well as send and receive messages to a user located at a central headquarters. Location information of the mobile user is obtained via a Global Positioning System (GPS) receiver and sent to the central headquarters by way of amateur radio. The server operator at the central headquarters is able to locate any mobile user at any given time as well as communicate with him/her. The software includes a Java client application and a Java server application. The client machine is an Intel based laptop running RedHat Linux 5.3. The server machine is an Intel based system running RedHat Linux 5.2 acting as both an Intranet server and an Internet gateway for the laptop.

2. Introduction

As our society evolves into a state of connectivity, TCP/IP and Internet access becomes as important in mobile situations as it does in the business community. The ability to send and receive feedback from workers as well as monitoring their productivity is a powerful tool for managers in the corporate world. This project extends wireless TCP/IP to vehicles providing services such as data communications and mapping systems based upon conventional networking technologies.

3.1 Client Services

The client user interface to the Wireless Digital Vehicle Mapping and Tracking System is a Java application made up of a mapping display which references the United States Bureau of the Census's Tiger Mapping Service. This provides both clients and the server with data of the vehicle's current position. The system provides two data frames: the first for intranet communications with the server and the second for displaying GPS data.

When the Java application is loaded, the data frames and the map image frame are instantiated and placed onto the desktop. The vehicle operator then supplies a username and password to gain access to the application's functionality and to identify him to the central server. After the operator has logged in, a socket is created between the client computer and the server computer and the input stream and print stream are obtained.

Once the data streams are obtained from the socket, the client receives a National Marine Electronics Association (NMEA) protocol string from the GPS receiver at a rate of one per second. The NMEA string that is received is of the form:

```
SGPGLL, 40.10000,N, 76.35700,W
```

where "SGPGLL" defines the specific protocol of the string, "40.10000" defines the latitude position, "N" defines the latitude position, "76.35700" defines the longitude, and "W" defines the longitude position. This string is then parsed, and the latitude and longitude are sent in the form of an IP packet to the server computer via the socket (and Amateur Radio Service). The client computer then downloads a Tiger map from the Internet and displays it in the map image frame.

The client Java application is also capable of sending and receiving lines of text via a dedicated socket service. This capability allows the server computer to communicate with the client computer and visa versa. When an operator pulls over to the side of the road, he is able to enter, via one of the data frames, text that is sent to the server computer as an IP packet via the socket (and Amateur Radio Service). The server computer can reciprocate this communication. When the server operator sends a text message, each client gets the message; however, the clients filter the message and only the client to whom the message is directed receives it. When the client computer receives the server computer's text message, the Linux computer is capable of speaking the text message. This allows the vehicle operator to receive messages from the server computer without having to look at the computer screen, thus making it safer for the vehicle operator to receive the message.

3.2 Server Daemons

The Wireless Digital Vehicle Mapping and Tracking System server software coordinates all aspects of the networked system. The server accepts connections from the Java client to receive position data, to send Tiger map images, to send and receive text messages, and send commands to the hardware. The server also maintains a database of client computer identification numbers and operator identification numbers.

The Digital Vehicle Mapping and Tracking System server displays a Tiger map image similar to that of the client. The server also displays a non-editable data frame that includes an identifier for each vehicle operator, allowing the central coordinating server operator to select a vehicle operator and view his/her location. Another data frame is also visible to the server operator for communication with any or all of the vehicle operators.

A position daemon is responsible for accepting connections from the client computer and creating sockets. The daemon then receives latitudes and longitudes in the form of IP packets that it uses to retrieve Tiger map images from the WWW. The Tiger map images are displayed on the server computer so that the server operator can track the path of the vehicle operators.

The communication daemon is responsible for sending and receiving text messages. The server operator selects the vehicle operator to whom he wishes to send a message. The server operator then types the message, which is then sent through the socket (and the Amateur Radio Service) to the client computer. Any message sent to the server computer appears preceded by the message originator's identification number.

4. Data Communications Infrastructure

The goal of the data infrastructure was to be as transparent as possible, yet emulate a system that could be used in a commercial environment. Careful planning led to the use of a TCP/IP-based system over packet radio in the Amateur Radio Service.

The network server consists of an Intel computer running RedHat Linux 5.2, kernel version 2.2.1. Linux includes Amateur radio support—including AX.25 and KISS protocol support—in the kernel, making it an ideal operating system to act as a bridge between the Internet, intranet, and the remote clients operating via radio.

Both client and server machines are connected to their own dedicated Terminal Node Controller (TNC). The TNC acts as a modulator/demodulator bridging the RS-232 ports on the server and clients to the radio transceivers. Each computer uses a series of protocol layers to allow TCP/IP to operate over the TNCs. The KISS protocol is the first protocol layer, allowing the computers to control the functions of their TNCs.

The second protocol layer of our setup is AX.25. The AX.25 protocol is similar to the more common X.25 protocol layer; however, it adds some features to make it more suitable for amateur radio. The AX.25 layer operates transparently to the user, and requires no additional attention other than being compiled into the kernel.

The AX.25 and KISS software allows the operating system to view the TNC as another network device. Thus on client machines, the TNC becomes the gateway to both the intranet and also the Internet. On the server, the TNC device is set up as a network, on the 192.168.1.0 subnet. Internet access on client machines is done using IP forwarding, masquerading, and firewalling on the server.

Since the system acts as any other broadcast network, multiple clients can share one radio frequency. In the case of collisions, a random backoff algorithm is used to time retransmission of the packets. Thus, companies implementing a system like this can purchase one frequency for multiple clients, and expand only when congestion occurs on that frequency.

Due to the transparency of the physical network layer in this system, network client applications act completely normal and need no modification. This allows web browsers, telnet clients, and future TCP/IP-based software to operate on this system, unless locked out at the server's firewall.

To reduce development time, Java applications for our system were developed in the lab on a 10baseT network. After the applications were finished, they were moved to the wireless system where they were executed in the same manner as in the lab.

5. Future Work

Although this project is complete, additional features could be included. Currently, when the client or server application is started, three frames appear on the screen. These frames should appear in the same window, allowing for better organization on the desktop. Another feature would designate different colors for different messages in the chat window. One color could denote a message from the server that is intended solely for the client, another could denote a broadcast message from the server to all clients, and another could denote a message that was sent by the client.

Additional features could also be added to the mapping system. One feature would be to include client identification numbers on the maps of the server computer. This would allow the server operator to view the position of several vehicle operators at the same time. Another feature would allow the server operator to choose from various mapping systems.

With today's computers getting smaller in size, this system could be made into a solid-state machine. The recommended hardware for this could be developed using a PC/104 based system along with a PC/104 based GPS card. This would reduce the size of the system to 3 ½ x 3 ½ x 3 ½ inches (H x W x D).

6. Conclusion

This paper describes the Wireless Digital Vehicle Mapping and Tracking System. This system uses a TCP/IP network foundation to allow mobile clients to access an intranet and the Internet in the same exact manner as accessing these networks in a conventional fashion. This allowed us to develop our network applications and run conventional client application with no special modifications for wireless use. Server operators are able to track drivers precisely and effortlessly. More information can be found at the Wireless Digital Vehicle Mapping and Tracking System page, <http://wireless.millersv.edu>.

Privacy, the Workplace and the Internet

Seumas Miller and John Weckert
Centre for Professional and Applied Ethics
Charles Sturt University, Australia
smiller@csu.edu.au
jweckert@csu.edu.au

Abstract: employees do not lose all rights to privacy with respect to their employers by virtue of being employees. This paper considers various arguments for the surveillance and monitoring of employees, including both those that look at the benefits or supposed benefits to the employees themselves and to the employers. It is shown that most of these arguments do not have much force.

The existence of the right to privacy, and related rights such as confidentiality and autonomy, is sufficient to undermine extreme views such as the view that employees ought to be under surveillance every minute of the working day, or that should they be in a situation where they suspect that they might be under surveillance all day, or that there should there be surveillance of a nature or extent in respect of which the employees are ignorant. These extreme situations involve unjustified invasions of privacy. Employers have certain rights in respect of their employees, but there is no general and absolute right to monitor and control employees. To what extent can an employer justifiably infringe an employee's right to privacy. There is a right to privacy, and, other things being equal, employees have this right. The violation of the employee's right to privacy of concern in this paper, is that posed by the electronic surveillance and monitoring of an employee's activities made easy by current computer technology, particularly networking. Keystrokes can be monitored for speed and accuracy, and the work on your screen may be brought up on the screen of another without your knowledge. Common software for accessing the Internet logs all activity, so that a record is kept of all visits to all sites, and email, listservers and so on can monitored.

Employees, as well as having at least a prima facie right to privacy, are also accountable their employers because their employers have a right to a reasonable extent and quality of work output for the wages and salaries that they pay, and it is in the employees' interests (as well as the interests of employers) that their employers make a profit. Given potential conflict between these rights, perhaps an employees' right to privacy, *qua* employee, can, in a range of circumstances, be overridden.

The claim is that computer monitoring of employees has multiple benefits, at least potentially. It improves the quality of goods and services, and so is good for customers; it makes businesses more efficient, so profits rise, which benefits employers; and it helps employees get higher pay and promotion, and assists them in doing their jobs better. Given all these benefits, why is it questioned? There are two types of reasons, one type based on the unacceptable consequences to the organisation of monitoring and surveillance. Such consequences include ill health, stress and lowering of morale. The other type of reason concerns the harm to employees, including as a harm, infringement of employees' rights to privacy. Other harms relate to employees' well-being. There is evidence that computer monitored employees suffer health, stress and morale problems to a higher degree than other employees. If it does indeed generate these sorts of problems, then these problems must be weighed against the benefits. It might be countered that if the problems are too great, then monitoring will not make organisations more efficient, and so the practice will stop. Alternatively, the organisations who practice it will not be able to attract good employees, and so will be forced to discontinue it. One weakness of this counter is that workers are not always free to pick and choose their employers, particularly in times and places of high unemployment. Many will almost certainly prefer to work under conditions which they do not like, than to not work at all. Another flaw is that it is not necessarily true that practices which are detrimental to health and morale will lead to less efficiency, at least not in the short term. For example, forcing workers to work for long hours without rest over extended periods could increase productivity in the short term, but lead to longer term health problems. Raising the levels of stress through continual monitoring could have the same effect. If the work requires a relatively low level of skill, and if there is unemployment, workers are easily replaceable. If the motive is short term profitability, long term effects are irrelevant. More importantly, treating workers in this fashion may be good for the profitability, long and short term, of that particular business. The problem may be the long term ill effects on the business sector in general, or on the specific industry sector in question.

The moral objection to computer monitoring is based on the principle that a right cannot be infringed without very good reason. It would be rare that greater efficiency or profitability would constitute such a good reason. There clearly are times when a person's privacy rights can be overridden. An unconscious and unconsenting hospital patient, for example, may need constant monitoring, but that is for the patient's own good. A prison inmate might also need constant monitoring, but that might be for the protection of the community. Monitoring of employees however, does not, in most circumstances, secure these fundamental rights to life and protection.

A defender of computer monitoring might argue that the moral problem only arises if employees have no input into the establishing of the monitoring system, or if they are not fully aware of its scope and implications. If these conditions are satisfied, there is no moral problem, because the employee has, in effect, consented to the system's use, by accepting employment under those conditions.

While this has some initial attraction, on closer examination it is not so plausible. When unemployment is high, or if the person badly needs a job, there is not much force in consent. It is rather a case of economic coercion. A second problem is that even if people do consent to some sort of treatment, it does not follow that it is moral to treat them in that manner. Slavery cannot be justified on the grounds that some slaves may not have minded their condition too much if they knew nothing better. Likewise, violation of privacy cannot be condoned simply because some employees are willing to accept it.

What can be made of the argument that employee monitoring can be to the benefit of the employees themselves. Their privacy is violated, but it is in a good cause. Three benefits to the employee have been suggested. One is that it can, if used properly, help them to improve their work practices. This might be true, but it would at best only justify short term monitoring, and only with the employee's consent. Perhaps the techniques and satisfaction of clumsy lovers could be improved by information gained from spying on their activities, but that hardly seems to justify spying. A second benefit is said to be that employees can be assessed on purely objective criteria, say number and accuracy of keystrokes. While objectivity is good, assessment of an employee's worth will usually have a substantial subjective element as well. A highly responsible or experienced person who types slowly may well improve the productivity of others. So at best this is a weak justification for infringement of privacy. Finally, it is argued that this monitoring will help get rid of 'dead wood', workers who are not doing their fair share of the work. This will not only be good for the employer, but also for the other employees. However, while none of us want to support lazy and incompetent colleagues, it is not clear that this will not have countervailing effects, namely, on the hardworking and competent workers also thus monitored. There could, of course, be limited and targeted monitoring where there was good reason to believe that particular employees were not meeting reasonable standards. This would seem to be a far more reasonable policy. However this is clearly not *general* monitoring and surveillance of the kind being discussed here. Supporting such colleagues is not good, but violation of privacy would, to many, seem even worse.

A stronger argument for employing surveillance is the control of crime in the workplace, especially theft and financial fraud. Victims of crime have moral rights which sometimes override privacy rights. Theft and fraud in the workplace are still theft and fraud, so some surveillance can be justified in order to apprehend culprits.

What about monitoring employees' email? While this might be thought to be akin to opening private mail or listening in to private conversations, the argument is that because the system on which the email operates is owned by the employers, they have a right to read any messages. But do they? The fact that two people are conversing in my house does not give me an automatic right to listen to what they are saying. But what if the two people are my employees? Does this make a difference? One argument that it does not, might go as follows: All I am paying for is my employees' labour. What they say to customers might be my business, but what they say to each other is not if it does not obviously and directly harm the business. Perhaps the cases are not analogous, because in the email case they are using my equipment, while in the other they are not. But what they say is still none of my business even if the consequences of what they say might be. The fact that they are continually having conversations might be overloading the equipment or hindering the work of others or themselves. Accordingly, banning or limiting private conversations might be justified. But this would not justify *monitoring* conversations. Does this miss the point? How will I know if the email is being used for private discussions unless I monitor it? I will not know unless I am told. But if no problems are being caused by overuse and so on, then there is no need to worry. If no harm is being caused by personal email, either to the computing equipment or to productivity, then monitoring what is said can have no purpose, except perhaps to satisfy curiosity. This is hardly a justification for violating a right. There could be a limit put on the length or number of messages, or the productivity of employees in question could be investigated. Employing people does not confer the right to monitor their private conversations, whether those conversations be in person or via email, even if they are work related.

Abstract: We are developing a geometric inference system on Internet. A rough geometric figure drawn by a student is transformed into an ideal one that satisfies the assumptions. The system extracts particular patterns in this figure and tries to connect the assumptions and the conclusion. The present paper extends the visualization of the proof by introducing a multiple view which consists of (a) sentence view, (b) inference tree view, and (c) figure view. The sentence view gives a proof written in usual sentence. The inference tree view shows a diagrammatic inference tree whose leaves are assumptions and whose root is the conclusion. Each pattern has three appearances in the multiple view. And they are related to each other. When the student clicks a pattern in one view, the counter parts are highlighted simultaneously in other view. With this system, students can learn geometric inference visually and interactively.

1. Introduction

Geometric Inference systems have been studied since early days of computer history. Those systems used character-based user interface. So they were not easy for students. Recently, some systems, e.g. Gex [Chou 1996], have a graphic user interface. But most systems use only literal expressions to show the result of the inference. These systems are difficult to understand the proof as a result of inference. As we know, figures are more intuitive than words. There should be suitable forms for showing a proof of geometric inference. We are developing a geometric inference system SK. Main feature of SK is its GUI and availability on Internet. Anyone can use the system directly at <http://matu.cc.kyushu-u.ac.jp/~mishima/sk-e/>.

2. Overview of the system

SK is a geometric inference system on Internet. The system consists of 4 components:

- (1) GUI to draw figures and express hypothesis and conclusion,
- (2) a numeric engine to transform a rough drawn figure into a precise figure which satisfies the hypothesis,
- (3) a geometric inference engine, and
- (4) proof visualizations.

The geometric inference engine adopts Koedinger's DC-model method [Koedinger1987, Suwa1995]. This method is one approach from the cognitive science to overcome the explosion of search space. A DC-model represents a prototypical geometric image. The method needs a precisely drawn figure to detect such patterns. Those patterns are used to guide the inference process. The GUI components are implemented as Java applets and the engines are implemented in Lisp. The four components are integrated on Internet with a server/client model.

Students draw a geometric figure and specify the hypothesis and the conclusion simply by clicking and dragging their mouse [Fig. 1]. The system considers the hypothesis as constraints and transforms them into equations. The numeric engine solves the equation by approximation. An ideal figure is obtained as a solution.

The geometric inference engine makes an inference. When the system succeeds to prove, the proof is displayed as a sentence and as a inference tree.

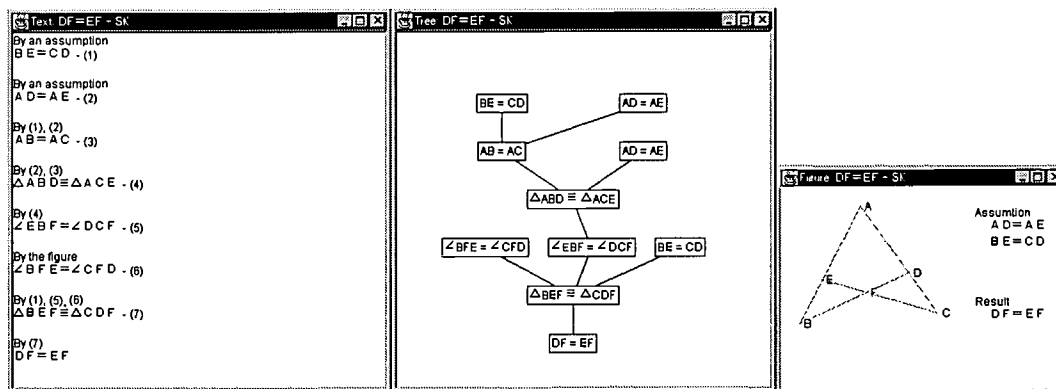

Figure 1:Figure drawing on SK

3. Multiple view of the inference

The proof visualization is realized by introducing a multiple view which consists of (a) sentence view, (b) inference tree view, and (c) figure view [Fig. 2]. The sentence view gives the proof written in usual sentence. The inference tree view shows a diagrammatic inference tree. The leaves of the tree are assumptions. Each pattern is highlighted in the figure view when the counterpart is specified in the tree view or the sentence view. In this way, when the user clicks a component in one view, the component in other views is highlighted simultaneously.

(a) sentence view

(b) inference tree view

(c) figure view

Internet Customized Teaching/Learning Environments

Dr. John Mugane

Department of Linguistics, Gordy Hall 383, Ohio University, Athens, Ohio 45701, USA

Tel: (740) 593-4564 | Fax: (740) 593-2967, E-mail: mugane@csl.stanford.edu

Abstract: The educational sector, while inclined to conservatism, has been active in its attempts to understand the impact of technology on teaching and learning approaches. The Internet design described in this paper places students at the epicenter of their learning experience in consultation with teacher-facilitators. It places a premium on innovation (creativity) in the making of coherent plans for action within culturally rich environments. The Internet is viewed as a huge physico-digital world in which student engagement, participation, initiative, and creativity are the foundational premises of a wholesome pedagogy.

Within educational institutions (and for that matter in the world at large), we are currently grappling with the need for major changes in approach as to how we conduct education and our lives. This is already apparent in e-commerce and e-trading now taking place on the Internet at levels that would have been unthinkable at the inception of the WWW some six years ago. We are standing at a continental divide the outcome of which we are unable to predict with any degree of certainty. There seems to be little doubt that computers and the Internet will eventually find their way into every home (living center) on the planet. That being the case, it behooves us to insure its fullest possible introduction into the educational process beginning with the earliest years of tutoring and proceeding to the highest levels of learning.

The educational sector, although inclined to conservatism, has been extremely active in its attempts to understand the impact of technology on teaching and learning approaches and has already proposed innovative and perhaps more effective approaches than have been used in the past. Various models are being developed around the world, all to some extent expressing the individual insights of educators and developers as they ask fundamental questions such as:

- Are customized web environments a good idea?
- What types of activity are possible on the Web with regards to language learning?
- What learning/teaching styles can the Web support. Will learners experience more freedom in explorative mode or will it be expository at best and rigorously regimented at its worst leaving learner curiosity and inventiveness curtailed and teachers firmly in control?
- What kinds of learners and instructors are likely to benefit from customized environments?

SALAMA--the acronym for the Stanford African Language and Multimedia Applications site--is, in fact, a digital arena using the World Wide Web (<http://www.aramati.com/salama.html>). The word SALAMA in Swahili means 'peace'. This new site pioneers the idea of a customized browsing environment for learning and teaching. SALAMA was created with the conviction that learning autonomy and teacher-facilitation are co-valued and optimal states in the learning arena. The Internet is viewed as a large physico-digital world in which student engagement, participation, initiative, and creativity must be nurtured. These qualities are the foundational premises of an effective pedagogy.

SALAMA is an arena enabling bi-modal search and includes enlightened exchanges between individual learners. It encompasses the access to information and the exchange of ideas in a style allowing learners to call on their individual talents and ingenuity in the process of learning a language. Bi-modality refers to two initial concepts: GUIDED browsing and FREE browsing. Learners are encouraged to select either one. The GUIDED browsing approach is recommended for complete beginners and requires teacher facilitation and suggestions while FREE browsing leaves all decisions to the learner (thus including the sophisticated user). Within SALAMA unrestricted asequential movement in a multi-directional web setting is governed by the learner's search for areas consonant with her/his unique learning pace [Mugane 1997].

As a learning arena, the SALAMA site offers numerous features promoting the use of technology towards humanistic ends. These include:

- Seamless interface with the internet both at local and world-wide levels.
- Access to resources---Internet and other---as a first step in implementing project-oriented action.

- Exploration of content in such a way that learners become involved in comprehending, manipulating, and interacting in the focus language, attending mainly to meaning rather than form [Moeller, 1997:8] exploring the modalities of discourse as it is applied to the real world.
- Provision for shifting the role of teacher to that of facilitator.

The vast materials within SALAMA site include:

- State of the art resources from other African language teaching centers (significant among these are video-clips from the University of Georgia.
- Leading scholars in African linguistics and language teaching and learning for pedagogical consultants.
- Customized environments making it possible for language professionals to judge for themselves what constitutes optimal learning sites and materials.

As pointed out by Levy [1997:30], what is important is to "shift from a naive search of a superior teaching machine to a more atomistic study of the characteristics of new media in relation to key factors associated with learning, the learner, and the learning context". It is the complex of the language learning process coupled with learner individuality and the arena in which thoughts develop that prompts the need for customization. Used instrumentally, the Internet will provide useful insights into how learning evolves when learners discover the importance of being in partnership with others--including distanced learning partners--and in constant touch with information resources. That learning can be perpetually taking place anywhere as long as there is a networked infrastructure helps learners to manage appropriately the navigational cost of time. The Internet has in fact cancelled the notion of distance and seriously undermined the primary importance of locus of activity.

Customized environments such as the SALAMA site are arenas in which learner autonomy (e.g., self-pacing, supportive instructors and the interactions with other learners (social dimension) can be maximized while maintaining the focus on relevant material. Customized environments deal with the all-too-familiar problem inherent in Internet design: scattered information (the link-labyrinth phenomenon). In addition, categories being sought often lead to larger and more general categories the quality of which varies considerably. One must even view the content of the Web as falling short of total accuracy. There is no GENERAL WEB EDITOR or system of assuring quality control and exactitude.

The SALAMA site--specifically the guided browsing section--is a place where learners can always return and seek clarification, continuity, and even evaluate their own progress relative to a significantly broad instructional base. In proposing a course of Swahili instruction, SALAMA is dealing with certain vexing issues concerning Internet design mentioned above. It is also proposing that students be at the epicenter of their learning experience and work in consultation with a teacher-facilitator. It places a premium on innovation (creativity) in the making of coherent plans for action within a culturally rich environment. Iterative and incremental in nature, learning takes place both in the classroom and the world beyond it thanks to the Web's technological infrastructure. SALAMA shares with all other Web sites, the infinite possibility for expansion. In this respect the site becomes a place where the efforts of learners as well as those of teacher-developers can contribute to the ever-expanding resources available for African languages and Culture.

In keeping our eyes focused on the meaning and mediation of learning, we provide our students an ideal opportunity to foster the acquisition of languages--no longer viewed exclusively as a content matter but as means to an end: the appropriation of linguistic know-how for expressing one's individuality and a spirit of world-collaboration.

Abstract: The Web-Based Interactive Shared Journal System (WISJS) is a tool that was created at the Center for Technology Innovations in Education to facilitate learning from field experiences by providing students with the capability of creating media rich journal entries that can be shared with mentors and other students. Journal documents are created, edited and shared using a web browser. The system is being used in a variety of test-bed learning communities including teacher education students engaged in field experiences, high schools mathematics and science students engaged in project-based learning, and library science students engaged in practicum.

Internet-based tools, such as *Web Course in a Box* and *WebCT* are rapidly increasing access to distance teaching through cyber courses. Web pages of support materials, listserves and bulletin boards of threaded discussions often extend and enhance what heretofore had been accomplished in classroom settings. Distance teaching and classroom teaching each have strengths and weaknesses that must be considered when selecting a format for instruction. For example, working through a problem or providing a complex explanation for why a student's work is insufficient is often more easily mediated face to face than via chat or asynchronous messages. However, asynchronous and distance approaches often allow more students to participate in discussions, and reviewing assignment materials or contributing to a discussion when you are ready at 10:00 pm rather than getting up for an 8:00 am class can be very attractive to students. Working through these trade-offs and either integrating distance teaching tools into classroom instruction or improving the implementation of distance teaching tools is receiving much attention.

The development of the Web-Based Interactive Shared Journal System (WISJS) has been an effort to facilitate learning from field experiences, a type of learning not well supported either in classroom or cyber courses. Field experiences are approaches to learning implemented in many professional development programs that emphasize apprenticeship and contextual learning. For example teachers do student-teaching, nurses and librarians have practicum experiences, and doctors and lawyers do internships. Other forms of apprenticeship learning are emerging in K-12 and higher education as projects and problem-based learning. Key to learning from field experience or from apprentice forms of education is the having and processing of experiences in legitimate settings of practice. Ideal learning systems will include support (1) for making sense of experiences and solving problem in situ, so that the learners is supported in taking on authentic challenges of the practice setting, and (2) for capturing and representing those experiences, so as to share with mentors and other students, as well as for later review and reflection.

The Web-Based Interactive Shared Journal System (WISJS) is a tool that can augment either classroom instruction or cyber courses by enabling students to easily capture and organize experiences in ways that allow rich-mediated representation and sharing across the Internet. WISJS is a client-server system that communicates over the Internet using TCP/IP connections. The client is implemented within a DHTML browser environment (using 4.0 Netscape or Internet Explorer). A custom server was created for connecting and maintaining a login between the client and server, and provides communication between the client and an Oracle database. WISJS is a re-implementation and advance of an earlier, Macintosh client based journal system (1998). WISJS has been designed to support four key processes of distributed learning: representation, guidance, feedback, and shared memory. These processes are undertaken in the context of a community made up of four roles:

- administrators, who are responsible for the system
- mentors, who are responsible for instruction and modeling
- students, who are responsible for articulation of experiences
- guests, who have limited access to public information

WISJS is being used with a variety of test-bed learning communities, including teacher education students, high school mathematics and science students linked to University students to support project-based learning, facilitation of practicum experiences for graduate students in Library Science, and graduate courses at the University. Another test-bed for the Journal system is to support team work and problem solving among children across the nation as they take on an authentic challenge (this project is supported by Motorola University for children of Motorola employees.)

Users have secure access into a community of learners through a login. A set of services is available to the user upon entering the community, including an inbox of recent activity, an ability to create documents, access to their documents, access to documents in the journals of other members of the community, mail and note services, and chat for synchronous communication. The News section of the window also serves to alert the user when new tasks, notes, or appends are relevant.

Users of WISJS can use a point and click approach to placing text, graphics, audio and video, and hyperlinks to URL's or other journal documents in their journal documents to articulate their experiences. Document creating and editing takes place in the browser using a web-based interface.

Mentors in WISJS can provide tasks to learners. A task is a journal document created by the mentor, converted from an ordinary journal entry into a task and then distributed through WISJS to the appropriate learners or teams of learners. A learner is notified of a task as part of the login. When the learner opens the task they see the instruction, assignment and support information provided by the mentor. The learner can then "edit" the document to complete the task or report on completion of the task. In the process of working toward task completion the learner can indicate through a pull-down menu their advancing status toward completion by setting task completion from 0 to 100%. The mentor can quickly review task completion by reviewing the distribution list for a task. A distribution list carries information about task completion status and allows direct access into the learner's task response. Tasks are a medium for providing guidance from a mentor to a learner. The progress status indicator saves time for the mentor and facilitates communication between mentor and learner

Feedback is provided through appends that can be attached to journal documents so as to make a suggestion, reinforce the representation, ask a question, or establish a dialogue about the experience represented in the journal document. Appends allow other system users to provide feedback or commentary, in a sense establishing a discussion list or personal seminar, to journal representations. The database of experiences captured in each individual journal entry form a community memory of learning experiences. A system such as WISJS, which captures experiences, can grow dynamically. WISJS has potential to support learning from field experience by providing learners access to a shared memory of experiences, and by facilitating feedback and reflection upon the field-based experiences of the learners.

A Web-Based Homework Notification System

Abstract: The Homework Notifier (HN) is a web-based system to facilitate communication and collaboration among the key parties about an important work effort of school, homework. HN is a prototype system designed and implemented in a test-bed school (Oakland Junior High School in Columbia, Missouri) to teach us how to electronically mediate and facilitate the processes of school to home communication around homework. Homework Notifier was developed at the Center for Technology Innovations in Education.

Educators and society have great hopes that information technology can contribute to school improvement. However, even the most optimistic technologist must admit that while computer and network technology continues to rapidly advance, little has changed in schooling except for increasing amounts of the budget being devoted to technology purchases and teacher training. After a review of the status of educational technology, The President's Committee of Advisors on Science and Technology [1] concluded that, "During a period in which technology has fundamentally transformed America's offices, factories, and retail establishments, however, its impact within our nation's classrooms has generally been quite modest." Curiously, business and industry were drawing similar conclusions, the productivity paradox, for their investments into information technology during the 1980's. Not until businesses revamped and improved processes toward flatter organizations, more responsiveness, and greater empowerment that took advantage of information technology did the benefits of technology start to show-up on the bottom-line. Key to many of these initiatives were the ideas of empowering people with information, synchronizing work teams, and building closer and more cooperative relationships with customers.

The Homework Notifier (HN) is a web-based system to facilitate communication and collaboration among the key parties about an important work effort of school, homework. HN is a prototype system designed and implemented in a test-bed school (Oakland Junior High School in Columbia, Missouri) to teach us how to electronically mediate and facilitate the processes of school to home communication around homework.

Homework provides an opportunity for children to take responsibility and work independently. Being consistent and thorough in doing homework can build good work habits for later schooling or work opportunities. Homework is also a chance to extend learning and practice skills and to use knowledge learned in school. Thus homework can contribute in a number of important ways to a child's education. Homework is also a place of great variability among students. The best students do homework thoroughly and consistently:

The poorest students may rarely complete their homework. Parents are often frustrated by an inability to know what is expected of their son or daughter and sometimes with an inability to help a student who is struggling with homework. Some students may be similarly frustrated when sitting down to do homework and realizing they do not have all the information they need to do their assignment or may need more help to successfully complete the assignment.

Homework Notifier was developed to provide direct communication to parents and students about homework assignments. Parents and students can log-in to Homework Notifier and easily see the assigned homework. Homework Notifier also makes it easy for a parent or child to send a note to the teacher. The parent or student access a URL through a browser. For our current test-bed of parents the most common access is through AOL. Using an ID and password the parent or student gains access to their account. From here the user can review assignments, access resources (such as, links to general homework support pages, etc.), seek specific help in using HN, or logout. Links are provided to the web page and email of the teacher. Within the body of this assignment the teacher can provide web links. Clicking on a link will open another browser window and access the appropriate URL. This feature allows the teacher to create mediated and well-supported assignments. The parent or student can also review previous assignments.

When a teacher logs into the system he or she has access to additional functionality for creating assignments, managing classes and groupings, as well as adding users at the student level. Within the assignments area teachers have the ability (1) to create new assignments, (2) to view, modify, or delete existing assignments, and (3) to manage the distribution of assignments to students.

Feedback from teachers, parents, and students indicate that HN is simple to use and provides an empowering feeling. Some parents who want to help their children by providing close supervision of school work see the system as enabling them to have the information they need to make decisions, e.g. can the child go to a movie or do they have unfinished homework. Other parents see potential for helping them help with homework. To the extent that links can be made to resources that provide explanation or backup information the parents can help with the process of bringing that information to bear on the assignment. The teacher feels that the system gives her another tool for working with parents and for extending her impact into the homework of the children. Similarly most students look favorably upon the system, because it can help them from falling behind if they are ill, and for having the right information for doing assignments.

We are in the early stages of implementing the test-bed and learning about facilitating the homework process, but it is easy to see ready benefits in building communication tools between the home and school that enable parents and teachers to work in partnership.

THE INTERNET AS A RESEARCH TOOL: Cheers or Tears?

Mikiko Nakata, Assistant Professor
Hiroshima International Gakuin University, Japan
mikiko@g.hkg.ac.jp

Rowena Santiago, Professor
California State University San Bernardino, USA
rsantiag@csusb.edu

Abstract: The purpose of this anecdotal study was to find out how well the Internet could serve as a tool in conducting research. While doing a regular research on gender issues among US and Japan female faculty in computer-related programs in higher education, a concurrent study of the use of the Internet in four research activities was carried out. These research activities were: development of research instrument, data collection, literature search, and search for survey participants. This report describes the procedures taken, and, the benefits (cheers) and difficulties (tears) that the use of the Internet brought to each research activity.

INTRODUCTION

Information literacy is broadly defined as the "ability to recognize when information is needed and the ability to locate, evaluate, communicate, and use it effectively" (Behrens, 1994). Of the various information technologies that have been developed recently, the Internet, in particular, has become an indispensable tool in the location, processing, and communication of information. The challenge to educators then is to better understand the Internet so it could be utilized more effectively as a research tool.

PURPOSE

This paper is an attempt to study the Internet as a research tool: what works and what does not work. It is a report about a concurrent anecdotal study of the Internet that was conducted while doing a regular research on gender issues among US and Japan female faculty in computer-related programs in higher education.

Research work, in general, consists of various phases: identifying a problem, reviewing related literature, formulating hypotheses, selecting subjects, developing data collection instrument, collecting data, analyzing data, and, interpreting and communicating results. With the advent of the Internet, some phases of research work began to take new approaches. For instance, when doing review of literature, an Internet search can help find online journals. While authorities continue to voice concerns about the quality of Internet materials, users are multiplying in numbers and online information is increasing in exponential proportions. Another recent use of the Internet is for online surveys. The assumption is that putting online surveys will reach more respondents and hopefully get more responses. Yet, to date, little is still known as to how the Internet fares as a research tool.

STUDY

This study selected four phases of research work and within each, conducted activities to find out how well the Internet worked as a research tool. These research phases, plus the benefits (cheers) and difficulties (tears) that the use of the Internet brought to each research phase are described briefly in the following sections.

A. Developing an Online Research Instrument. An online 90-item survey questionnaire was developed to collect data on factors that influence women representation in computer-related programs in higher

education. The expectation was: an online questionnaire would facilitate the fielding of the survey, the analysis of responses from participants, as well as the statistical computations.

Cheers and Tears: The online survey successfully and automatically sent responses to a data input file, and then to a spreadsheet. (This session includes a quick demonstration of how the online survey was set-up.) It eliminated the time required to manually input responses from printed surveys. A perfect transfer of data from 90 items was made, where spreadsheet columns received the responses in the order they were sent (including items left blank). Except for two cases where respondents used a comma in their text response, the integrity of the data remained intact. By including the survey's website address in the email sent to participants, they were able to access the survey website easily. Feedback was also received immediately. When using the Internet for developing online surveys, a good HTML programmer, preferably a student assistant, is needed, as well as some budget to pay for programming time. There are also hardware and software requirements before an online survey can be developed.

B. Data Collection. Will the Internet be a better tool for collecting survey data? It was the expectation that the Internet survey (sent to 159 participants in US and Japan) would generate more responses than the print survey (sent to 184 participants) because of the ease and speed that are available to participants when answering and submitting the questionnaire.

Cheers and Tears: In the US, more print responses (40%) than email responses (22%) were received. In Japan, email responses were almost nil (3 out of 60) and print survey responses were 23%. The difference in responses could indicate that the Internet, compared to print surveys, may not be the better tool to use when collecting data.

C. Literature Search. Will websites used as online references still exist after a given time? Fifty (50) websites used as references in the gender research study were saved and then were accessed again after one year to find out if they still exist.

Cheers and Tears: Of the 50 websites used as references, only 12 websites could be accessed successfully after one year. Most of those that were not accessible had changes in their addresses or URL's. One website had a message that the link is "no longer working", while another website has turned commercial and requires access fee.

D. Search for Survey Participants. Is the Internet a good tool when looking for potential survey participants?

Cheers and Tears. Using the Internet, it was very easy to locate homepages of female faculty in computer-related programs. However, more time was spent in locating the addresses of their universities. Although university homepages had lots of information on academics and admissions, it was not uncommon that the address and main phone line of the university were not provided on the main homepage, requiring one to access links and sub-links before this basic information was found.

SUMMARY AND RECOMMENDATIONS

The benefits of using the Internet as a research tool include the ease and facility of transferring data from an online survey to a spreadsheet or statistical application. However, careful consideration is recommended when deciding between an online vs. printed version for data collection. The design of the online survey, the length of the website address, and users' trust of the Internet are possible factors that could affect the use of an online survey vs. a printed one. When using online materials as references for a research study, it is recommended that disk or hard copies of these websites are kept. Bibliographies that include online references may not be accurate and useful to readers after a year or so because website addresses undergo changes and become inaccessible. The Internet is also useful when locating faculty to be participants in a study, but this is not problem-free. Because of poor homepage designs, some websites do not include basic information such as complete addresses and phone numbers, thus requiring further searches. It is recommended that website designers include complete information for university, department, as well as individual faculty. Overall, the Internet can serve as an efficient tool for research, but just like other technologies, awareness of its strengths and weaknesses need to be considered carefully when used as research tool.

Abstract: With the support of the European Union, the SIMULAB consortium have developed a concept for Web-based collaborative tasks, mainly designed for language learning. A customized Web-based software, Telsi, has been created to cater for the needs of this type of international activity. This paper is an introduction to both the pedagogical concept and to the rationale behind the software and aims at presenting both the present and the future potential of SIMULAB.

SIMULAB and the simulation concept

One of the main and often most difficult tasks of language teaching is to create and implement methods that will motivate their students to use actively the target language, both orally and in written form, in a way that appears meaningful to them and therefore leads to real learning. The SIMULAB concept provides language teachers with such a method and it has the added values of integrating ICT into the learning process as well as connecting the classroom with the outside world and encouraging internationalization and collaborative learning.

SIMULAB is a concept that involves WWW-based communication between language students across national borders, around a specific problem or SIMULATION. The concept of simulation used in this pedagogical approach is based on the French "simulations globales", developed in the 70s and 80s. The term simulation is here used for an activity that is based on roleplay and involves the use of fictive identities for a negotiation between different groups that will try to solve a problem together. Paradoxically enough, the use of a fictive frame makes the communication more real. Pedagogic research has proved (Randall Davis, 1996) that "simulations provide a way of creating a rich communicative environment where students actively become a part of some real-world system and function according to predetermined roles as members of that group."

The TELSI software

The SIMULAB laboratory, based on the specially designed TELSI software, is an Internet-based tailor-made environment for role-play activities in language learning. The environment consists of a flexible system of authoring tools, which allows any language teacher to create simulations on the Internet for their pupils. This includes systems that give access to internal e-mail systems within a group; communication with others outside the SIMULAB environment; internal recordable "chat" forums in real-time; easy creation and editing of documents on-line and easy linking and hypertext creation.

The pedagogical frame

The main aim of the simulation activity is to stimulate the production of authentic, spontaneous oral language in classroom discussions and of written language in the communication with other groups through the WWW.

All student groups (preferably not more than 3 or 4 in each simulation) are presented with a problem that has to be solved by the whole network. Each group gets a "group identity" that will differ from that of the other groups. Within each group the students will then have to choose and define their own personal identity, which will be identical with the role they play in the simulation. Since both the group's and the individual identities will be placed within the frame of the culture pertaining to the target language, students will be faced with the need to find relevant information about that culture. During this phase, most of the activities will be centred around discussions in class. Computer communication will be used only as a source of information.

Once the individual identities have been established, the students will start the communication with the other groups in the network, by introducing themselves in their new personalities. The second phase of the activity can then start: the students in each group will discuss among themselves what will be their first suggestion for a solution of the problem presented to the network. Once they have agreed on a strategy, they will communicate it to the other groups. On the basis of those suggestions negotiations can begin. Because the student groups have spent some time discussing the problem, they "own" , psychologically speaking, the suggestion that their group presents. The need for "fighting" for their solution, that will surely arise during the negotiation phase, will create the basis for real communication. The TELSI software, created by the SIMULAB project under the TELEMATICS in Education and Training programme, makes it possible for the teacher to structure and control the simulation process. The experience gathered in the validation phases of the mentioned projects shows that it is possible and desirable to use the simulation activity as a frame that can provide links for all the different disciplines contained in the process of language learning: comprehension, production, grammatical correctness, structure of discourse, etc.

SIMULAB as innovative method for language teaching and learning

The SIMULAB project has been awarded the European Label for Innovative Language Teaching and Learning 1998. The jury mentioned as background for their decision: „The SIMULAB concept creates international networks of student groups that will work together to accomplish the task indicated in the script. The simulation scripts can be adapted to different languages, themes, levels or specific language needs and can be used as soon as an elementary discussion is possible.”

The future of SIMULAB

The future of the concept will to a large degree depend on the creation of networks between motivated teachers who are familiar with the concept and the use of the software. Experiences with the SIMULAB concept have shown that it is essential that the teacher understands and feels familiar with both the concept and the software before starting a simulation with his or her students. In recognition of this fact, the consortium are currently offering teachers from all over the world the free participation in "teacher simulations" in which they can learn about the SIMULAB concept, become acquainted with the TELSI software, have first-hand experience of the role play activity, and network with other language teachers

For more information about the project, please see <http://oyt.oulu.fi/tsimulab>

Abstract: Rapid changing demands on the firms and employees within the field of information and communication technologies have forced Swiss universities and enterprises to set up a virtual campus for life-long learning. The presentation gives an overview of the organizational structures, the tools and methods, and the way of information sharing between teachers.

1. Introduction

The new information and communication technologies induce a fundamental change in contents and methods of the working process. A continuing educational system has to adapt rapidly to corresponding requirements. Some of the key words are learner-centered, problem-based, experiential, collaborative and interactive distance learning. Therefore we are setting up a virtual campus for post-graduate studies in information and communication technologies. Methods and tools relating to new learning technologies are elaborated within the project CLASSROOM 2000. The corresponding information, knowledge and experience is shared within a common workspace called HEURIS, an information system which is accessible through the Web.

2. Setting up a Virtual Campus

Rapid changing demands on the firms and employees within the field of information and communication technologies have forced Swiss universities and enterprises to set up a training partnership. The post-graduate studies called NDIR/FPIT (Nachdiplomausbildung in Informatik und Telekommunikation / Formation postgrade en Informatique et Télécommunications) is a successful example of a collaboration between universities and technology oriented industry. The partnership is organized according to the model of a virtual enterprise. Over 40 partner institutions contribute with standardized modular courses in their special domain. The compact courses are held all over Switzerland at the sites of the contributing partners. The target public are engineers and project managers in the field of computer science, business information systems, telecommunication and multimedia. Today about 160 students are enrolled in the post-graduate courses, and they assemble their individual curriculum from the modular program according to their professional needs. The partnership network is managed by a slim organization which elaborates the study concepts, specifies the curriculum and cares about the marketing and financing of this virtual university. The geographically distributed course providers, the collaborative organizational concept with modular courses and highly skilled and motivated students make this program an ideal test-bed for the implementation of new educational technologies.

3. Elaborating Tools and Methods

Two years ago we founded a consortium of institutes and firms working in the field of new educational technologies. The ongoing research and development activities are running under the name of CLASSROOM 2000 (cf. <http://www.ndit.ch>). Some of the main activities can be summarized as follows:

The MEDIT research project aims at developing a Web-based environment for a variety of pedagogical modes. For the design of this hypermedia authoring system a joint collaboration between different but complementary know-how is mandatory: computer science, telecommunications, human computer interaction, pedagogy etc. The originality lies on the use of highly structured documents which results in an efficient management of all document classes. For instance, from the same set of course documents, the system can provide a classical view (by chapter or by session), but also a new one, namely the semantic view. It allows a student to create and maintain his private working space. This does not only permit attaching annotations to an existing document, but also integrating course documents according to his way of learning.

For two years we have been running different prototype courses in a virtual classroom environment. We propose an intermediate tele-teaching form, which is based on the public telecommunication networks ISDN (Integrated Services Digital Network) and Internet. The students communicate among themselves and with their teachers by video telephony, e-mail, electronic blackboard, documentation service and forums. One main objective of the project is to set up a handbook for future implementations of the same kind.

An important aspect of the CLASSROOM 2000 project is the elaboration of pedagogical and didactical guidelines for teachers. We have to keep in mind that learning technology is about learning, it is not about technology! Given all the sophisticated multimedia, information and communication tools, it is tempting to use them without a thought about cognitive and social aspects. We have to think about new norms and rules of interaction. It is our goal not only to replace traditional educational technologies by new ones, but also to use them in a way that can improve our teaching results. Therefore we have set up an evaluation concept for a virtual classroom, which takes into consideration ergonomic, pedagogic, technological, social and economic aspects.

4. Sharing Information

During our activities within the CLASSROOM 2000 project and the NDIR/FPIT program we have become more and more aware that the specific information, knowledge and experience concerning the technical and didactical use of new learning technologies has to be shared in a common pool. For this purpose we have decided to develop an information system called HEURIS, which at the moment is available in a first version. It implements a push and pull approach, what means that users will not only benefit from the available knowledge, but they will also upload bits of their own information and experience.

The shared information can be characterized by four dimensions:

- **Technology:** HEURIS provides information concerning the technical aspects of a certain tool. It describes the main characteristics, gives an overview of the required infrastructure, discusses the time needed for installation and support, and offers pointers to some available products.
- **Application:** HEURIS gives not only technical but also practical advice. A view of the range of applications is crucial to the extent that a certain tool's potential concerning communication and knowledge transfer is no guarantee of its success. We often recognize a significant gap between the potential of a tool and the way it is really used.
- **Didactics:** A main goal of HEURIS is to bridge the gap between technology and didactics. Therefore it deals with different topics concerning objectives and methods of teaching and learning. For example each tool is discussed in relation to its didactical suitability for either teaching the skill of knowledge reproduction, method application or problem solving. Or it is classified concerning to its potential for teacher-directed, team-directed, or self-directed learning.
- **Experience:** As there is quite a lot of knowledge available that is based on personal experience with some specific tool, one part of HEURIS is dedicated to practical reports.

The first version of the information system contains knowledge about tools which are used within different NDIR/FPIT courses. These are mainly tools for asynchronous or synchronous communication (e.g. mail, discussion list, video conferencing, application sharing, chat). In a second version we would like to provide also more specific knowledge such as information concerning format standards (e.g. text, graphics) or multimedia components (e.g. audio, video, simulation). During the first phase the information is accessible for project members only, in the future we would like to open it also for external users.

5. Conclusion

Up to now we have carried out 8 courses, two of them offered simultaneously in Switzerland and Africa in collaboration with ESMT (Ecole Supérieure Multinationale des Télécommunications) of Dakar. In the near future more of the NDIR/FPIT courses will be upgraded with the newly developed interactive courseware or prepared for new dissemination methods. All courses are stringently evaluated with the collaboration of the students and the teachers. The experiences gained up to now show excellent progress in the quality and acceptance of the virtual classroom courses. The aim is to provide a substantial part of the full program in this form. This will facilitate access to this program for students who are fully involved in their professional work and who therefore could not take advantage of an in-deepening continuing education.

CLASS™ - Using Innovative Technologies for Distance Education

Kathy Northrop
University of Nebraska-Lincoln
Division of Continuing Studies - Department of Distance Education
Lincoln, NE USA 68583--9809
Tel: 402-472-0250, Fax: 402-472-0905, E-mail: northrop@unlinfo.unl.edu
<http://class.unl.edu>

Abstract: The CLASS™ (Communications, Learning, and Assessment in a Student-center System) Project at the University of Nebraska is creating an accredited, electronically delivered high school diploma sequence for delivery on the World Wide Web. Because of the unique distance learning environment of the Web, the CLASS™ Project has developed an instructional created Web-based instructional design features to maximize the learning opportunities afforded by this electronic education environment. Both the CLASS™ design features and instructional design model are transferable and scaleable to the needs of other distance learning programs.

The Project

The CLASS™ Project's goal is to make available on the World Wide Web a complete, accredited, high school diploma sequence. The Department of Distance Education of the University of Nebraska-Lincoln (UNL) is recipient of \$18 million in federal funding to develop the sequence. When completed in 2001, CLASS™ will have available to students 55 courses from which to choose to complete these requirements.

The Department of Distance Education is uniquely suited to provide this diploma sequence. Among its units is the Independent Study High School (ISHS). The ISHS is the only university-based, fully accredited, independent study high school in the United States. In operation since 1929 and accredited by both the North Central Association of Colleges and Schools and the Nebraska Department of Education (NDE), the ISHS currently serves about 15,000 students annually in 136 countries. The students can choose among 138 print-based courses in addition to the electronic courses. Enrollment is open, with students registering throughout the year.

The Course Design

The development of the courses for this project required the recognition of several factors. Paramount among these was the World Wide Web offered a new and different educational delivery method. Therefore, current print-based courses could not simply be transferred to the Web. Second, in order to fully utilize the potential of the Web as an educational delivery system there would need to be new software and technologies developed. Third, and premised on the first two points, production of these courses would take place in a manner different than traditional multimedia production. To put it simply, the project would require invention in both the areas of instructional design and technology.

CLASS™ is a dynamically interactive, student-centered course environment delivered electronically via the World Wide Web. Students access moving imagery, graphics, sound, and text within a seamless navigational system that encourages individualized learning, discovery and exploration. "Seamless" means that students do not have to open and close applications to move from—for instance—a text screen to simulation (or to a video or discussion group). The technology for supporting all the media of a course is included in CLASS™.

CLASS™ provides new avenues of educational access through cost-effective alternatives to conventional classroom teaching situations. These new avenues are particularly important when reaching

out to all levels of students, including nontraditional, geographically isolated or disadvantaged segments of the population, at-risk and the gifted.

CLASS™ provides individual learners with access to interactive, flexible course materials, including data, graphics and video, and incorporates electronic interaction between learners and instructors. CLASS™ helps students manage this multitude of materials by providing an electronic “notebook” where students can store and sort everything from video to text. They can share this information with other students or with the teacher.

Courses are formatted especially for electronic delivery. Students are responsible for their own learning, making choices in the paths they take through the course, and selecting from many different learning activities and experiences. Course units develop increasing levels of complexity and sophistication within the course content. As students move through the units, their interaction with the materials requires an ever-widening understanding of the concepts being presented.

Students determine their own mastery of the material by taking practice exams that are electronically evaluated, students receive the results in only a few seconds. Examinations and projects are evaluated electronically or by the teacher.

CLASS™ instructional design provides for interaction between learners and instructors, stressing the development of life and workplace skills, citizenship responsibilities and critical thinking. New technologies provide learners with access to digital libraries from national, historic, scientific and research centers over the global and national information infrastructure.

Conclusion

The CLASS™ instructional design model is a work in progress, regularly revisited and revised. It is used for developing all CLASS™ courses and easily transfers to a variety of Web-based instructional needs. Whether one is developing a single lesson tutorial or an accredited semester-length course, the CLASS™ instructional model is sizable to the situation. This instructional design model enables input from a variety of sources, and empowers the designers with feedback before, during and after the process.

CLASS™ instructional features give distance education students the opportunity to learn using a myriad of learning tools that are unique to Web-based distance education, including student-to-student communication, dynamic learning activities, student-selected learning paths, multimedia-reinforced learning, self-monitoring of progress and the ability to create multimedia portfolios, all in a seamless learning environment not bound by time nor space.

Because of its size and scope, the CLASS™ Project has the potential to revolutionize the distance delivery of courses to individual students, learning centers and schools that cannot afford or do not have the ability to offer specialized courses such as English as a Second Language.

Currently 32 courses are open for enrollment. Examples of the courses, along with additional information on CLASS™ can be found at <http://class.unl.edu>.

On-line Learning 'Assumes' On-line Delivery Skills

John O'Donoghue
Delta Institute/ LTSC. University of Wolverhampton. UK
j.odonoghue@wlv.ac.uk

Abstract: Remote, distant, on-line learning is gathering momentum. However the ability of traditional 'class-based' teachers and lecturers is not keeping pace with this change. The framework being developed at the University endeavour to provide a variety of means and mechanisms to address the needs of the staff at both the conceptual and practical level.

It is often said that we are entering or even part of the Information Age. This coming period could equally be called the Age of Learning: The sheer quantity of learning taking place in the world is already many times greater than in the past. For example, not very long ago, and in many parts of the world, young people would learn skills they could use in their work throughout life. Today, in industrial countries, most people are doing jobs that did not exist when they were born. The most important skill determining a person's life pattern has already become the ability to learn new skills, to take in new concepts, to assess new situations, to deal with the unexpected. The competitive ability is the ability to learn. Information technology, from television to computers, affords an opportunity to enhance the learning experience. However, to date, classroom enhancements have replaced traditional apparatus rather than the process or didactic model of teaching:

- ⇒ The chalkboard replaced the slate;
- ⇒ the whiteboard replaced the chalkboard;
- ⇒ the OHP replaced the whiteboard;
- ⇒ software (Microsoft PowerPoint™ et al) replaced the OHP

Teachers/ lecturers felt comfortable with these changes as they were replacing the quill with the keyboard, the delivery mechanism, process and interface was essentially the same. So how to progress, there is a need to enable staff to consider the pedagogic implication of the on-line learning environment rather than the content. In order to implement and sustain remote, distance based computer mediated courses with a high probability of success, the following should be considered as the critical areas:

- enhancing/extending autonomous learning and productivity in the face-to-face traditional classroom setting
- creating a Web-presence with easy access to 'basic' information about online courses and interactive learning materials
- discovering/developing tools and standards to support new learning environments
- advancing our understanding of the virtual and distance university
- increasing community/off-campus access to the teaching-learning community
- providing evidence of the viability of these concepts

Staff are currently being asked to develop material for on-line delivery. This is an anathema to them. Not because of any motive other than competence in the pedagogy, technology environment etc. They generally teach the way in which they have been taught. As tutors they feel in control of this environment of physically teaching students, they are 'happy' with the quality and control and standard of the 'interface'. To introduce another medium is quite threatening and may well affect the quality of the experience. There is a need to maintain quality within our content and delivery. According to the literature, quality is concerned with meeting a defined specification(s). Clearly, for learning to be considered as quality learning, it must also meet prescribed and accepted criteria. Nightingale and O'Neil (1994: p. 54), suggest that the indicators of high quality learning having taken place are: -

- being able to discover knowledge for oneself
- long term retention of knowledge (implying that there is understanding)
- being able to perceive relations between old and new knowledge
- being able to create new knowledge
- being able to apply knowledge to solving problems
- being able to communicate one's knowledge to others
- wanting to know more

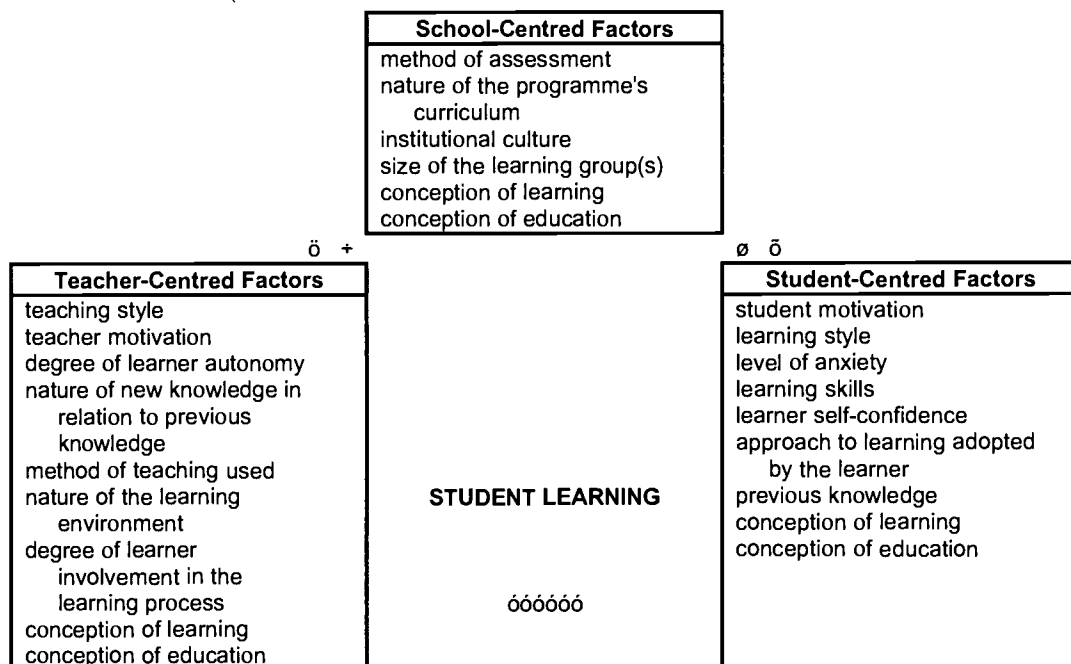

But, they add the caveat that it is only possible to achieve this specification where certain pre-requisites for quality in learning are in existence:-

- the learner is ready to meet the demands of the learning task(s)
- there is a reason for learning (acceptable reason, to the student)
- the learner is active during learning
- adequate support is provided by the environment in which that learning occurs

The adoption and implementation of such a model by staff in developing for an on-line delivery platform or for an on-line supported delivery platform will require a greater understanding of both the learning process itself, and also the most appropriate means to facilitate that process. This understanding is a pre-requisite for effective course design. But, I would suggest that at present, part of the problem is the differing conceptions held by academic staff as to exactly what; a) learning is, and b) what on-line facilitated learning is. But perhaps more importantly, future developments in course design, structure and delivery will continue to be at best misguided, and at worst potentially damaging to the quality of the learning experiences that are offered.

The challenge is to develop a curriculum which can emphasise interconnections between learning pathways, the practical application of knowledge in a variety of contexts and flexible relationships between core and specialist knowledge. It must be based on sound pedagogy. The focus on tutors is not on the training but on the facilitation of central processes of learning which too often is interpreted as something which is transmitted to people rather than an activity for which they themselves have responsibility. The teachers of tomorrow must have some involvement, experience and opinion of 'student-centred learning', 'flexible learning', 'open learning', 'active learning', 'on-line learning' etc. Effective learning within this environment is:-

- 1) a function of the interaction between, *and* the interdependence of, 3 groups of factors
- 2) and a cause of that interaction

Robotham, 1996

The approach of the tutors in allowing cross fertilisation and conceptual development of the student and tutor and technology must be fostered. It must allow various "partnerships" into which students will enter. Successful learning depends on success in establishing and developing such partnerships - with tutors and with collaborators. However, such an attitude is not free of complication. It may be argued that one important goal of formal education is to cultivate a capacity to learn independently; in a sense to find some release from learning - as - partnership. Now, claims of this sort introduce an element of tension: we wish to develop partnerships for purposes of socially mediated learning, but we also wish to cultivate in the learner a certain autonomy. Tension of aims need not imply conflict of aims. Indeed, far from being in conflict there may be necessary developmental relationship between socially organised cognitive functioning and that which is 'private' or autonomous to the individual (Vygotsky, 1978).

Thus, in practice, one thing teachers much surely consider is how they should manage the learning process in terms of a balance of emphasis between pupil autonomy and interpersonal exchange.

July 1999

Abstract: Since 1993, De Montfort University and eight other institutions situated in the United Kingdom, Belgium, Ireland and the Netherlands, have been working on a project called "Electronic Library Image Service for Europe" (ELISE). This paper introduces the ELISE project and outlines a scenario that involves establishing an operational electronic image retrieval service in Europe that can accommodate additional image banks.

1. Introduction

The European Commission has funded the ELISE project through two phases. The initial phase began in February 1993 and concluded in 1995, it resumed in 1996 and is due to be completed by the end of this year.

In the initial phase, ELISE was successful in producing a working prototype for providing image access from remote sites (using the Internet, but before the World Wide Web was established). It modelled a European Community facility that provided access to full colour image banks with supporting textual data and was held in the different project partner states. With the conclusion of ELISE I, several demonstrations and product launches took place in both the UK and in the Netherlands. ELISE II has been investigating the feasibility of providing images over the Internet, using standard Web facilities, but providing additional user control, copyright support and charging models. The project has developed a comprehensive JAVA based, distributed demonstration system that provides controlled access to images and associated textual information. Eight of the partners are providing a variety of image content, from cultural and artistic, to scientific and medical subjects.

2. Scenario for ELISE

As part of the project an investigation into the possibility of commercialising ELISE is taking place. An economic model has been completed as a result of the project team assessing the current demands and needs of the picture library market. This model is currently being tailored to a potential ELISE consortium and a business plan is being developed that considers possible commercial opportunities for the service.

The project partners have established the following objectives:

- ◆ To identify areas where there is greatest benefit to be gained from networked image banks.
- ◆ To promote partners own image collections and provide access to the world-wide market via the ELISE web-site.
- ◆ To continually advance ELISE with technological developments so that the service becomes and remains competitive in the world-wide market.
- ◆ To participate in the development of image related services to the educational community and cultural sectors.

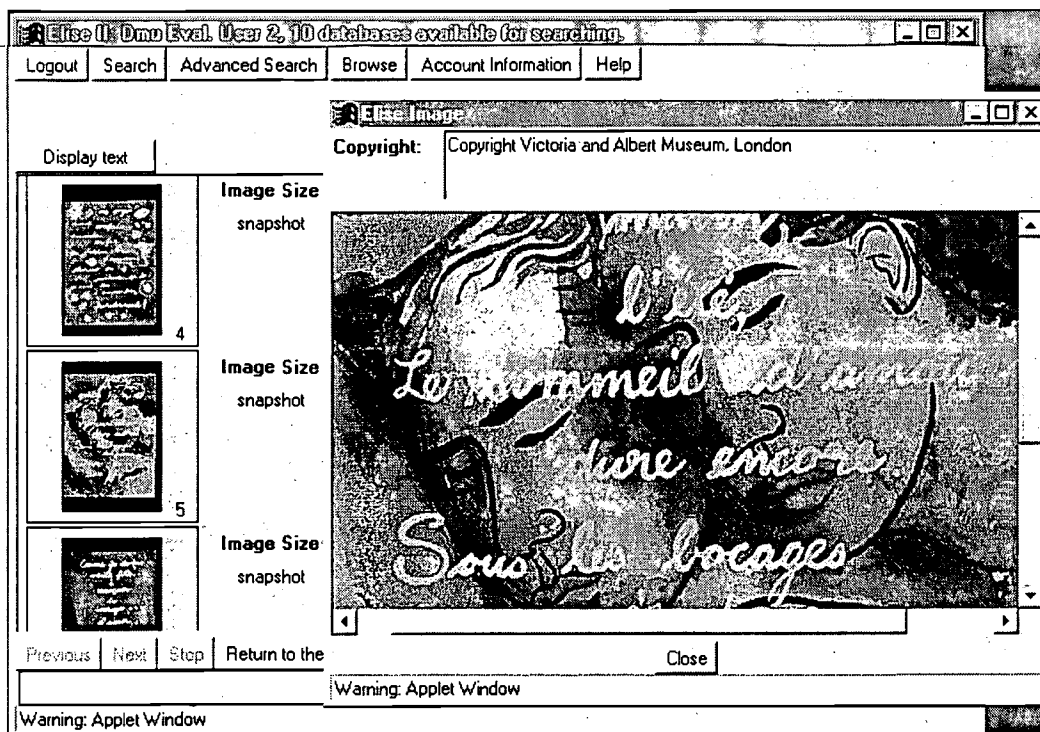

The ELISE Business Plan will target the educational and cultural sectors initially in the United Kingdom and expand into Europe within five years.

BEST COPY AVAILABLE

The third annual Picture Agency Council of America (PACA) International conference was held in New York in November 1998. At this conference, Jonathon Klein of Getty Images acknowledged that "sites which provide an opportunity for smaller libraries to place their images on a collective site may potentially provide a solution to the dilemma facing small and mid-size companies" [Harding 1998].

It is envisaged that ELISE will continue to be a distributed system with centralised access and administration. Individual institutions will make their collections available to the educational and general world-wide market via a central web-site operated by an ELISE European Economic Interest Grouping (EEIG). Centralised search and billing facilities would be provided at the image banks request. Image banks and picture libraries connected to ELISE would maintain ownership rights and maintenance of their collection/s.

There are already a number of image banks on the Internet, some operate on a non-profit basis while others are commercially oriented. Some image banks are very content specific whilst others are more generalised and cover a wide range of subject matter. With ELISE, all image banks/picture libraries have equal opportunity of their images being requested/accessed.

Existing image banks/picture libraries can become associated with ELISE, either by adding a Standard Network Interface (using Z39.50 protocols) to their server, or by filling in an online form and submitting their collection. Where the collections of the image banks/picture libraries are not digitised, ELISE has the opportunity of providing the service of digitising, cataloguing and maintaining the collection on their behalf. ELISE would activate accounts for potential users in the form of subscriptions for the higher education sector to enable ease of administration, and user accounts for the general market.

Effective Online Teaching/Learning: A Case Study

Dr. Jaishree Odin

Liberal Studies Program, University of Hawai'i at Manoa, Honolulu, Hawaii, U.S.A.

Tel: 808-956-3296, Fax: 808-956-2191, E-mail: odin@hawaii.edu

Abstract: The University of Hawai'i at Manoa was funded by the Alfred P. Foundation to create and offer an asynchronous learning network (ALN) course to outreach students on neighbor islands of Maui and Molokai. The delivery of the course resulted in data which showed that effective collaborative asynchronous learning environment incorporates a carefully planned learner-instructor, learner-content, and learner-learner interaction.

As distance education begins to get increasingly defined in terms of online education, there is a trend toward reintegrating the learner-instructor as well as learner-learner interaction in teaching at a distance. The focus is increasingly on rethinking teaching-learning process so that all distance students become active learners. Online education is shown to be effective in creating collaborative learning situations. It has also been seen that unless specially designed activities are integrated to promote learner-content interaction, the nature of peer interaction can be quite superficial.

We kept the above pedagogical issues in mind as we designed and delivered an experimental asynchronous learning course at the University of Hawaii at Manoa. The project was funded by the Alfred P. Foundation to study the feasibility and effectiveness of an asynchronous learning network (ALN) course for the outreach students on neighbor islands of Maui and Molokai.

The Course and the Students

CAS 403-Information Technology and Culture was an upper division interdisciplinary course. The course materials used in CAS 403 came from a variety of sources: print resources, the instructor's online overviews of weekly reading assignments, books, journal articles, various online resources, and even online student projects from previous courses. Lotus Notes' LearningSpace was the software used for delivering the course. For participating in the course, students had to visit the course site regularly and participate in all activities on a weekly basis. As we designed weekly class activities for students, we focused on creating a learner-centered environment. The class lectures or lecture notes were replaced by weekly overviews and specific discussion topics. Even students' detailed responses became part of the reading materials. We focused our attention on creating a learning environment that would allow learner-content interaction, learner-teacher interaction, and learner-learner interaction regularly.

As far as the general format of the course was concerned, each student was required to read the assigned reading material and respond to it on a weekly basis. The learner-content interaction was facilitated by the instructor's weekly overviews of the reading assignments. The purpose of the reader responses was to see that the instructional goals were being achieved and when they were not, timely intervention became possible in maintaining student interest in the subject matter or in the learning situation as such. By the end of the second week, it became clear that the quality of a great number of responses was so good that other students should be given an opportunity to read them. So starting from the second week, the instructor started posting the responses for everybody to read; initially, just the best ones, but as the semester progressed, all responses were posted for everyone to read. Different perspectives helped them understand ideas that they had missed or not understood in their own reading.

Whereas reader responses were focused exercises to evaluate students' understanding of the content, the discussion assignments were meant to serve as a platform for the application of ideas. We initiated one or two discussion threads every week and these were directly linked to the content overviews for that week. The students were free to initiate other discussion threads which they frequently did. We reinforced right from the beginning that there was no wrong or right response to the discussion assignments, only different perspectives and different levels of understanding. The open-ended nature of discussions gave students freedom to choose how they wanted to respond to the entries. In this controlled, yet very open discussion space, students got actively involved and responded to each other in creative ways. A lot of faculty who have incorporated electronic conferencing tend to

complain that it takes too much of their time since messages come pouring in at different times. In CAS 403, discussions were primarily a space where students interacted, even as they were constantly aware that their discussion was being monitored by the instructor who intervened only when students needed help or if they went off track. Since the instructor held back, soon more advanced students began to help those who were having difficulties with comprehending ideas or their relationship. The instructor's occasional strategic intervention reassured students that the instructor was indeed monitoring all class discussions even though she did not actively participate. This strategy was very useful in handling on the average 80-90 submissions/week.

In order to increase learning effectiveness, we integrated assessment activities into the course design right from the beginning which allowed us to monitor on a weekly basis if the learning goals were being achieved. A background test before the course actually began gave us an idea about students' prior knowledge. Similarly the reader response and discussion assignments that students were required to submit on a weekly basis showed us if students were learning the concepts or skills that were part of the course objectives. The Paper-Prep quiz at the end of the first two units and the second one at the end of the last two units allowed us to see if students had in fact mastered the assigned texts at the conceptual level. If some students were having difficulties understanding the subject matter, the instructor intervened in a timely fashion before it was too late. As in a face-to-face course, students were also required to write two essays. In light of the fact that students wrote long reader responses on a weekly basis, the number of essays assigned in this course was reduced from three to two. Students were asked to write one short essay in the middle of the semester and one long research paper at the end of the semester. Except for one or two essays, all the essays were posted for everybody to read. The gradable assessments, essays, were thus only one aspect of the course where the focus had shifted from teaching effectiveness to learning effectiveness.

It was obvious both to the instructor and the students by the end of the second week about the importance of time management. Each week the twenty students enrolled in the course generated on the average a total number of 80 submissions which were dispersed over different days of the week. Some sort of time-frame needed to be developed in order for the course to run efficiently and to keep the students motivated to participate actively. The external pacing, it was obvious, was crucial for the collaborative work to take place. All assignments for the week were due by the Sunday of that week. Similarly, the instructor provided individual feedback by the Tuesday of the following week. The instructor checked on the course discussion everyday, only occasionally participating. The class discussion become primarily a space for peer interaction. All new assignments and weekly overviews of the reading assignments were up on Monday of every week. As the instructor strictly followed the schedule herself, the students too were motivated to do so. She provided feedback to students' individual responses on a weekly basis. It created a context where each student felt directly linked to the instructor while at the same time feeling a part of the community of learners. It also created a classroom dynamics where students felt that the instructor was monitoring all class discussions and individual submissions, even though she did not participate actively in class discussions.

Conclusion

Through teaching this course, it became obvious that an effective multi-layered learning environment incorporates learner/content, learner/ instructor and learner/learner interaction which creates a social context for receiving, exchanging and transforming knowledge. The process of teaching/learning becomes a complex mode of interaction amongst the learners, the instructor, and the content of the course. We also noted that the role of the instructor is crucial as the content expert if deeper learning is to take place—to explain, to clarify, to direct and guide students as they learn new concepts and their relationships. Since the work done by students in an asynchronous course is in writing, it can be reviewed both by students and by the instructor anytime from anywhere. The learning-teaching act thus need no longer be separated in distance courses even as self-learning is still one of the important aspects of distance learning. In this respect, asynchronous online education can be compared to face-to-face seminar classes which usually focus around student discussions rather than instructor lectures. An asynchronous class can be run in a way that promotes genuine collaborative work where the more advanced students begin to help those who are less advanced. Students can indeed feel a sense of ownership in such a course, as the energy they invest in their work does not dissipate at the instructor's desk, but is passed on to their peers.

Development and Use of Interactive Websites K-12

gwbright@uncg.edu

Abstract: Two interactive websites, focusing on a national estuary and a shipwreck, have recently been developed. These websites have been used in classrooms to help students understand the attributes of each environment, while preserving the sanctity of the sites. During interactive sessions, students can watch activity through streamed video and then pose questions through a chat-room capability. Local experts at each site respond to students' questions. Both teachers and students report high interest in these interactive sessions, in spite of some technical difficulties during initial use of the websites. Both sites have also proven useful as contexts for creating interdisciplinary instructional activities.

Estuary Project

The Estuary Project website is a cooperative effort of the North Carolina National Estuarine Research Reserve, the North Carolina Department of Public Instruction, the Center for Science, Mathematics, and Technology, and Marine Grafics. The Estuary Project is designed to educate school children and teachers about estuarine environments, with the expectation that this knowledge will help future generations protect the estuary environment at the Rachel Carson Sanctuary on Pivers Island, off Beaufort, NC. The website lets public school students interact with this work without physically being at the Sanctuary. Virtual visits encourage the development of understanding about estuaries without causing environmental damage.

The Estuary Project website (<http://www.marinegrafics.com/livecam/mainpage.htm>) was created in fall 1998 by Bill Lovin of Marine Grafics and Susan Lovelace, Director of the North Carolina National Estuarine Research Reserve. The main page contains a live shot (updated every minute during broadcasts) transmitted from the Sanctuary, a live underwater shot (updated every 15-minutes) showing a data-logger which checks weather and water conditions (e.g., Air Temperature, Water Temperature, Dissolved Oxygen). In addition there are links to resources, lesson plans, frequently asked questions, a scrapbook of pictures, and acknowledgments of sponsoring agencies.

Shipwreck Project

On March 3, 1998, North Carolina Governor Jim Hunt announced the discovery of what is believed to be the remains of the Queen Anne's Revenge (QAR). The long lost flagship of the infamous pirate, Blackbeard, ran aground on a sandbar and sank off the coast of Beaufort, NC, in June 1718. The discovery of the shipwreck was first made on November 21, 1996, when divers from Intersal, Inc., reported a 20-foot by 30-foot mound of artifacts, such as cannons and ballast cobbles, as well as portions of a wooden hull, buried under the sand. The wreck and its contents are very fragile because of age and underwater location. Over the next few years, divers will explore the shipwreck, and artifacts will be brought to the surface.

An education website (<http://blackbeard.eastnet.ecu.edu>) for QAR was developed in April 1998 by the Division of Archives and History within the North Carolina Department of Cultural Resources, UNC-TV, the

North Carolina Department of Public Instruction, and the Center at ECU. (Interestingly, the mascot for ECU is the Pirates!) The goal of this website is to protect, research, document, recover, and interpret the archeological find. This website has is the official educational site for information about QAR and includes five categories of information: Dive Logs (details of the exploration and archeological dives), Historical (information on Blackbeard and the Queen Anne's Revenge), Photo Gallery (photos of the archeological exploration and artifacts taken from the site), Educators (lesson plans to help students become scientists and historians), Artifacts (methods used to recover and restore artifacts).

Use of the Websites in Classrooms

There have been two interactive demonstrations of the use of the Estuary website in classrooms. The first was in 1998 on November 3, 4, and 5 (for elementary schools, middle schools, and high schools). At a reserved time, registered classes used passwords to gain access to the live streaming video page. A video camera followed a group of students and teachers and transmitted live pictures from the Sanctuary. Throughout the transmission, a "Chat" window was open for communication. (Audio was not available during this demonstration.) Scientists at the site used this capability to explain what was happening in the video. At any time during the transmission, students could submit questions via this same Chat window, and responses were made by the scientists at the site or at the Sanctuary office.

The second demonstration was during the Supercomputer Conference in Orlando, FL, on November 9, 1998. Connections were made via IP technology among the Sanctuary, about 200 teachers at the conference, and schools in Illinois, Iowa, and North Carolina. This demonstration was essentially the same as for the earlier demonstration, with only video and "Chat" capabilities being available.

Students asked a surprising range of questions (not all necessarily appropriate!). The on-task questions below indicated that students were focusing on critical features of the environmental work.

- How tall can the grass grow?
- How much salt is in the water?
- What is the data logger hooked up to?
- Is there a special kind of net you use to gather the samples?
- How does erosion material affect the marine life?
- Can you use the number of snails to determine how pollution is affecting the estuary?

Recommendations

One of the lessons learned is that students can easily flood the system with questions. •Both teachers and students need to be prepared about what kinds of questions are appropriate and how many questions one class might reasonably submit. It might also be advantageous to identify a set of frequently asked questions and prepare a "study guide" ahead of time so that answers to these questions can be in each classroom at all times. Alternately, a moderator might filter the questions to prevent duplicate or inappropriate questions.

Both teachers and teacher educators who participated in the demonstrations recognized the need for broadening our views about communication. As Internet conversations become more widely used in classrooms, considerable thought needs to be given to how to design responses to support students' learning. Too, ways of threading discussions need to be studied so that students are not lost in mountains of information (e.g., rapid-fire questions submitted from multiple sites simultaneously).

There might be advantages of preparing video clips ahead of time, rather than using live streamed video. These clips could be accompanied by predesigned questions that focus students' discussion more directly on the content to be learned. This kind of environment should not replace the use of live video, but it might be a better introduction to the study of the content of a website than simply putting students on-line immediately.

Partial funding for these projects was provided by PCS Phosphate and Grady White Boats.

Transporting Environmental Communication Across International Boundaries

Lea J. Parker, School of Communication
Northern Arizona University, USA
lea.parker@nau.edu

Environmental problems have no boundaries; the World Wide Web and the Internet have no boundaries. That's why the World Wide Web and the Internet are the perfect tools for international communication about environmental issues.

Overpopulation; pollution of land, water and air; and resource depletion are environmental concerns that cross man-made national boundaries to affect living systems globally. Engendering human awareness and initiating solutions to environmental problems require cooperative efforts of environmental communicators from all countries, working together to promote global environmental sustainability. The Internet enhances opportunities for dialogue that involves citizens as well as professionals and leaders in the search for solutions to common problems. It is in this spirit of international cooperation for environmental protection that the I-STEP Project was formulated.

The I-STEP Project is an international environmental communication project that utilizes the World Wide Web for research and information dissemination concerning environmental issues and that utilizes the Internet as a means to achieve dialogue about environmental issues. The I-STEP Project is an example of an educational application of the World Wide Web and Internet as teaching, learning and pedagogical tools. The project can be used as a "model" for future educational and information dissemination projects about environmental and social issues because this project fosters collaborative education and problem-solving by means of the World Wide Web and the Internet.

I-STEP stands for "International Students Together for Environmental Protection." The meaning of the I-STEP concept for those involved is as follows: "I, as a citizen of Earth, will take steps in the direction of environmental problem solution." The philosophy behind the project is that if each person takes steps toward environmental protection, the collective effort can result in dramatic improvement in the environmental health of the planet. The "steps" that people can take as a result of this project and the methods to evaluate such actions are outlined on a website with free access for the public.

The I-STEP Project began with an international faculty exchange in which faculty from the United States and The Netherlands utilized the Internet and teleconferencing to formulate a program of collaborative learning. The project involved a student exchange in which students of different countries worked together to produce environmental communication campaigns to increase public awareness of environmental problems (including implications of such problems), and to initiate individual, community and company actions in pursuit of solutions. The World Wide Web was utilized for research and information gathering and the Internet was used as a communication tool for dialogue.

The first I-STEP Project involved an exchange between faculty and students at Hanzehogeschool in Groningen, The Netherlands, and the School of Communication at Northern Arizona University in Flagstaff, Arizona. This exchange took place during Spring and Summer of 1998, at which time Hanzehogeschool van Groningen was conducting its "English Semester." During the "English Semester," which is hosted each year at Hanzehogeschool van Groningen, students from various European countries and the United States attend Hanzehogeschool van Groningen for the purposes of working together on communication campaigns with all classes taught and work produced in English, which is considered to be a "common" international language. Students participating were not only from The Netherlands and the United States, but also from England, Spain, Italy, France, Belgium, Germany, and Sweden.

The topic for student-produced communication campaigns for the I-STEP Project was "Global Warming," which was appropriate due to the recent Koyoto Conference and since the topic and its related issues and consequences are of relevance to people from all countries. The sponsor obtained for the project was Greenpeace, International, whose international offices are located in Amsterdam, The Netherlands. Greenpeace sent a representative to Hanzehogeschool to discuss the topic with students, and Greenpeace

also allowed students access to all Greenpeace files. The agreement was that students would produce communication campaigns that could be used by Greenpeace, if desired, and that these campaigns would also be placed on the Internet for public access.

Because the issue of global warming is complex and since it involves many issues of conservation of resources as well as sustainability issues, a great deal of research was conducted on the World Wide Web prior to the determination of communication campaign procedures. Examples of websites explored included those of Greenpeace, the Union of Concerned Scientists, Kyoto Conference, Second Nature, the President's Council on Sustainable Development, as well as appropriate links to additional information about the topic at other locations. One website that was particularly helpful in formulating "electronic brochures" and "electronic evaluation methods" was the site for the Nordlicht Campaign, hosted by the Institute for Psychology at University of Kiel in Germany. Communication techniques, research techniques, audience analysis, and many other necessary components of successful communication campaigns were studied and practiced before work on the campaigns for Greenpeace. Once research was complete, students then worked in teams to produce actual campaign materials. Such materials included brochures, posters, videos, letters and feature articles on issues related to global warming.

Because one cause of global warming is excessive energy consumption, many campaigns are directed to the conservation of energy. Examples of student produced campaigns follow. One group produced a campaign entitled "Turn Down the Heat" targeted to students in higher economic polytechnic schools in The Netherlands. The goal of this campaign is conservation of electric energy by means of individual actions such as turning down the heat when leaving a room and buying energy efficient light bulbs. Another student group produced a campaign entitled "Are You Ready for a Long-Term Relationship?" directed at homeowners. The goal of this campaign is for homeowners to reduce energy consumption by purchasing energy saving devices including domestic appliances and light bulbs, increasing wall and floor insulation, and adding solar panels. The communication plan of another group was directed to school children between the ages of 12 and 18 to increase their awareness of the problem of global warming through a series of educational activities and experiences.

While students at Hanzehogeschool were producing campaigns for the I-STEP Project in The Netherlands, students in environmental communication classes at Northern Arizona University were also producing campaign materials, with students in an environmental research and reporting class writing articles for publication on the Internet. Titles of published articles are as follows: "Monorails and People Movers," "Bald Eagles and the Threat of Global Warming," "Power Plants or Power Plants?," "Implications of Global Warming for Riparian Areas," "Make Your Vehicle Environmentally Friendly," "The Impact of Recycling on Global Warming," "The Issues Behind Global Warming and Economic Policy," "Jobs: The Next Global Warming Crisis," and "Wildlife Predictions due to Global Warming."

The I-STEP Project's "Global Warming" Campaign materials have been made available to an international public audience at a website on the Internet. Communication campaigns and articles may be viewed at: <http://www.nau.edu/soc/ecrc/> under the heading I-STEP Project. It is hoped that this information will increase public awareness and action concerning global warming issues, and it is hoped that these campaign projects will be used as examples for similar public awareness/action campaigns globally. It is with this spirit of sharing information and ideas for solving environmental problems that the I-STEP Project was designed. Technology (World Wide Web and Internet) that wasn't available just a few years ago has enhanced the success of this project and is expected to further enhance public knowledge in the future.

One of the most valuable outcomes of this first I-STEP Project is the bond formed by international students in the quest for solutions to environmental problems that confront living systems today. These students are remaining in contact with each other via e-mail as they return to their respective countries where they are assuming positions as environmental communicators. It is expected that these individuals will continue to share ideas and communication plans as they become leaders in efforts to promote environmental sustainability in their own countries. The World Wide Web and the Internet are the tools that are making this possible.

An innovative use of the Internet to teach alcohol awareness to grade 7 and 8 Students

Robert Pearson, Performx Inc., Canada, rpearson@passport.ca
Judy Roberts, Roberts and Associates/Associés, Canada, judyrobe@istar.ca
David Connal, Performx Inc., Canada, connal@passport.ca
Henry Cowan, University of New Brunswick, Canada, hcowan@unb.ca
Thomas LeBlanc, Université de Moncton, Canada, leblant@umoncton.ca

Abstract: This paper describes the innovative use of the Internet to teach alcohol awareness to French and English Grade 7 and 8 students in the province of New Brunswick, Canada. The initiative got its start with in 1997 with a \$1.2 M (CDN) grant from the Brewers Association of Canada. Student access and maintenance concerns have driven the choice of delivery technologies. The primary resource is a set of Internet-based learning activities and resources that teachers can use to supplement their classroom activities. While evaluation efforts are on-going, initial reactions to the site have been favorable.

The NEW BRUNSWICK EDUCATIONAL RESOURCE DEVELOPMENT PILOT PROJECT PARTNERSHIP got its start in 1997 with a \$1.2 M (CDN) grant from the Brewers Association of Canada (BAC). The Brewers Association designates monies each year to support education and awareness programs in the community around responsible alcohol use. In funding this Project, the goal of the BAC is to improve the quality and breadth of alcohol abuse prevention education in Canadian schools. The BAC and its partners are developing and pilot testing educational resource materials in New Brunswick classrooms that will then be made available to all Canadian teachers and students. More specifically, the Project's goal is to develop educational resource materials, in French and English, for 13-14 year olds that provide them with appropriate information on the use, misuse and abuse of alcohol. While the focus of this Project is on prevention of underage consumption, it also incorporates some harm minimization strategies. A group of curriculum specialists, content experts, instructional designers and multimedia specialists has been charged with building an engaging and effective technology based set of curriculum materials. The Project involves partnerships with the Université de Moncton, the University of New Brunswick, the Provincial Department of Education, NBTel, and Performx Inc., one of Canada's largest technology-based learning development companies.

Student access and maintenance concerns have driven the choice of delivery technologies. The primary resource will be Web and Internet-based electronic learning activities and resources that teachers can use to supplement their classroom activities. The development team is using a third generation browser and no software "plug-ins" will be needed. The development team is also limiting the graphic richness of the site to ensure fast download times over 28.8 kbs modems. The site will contain interactive activities that students can use to acquire information, skills and attitudes. Contingent on policy advice from the Department of Education, e-mail, links to other sites like MADD, CCSA, simulations, and other techniques will be used. While there may be some print material associated with the Project, every effort is being made to keep such materials to a minimum to reduce the costs that schools would incur in utilizing the final product. Teacher, student and parent support materials will also be developed so that they know how to use the Project's resources.

From the outset, everyone involved felt strongly that technology should not be used simply to deliver alcohol-related facts and figures to learners through their classroom computers. Instead, the program developers believed that learners should be engaged through a series of collaborative activities or "projects" supplemented with individual web-based activities aimed at building student's knowledge of important concepts Grabinger (1996). The design of the site was inspired by the recent work of Wilson (1996) around constructivist learning environments and, in particular, by an article by Reeves (1996) which stressed the importance of creating learning environments where students learn *with* technology rather than through it.

The development process was aided by creation of two design documents, which helped bring focus to the early planning efforts. One, the site map, provided a one page conceptual snap shot of the finished site. The map detailed each of the major "content vessels" and -- at a high level -- how users would be able to navigate around the site. The other, the content matrix, provided additional detail on the contents of each part of the site. This matrix also provided Performx, the development company chosen to work on the project with enough information to adequately scope and cost the development work. Both documents envisaged designing the site for three target audiences (students, parents and teachers) and providing them with common tools such as an Information Resource Centre.

Project descriptions (as well as support materials for teachers) will reside on the web site. In addition, the web site will contain a rich repository of material related to alcohol use in society. These materials will include graphs showing patterns of alcohol use across different groups, audio clips of people describing the reasons they use alcohol or helping professionals describing their interactions with problem drinkers. Learners will be encouraged to work collaboratively both within the classroom and with learners at other schools. Projects will culminate with an "artifact" of some kind -- a poster or newspaper article, for example -- that would, in turn, be posted to the "gallery" section of the web site. Two other sections of the site will be designed specifically for teachers and parents. The teacher's section will include a variety of strategies around effectively deploying the web resources in the classroom. The parent's section will, among other things, provide information about how to discuss alcohol-related issues with early teens.

While building on the same fundamental structure, the French and English teams have developed a unique set of activities and used strikingly different visual metaphors to frame their sites. The French team chose a "gritty urban" look for their site. The main menu contains six Polaroid snap shots that give students access to the contents of site. For example, students click on a "Polaroid" snap shot of a locker to reach a set of learning activities. In contrast, the English site uses the metaphor of a town to portray the site's main menu. On the English site, student activities are found in an Arcade, teacher materials are found in the school and parent materials in houses along the main street. The visual look of the site is also very different from the French site. The English look is light and whimsical.

The finished curriculum materials will be piloted in the province of New Brunswick and then made available to schools across Canada throughout the fall of 1999. Considerable time and effort was also spent working with teachers and government officials to ensure the learning materials met the province's curriculum standards and could be used easily by teachers and students. All project stakeholders have been consulted frequently during the design process. A sequenced, phased evaluation design has also been developed by both the French- and English-language teams that incorporates bench-marking knowledge, attitudes, skills and behavior in an experimental research design. Teacher and student reactions to the materials will also be examined.

Comparing Computer-based and Text-based Research Writing: a Course Model

Michael Petracca, M.A., M.Ed.

South Hall 1520, University of California at Santa Barbara, CA 93106-3010

Tel: 805.893.8537, E-mail: petracca@humanitas.ucsb.edu

Abstract: Since 1996, several lecturers in the University of California, Santa Barbara, Writing Program, have been teaching an upper-division university-level research course that combines traditional, text-based writing with computer aided research presentation, the latter using World Wide Web pages as tools for developing ideas and supporting materials in a non linear way. Each student chooses a topic area of interest and creates a research project on that topic, using two different formats: an expository essay and a website. At the end of the course, each student writes a final exam comparing the two research presentation methods, discussing the advantages and drawbacks of each. Through comparing these two very different approaches to writing, students learn to appreciate the strengths and limitations of traditional academic discourse and Web-based writing and researching.

All of the University of California at Santa Barbara Writing Program's intermediate-level research courses make use of computer technology, but most use it to a limited degree. Listed in the general catalog as "Special Topics in Writing: intermediate writing course with emphasis on critical analysis, exposition, argument and university-level research," these courses are required for graduation in most majors and are designed to provide students with expository writing and research skills that will enable them to develop and present research across a range of academic disciplines. It is expected that, as they complete the requirements for this course, students will increase their competence in identifying and critically evaluating information and in accessing the most relevant sources through computerized library databases and the internet, personal interviews and surveys, and any other measurement instruments they care to design. Students also refine argumentative writing skills, particularly in relation to effectively incorporating research into their writing while maintaining a clear stance and distinct academic voice.

The Writing 50 course described in these conference proceedings builds upon the above-described "typical" Writing 50 course in that it is grounded on an additional underlying principle: namely, that information skills—finding research material via electronic means, reading that material, analyzing it, interpreting it, applying it, and transmitting it in a variety of computer-driven forms—are the foundation for successfully participating in post-millennial academia. As David Victor asserts in a recent article, "We are in the midst of an information revolution unmatched since the invention of the printing press. It is my contention that, just as printed publications gave birth to the institution of the university as it currently exists, the new information technologies are opening a doorway to a new form of institution for higher education" (Victor, 1999, p. 75). The challenge in designing this course, then, lies in taking the pedagogical spirit articulated by Victor and others (Conlon, 1997, Gorman, 1994, Hawes, 1998, Kenny, 1998) and giving it practical shape: creating a course that embraces computer technology as an increasingly important component of the writing and researching processes while meeting the requirements of an intermediate-level research writing course.

Toward that end, the Writing 50 course under consideration devotes equal time to traditional exposition and electronic communication theory and practice. Each student chooses a topic area of interest and creates a research project on that topic, using two different formats: an expository essay and a World Wide Web site. In the expository portion of the course, students learn and practice research skills that enable them to develop and present research in across a range of academic disciplines. They develop increased competence in identifying and evaluating information and in accessing the most relevant sources from the vast amounts of data available through the computerized library databases, the Web, along with first-hand sources such as personal interviews and surveys. During this portion of the course, the instructor covers specific techniques for finding and evaluating researched information and addresses issues of audience, persuasive purpose, argument: rhetorical concepts which

assist students in keeping their thesis statements in focus, in maintaining conscious control over tone, and in construct academic research essays logically and persuasively.

In the Web-based portion of the course, students meet in the university's Instructional Computing (IC) facility, where they explore concerns central to creating documents for the World Wide Web, and where they learn skills—including HTML authoring, Web design, and graphics production—necessary to presenting research material electronically. Weekly class time in the IC lab is devoted to assisting students in working on Web pages, using Adobe PageMill as an HTML authoring program. Inevitably, one or two computer science majors will show up in the course and express an interest in learning HTML and/or Java programming languages, because of the greater design flexibility inherent in writing raw code, and/or because they want a programming challenge. These students often become in-class mentors to those students who insist at the beginning of the quarter that "computers hate me." As regards the latter, one of this course's main goals is simple but crucial: to ensure that those students who enter the class as card-carrying technophobes leave the class feeling less antipathy toward technology ... if not wildly enthusiastic about computers, then at least a bit more confident in using computers as a composition and research aid. One student said in an e-mail at the end of last quarter, "Here is my website address ... It was a good idea to have us do this. I feel much less computer illiterate. Thanks so much!" Such unsolicited expressions are especially gratifying, since they validate Young's theory that learning Web page construction skills helps students achieve the computer literacy that the college guarantees them (Young, 1997, p. A25).

At the end of the course, each student writes a final exam comparing text-based and hypermedia-based research presentation methods, discussing the advantages and drawbacks of each. This assignment begins with the statement, "Rhetoric is the art of writing effectively and persuasively. Different modes of rhetoric serve specific purposes and appeal to certain audiences. An ad for Dial deodorant soap, for example, has a purpose—to sell lots of soap—and a target audience: anyone who smells bad, or thinks he or she smells bad. This in-class writing assignment asks you to consider the virtues and drawbacks of two rhetorical formats: the academic research essay and the World Wide Web page." The prompt asks students to consider the following questions: What are the elements that make academic research papers different from other forms of writing? Similarly, what is a World Wide Web page, and how does it work? What are the advantages of each of these forms of information-presentation? What are the limitations of each? To what sort of audience would an academic research paper appeal? Who would be likely to fall asleep or stop reading such an essay before the end? What audience would appreciate the unique qualities of Web pages? Most importantly, perhaps: who might criticize this electronic form of expression and why?

Having reported on these two modes of writing with some degree of objectivity, the student's next step in this assignment is to talk about her experience with each. What about the computer project and research essay did she like and dislike, and why? How did each format affect the student's style of writing, the kind of information she could present, her ability to organize this material effectively, and her ability to communicate your ideas clearly? In comparing these two very different styles of writing, students often end up reporting that appreciate the value of *both* traditional academic discourse and Web-based writing and researching. They therefore become better equipped to write in a range of styles and formats, and to be more critically active readers of printed and electronic texts.

Reinventing Electronic Commerce with Multimedia: Early Experiences with MCADE

Vincent Phuah, John Nicol, Chris Martin, James Paschetto, and Kimberly Rush
GTE Laboratories, 40 Sylvan Road, Waltham, MA 02451 USA Email: vphuah@gte.com

Abstract: Electronic commerce has gained popularity and acceptance among Internet users over the past few years. This paper describes how an online shopper's experiences can be enhanced with the aid of multimedia, as well as a brief overview of the MCADE architecture currently under development at GTE Laboratories.

1. Introduction

This paper provides a high level overview of MCADE (Multimedia Commerce Application Development Environment), an ongoing research and development effort in the Distributed Multimedia Applications Group at GTE Laboratories. The overall goal of MCADE is to provide a component-based, easy to use solution for implementing distributed multimedia applications related to electronic commerce. Applications developed using MCADE will enhance an online buyer's shopping experience using other media types such as audio, video, and graphics animation, in addition to traditional text and images. A premise of our approach is that video segments can convey more information to users than plain text, a differentiating factor that could be crucial in deciding whether to purchase the product. It can also benefit the seller as well. To the seller, the use of multimedia could provide a more effective way to influence potential buyers to make a purchase of the product (e.g., TV commercials). Part of our research goal in developing MCADE is to investigate how multimedia can help improve the electronic commerce process -- from the inception of selling a product online to a buyer execution of a purchase order.

2. The MCADE Architecture

The MCADE architecture consists of a number of software components, each of which can be regarded as an agent or an application. The agents are loosely coupled to promote reuse and ease of maintenance. Each agent is developed to perform specific designed task(s), and is not influenced by other agents' actions, unless required by the application. In addition, an agent can serve many applications simultaneously. Agents communicate with each other via messages to perform specific application-oriented tasks. Hence, applications are responsible for issuing these tasks.

The software agents in MCADE include 1) Price Comparison Agent, 2) Video Capture Agent, 3) Video Management Agent, 4) Text-to-Speech Agent, 5) Telephony Agent, and 6) Agent Monitor. The Price Comparison Agent provides support for retrieving price information of a particular product from the Web. The agent is being developed using the WebL scripting language from Compaq Research Lab (formerly Digital Research Lab). [1] (Note: WebL is based on markup algebra and provides a flexible and powerful way of "mining" information from the Web. It also provides a seamless integration to relational databases via ODBC library.) The Price Comparison Agent stores prices of products returned from the Web into a relational database such as Microsoft Access. Applications can then perform SQL queries on the data. In thinking about how to compile a database of pricing information, we identified two approaches. The first approach we considered is to develop the price comparison engine ourselves. The second approach is to rely on other price comparison sites such as *www.mysimon.com*, *www.bottomdollar.com*, and *www.webdata.com*, which have emerged on the Internet over the past few years. We intend to proceed with a variation of the later approach, using WebL to retrieve price comparison data from such sites. The Video Management Agent provides all the necessary record keeping of where all the video segments are stored and on which video servers. It is also capable of uploading and deleting video segments from the video servers. The Video Capture Agent is capable of capturing and digitizing the video into the desired format for streaming from a video server such Microsoft Netshow or RealNetworks G2. The Video Capture Agent also has the ability to start capturing of video segment based on keywords of interest in the video closed-captioning. For example, an application could request the agent to start recording whenever the word "GTE" is mentioned in the CNBC cable channel. Other techniques could be used in lieu of using video closed-captioning, but may not be as accurate, such as using speech recognition technology. The telephony agent provides the ability for an application user to place a POTS call. This is useful for example when the online user needs to talk to a sales representative

directly. The Text-to-Speech Agent, as the name implies, converts text to speech. The Text-to-Speech agent can be utilized in many ways. For example, together with the Telephony agent, we can easily implement an application that allows users to call in via POTS to check their emails. The Agent Monitor provides the ability to view message exchanges by all the agents. This is useful for debugging purposes. In the future, we may add other functionalities into the Agent Monitor such as the ability to administer other agents.

The Media Message Bus is the underlying framework that provides the basis by which dynamically binds the agents together. The Media Message Bus concept is modeled from our previous *Orchestrator Service* work, where we implemented a message broadcast and event notifications system using Java. [2] Here, we exploit the JavaSpaces toolkit developed by Sun Microsystems. [3] JavaSpaces provides a suitable platform for supporting distributed object persistence and data exchange, as well as event notifications. With JavaSpaces, the Media Message Bus provides the mechanism for agents to communicate with each other using short control messages. It is also used by applications to send requests (tasks to be performed) to the appropriate agent(s).

3. A Comparative Shopping Example

This section describes the first prototype application we have implemented using MCADE. This prototype is based on content captured from an online cable-shopping channel. The rationale for developing such an application is that we envision online retailers would benefit by partnering with Internet Service Providers (ISPs). ISPs would provide the networking know-how and infrastructure to support the bandwidth and latency requirements for multimedia data traffic, as well as high-level subscriber information for use in marketing purposes. This arrangement would enable the online retailers to concentrate on their core businesses, rather than spending valuable resources to manage the network.

With the current implementation, the prototype uses video segment captured from a cable-shopping network. The video segments are then digitized and formatted for streaming using the Microsoft Netshow server. Support for other video servers will be included in the near future. This prototype is a Web-based application that incorporates video streaming, price comparison information, and textual description of the product. The goal is to provide an online buyer additional value that a traditional buyer does not have by purely making a purchase decision based on what he/she sees on the cable-shopping channel. Furthermore, with the assistance of the telephony agent, if needed, the buyer can call a sales representative from the cable-shopping network directly.

We are planning to build a similar prototype, but with real-time video capture and digitization. Price comparison information will also be provided in real-time. In this version, online buyers will be able to purchase a product that is currently showing on the cable network. Nevertheless, there are implementation issues on how to find and aggregate the information such as prices into a database server and display the information to an online buyer in real-time. These issues are currently being investigated.

4. Future Directions

The rationale for an environment like MCADE is to enable prototyping of new application services quickly and efficiently. We envision many electronic commerce-based applications can be developed using MCADE. For example, the auction companies such as Ebay (www.ebay.com) and Ubid (www.ubid.com) could attract more buyers by enhancing their respective web-sites with video content about the products. We are also currently working of a stock quote application that will alert investors of certain price fluctuations in stock as well as capturing video content, if applicable, related to the stock in question from cable-business channels. Investors will have access to the video segments in addition to the stock quote and report.

The Evolution of Faculty Development and Course Design at the SUNY Learning Network

Alexandra Pickett, SUNY Learning Network, State University of New York, USA

Apickett@sln.suny.edu

Peter Shea, SUNY Learning Network, State University of New York, USA

Pshea@sln.suny.edu

Abstract: This paper describes the creation of a scaleable and replicable faculty development process at the SUNY Learning Network. This comprehensive approach includes: an online faculty resource and information gateway, an asynchronous conference for all developers, an asynchronous faculty orientation, a series of workshops for new faculty, instructional design sessions for returning faculty looking to improve their courses, a developer's handbook, a course template, a faculty helpdesk, online mechanisms for faculty evaluation of SLN services, and an assigned instructional design partner to support faculty development and course design.

The SUNY Learning Network (SLN), with grants from the Alfred P. Sloan Foundation and the SUNY Office Advanced Learning and Information Systems, has built an online, asynchronous learning network for the sixty-four State University of New York campuses. This paper discusses the evolution of the SUNY Learning Network faculty development and course design methodology, the technology used, and processes developed for these purposes.

Stage 1

The purposes of stage one is to get the faculty online as soon as possible, so that technology and access issues are addressed right away. It also serves to familiarize the faculty with the program, the components of the faculty development process, and with our web resources for new faculty.

This stage also introduces new faculty to the SLN online community. It also:

- Provides opportunity to network with other new and experienced faculty.
- Introduces them to the SLN web course interface.
- Gets faculty to take the role of "student."
- Models effective instructional design and moderation of asynchronous discussion,
- Provides an opportunity to participate in asynchronous discussion

Stage 2

This is the conceptualization stage in the faculty development process. The most important component of stage two is the observation of "live" online courses. Course observation is essential for new faculty for a variety of reasons. It allows new faculty to see what a complete course looks like. They can see how a variety of courses are structured, how each course is unique and defined by the content area and instructor in spite of the use of a template, the wide variety of on online and offline learning activities that make up a wide range of courses, how courses are organized or "chunked" into modules, how learning is evaluated by different instructors, and in addition, the courses for observation allow the new faculty to experience how a course grows and unfolds with active participation by students.

Stage 3

Stage three marks the beginning of the seven-step course design process and begins with the first of three face-to-face trainings for new faculty. At the Introduction workshop faculty are given their user names and

passwords to our system, introduced to the course development GroupWare application used by the program including our course template and our email system. During stage three faculty continue to have access to the All Faculty Conference and the courses for observation. In addition, they are given access to the SLN Faculty Center, a password-protected website that builds a personalized web homepage for each faculty person including links to:

- Send and receive personal SLN and Internet email.
- The SLN Faculty HelpDesk.
- Get and submit information such as: submitting course descriptions and materials order information.
- Download the SLN course template database.
- Check SLN program announcements.
- The All Faculty Conference, including live courses for observation, a sample course, and a best practices examples area.
- Access link to the individual's course on the web.

The second face to face training occurs in this stage and generally takes place about a month after the first training giving time for the faculty to do some work in their template. The Instructional Design Intensive brings the faculty back together to discuss instructional design issues in the development of online courses and is specifically designed to address actual questions faculty have in the design of specific learning activities for their courses.

The remainder of stage 3 involves the faculty working on the design and development of their course. The role of the Multimedia Instructional Designer (MID), who is very active in this stage, is to help the faculty develop technically and instructionally robust teaching and learning environments for both instructor and students that are appropriate to the instructor's style of instruction, content area, level of the students, and technology being used.

Stage 4 of the SLN Faculty Development Process begins with the third face to face training. The Teaching-and-Managing-Your-Course workshop marks the transition for faculty from the course development phase to the delivery phase. This training prepares them for students entering their course. Everything from technical issues to what to expect are discussed, demonstrated or addressed. Stage four is the "pilot your course" stage. New faculty and their new courses are closely monitored during the first three-four weeks of the semester by the MID. Weekly check-ins, phone and email communications, and intervention when necessary take place behind the scenes. Faculty are asked to take notes on what is working and what needs improvement as they teach the course to make evaluations and revisions easier the next time they teach the course.

Conclusion

For 98/99 academic year, with 37 of the 64 SUNY campus participating, we supported the development and delivery of 460 courses with over 6,000 enrollments. We are well into the seventh faculty development and course design cycle for the fall of 1999 semester with over two hundred and seventy-five courses "in development," a nearly seven-fold increase in the total number developed in the first two cycles. We expect that we will have over 12,000 student enrollments in the 99/00 academic year and the participation of 42 SUNY campuses.

Answering the Needs of Rural Communities: The Virtual High School of Newfoundland and Labrador

Terry Piper, Memorial University of Newfoundland, Canada tpiper@plato.ucs.mun.ca
Ken Stevens, Memorial University of Newfoundland, Canada stevensk@morgan.ucs.mun.ca
David Piper, Acadia University, Canada dpiper@ns.sympatico.ca

Abstract: In September of 1998, the first four courses were offered by the Virtual High School of Newfoundland and Labrador. The school was conceived and designed to meet the needs of approximately 80,000 students in this remote Canadian province who live and attend school in small, rural communities whose survival is threatened unless the schools remain competitive with urban schools. This presentation describes the early stages of building the Virtual High School and early assessments by teachers and learners.

The relationship between rural economic development and schooling is clear: people go to live where there are jobs; although most jobs are in cities, there is evidence that people are beginning to return to small communities; their doing so will depend on a number of factors, not the least of which is the availability of services, not the least important of which is schooling.

The move from the industrial to the ICT age has begun to have a profound impact on rural communities. Relative equality of access to education and training combined with a job market that is increasingly independent of place offer new hope for the survival of small, rural communities. The Vista Digital Intranet project is contributing the equality of access for students in rural Newfoundland.

Background

Newfoundland is Canada's newest, least populous and poorest province. Its population of just over half a million is scattered across the province's 402,000 sq. km. While fishing and agriculture were once the mainstays of a vibrant economy, official policy and a once-abundant fishery caused people to abandon agriculture in favor of the fisheries. By the late 1960s, fishing was the only pillar of the economy, and thus when fish stocks were depleted, the province's economic well-being and population began to plummet.

Also in the late 1960s, the provincial government undertook a massive scheme to relocate people from a number of very small remote communities. This was an extremely expensive operation, an emotionally wrenching one for thousands of families, and probably unnecessary given the natural decline in population that the province experienced in subsequent years. The legacy of that experience is strong commitment by government to sustain small communities.

True to David Foot's prediction in *Boom, Bust, and Echo*, migration back to smaller communities has begun. The ICT age has neutralized the variable of location for many jobs, new high-tech cottage industries are sprouting up, and e-commerce is breathing life into small businesses. In order to participate fully in economic recovery, i.e., in order to draw people back from cities to smaller towns, these towns will need not just jobs but services, of which education is arguably the most important since people will not remain in small communities unless they are assured that the schools offer a competitive standard of education. The survival of small, rural schools, then, is paramount to the survival of rural communities. The Government of Newfoundland and Labrador, recognizing this crucial fact, has designated approximately 80 schools as "necessarily existing schools," meaning that they are the recipients of teacher allocations and other funding above the norm for the province. Laudable though it may be, this does nothing to protect the educational quality of the other 180 rural schools across the province, 60 percent of which have (K-12) student populations of fewer than three hundred.

Obviously, rural schools cannot afford to offer the full mandated curriculum. In some cases, to do so would mean that there were more teachers in the school than students and this is obviously not feasible. And yet, more than a skeletal curriculum is needed if students are to compete on an equal basis with their urban peers for university entrance and for jobs that increasingly demand not only a good basic education but a high level of competence in information and communication technologies.

The Virtual High School of Newfoundland and Labrador

The Virtual High School was conceived and designed to meet the needs of approximately 60,000 students in the rural communities in the province. The partners in the project¹ provided the infrastructure and the expertise to create and deliver the first four of the High School's courses, advance-placement mathematics, chemistry, physics and biology. These are courses to which students would not have otherwise had access.

Although we are calling this a "Virtual High School," "virtual" has come to imply asynchronous delivery. In fact, delivery is synchronous with a teacher in one school teaching a class distributed across nine high schools in the district. The courses were prepared to meet the requirements of advance placement courses over a four-month period in the summer of 1998. The development team consisted of four groups, one for each subject, who worked together in a single laboratory. Each team consisted of a teacher seconded from the school district, a recent university graduate from the appropriate discipline, and a graduate student in the Faculty of Education. A project manager, technicians and other multi-media consultants were also available to offer assistance. The four teachers who worked on the course development were the same ones who taught the courses when they were offered for the first time in September of 1998.

Class sizes averaged 10, physics being the most popular with 13 students. Teachers worked from specially equipped rooms in the schools with which they were affiliated. Because all nine high schools were located in the same district, potential scheduling problems were avoided. Teachers treated the distributed class like any other, making themselves available, for example, for after-school on-line help sessions. After the first few weeks when technical problems were sorted out and participants became used to the new mode of instruction, students and teachers responded very favorably. There was one exception. In a school with a large cohort of students requesting advance-placement mathematics, a teacher not involved in the project wanted to teach the course in a traditional manner. The District Director had already made the decision to offer all AP courses through the Virtual High School and declined the teacher's request. Unhappy with the decision, the teacher raised doubts in the minds of both parents and students about the quality of instruction they would receive. The Director stood firm, however, and with the intervention of the school principal, parents and students were eventually calmed and persuaded to continue with the course.

When the school year ended in late June, students took the standardized tests in the AP subjects. At this writing, those results are not yet available, but there are other outcomes to be reported:

1. Retention rates were about the same as for AP courses offered in the traditional way;
2. Although there is no hard data to support the observation, teachers believed that the demands on their time were greater than with a traditional class;
3. Although the project used two-way video, once the instructor had the class underway, students usually turned off the "talking head" and made more use of graphics.
4. The students and teachers used e-mail as a supplemental mode of communication outside class hours.
5. Student satisfaction remained high at the end of the course.
6. District officials were generally pleased with the first year offerings of the Virtual High School.
7. Although expensive, the delivery costs were less, even including equipment costs, than the cost of delivering four courses to relatively few students in nine high schools spread over a vast geographical region.
8. Professional development for *all* teachers in the receiving schools is essential to success.

Next year, the Virtual High School adds two new subjects, Global Issues (social studies) and Art Technology. At the same time, Memorial University has developed a diploma in Rural Education and TeleLearning to assist teachers in coping with this project and with others that are certain to emerge as ICT continues to have a major and positive impact on rural schools and rural economies.

[1] The Virtual High School is funded by a consortium of partners, chief of which is Industry Canada. Their hope is to make these and other high school courses available across Canada on their national network, SchoolNet. Evaluation and some equipment costs are supported by the National Centre's of Excellence TeleLearning Project. The Vista School District and Memorial University's Centre for TeleLearning and Rural Education contribute space, expertise, and some equipment costs, and the entire project is made possible by the pioneering work of STEM-Net, the provincial educational computer network that has had all schools in the province connected since 1994.

Evolving from Face-to-face to Online Teaching for Large Student Groups: Phase 3, Restructuring in a Computer Based Student/Subject Management System.

Abstract: This paper discusses the third phase in the development of an online subject. The first phase may be described as traditional lecturing, the second as using html code to provide resources on the WWW, the third as utilising a computer based student/subject management system for online support for students (WebCT) and the fourth as the provision of a subject over the web. This paper is written between phases two and three. At the time of writing this paper the lessons learned from the earlier phases are due to be implemented as a program of student support is to be implemented in WebCT. The talk will present the path to fulfillment (or otherwise) of the objectives.

Phase1: Traditional lecturing

Why not go directly to the task of developing a subject for the web? Sheer terror. Like many of my colleagues I (first author) am a good classroom teacher and not overly familiar with the technical aspects involved in delivering on the World Wide Web (WWW). The teaching load during teaching times is such that there can be no technical hitches to solve. In this case development of an online subject was a secondary goal. The primary reason for developing material on the WWW was to provide support in the process of teaching and learning. It was the mechanism to contend with difficulties teaching in the traditional lecturing environment. Principally it was to enhance my ability to teach in a student centred manner, to a class of three hundred students.

Teaching Statistics is a notoriously difficult task. Most of the students undertaking Statistics subjects are compelled to do so. Many students attempt to rote learn feeling that they have little chance of understanding the material. In 1998 the principal co-ordinator set out to adapt and extend her experiential and activity based statistics program developed and successfully trialed in small classrooms (30 students) to the class of three hundred students (STAT131). The aim of this approach was to have students generate ideas upon which the lecture material, statistical theory and processes could be developed. One of the primary benefits of this approach is that students must communicate with the lecturer. It is this communication that guides the lecturer in adapting and modifying the materials in order to respond to student needs whether it is a need for approaching the material from a different perspective or attending to the learning concerns as students encounter work about which they are uncertain. Many students in STAT131 faced the dilemma of whether to take notes or to participate fully. They needed both

Phase2: Using html to provide resources online

During phase 2 lecture activities, student responses and debriefing were mounted on the WWW using html coding. Production was sustained for the seven weeks of session, at which time the task became too onerous, and could not continue without funding and time. (Students were aware that the continued production was dependent upon goodwill and that with other commitments was likely to cease with little notice).

Observations highlighted during the second phase of the development:

- For many students there is a degree of uncertainty and anxiety attached to relying on their own ideas, rather than being able to surface or rote learn from the lecturers notes. To be free to fully participate students needed to be able to re-enact the activities, and to have access to the dialogue that took place in lectures. The resource base developed in the second phase provided a capture of lecture activities and debriefing, some laboratory and tutorial work, past examination papers and subject requirements. This needed to be extended.
- A theme 'what, how and why?' introduced in lectures. This was to extend students' focus from the safety of how to do the sums or draw the graphs to what features of data, theory or concepts would lead to the selection of a particular technique and why the techniques would be revealing, that is interpretive skills. A self and formal 'assessment for learning' system that explicitly taps theoretical and conceptual understanding, technical skills and interpretive skills needed to be developed.
- Use of the online web resources for asynchronous discussion and e-mail enabled students to communicate with each other and the lecturer, providing another source of communication. Students were able to indicate what they needed, whether it was an alternative text or the need to clarify ideas, or to seek extensions.
- Students were responsive to the activities and experiences and wanted these extended to all topics. Attendance rates at lectures remained high. Lecture attendance was associated with higher pass rates on midterm exams. The overall failure rate was approximately 14% lower than the previous year.

Phase 3: Online Support Using a Computer Based Management System.

The objective in the third phase was to develop a comprehensive online resource based teaching and learning support system for Introductory Statistics. The system needed to be easier to establish and maintain than had been the direct use of html on the WWW. For this reason a package, WebCT, which has just been adopted as the University standard, was chosen. WebCT is a computer-based system for the management of subjects and student assessment and learning. The system provides a user-friendly interface for students and developers. WebCT in this paper is conceptualized as providing a resource based approach to learning. It will support a traditional lecture subject but has the potential for students to draw heavily upon it to replace some aspects of the traditional subject.

The resource package was to include:

- all lecture activities and debriefs including sound, animation and slide-sound sequences;
- self and formal 'assessment for learning' systems which were to explicitly tap theoretical and conceptual understanding, technical skills and interpretive skills;
- materials suitable for students from a variety of disciplines;
- a glossary of notation which was to be compatible across the department's statistics subjects;
- a pre-test of mathematical skills; materials to review pre-requisite mathematical techniques;
- facilities for online evaluation of the subject, lecturing, learning and online resources;
- communication links such as email, chat and hot links to data sources and relevant statistical sites;
- subject requirements, tutorial and laboratory tasks, past examination papers and solutions.

In a class of three hundred there are many learning styles. Students were to be provided with a mix of experiential, activity based and traditional lecturing. The resource based teaching and learning system whilst targeting specific learning goals (knowing what, how and why) was to provide students with an alternative and/or complementary approaches to learning

Phase 4: Delivery of a Online Subject

This talk will report the experiences of the team, lecturer, educational developer, students and laboratory teachers using a learning resource accessible through the WWW to supplement lectures. It will discuss the challenges of delivering online subjects that use symbolic languages. It will also detail the modifications of the resource base which are necessary in order to replace the face-to-face lecturing component of the subject with an online version for a remote campus.

Formalization and Integration of Scaffolding in a Web-Based Learning Environment

Sadhana Puntambekar

Abstract: With numerous courses being offered via the WWW, it is important to focus on the design of course content. In this paper we discuss a constructivist, problem based approach in designing web based learning environments which we are using this approach in the design of online courses in the School of education. We discuss the importance of various levels of scaffolding – cognitive, social and metacognitive, to enable students to learn in the problem-based environment.

With the availability of cheap and powerful computers and advances in technology, there are now numerous courses that are being offered to students via the World Wide Web. As reported by LaRose, Gregg and Eastin (1998), over 200 college courses from 100 Universities were available over the internet in 1998. However, with rapid advances in technology and the demand for such courses, pedagogical issues are often being overlooked in the design of web based courses. Most of the courses offered on the WWW are no more than a set of linked pages with a syllabus, a class schedule, lectures in the form of essays or PowerPoint slides, a set of readings on the web or on paper and a set of assignments. Tools such as webCT are now available to make the building of these features less time consuming. However, little attention is being paid to the design of the *course content*. We believe that the design of the course content itself should be learner-centered (Jackson et al. 1998), so that the educational benefits are maximized. Furthermore, decades of research in designing and implementing computer based learning (drawing from fields such as Psychology, AI, HCI, Cognitive Science) can provide the necessary pedagogical foundations for the design of an educationally effective web-based interactive environment for learning.

A constructivist, problem-based framework

In this paper we describe our work (in progress), on designing an introductory course in learning theories as a web-based interactive learning environment. The course is a Graduate course in the school of Education and will be offered next spring after initial testing in this summer and fall. We are organizing the course around a set of complex ill-structured problems. The problems or scenarios that we are choosing for the course are taken from real world learning situations (K-12 and college). Problem solving has long been regarded as a generative activity that could promote deep learning (e.g., Barrows, 1985), and recent research shows that, indeed, students learn content knowledge deeply by solving relatively complex ill-structured problems which can have multiple solutions (Bransford & Stein, 1994).

Such an environment affords rich opportunities for learning. The problems for the course are from the world of practice, from real world learning situations. Each problem needs to be explained in terms of the learning theories (or concepts therein) that students are required to study for the course. As they work on solutions to complex problems, students have the opportunity to construct and generate rich meanings. In addition, students need to reflect on their ideas and solutions, provide explanations and justifications, all of which can augment their understanding of the domain knowledge.

Levels of Scaffolding

An important aspect of making this approach work is the scaffolding that students require in order to successfully negotiate within an ill-structured problem space. Scaffolding in a complex environment such as problem solving needs to be *distributed* among many agents (Puntambekar & Kolodner, 1998). This is because complex problem solving involves many stages and any one agent of scaffolding, such as the teacher or the software cannot

provide students with the support and adaptability that scaffolding in such an environment requires. We are designing and implementing three levels of scaffolding: cognitive, social and metacognitive.

Cognitive level

Based on the Vygotskian notion of making abstract processes more visible, the cognitive scaffolding that we are designing provides students with support for the processes or steps in problem solving. This involves helping students to restate the problem, generate ideas about how they might solve the problem, providing a concept map that will help students to become familiar with the vocabulary, and find the necessary information from the resources provided. We are designing concept maps that will serve as scaffolds in the form of the conceptual representation of the theories and concepts that they need to solve the problem. Maps to provide a historical perspective for the theories, which is an objective of the course are also being developed.

Social level

Scaffolding at the social level comes from the electronic discussions that students engage in. Learning in a web-based environment is a truly distributed event because learners are physically removed from one another. Learners can play an important role in supporting each other in the process of learning. They can post ideas, critique each others' ideas and reshape their own, ask questions and provide explanations. Thus numerous ways to reflect and articulate can be built into the environment which enables the individual learner to construct meaning. Research on computer supported collaborative learning suggests that discussions are more fruitful when they are anchored (Guzdial, et al. 1997). In our course, we are designing discussions to serve as scaffolds during at least three stages in problem solving: initial brainstorming, generating ideas to solve the problem, and for explanations and justifications. The instructor plays a major role in mediating these discussions.

Metacognitive level

An important aspect of both these levels is that metacognitive prompts to encourage reflection are embedded in them. Thus, for example, students are provided with prompts that will encourage them to explain any problem from multiple perspectives drawing from concepts from different learning theories, thereby providing them with an opportunity for generating richer understanding and integration of theories.

Integration of the multiple levels of scaffolding

Although we have described three different levels of scaffolding, they are not mutually exclusive and we need to align all the affordances so that they are well-integrated and taken advantage of. We are integrating the levels in such a way that in the initial stages of the problem, the instructor plays a major role in providing the cognitive scaffolding. Thereupon, the learner-learner interaction becomes more prominent with the learner asking questions and providing answers and justifications. The metacognitive scaffolding is embedded in both these levels by having the students reflect upon and articulate their problem solving experiences.

Abstract: The paper describes a system to support student collaborative and metacognitive activities in distance education settings, called an *education recommender system*. This Internet-accessible system allows students to share and view ratings, opinions, and recommendations about resources on the Internet and World-Wide Web based on a social information filtering system. We believe that this approach promotes more mindful and reflective engagement with Internet-based information. Use of the system also helps support collaborative and community-building learning activities in a distance learning setting.

1. Introduction

Recent government initiatives, paired with changing education policies and the falling cost of hardware have prompted a huge influx of information technology into the classroom. Beyond the traditional tutorials and drill and practice programs, many classrooms are placing a great deal of emphasis on the use of the Internet and the World Wide Web for teaching and learning. Teachers hunt the WWW for instructional resources, while students use the web to communicate with pen pals, research topics, and share information. Yet, while much money and effort has been expended the networking infrastructure of the WWW, considerably fewer resources have been spent on developing pedagogically appropriate models in the context of ubiquitous – but unstructured-- digital information. Rather than providing access to instructionally sound, validated, and edited resources, the web merely represents the information delivery truck, ready to unload its cargo without any assurance of consumer satisfaction. This emphasis on “access to information” has led to a “copy-and paste” generation of learners. Learners accessing the web have no resources for judging the accuracy of data, the usefulness or currency of the information, or identifying the context for which the information was intended. Furthermore, there is no infrastructure to facilitate learning; instead information is merely presented to the learner in a “take it or leave” context. If educators are going to harness the educational utility of the Internet, researchers need to begin to examine methods that support structuring information in a meaningful way, and promote engagement of the learners with the content and with each other. In this paper, we describe and discuss an information architecture that promotes more mindful and reflective engagement with Internet-based information. We argue that this approach leads to collaborative sense-making of digital documents in a way that is relevant to the needs and goals of particular classrooms and settings.

2. Recommender Systems

The explosive increase in the number of World-Wide Web resources has exacerbated the problem of finding relevant, quality, and validated information. Since the Web supports unstructured information access, there are few mechanisms in place to aid in the collection and evaluation of filtered information for particular community purposes. There are, of course, the commercial search engines (e.g., Infoseek, Snap) which filter information based on key content concepts. There are also compiled lists of URL addresses related to a particular topic (e.g., Yahoo). Both of these filtering systems focus on content while neglecting the utility, quality or relevance of the information contained within them for a particular community of users. Within the human-computer interaction (HCI) literature, a new paradigm of categorizing, collecting and filtering information, called “social information filtering,” has emerged. This approach is based on propagating word-of-mouth opinions and recommendations from trusted sources. As proposed by many, it holds promise for the adding structure to the Web [Shardanand & Maes, 1995].

3. Educational Applications

Projects implementing social information filters have been demonstrated in a variety of areas from music recommendations to Usenet groups. Yet to date, these systems have been fairly constrained in their intent, audience and utility. We believe that more highly evolved systems have the potential to become powerful educational tools. As we will argue, these are tools that help to develop, define, and nurture communities of learners.

In our project, we currently are developing a system that will allow learners and teachers to share ratings, opinions, and recommendations about content on the Internet and Web, using an existing index of Internet-based learning resources (e.g., www.TeacherLink.usu.edu). Through using our system, users will be able to access the recommendations of other users (called metadata) in order to help them locate quality information, and avoid wasteful sites. Users can also contribute opinions about sites that they visit. These metadata, in turn, become part of the recommendation database. The development of our recommender system is guided by several issues important both from educational and technological standpoints. First, we note that contributors to the recommendation database form a community. Information about who contribute opinions is as important as the contribution itself. Second, because contributors form a community, they have their own language and set of values. Hence users must be able to create and modify the representational vocabulary of the metadata. Third, evaluating information sources and contributing ratings is a metacognitive activity. Engaging in such tasks forms an important learning goal in a knowledge society. Nonetheless, it must not add an undue cognitive load, or users will ignore the tool. Finally, a critical mass of users must participate to ensure rating reliability and validity. This suggests that use of the tool must be embedded in tasks and activity that are authentic and relevant to the particular community.

Our approach complements recent results from educational research, which calls for a shift from teacher-oriented, didactic classroom strategies to learning environments that are focused on students' engagement and knowledge ownership. Such approaches focus on creating a "community of learning." Within a community of learning, understanding arises from group consensus, rather than from individual fact finding. Each member of the community has a particular expertise that is brought to bear on problems being solved by the collective, and it is with the advancement of the entire group's understanding that learning is pursued [Brown and Campione, 1990].

We're Wired – Get Connected!

A District Model for Web-Centric Educational Services

Pat Ridge
 Brussels District Superintendent's Office
 US Department of Defense Education Activity (DoDEA)
 Belgium, Email: pridge@educ.odedodea.edu

The Brussels District Schools are part of the US Department of Defense Dependents Education Activity (DoDEA) serving the children of US Military and Civilians working outside of the continental United States. By early 1999, the District had implemented INTERNET Connectivity in all 13 of its Elementary, Middle and High Schools located throughout Belgium, the Netherlands and Germany. Additionally, school-wide Local Area Networks with 8 drops per classroom had been installed in more than half of the schools, with plans to wire the remaining schools well underway. The challenge facing the District was to build a program based on a system-wide consensus that would assure the educational utilization of these resources by the entire "Learning Community" of students, teachers, administrators, parents and other community members. The foundation for this program would be the President's Technology Literacy Challenge comprised of Four C's (Computers, Connectivity, Competencies and Curriculum) and the DoDEA Technology Plan. See <http://www.whitehouse.gov/WH/EOP/OP/edtech/> and <http://www.odedodea.edu>.

As a result of extensive interviews, surveys, meetings and workshops, the Brussels District has begun to develop and implement the following plan, which envisions a hierarchical Web structure (See Graphic) comprised of sites on an INTRANET, an EXTRANET and the INTERNET.

The INTRANET Site will be accessible on the School Local Area Network only, and it will focus on "Electronic Portfolios," "Collaborative Workspaces," and "Multi-media Showcases." The EXTRANET Site will provide remote secure access by id and password to the school INTRANET Web Site for authorized District Community Members. Finally, the INTERNET Web Site will be the "Official School Web Site" accessible to all, and featuring public information as well as "Exemplary Student Work".

Current Status of Web Server Implementation in Brussels District – July 1999

The Brussels District has been operating an "official" web server for 15 months (March 1998) at the following URL:

(<http://www.brus-dso.odedodea.edu>)

This server functions as the "official" web site for district business as well as hosting the web pages for all 13 of its schools. Teachers have been trained to serve as webmasters for their school, and they receive "extra duty pay" for their work with the local Web Team. All schools have complete autonomy in publishing and managing content on their web site.

The conference presentation will demonstrate the preliminary results of this district model for web-centric education with examples from the First Phase of the Project concentrating on the schools INTERNET and EXTRANET Web Sites.

AFCENT International School (The Netherlands)

Techniques for Promoting Participation and Ownership for Learning in Web-based Instruction among In-service Teachers

Paul Rodes, Dennis Knapczyk, Carrie Chapman, and Haejin Chung
Indiana University, Bloomington

Abstract

In distance education, instructors often need to guide and enhance the transition from a traditional model of pedagogy in which the learners' role is passive, to a model in which students take a full, active role in directing their own learning. This paper describes techniques for using web-based instruction to promote student participation and ownership in learning in three important areas: moving learners from passive participation to active participation, moving learners from instructor-directed tasks to self-driven tasks, and moving learners from non-evaluative sharing to true collaboration.

Introduction

One day, a prospective student was speaking to us about our distance learning program, and we were pointing out the advantages it offered for her, as she could save an hour-long commute to the campus-based classes. "Oh, no," was her final reply, "I don't think I would like that. I want to be able to see the teacher."

It is easy for those versed in computer technology to overlook the very foreignness that can confront learners taking their first class using web-based instruction, especially if this instruction is provided at a distance. The absence of a live instructor, the strangeness of the presentation format, the different roles demanded of students are factors that can create a significant level of anxiety and discomfort in students more used to the conditions of traditional classroom instruction [Foegen, Howe, Deno & Robinson 1998].

Studies show that highly motivated learners are the most likely to benefit from distance education [Riddle, 1994; Wagner & McCombs 1995]. But to be effective, distance education needs to reach out to average students who may not be comfortable with the demands of web-based instruction [Knapczyk, Rodes & Chung 1998]. In our program we have found that the solution to this problem lies not in communicating clearer expectations for the way our courses are structured, but in shifting the learners' own expectations for what their roles and experiences in the classes can and should be. We have thus come to view instructional development for distance education not so much as a matter of setting standards and practices, but rather a matter of defining a process that increases students' comfort level and involvement in web-based instruction. This process leads students from their initial expectations of teacher-centered, passive instruction to adopting a more learner-centered, collaborative model which gives them ownership and direction over their own instruction [Knapczyk et al. 1998].

Background: The Collaborative Teacher Education Program

For the last thirteen years the Collaborative Teacher Education Program at Indiana University (CTEP) has been offering continuing education courses by distance education to teachers in rural communities [Knapczyk & Rodes 1995; Knapczyk et al. 1998]. Participants in our courses are teachers, administrators, and other in-service professionals in rural communities who have difficulty accessing coursework in traditional campus-based settings. In addition to attending weekly classes via videoconferencing, the students share their work and discuss course content using web-based conferencing and e-mail.

Techniques for shifting from instructor-centered learning toward student-centered learning

The approaches we have developed in our classes recognize that students are likely to be unfamiliar with the course delivery format for the first few class sessions, and that they will feel overwhelmed if we expect them to show the level of independence and activity in the beginning of a course that we hope to build in them by the end. Therefore, we have learned to view our role from the start as promoting or facilitating a shift toward greater student participation and ownership of their own learning. Web conferencing, with its capabilities for student collaboration and independence, is a significant tool for bringing about this shift [Knapczyk et al. 1998]. Through our use of AVF and the other components of our distance education technology, we promote learner-centered instruction in three main areas: participation, course tasks, and student collaboration.

Techniques for moving learners from passive participation to active participation.

Much of the success of distance education rests on encouraging an active role for learners [Risenberg & Zimmerman 1992; Spooner et al. 1998]. Students must learn to rely on themselves not only to access and master technology, but also to make up for the range of subtle directions, cues and information that they are used to receiving from live instructors. Both in class meetings and on the web, we encourage an active role for learners. But students coming into our classes are typically used to a more passive format of instruction. We have found that students respond indifferently to many of our initiatives if we present them too early in the semester, and that patterns of independence and ownership must be built gradually in them rather than thrust upon them suddenly.

Accordingly, we begin our courses with a more traditional, teacher-centered approach, and proceed toward a more learner-

centered model as the students become familiar and comfortable with the distance education format and technology. When class first begins, we do not require a strongly active participation. We ask for volunteer coordinators, but lead discussions ourselves. We encourage student input, but give them time to script their answers. We follow this same pattern in our use of web technology. Early in the semester, we rely heavily on e-mail to communicate with students between classes. Their contact with us is typically one-sided, and our responses are detailed and individualized. As the semester progresses, we begin demanding more of their contributions. We move more class activities to AVF, so that their web-based communication becomes an integral part of the class.

Techniques for moving learners from instructor-directed tasks to self-driven tasks.

In the past we started off a course giving students very liberal reign in the types of responses they made on the web forums. Our reasoning was that we wanted to use this learner-centered technology to build independence. What we found instead was that responses were short, sporadic and aimless, and that students saw the web technology as an extra chore rather than as a space for meaningful work.

To remedy this problem, we now begin the semester with very specific activities that students carry out on the web. The content of these activities is deliberately kept simple so we have tight control over the learning that takes place. As the semester continues, we build in elements to make the assignments increasingly individualized and independent. By completing web assignments that are increasingly shaped by real world demands and considerations, students can take on more and more responsibility for their work with minimal management and oversight by instructors [Honebein, Duffy, & Fishman 1990].

Techniques for moving learners from non-evaluative sharing to true collaboration.

Perhaps the most important element of developing learner-centered instruction is building collegiality and collaboration among students to take the place of instructor direction [Friend & Cook 1993; Slavin 1990]. Through careful nurturing of teams and teamwork, we are able to encourage students by the end of the semester to take on many of the roles they would normally expect campus-based instructors to fulfill.

We first began using web instruction in our courses to encourage students to give each other support and advice about their work. This is particularly desirable when working in such professional development fields as teacher education, as the learners typically have a wealth of experience and expertise to share that goes well beyond what instructors can provide. But we found in actual web-based discussions that teachers were reluctant to offer genuine critical assessments of their peers' work, and that most of the interaction was cursory or off-topic.

Accordingly, we have learned to progress toward real collaboration by beginning with simple opportunities to share information and gradually including opportunities for real contributions to and critiques of peer work. We start the semester with simple sharing of work samples, exchanging basic information, and describing school situations and personal experiences. As the students familiarity with one another increases, we ask them to offer examples or suggestions based on their peers' work, rather than their own. By the end of the semester, we expect them to give full-fledged support and critiques of one another's projects.

Conclusion

In order for distance education to be effective, instructional planning must consider the gap between the typical student's expectations about the learning process and the capabilities and characteristics of instruction over distance. Careful, gradual introduction of web-based technologies can guide and enhance the learners' transition from a traditional model of pedagogy in which their role is passive, to a model in which they take a full, active role in directing and achieving their own learning.

How Does Achievement Differ in Comparing Learning By Distance to Learning On-Campus: A Preliminary Analysis

By:

Jonathan L. Ross

Doctoral candidate in Educational Technology
The University of Calgary, Canada
jross@ucalgary.ca <http://www.ucalgary.ca>

Methodology

Research Question

Does student achievement differ in comparing conventional and web-based course environments?

Overview of Procedure

In the winter of 1999, the University of Calgary's Community Rehabilitation program offered the undergraduate half-course, *Law and Disability*, fully on-line via the World Wide Web to students across Western Canada. At the same time, a group of on-campus students at the university were enrolled in a conventional version of the same course. Both the on-line and conventional courses were taught by the same instructor who is a practicing lawyer and experienced sessional instructor with the Community Rehabilitation program.

The course web site was carefully constructed to provide students with many of the same learning opportunities provided to on-campus students. For example, the instructor placed lecture summaries on-line in addition to other content that was covered in the conventional classroom. In this way, students in both groups had similar exposure to *course content*, and thus, valid assessment of learning outcomes between groups could be made.

Insofar as the web has tremendous potential to enrich student learning experiences, it was difficult to equalize the treatments in both groups. While each group had one instructor-led lecture conducted per week and were given the same notes, assignments and examinations, the on-line group had a number of supplemental resources and tools. Because this study's goal was to compare directly the nature of learning on-line and face-to-face, maximizing the resources afforded by the Web was essential.

The web site learning environment adhered to most features included in the distance education course creation checklist created and published by Ross [1998], and was deemed instructionally sound by a focus group of five students and two learning technologists.

Instruments

To validly assess learning outcomes, a 40-question multiple choice examinations was administered to participants at the beginning and the end of the course.

Subjects

A convenient sampling method was used for the purposes of the study. Thirty-eight students enrolled in the on-campus version participated in the study, while 36 web-based course learners chose to participate in the study.

Independent Measures

Treatment Group—Two groups: 'By Distance' and 'On-Campus' were examined for the purpose of this study.

Dependent Measures

Learning Outcome-- Achievement levels were measured by students' post-test score as measured by a 40-question multiple choice examination and by students' final course grade recorded.

Results

Analysis of covariance (with significance set at the $p < 0.05$ level) was performed on the 2 subject groups: 'On-Campus' and 'By Distance' using post-test scores as the dependent variable and pre-test scores as the covariate. The hypothesis of equal slopes was accepted ($F[1,74]=8.25, p=0.137$) and that of zero slope was rejected ($F[1,74]=8.74, p=0.005$) which indicates that ANCOVA was an appropriate model for data analysis.

Controlling for pretest, there was significant group effect on post-test scores ($F[2,72]=4.17, p=0.019$).

Source of Variation	SS	DF	MS	F	Sig of F
WITHIN CELLS	204.27	72	2.84		
REGRESSION	.03	1	.03	.01	.916
CAMPUS	23.55	1	23.55	8.30	.005
(Model)	23.68	2	11.84	4.17	.019
(Total)	227.95	74	3.08		

Ancova results revealed that the 'By Distance' group performed significantly better on the 40-question post-test than did the 'On-Campus' group. Descriptive information indicated that the 'By Distance' group recorded a final mean score of 35.2 while the 'On-Campus' group obtained a final exam average of 33.4.

Discussion and Conclusion

This study sought to compare student achievement in a course taught on campus and by distance. Preliminary results found that when controlling for pre-test knowledge disparities, the 'By Distance' group performed significantly better on the 40-question multiple choice test than did the 'On-Campus' group. Mean averages differed by almost two points. It would appear that, in this instance, off-campus students were more successful in demonstrating their course knowledge than students who took the same course on-campus.

This study illustrates the potential power of the Web to support learning if the instructional environment is structured according to instructional design principles as outlined by Ross [1998].

Future Analysis

Future research questions to be explored as part of my dissertation include:

1. How does learning style (as measured by the Gregorc Style Delineator) relate to achievement and attitudes towards the course, instructor and learning medium?
2. Are there differences in:
 - Student-student interaction;
 - Student-instructor interaction; and
 - The amount of time (in hours) spent on course-related learning?
3. What are some of the characteristics of on and off-campus student learners?

Normative Influence and Emotionality throughout Web based discussion

Khaled Sakhel

Department of Psychology, Maastricht University, Netherlands. E-mail:
k.sakhel@psychology.unimaas.nl

Abstract: An important feature of Computer-mediated Communication (CMC), compared to other modes of communication, is anonymity of its users. Two theories comparing anonymous and identifiable behaviour during CMC are discussed. An experiment is conducted to test the Social Identity Model of DEindividuation (SIDE, Spears & Lea, 1992).

1. Introduction

An important feature of computer-mediated communication (CMC), compared to other modes of communication, is anonymity of its users. Some researchers studying CMC believe that this anonymity accounts for an impersonal interaction with others, and therefore responsible for a diminishing in social influence during CMC (e.g. Kiesler, Siegel, & McGuire, 1984). Furthermore, because of the interpersonal form of interaction, emotionality (the term used to indicate the expression of emotion) is highly reduced, therefore CMC users are expected to perform communication styles, which are mainly task oriented. Some other experiments showed that anonymity could also lead to an increase of social influence within a group (Postmes, 1997; Spears, Lea, & Lee, 1990). An explanation for these findings is provided by the Social Identity model of DEindividuation (SIDE-model; Spears & Lea, 1992). The SIDE model derives from Social Identity theory and its practical implications on mass behaviour (Reicher, 1984). The Social Identity theory notices that the self encompasses a scope of possible social identities, ranging from individual identity to group identity (Tajfel & Turner, 1986). Anonymity can strengthen group behaviour when the perceived social identity of the group is strong. It is the appropriate social identity, which allows anonymous group members to fully express behaviour according to the norms and rules of the social group they belong to.

The aim of the present study is therefore twofold, first a group norm is manipulated, CMC users communicate either using a task- or an emotional-oriented groupnorm and secondly the context in which the groups discuss is manipulated; CMC users are either anonymous or identifiable for each other.

2. Method

Seventy-five subjects were randomly divided into 21 groups of three (nine groups) or four (12 groups) persons. All participants were then directed to an isolated cubicle with the instruction to start with the experiment which included the group manipulation (Doosje, Ellemers, & Spears, 1995). At the end of the discussion subjects were asked to fill out a questionnaire.

3. Results

All analyses were conducted at the group level. The content was coded using Bales' "interaction process analysis" (IPA) coding scheme (Bales, 1950). Compared to identifiable groups, the anonymous socio-emotionally activated groups suggested more socio-emotional solutions ($M = 3.49$) and anonymous task-oriented primed groups favoured more task-oriented solutions ($M = 2.30$) for the problem, and simple main effects indicated this to be a significant difference, $F(1, 17) = 9.59, p < .01$. In the individual solutions for the presented dilemma (open question on the questionnaire) there were no significant main effects. The expected interaction anonymity and priming however was highly significant, ($F(1,17) = 11.93, p < .01$).

Table 1: Mean score (Standard Deviation) on some dependent variables.

	Anonymous		Identifiable	
	Socio-emotional <i>n</i> = 6	Task-oriented <i>n</i> = 5	Socio-emotional <i>n</i> = 5	Task-oriented <i>n</i> = 5
Individual solutions [†]	3.49 ^a (0.28)	2.30 ^b (0.87)	2.25 ^b (0.71)	3.02 ^{ab} (0.65)
Number of empathic words	3.20 ^a (1.65)	2.33 ^{ab} (1.33)	1.37 ^b (1.12)	3.15 ^{ab} (1.23)
Number of task-oriented words	3.23 ^{ab} (1.69)	5.16 ^{ab} (2.80)	5.97 ^a (1.98)	3.12 ^b (0.92)
Development of solutions in time [†]	.13 ^a (0.25)	-.11 ^b (0.42)	-.22 ^b (0.36)	.14 ^a (0.13)

[†]Higher scores indicate more empathic solutions, individually or in time.
Means in row with different superscript differ significantly, $p < .05$.

Interestingly, the regression coefficients did show a significant interaction in the predicted direction, $F(1, 17) = 5.06$, $p < .04$, $MSE = 0.09$. Across time, the anonymous socio-emotional groups suggested more socio-emotional solutions ($M = .13$, higher scores indicating more socio-emotional solutions over time) compared to the identifiable socio-emotional groups ($M = -.22$). The anonymous task-oriented groups however proposed solutions that became increasingly task-oriented ($M = -.11$), while the identifiable task-oriented groups became more socio-emotional in their solutions, although the difference failed to reach significance ($M = .14$, $F(1, 17) = 1.71$, $p = .20$).

4. Discussion

The reported experiment set out to demonstrate that anonymity in a group could lead to enhanced normative behaviour. Results show that anonymous groups choose solutions to a dilemma that are consistent with the prime, whereas identifiable groups do not. This effect occurs both in the solutions to the problem and in the language used during discussion. Moreover, suggested solutions show a predicted development over time, such that anonymous groups tend to behave more prime-consistent over the process of discussion, whereas identifiable groups behave prime-inconsistent over time. This development of primed behaviour in the course of interaction is reinforced in anonymous groups, whereas it is restrained in the groups where individuals are identifiable. The experiment succeeded in demonstrating that CMC is not necessarily more task-oriented. Rather it was demonstrated that socio-emotional interaction styles are very much possible via CMC.

Surfing in the Web: an Experience of the Use of Internet in Educational Process

Nicoletta Sala
Academy of Architecture of Mendrisio
University of Italian Switzerland
Largo Bernasconi
CH 6850 Mendrisio - Switzerland
nsala @ arch.unisi.ch

Abstract: The Internet has changed the process of communication in these years. The net or cyberspace provides much useful information as we navigate URL's, browsers and hyperlinks. The explosive growth of the Internet and the convergence of information and communications technology is opening up new educational opportunities. The Internet can be used to modify the teaching methods and the process of learning. The aim of this paper is to present how to use the Internet and its resources in the learning process in a senior secondary school. I refer of my experience how supervisor in a teaching project in a technical institute in Italy (students aged 16-18).

Introduction

The computer technology has become a fundamental part of education across the curriculum and will likely be more so in the future. Instead of simply being a source of information, computers are becoming multimedia workstations for students. Innovative use of technology combines telecommunications (e-mail, online resources, Internet navigators), multimedia authoring (home page editors), user-friendly convenient applications software and are turns students into producers as well as consumers of content. The role of the classroom teacher is evolving from that of a giver of information to that of a facilitator of student learning. New technologies already exist to help teachers complete that evolution. The project "Surfing in the Web" is an example in this field. It has been divided in six stages: the knowledge of the Internet, the research in the Internet, the access to the FTP, the didactics with the Internet, the creation of Web pages, and the communication using the "Net".

The knowledge of the Internet

In the first stage the students, organised in eight groups each of two persons, have learnt the Internet directly in the Web using some special interactive lessons, developed by the Department of Science of Information at University of Milan. These lessons are available at the Internet address: <http://twilight.dsi.unimi.it/Users/sdi/barbacovi/prog1/Lezione/indice.html>. This hypertext has been developed for the course of Science of Education and it is a good example of educational hypertext. Using these interactive lessons the students have learnt: the correct navigation in the Internet, the recognition of the different types of hyperlinks (e.g. hot words, icons, buttons, and images), and the netiquette.

The research in the Internet

The search of information in the Internet still constitutes a bottleneck for the "net". For this reason, in the second stage, the students have learnt to use the search engines (e.g. Altavista, Yahoo, Virgilio), comparing their performances using the same keywords. They have also discussed these results.

The access to the FTP

The Internet is a big archive of information. In the third stage the students have analysed the capability to download, to install and to use some shareware and freeware software (on mathematics, geometry, Italian literature, and information technology) in their educational process.

The didactics with the Internet

The Web is argued to be the next technological tool to be used in the delivery of educational material. In this stage the students have used some educational Internet sites dedicated to the Italian literature, to the mathematics, and to the geometry. To study Italian literature I have proposed three interesting Internet sites:

- <http://tutti-c611.uibk.ac.at/nanda/Manuzio/000ind.htm> (it contains texts of Italian literature);
- <http://www.ecs.net/scrivere/DANTE/GUIDA.HTM> (to study Dante Alighieri's literary works);
- <http://www.augustea.it/~banfi/INFO/TG2/CARTELLI/LAVORI.HTM> (dedicated to the Italian poems).

After the exercises proposed on these Internet sites the students have improved their composition technique.

To analyse the patterns and the groups of symmetry they have visited the Internet site:

<http://www.geom.umn.edu/apps/kali/about.html>.

It contains the following applications: **Kali** (is an interactive editor for symmetric patterns of the plane, as seen in some of the woodcuts of M.C. Escher); **QuasiTiler** (that generates the famous Penrose tilings, or design nonperiodic tilings of the plane; in the process, we can select and visualise plane cross-sections of a lattice in anywhere from 3 up to 13 dimensions); **Unifweb** (that visualise families of Riemann surfaces with a specified group of symmetries.); **Lafite** (that works with any discrete symmetry group of the hyperbolic plane).

The creation of Web pages

In the fifth stage the students have created a collaborative hypertext (using HTML) dedicated to Bonaventura Cavalieri (1598 - 1647) (an Italian mathematician) for an International Conference of Mathematics. In course of execution the phases have been: the bibliographical research of information (using some traditional textbooks or the Internet); the choice of information to put in the hypertext; the hypertext's story board; the realisation of the user Interface; the encoding of information in hypertextual form; the control of hypertext (links, hot words, and so forth). Fifteen students, organised in seven work groups, have developed: "Cavalieri's biography"; "Cavalieri: the religious figure", "Cavalieri's scientific production", "Cavalieri and the town of Verbania", "Bibliography", and "Other sites on Cavalieri" (with some links to other Internet sites). During this hypertext development, the students put a particular care to make "friendly" the user interface for easy navigation [Sala, 1999]. This hypertext is written in two languages: Italian and English, and it is at the Internet address: <http://www.verbania.alpcom.it/scuole/cavalieri/cav0e.htm>.

This stage is an example of "learning by doing" environment because the students have also learnt the history of mathematics during the hypertext development.

The communication using the "Net"

The sixth stage has been dedicated to the communication with other European schools using the e-mail. In a particular case a disabled student of my classroom has researched (and found) some Italian and Swiss "cyber-friends". Internet became for him a new way to socialize (going out from the isolation of his classroom) and to overcome his handicap.

Conclusion

This project demonstrates that the Internet offers significant benefits in educational process, and it shows that there are clear educational advantages to be derived from collaborative student activities. When students work in groups and small teams, the interactions and activities frequently involve higher order and reflective thinking. Collaboration helps individuals to progress through their zone of proximal development through the communication and the joint activity in which they are engaged [Oliver, Omari & Herrington, 1998].

Teacher Development, Educational Reform and The Web

Marilyn Schaffer, Ph.D., Director,
International Center for Education and Technology
University of Hartford
200 Bloomfield Ave., W. Hartford, CT 06117 USA
mschaffer@mail.hartford.edu

Abstract: In many countries public school education is currently under severe pressure to change methods, content and mission. Many of us are struggling with ways to utilize technology, especially the WWW, to improve educational opportunities for all students and to assist teachers in developing the skills they need to support educational change. This paper will report on a variety of action-research projects conducted by our International Center for Education and Technology, both locally and internationally, in which teachers and teacher educators, including college and university faculty, are assisted to develop new skills and strategies in using technology to improve students' skills and concepts and to help prepare them for a productive and rewarding future.

Educational Reform and the Role of Technology

Many teachers are eager to make significant change in their classrooms but they lack needed skills in the use of technology to enhance and support new learning paradigms. They want to do a competent job, but feel overburdened and isolated as they attempt the task of revamping curricula. Teachers, for the most part, are well aware that they must use the internet and especially, the WWW, to find information to help themselves and their students to broaden their subject knowledge with current, as-it-is happening news and information, deepen their conceptual understandings of curricular areas, get a broader view of issues by discussing, and getting feedback from peers and specialists with whom they can interact.

Our Approach

In each of the following sections, an aspect of our approach to teacher development and support will be briefly discussed, followed, by way of illustration, with description of a particular project.

The Teacher as Innovator

Instead of being the passive transmitter of canned curriculum, the teacher in our model creates a learning environment which takes account of students, their interests, needs, and strengths, and that focuses on the development of problem solving, creative thinking, and communication skills that will be needed by future citizens of the world. By example, the teacher demonstrates the value of using new technologies as she/he guides students to define and explore problems and issues that affect our planet, working cooperatively to find solutions that are acceptable to our larger communities.

Sample Project: Fabulous Frogs

In this project a teacher and her class of primary students gather information about frogs and, as they learn more, add their findings to a HyperStudio stack that the teacher has created to support the investigations of her students. The program consists of various options for students to explore what the group has already found and/or created. Possibilities include: an animation of the life cycle of a frog; a collection of facts about frogs from around the world; a section entitled Frogs in the News, which highlights scientists' concerns over diminishing populations of frogs as well as discoveries of many mutations in recent years; poetry, songs and stories about frogs; and web sites that concern issues relating to frogs and other amphibians. After reviewing these options, students choose to work in one of the areas with the goal of adding new material to the program. This stack is posted on the Web and other classes of students are invited to interact and contribute.

The Learner as Thinker:

Our view stresses the active exploration and manipulation by students of both concrete and abstract objects, and places a high value on the need for interpersonal communication, cooperative planning and problem solving. It values the construction of new insights and ways of thinking, and joint problem solving by students and teachers alike, by means of project-based sequences of activities that formulate an integrated approach to learning.

Sample Project: Learn About Dinosaurs

In this project, the teacher and her students together gathered information about dinosaurs, visited local sites which house evidence of dinosaur life, interviewed several dinosaur experts and then created a multimedia CD of their learning, which includes: a timeline delineating the periods in which dinosaurs lived on Earth; discussion of the theories on the topic of why and how dinosaurs became extinct; evidence of dinosaurs in our local area; links to web sites with information related to a range of topics involving dinosaurs; a gallery of dinosaur drawings by students; and a quiz of dinosaur facts. The teacher and students had to learn HyperStudio, web browsing, html, sound editing and animation in order to share their learning with others.

Learning as a Collaborative Activity

One of our aims is to encourage teachers to develop support systems, within their own schools, with peers in other locales and with the scientific community. Teachers have told us that our projects have allowed them to step outside of their own classrooms to interact with other adults via the internet. They have been reflecting on their growing desire for collaboration and are realizing what a lonely profession teaching sometimes can be. Teachers are also helped to carry the concept of collaborative work to their students and their parents.

Sample Project: Save the Beaches

In this project, via a web site, a teacher has created an international community of students and teachers who visit beaches in their local regions, observe and collect data on the number and types of debris found there, and then analyze and report their data to the larger group. In this way, students are actively involved in the collection of information that contributes to producing a larger pattern of data than they could gather on their own. Teachers, alike, are collaborating with their peers in other regions and countries.

Sample Project: Raining Books: a Guide for Parents

In this project a teacher who desired to reach out to parents, learned how to use multimedia and the WWW to prepare a guide which parents could access via a web site. In the guide are: an overview of the reading program in the teacher's school; a wide range of ideas to help parents to stimulate their children's reading at home, while shopping, etc.; web links to sites on children's books; and an email connection for parents to directly communicate with the teacher.

Summary

Telecommunications and multimedia, including CD-ROM technology and the WWW, have the capacity to transform classroom learning from a closed didactic system to a open, exploratory and collaborative experience. We view the technology that we use, such as telecommunications and multimedia as providing opportunities to authentically accomplish the hands-on, inquiry-based learning that are essential to systemic reform in education. With these tools teachers can assist students to communicate ideas to peers, and to the larger community, rather than produce work for the eyes of their teachers only.

1. On-line seminars

Distance learning via the WWW is a new field for higher education. In times of financial restrictions, the demand for more efficiency and effectiveness is often connected to the potential of tele-supported university teaching. New media require different styles of conveying knowledge and it raises questions about which didactic methods are applicable to Web-based teaching. New methods also demand intensified preparation. Whereas it is becoming more popular to use the Internet as the technical platform for the distribution of on-line study, many descriptions, and reports, promote the thesis that almost unlimited possibilities exist in education that just have to be implemented. Frequently, a positivistic view is held which pushes the discussion of problematic areas such as interactivity, appropriateness of web delivery, and learner control that on-line learning offers into the background. The educational gain in relation to the effort for development and realisation of effective instruction is seldom mentioned.

The on-line seminars (<http://seminar.jura.uni-sb.de>) of the Institute for Law and Computer Sciences (ILCS) at the Saarland University have proven to be far more time and personnel intensive than regular courses, but they open up new possibilities for students and teachers, and afford interdisciplinary and international collaboration. One advantage of on-line courses is the potential for communication, collaboration, and the exchange of knowledge between students and educators which can be made available that can bring them closer to (and perhaps supersede) "real life" teaching. Computer-mediated communication (CMC) therefore becomes an important research area for education.

2. Design and development

Designing and developing effective on-line courses requires attention to technical execution, adaptation of content and course concepts, attention to motivation, and must afford interactivity. On-line support during the on-line seminars consist of technical work as well as on-line mentoring support. We have found that communication between participants need to be regular and that these communication processes need to be checked continually (several times daily) to detect potential problems and initiate immediate intervention to avoid negative outcomes. During the 1998 seminar an average of 87 messages a day was written. The majority of these communiqués (38) were between participants, additionally there was an average of 8 messages to the team that required immediate response. Given these facts, participant interaction and their mails have to be monitored constantly - even on weekends.

2.1. Mentoring the Process

Mentoring takes on a new dimension in an on-line environment. We are challenged to "mediate" in ways that Reuven Feuerstein, Lev Vygotsky [Feurstein et al 1980, Vygotsky 1986, 1987] and others define as mediation. By facilitating, modeling, and coaching we begin to have new insights into mediation, instructional

strategies, response to learner queries, and facilitating online discussion and fostering critical thinking. We anticipate, through an analysis of the discussion threads and collaboration threads, that we will be able to identify types of dialogue as well as a framework for guidance to support and facilitate a collaborative on line environment.

Our goals as moderators and discussion facilitators is to keep the “conversation” flowing, focus and refine ideas, challenge/ask learners to explore deeper into critical issues, and support and scaffold an on-line community. Marrying strategies related to electronic communication and critical thinking, will help foster a community of learning in a virtual environment. On line collaboration as well as effective moderating *must* be designed if it is to have comparable impact to face to face instruction. Through conscious effort and application we can bring voice and tone to bear in an otherwise sterile and distant environment. We can become reflective guides, or a personal muse to a learner. We are mediators and facilitators; generative guides and conceptual facilitators. The same environment issues that can be weaknesses in a learning environment can be exploited creatively to make learning come alive.

2.2. Design More than a Technical Matter

Apart from technical aspects, designing the virtual learning and work environment for students requires an interdisciplinary approach which incorporates research from various disciplines including: sociology, educational psychology, systems theory, communications theory, instructional design, diffusion of innovation, and visual perception/literacy.

In the field of sociology, recent attention has focused on creating successful group environments as well as dynamic group interactions. To inspire co-operation, crucial elements are arranged so that individuals will be able to meet each other again, and in doing so they must be able to recognise each other and last but not least they must have information about how the other has behaved until now [Axelrod 1984]. The system should also support some form of history of who has done what, this is echoed in the research of Mike Godwin in his *Nine Principles for Making Virtual Communities Work* where he points out that the system must provide institutional memory [Godwin 1994].

As we move toward a global community, this course demonstrates that the presence of the Internet paves the way to unlimited inter-cultural collaboration. This is true for learners as well as for educators who can now offer joined courses regardless of large geographical distances. The development of on-line courses presents a variety of new challenges. In today's world, an international orientation is welcome and necessary - not only for students as the evaluation of the courses shows - but the evaluation also suggests that students really value on-line learning which allows them to study independently of a specific time or place.

On the other hand, the development of on-line courses presents many new challenges for teachers. One of the challenges of on-line courses is their design, diffusion, and integration into daily university life within feasible economic constraints. To develop an approach that is both efficient and effective, special attention has to be given to the user utilising instructional design principles that consider learner needs, existing skills, learning habits and work conditions.

Are we Creating New Teaching Environments with Web Courseware Tools?

Kathy Schmidt

Abstract: During the fall of 1998, the University of Texas at Austin adopted WebCT as a courseware tool for faculty who opted to enhance instruction. This poster session will present an overview of some of the online pedagogical issues and assumptions that must be addressed as faculty use this new learning environment. Most of UT's faculty training has concentrated on the mechanics of the software. since there tends to be a resistance to theoretical discussions. However, there is valid concern that technological convenience can take precedence over instructional practice. We are finding that faculty can create a course with WebCT, but need assistance finding ways to provide students with adequate information delivery, analysis, and in application opportunities. With online environments, learners can be more in control of learning, but they need guidance in order to activate appropriate learning strategies. Lessons learned and ways to address improving courseware instruction will be discussed.

Online Robotics Education at NASA.GOV

Stephanie Smith

NASA Information Technology Office, NASA/JSC GT, Houston, TX 77058
Tel: 281-483-9626, Fax:281-483-9988, E-mail: stephanie.l.smith1@jsc.nasa.gov

Abstract: Robots were once the stuff of science fiction and the future. Now they are everyday real science and yet still, endlessly fascinating. This fascination coupled with a curiosity of how and why robots work is a learning opportunity that can be explored across many disciplines. To tap this educational potential and share the large body of work the agency performs in robotic technology, NASA makes current events, research results, and educational activities available to the public via the Internet and Web technologies. This paper identifies some of those educational sites associated with NASA robotic development and space exploration.

NASA studies our universe by sending science instruments into interstellar space, creating a virtual presence among the stars. Robotic probes and Remote Operating Vehicles (ROV's) help develop the scientific knowledge future human exploration missions will need to be successful. The robots gather information about remote destinations and promote flight readiness with their new technologies such as advanced miniaturization, intelligent systems, autonomous operations and simulation-based designs. The knowledge generated by the space science community in these projects is disseminated to the education community at large to communicate research results, share the excitement of space exploration and promote educational improvement. Information about NASA's robotic development, exploration and technology can be found at many Web sites and appears to fall into several categories; traditional course materials using the Web as a distribution mechanism, physical robot hardware with an online interface, interactive projects, and simulation-based robotic activities. This short paper identifies online NASA robotic resources as applied to math and science education.

NASA's increased focus on robotic missions is well represented by traditional types of course materials published on the Web. For example, the Mars Pathfinder and Sojourner ROV landed on Mars July 4, 1997 and sent collected data to Earth about the environment and composition of Mars for about 3 months. Right now there are 3 more ROV's orbiting or in flight to Mars within the Mars Exploration Program; the Mars Global Surveyor, the Mars Climate Orbiter and the Mars Polar Lander. Lessons and info about these robotic technologies, instruments, and experiments are available online to educators at a variety of locations. The Mars Exploration Education Program provides curriculum guides, fact sheets, slides, and images in an online environment and the Planetary Data Systems has an in-depth profile of the red planet. Information and activities about Mars and other innovative programs can also be found at the Live from Earth and Mars site, Mars Quest and Spacelink. NASA is also currently studying Jupiter's atmosphere, structure, and composition with the Galileo spacecraft and recently launched the Stardust mission to return captured comet particles to Earth for study by the scientific community. These are a small sample of the online curriculum materials available in the area of robotics. For other resources, in the nasa.gov domain, activate the search function from the NASA homepage or visit the NASA Space Telerobotics Page.

There are several NASA supported school programs in which students have an opportunity to build a physical robot to accomplish a given mission. These projects require students to perform practical tasks in the areas of mechanical engineering and computer programming while being mentored by engineers. The robot hardware is typically underwritten through grants and corporate sponsorship and information is accessible on the Web. Botball is a high school based program set up to interest students in science and engineering. Teams of students and engineers design and program a small mobile robot to compete in a

regional tournament. The project includes Internet research on robotic topics and a robotic design contest. A larger scale robotics competition is known as the FIRST Robotics Competition. FIRST is an acronym which stands for "For Inspiration and Recognition of Science and Technology" and is a non-profit organization that seeks to generate scholastic interest in science and engineering. Students team up with NASA, university and industry engineers during a six week period to design, construct, and test their robots. The teams then compete in regional tournaments and a national tournament at the Epcot Center in Florida. Individual teams web pages report the progress and status of robots under construction.

An example of an interactive, robotic Web activity educators can access is available at the Learning Technologies Channel. The LTC recently presented a series of Internet broadcasts on NASA's Marsokhod Rover testing from the California desert. The Real Media audio and video streams were broadcast live and are now available in the LTC archive. During the live LTC media broadcast, students asked NASA experts questions in a moderated chat room. The Marsokhod broadcasts covered topics such as the onboard science instruments, navigation, traversal, task performance, environmental analysis and sample retrieval. The LTC also broadcasts university courses in robotics as part of NASA's partnership with the University of North Dakota and Western Governor's University. The Telescopes in Education program allows students to operate a remotely controlled telescope and charge-coupled device (CCD) camera in a real-time, hands-on environment. The TIE program utilizes a science-grade, 24-inch, reflecting telescope at the Mount Wilson observatory which is used by students around the world to observe many different types of astronomical phenomena. Students increase their knowledge of astronomy, astrophysics and mathematics while remotely operating the telescope.

Simulation-based software called the Web Interface for Telescience or WITS was developed at JPL to allow scientists to participate in real planetary rover missions from any location. The public version of WITS allows the user to view and download science data and interact as a mission scientist with a simulated rover. The user plans and executes a rover science mission within a panoramic view of the extraterrestrial environment. WITS is an adaptation of a sophisticated tool and is most appropriate for high school and college audiences. Currently under assessment for educational use is the development of an Internet-based haptic interface. The haptic interface will give users a sense of touch in their online environment as they explore elements of robotics. A robotic simulation developed for students to build, train and run an online robot is called the ROVER Ranch. Remote operating vehicles are created and trained to perform missions in physically remote environments. Students create their vehicle at a workbench consisting of idealized body parts like thrusters, roller wheels, propellers or independent legs as locomotors; solar panels, generators, batteries as energy sources; and light, heat, chemical or tactile units as sensors. Students train the ROVER in basic movement techniques and required conditions for decision-making. Appropriate and optimal combinations of ROVER parts and training are directly correlated to task success. The completed ROV then runs in a simulated environment performing tasks such as mining, exploration and object location/retrieval.

While the robotic information NASA publishes is a rich body of work for educators to use when teaching math and science, it is important for educators to identify the sites that fit their teaching styles and needs. The sites mentioned encompass concepts and problems associated with engineering a viable robot or remote operating vehicle. Some sites are geared towards gears literally, while others are an abstraction of the concepts of robotic technology. Project oriented and/or student-centered learning environments can use many of NASA projects as an entire module. Other teachers may find that pieces of a project or projects fit best within their teaching curriculum and time constraints. There is enough variety and depth of information to convey basic robotic information to different age levels and learning styles. It should be noted that projects which involve building actual hardware robots may require corporate underwriting or financial grants from organizations such as NASA. An annotated reference list can be found online at <http://prime.jsc.nasa.gov/references.html> which lists traditional curriculum Web sites, projects with physical robots, interactive projects, and simulation-based software.

Developing Interactive Lecture Notes

Dr. Janak Sodha
Department of Computer Science, Mathematics & Physics
University of the West Indies
Cave Hill, Barbados
Email: jsodha@uwichill.edu.bb

Abstract: With the appropriate use and organization of Internet based technologies, interactive lecture notes can be developed which not only help to stimulate a student's learning experience, but more importantly, attempt to truly educate as oppose to merely providing information to a student. By identifying the key features of the complex human learning process, a practical approach towards the goal of creating a truly self-instructional web-based lecture course is presented.

1. Introduction

Lecture notes that merely present web-based textual information with static diagrams only scratch the surface of the educational process. This is because of the complex human learning process, which essentially consists of utilizing any prior knowledge and experience to comprehend new concepts, and to subsequently strengthen ones understanding by working through examples. Throughout this process, several discussions may be necessary between a student and the lecturer, in an attempt to identify the root of any difficulty. The nature of these discussions will depend on the feedback provided by the student, and the lecturer's ability to make an educated response, targeted at the skill and ability level of the student. The subject of this paper is to address these issues by presenting some interactive web-based techniques, together with an effective interactive methodology. The interactive process may be separated into the following two modes. The first mode is the interaction between a student and the lecture material via a web browser. This form of interaction is based on the clever use of existing Internet technologies, including the facility for communication between students and the lecturer via email, message boards, or a chat forum. The second mode is the traditional face-to-face interaction between the students and the lecturer. The subject of this paper deals mainly with the first mode of interaction, with the underlining assumption that the second mode of interaction is available. Indeed, it will become evident in the sections to follow that the second mode of interaction is essential to complete the educational process.

2. Feedback and its incorporation

The most important aspect of developing interactive lecture notes is to create a feedback mechanism. For example, a JavaScript feedback form may be submitted by a student to the lecturer via email, which allows the student to specify via a drop down menu, whether the nature of the feedback is a comment, suggestion or a question [1]. As a consequence of the feedback, the lecture material need not be cluttered with further details. An elegant solution is to insert a tip or a hover [2] window at the appropriate place using JavaScript, in which respectively, the user either clicks or hovers the mouse over an image or an underlined text to launch a small additional browser window within which further clarifications are provided. Alternatively, with a little imagination, one can embed within the lecture notes, video clips or simple cartoon animations [3] saved in the standard AVI format to help clarify complex diagrams, and illustrate concepts. Sound clips may also be used to provide additional information. Unfortunately, a soundcard and speakers are not a common feature on most computers.

3. Interactive Internet technologies

Any form of interactivity will capture the interest of the student, and more importantly, help the student to gain a better understanding of the material presented. Typically, Java Applets provide a wonderful opportunity to embed interactive examples within a given lecture. For example, a student may interact with a graph plotting Java applet which re-plots the curve depending on the parameters set by the user [4]. A nice alternative is to use a general purpose graph plotting function [5] scripting applet, which is controlled by JavaScript. The added advantage of using such a scripting applet is that the student may specify the function to be plotted. Multiple choice questions are inherently interactive. Using JavaScript, one can also provide the option of checking any given answer, thereby allowing the user to learn from incorrect answers [6]. Solving tutorial questions is an essential part of the learning process. To encourage and help students attempt tutorial questions, an interactive tutor [7] based on JavaScript image roll-overs may be used as follows. For a given question, three images labeled "Hint 1", "Hint 2", and "Answer" are presented to the student. A hint or the answer is revealed by moving the mouse pointer over the corresponding image. To encourage a student to work out the full solution, the complete solution is not available, even with both hints revealed. An on-line *message board* [8], which is alternatively known as a discussion forum, provides an opportunity for the lecturer to answer common queries, and to enable discussions among the students. Microsoft FrontPage [9] provides a setup wizard to automatically create a message board. Finally, no matter which Internet technologies are utilized to create an interactive feature, it is extremely important the technologies are fully supported by a common web browser. Any interactive feature which requires the student to download and install a special plug-in software is unfortunately doomed to failure, no matter how effective the interactivity. This is because typically, students are unwilling to install additional software for a variety of reasons, which include the time required to download and install, and a lack of confidence to successfully install software.

4. Interactive Methodology

Interactive features of the type highlighted in sections 2 and 3 require an ability to exploit the available Internet technologies. This is a very important and often the most difficult aspect of developing interactive lecture notes. Furthermore, it very difficult to create an interactive medium which adapts itself to the skill and ability level of a student, and is able to respond with the appropriate material based on the nature of difficulty faced by the student. The only effective solution currently available is the traditional face-to-face mode of interaction, which enables a lecturer to quickly and effectively solve individual student difficulties. The added advantage is the inherent feedback which may be used to further improve the online lecture material, and its interactive features. A very effective technique is to copy the lecture notes from the web server onto a laptop computer, and use an LCD projector to enable the whole class to view the lecture material. By presenting the lectures in this manner, the lecture material will continually evolve towards a powerful self-instructional interactive lecture course.

A Three-Dimension Structure to Learning Object Management

William Song
SITI (Swedish Research Institute for Information Technology)
Box 1243, Isafjordsgatan 26, 164 28 Kista, Sweden
E-Mail: william.song@siti.se

1. Introduction

With the growing use of the Internet resources for purposes of teaching and learning, it becomes more and more important to develop a well-defined description for the management and distribution of learning information on the Internet both for the information suppliers and consumers [Song 1998a]. Many approaches to the management of learning resources in the Internet have been provided but with the aims to one particular aspect or another. Most of the research work on learning domain focuses on the description of learning content and pays little attention to the media maintaining the learning content. Even less effort is paid to the analysis of degree of ease-difficulty of learning objects. This factor is not only important but also a real demand from the end user.

In this paper we propose a managerial framework for learning object analysis, which is considered to be an overall view for descriptions of handling teaching and learning information, called learning objects. This framework contains descriptions (or attributes) of content, carrier, and knowledge intensity of learning objects. These three concepts are considered to be most important for management and analysis of learning domain.

The paper is organized as follows. In the next three sections we informally discuss three major aspects focused in the paper, i.e., learning domain, knowledge carrier, and learning intensity. In the section 5 we propose a formal definition of the three dimension structure for a learning object and point out how we will use the concept in applications in the following section. We conclude the paper in Section 7.

2. Learning Domain

A learning domain can be considered to be a collection of knowledge with specific characteristics for purposes of learning and education [Andersson 1999]. The collection of learning knowledge is organized based on semantic relations. Such semantic relations describe an intrinsic (collocation) structure of learning content. For instance, knowledge about computer programming is a basis and subsequence of knowledge about computer algorithm. The precedence of the knowledge about computer programming and algorithm depends on how we describe the two subjects, i.e., what attributes (or characteristics) we select for the subjects (or learning objects) and what values we assign to the attributes.

The extraction of attributes for a learning domain is critical for modeling the semantic relations. These attributes can be constructed from the characteristics of the collection of knowledge and their collocations. These attributes are used to associate a learning object to a set of values, which describe the learning object on one hand. On the other hand, the attributes are also used to create relationships between learning objects. The relationships relating an object with other objects form a **semantic** context for the learning object of interest [Song 1996]. Such cross references can capture an entire semantic picture of a learning domain.

3. Knowledge Carrier

Carrier is a medium that provides a display of knowledge content. A same content can be carried in different media. In a learning domain, the carriers maintaining learning knowledge play an extremely important role in providing versatile styles of learning and education information and therefore improving understandability and entertainment for the users. For example, two kinds of carriers for a conference proceedings can be a very thick book and a CD-ROM (the electronic proceedings). Obviously, people may prefer the CD-ROM to the proceedings book because the latter is difficult to carry whereas the former provides better search-ability for articles.

A carrier for a learning knowledge needs to be described in terms of a set of modeling attributes to distinguish it from other carriers.

4. Learning Intensity

Learning intensity indicates a spectrum of learning domain, where at one end the knowledge collection is common sense and on the other the knowledge collection from the experts. In other words, if we assume a scale to represent the learning intensity of how easy a course to be learned, we can say five degrees of very easy, easy, medium, difficult, and very difficult. For example, we may say the knowledge intensity increases in mathematics from primary school to high school. The importance of identifying the knowledge intensity (degree of ease-difficulty) for learning objects lies in the fact in which people need select learning objects according to their requirements, experiences and the already acquired knowledge.

The attributes used to describe the learning intensity can be included in those to describe a learning domain or a set of learning objects. However, these attributes are of special interest so that we need to consider them alone.

5. Three Dimension Structure

The above discussed aspects for learning objects can be grouped together to form a three dimension view or three dimension structure for describing learning objects. In other words, we intend to build up a metadata description framework (metadata model) for structuring learning resources. The metadata model will contain constructs based on the consideration of these three dimensions of learning objects.

We define that a learning object, denoted as lo , has three associated metadata, i.e., learning content (lc), knowledge carrier (kc), and degree of knowledge intensity (ki), i.e., a learning object is $lo = (lc, kc, ki)$.

The three types of metadata components are three sets of attributes for a learning object, each having the form of $\langle a_1, a_2, \dots, a_i \rangle$. The attributes of learning content for a learning object, e.g., a book, include subject, keyword, etc. The attributes of knowledge carriers, e.g. video, include topic, size, playtime, etc. The attributes of knowledge intensity degree for, e.g. lesson, include level, target group characteristics, etc.

One major requirement on the metadata model is that the model should be in accordance with the RDF (Resource Description Framework) Model, recommended by the World Wide Web Consortium (W3C) as an international metadata standard. The foundation of the RDF Model is a model for representing named properties and property values, with a form of

$\langle r, p, v \rangle$,

where r , p , and v stand for resource, property of the resource, and value of the property respectively. Using this RDF Model representation form, we can express a learning object as

$\langle lo, lc, lc.attr_list \rangle$

$\langle lo, kc, kc.attr_list \rangle$

$\langle lo, ki, ki.attr_list \rangle$.

Here $attr_list$ is a list of attributes and can be seen as a set of resources, which in turn have their own property and value. For example, $\langle BOOK, lc, SUBJECT \rangle$ and $\langle SUBJECT, "is", "metadata" \rangle$ represent a resource BOOK has as its learning content attribute SUBJECT with a value of "metadata".

6. The Use of Three Dimension Structure for Learning Objects

The diversity and massiveness of learning resources over the Internet brings the convenience for people to access to various types of learning knowledge but at the same time reveals the difficulty of quickly searching for exact learning information people require. A well-structured representation for these learning resources in a learning domain is indispensable [Song 1999b]. Our three dimension structure is proposed to meet this users' requirement. This description framework can be used as a metadata model or embedded in learning information systems as a basic structure for learning knowledge representation. Since the model distinguishes a learning object (resource) among its content, carrier, and degree of knowledge intensity, it greatly supports classification and management of learning domain. The application of the description framework can also be extended to other application areas, for example, digital document management and exchange [Ekengren 1999].

7. Conclusion

The three dimension structure for learning objects is developed at the SITI project LOUIS (Learning Objects for Usable Information Systems). Its advantages include helping people to consider a learning object along different lines of thought and to discover intrinsic structure of learning objects. As an example, it is suggested to include a fourth dimension to our description framework, i.e., process or versioning of learning objects.

An important phase closely related to learning objects is a so called "concept catalog", where a learning domain specific vocabulary is maintained. The concept catalog provides an interpretation of "words" (values to attributes) for different types of the attributes for learning objects. These words are used for identification of various attributes. In the next step of the LOUIS project we attempt to define such concept catalog.

A Component-based Framework for Description and Management of Learning Objects

William W. Song and Mats B. Andersson
SITI, Box 1243, Isafjordsgatan 26, 164 28 Kista, Sweden

1. Introduction

The growth of the Internet and the World Wide Web is transforming teaching and learning at all levels of education in the workplace and at home [IMS]. The information pieces or resources for purposes of learning and education construct a new type of web resources. This new kind of web resources with quite distinct features is evolving on the Internet, called Learning Domain. An important characteristic of these resources (asynchronous systems) is that it can be used as a teaching medium as well as a source of knowledge about a subject area [MBA1, MBA2].

Two major parts, closely related to a learning domain, are learning resource providers and consumers. The information providers supply learning resources and the information consumers use the learning resources. Usually, learning information, such as courses, is stored and managed in an information system or a local web site. The supplier may give a sort of description of the structure of the information. This description is termed as metadata. A means for the information suppliers to describe metadata is called metadata model.

From the point of view of the resource consumers, they expect to easily find the exact learning knowledge they need. The requirements and goals express what sort of learning materials they are seeking. The consumers may also provide their profiles as support. Indeed, profiles are sometime quite helpful. However, these requirements and goals can be vague, ambiguous, and even in conflicts. The profiles provided by the end users are very likely incomplete and bias-prone.

In the next section, we describe several concepts used in the paper. In section 3, we propose a metadata model for learning objects through defining possible components within a learning domain. Then in section 4, we discuss an implementation issue for learning system based on a metadata tool. In the final section we conclude the paper with some discussions of our future work.

2. Basic concepts

Granularity of learning objects define a relation between the degree of accessibility and what kind of information motivated to offer and how it should be structured. The granularity or refinement of learning objects in a learning system depends on the content and the carriers of the content. What **granularity** (i.e., how deep we shall decompose an object or a component) we should achieve relies on the users' requirements [WS2].

No matter how an education system will be used, it is necessary to handle the learning content in a modular form. Such module in a learning system is called learning object. **Metadata** and **metadata model** are used to support the organization and structuring of learning objects.

Therefore, metadata modeling and granularity should be taken into account for the management of learning objects, while the premise for granularity is the decomposability of learning objects [WS1]. We consider to break down a learning object into a number of sub-objects, called **components**.

3. A Metadata Model for Learning Objects

We propose a framework of metadata model, in which each component (node) in the metadata model consists of two major parts. One is the data description part and the other the operation description part. The data description part provides a set of building constructs for designing a metadata-modeling schema for a web document. The operation description part provides a set of operations that apply to the data of the components.

The framework consists of two models, a data model for data description and a component model for component and operation description. The data model contains three primitive constructs: objects, describing the concepts for e.g. documents, relationships, describing relations between objects, and attributes, describing object properties.

The component model describes different types of metadata, including e.g. carriers and operations. We consider that each piece of information has a sort of carrier. For example, a movie is a carrier of a story. The story can as well use another carrier, e.g. a textual document.

An object can be any component or unit in a learning domain. A learning domain is a collection of any educational, training materials (objects) or information. The learning domain also contains one or several description structures for the organization and use of the learning objects. Information providers

are supplying learning objects for a learning domain along with some structures (metadata) for learning objects. Information consumers will obtain the learning objects, which may be reconstructed and integrated based on the consumers' requirements and needs.

An object is described by a set of attributes and relationships. The relationships in the set relate the object to other objects. A subset of the set of attributes and relationships may be able to uniquely identify the object, called identifier.

We also maintain two kinds of modeling structures in the metadata model. They are hierarchical structure and network structure. In the hierarchical structure of learning object components, we maintain three types of relationships: part-of, is-a, and sibling. These three types of relationships are used for defining basic decompositions of learning objects. The part-of relationship indicates the fact that an object is a part of another object. This relationship is also called whole-part relationship. This definition is very useful when we attempt to group a number of components from different learning objects to generate a new learning object. For instance, a table may consist of a flat and four legs.

In the network structure, learning objects are related to each other based on their natural relationships. For example, a course may be related to teachers, locations, payment methods, etc. That means, if we take the course, the teacher, the location, the payment method, as some nodes in the network structure, the relationships established between them will be given_by, located_at, paid_in, etc.

4. RdfClient: A prototype to represent Learning Objects

RdfClient is a tool for viewing an RDF (Resource Description Framework) schema or document [DK]. It is intended to support users to authorize a metadata modeling schema and document in terms of the RDF syntax and constructs. The RDF metadata framework is defined for the representation and communication of various information items from the Internet or Intranet. RdfClient can be considered among few tools for the metadata information description to support particularly a hierarchical structure for the description and management of digital documents.

Based on the metadata model discussed previously, we use RdfClient for illustration of the structure and the use of learning objects. We consider it very useful to include the operations such as decomposition and re-composition. In accordance with the learning object methods, we maintain a hierarchical structure for the learning objects. By using the tool, we maintain three main components, a hierarchical structure of metadata information for documents, a descriptive information of the metadata schema especially designed for the documents, and a group of binary elements of relationships (called property type in RDF) and values for the metadata information of the documents.

5. Conclusion

The report has described a particular metadata model for learning domain and an implementation for the model in a prototype. Our next step for the project, other than further development and refinement of the metadata model and prototype, we will tackle the following three problems.

1) Establishment of a network structure for representing learning objects, its coupling with the hierarchical structure, and mapping both structures to a repository. 2) Design of a graphical user interface for authoring learning objects and their relationships, as well as operations on the objects. 3) Design of a goal-matching mechanism. For example, if we see the users' requirements on a particular course, which need to be built out of the other course components, how to compose such course from a set of other existing course components can be considered to be a process of goal matching. This issue is extremely important when hundreds of courses are managed in the repository and about ten requirements proposed from a user for a particular course. The issue leads to what strategies can be adopted to match the user's goals and automatically or semi-automatically find the right course.

Abstract: This paper explores the social and cultural issues faced in creating a new technology-based university. Issues and decisions around policy, faculty, industry relationships, program definition, and the use of web-based technology are addressed in the context of creating the new Technical University of British Columbia.

There are very few new universities being created anywhere in the world. Imagine the opportunity to pioneer a new kind of university. A university with a high technology focus. A university committed to the use of educational technology for learning development and delivery. What cultural and social issues would you confront in creating this university? What form and function would this new university take in response to its mandate? As one of the few new universities in the world the Technical University of British Columbia (TechBC) is meeting the challenge of innovating a new university culture while moving from concept to reality quickly.

Canada's province of British Columbia passed a bill to create TechBC in December 1997. By law TechBC is to:

- contribute to the economic development of British Columbia
- offer undergraduate and graduate degree programs in technological fields
- be relevant, and at the forefront of, industrial and professional initiative
- create strong links with other post-secondary institutions, business, and labour
- conduct applied research and development in collaboration and cooperation with business and labour

Another part of the Act decreed the university to have a unicameral governance structure with no academic senate. Immediately upon its inception TechBC was faced with an international boycott by faculty associations. The boycott was triggered by concerns that this mandate and structure would result in a loss of academic freedom. In addition, while the act makes no mention of tenure, the minister responsible had publicly stated that TechBC would not have tenure. Even before the university had a program, or faculty, social issues had to be resolved.

In response to academic freedom concerns TechBC created a policy extending academic freedom to the whole university community, including students and staff. Within its governance structure an Academic Planning Board was created. The universities' Board of Governors can only make decisions on academic matters that have the concurrence of the Academic Planning Board. Based on these resolutions the boycott was lifted.

TechBC has taken advantage of being a clean slate startup by breaking free from the historical legacy and entrenched practise of tenure in traditional universities. Faculty are hired on renewable, term contracts and are expected to spend up to forty percent of their time doing applied research in partnership with industry. Term contracts and applied research enable TechBC to ensure programs and staff are plugged-in to industry needs and at the forefront of initiatives. TechBC has been attracting entrepreneurial faculty from around the world, who are keen to be part of a startup and contribute to the creation of a new university culture.

TechBC had the opportunity to devise new programs of study focused on technology. The resulting programs are one of its biggest social and cultural contributions. Initial program areas are Information Technology, Management and Technology, and Interactive Arts. To help define the content and scope Program Advisory Committees for each area were created with industry representation. Industry was asked:

- What kind of graduates do they get now?
- What kind of graduates would they like to get?
- What kind of program would need to be devised to give them the kind of graduates they want?

Information Technology integrates four areas of concentration into a single field; computer systems engineering, telecommunications engineering, software engineering and software systems. This integration breaks down departmentalized notions of computer science and electrical engineering found in traditional universities.

Management and Technology acknowledges the unique business practises of technology industries and the way technology is changing traditional ways of doing business in all sectors. Project management, e-commerce, and global business are integral parts of this new culture.

Interactive Arts is a new innovative program linking design and art practise to emerging technologies. Interactive Arts defines a whole new field of practise as applied to the creation of local media, linear media, network media, performance media, and mechanical media.

One of the exciting themes to emerge is the way these three program areas inform and integrate with each other. This is exemplified in the first year of study, called TechOne. Comprised of course elements from all three program areas, along with process elements of Team Dynamics, Effective Communication, and Learning and Information, TechOne creates a shared culture and common frame of reference for all learners regardless of which program area they intend to specialize in. The culture of TechOne establishes a technology foundation, understanding of business fundamentals, and an appreciation for the socio-cultural aspects of human use of technology. Integration between the three program areas continues in subsequent years through cross program projects, team teaching, and electives.

To foster integration even more, faculty are hired in to the university as a whole. There are no departments. Even the seating arrangements of faculty have been structured to mix and integrate faculty from all three areas together. Every effort is being made to create a new culture, free of siloed departments. Interdisciplinary communication between programs is a key ingredient of this new culture.

Educational technology is also shaping TechBC's culture. TechBC has evolved a integrated learning approach. Integrated learning combines the best practises of face-to-face learning with emerging web based technologies. At TechBC a part of every course is on-line. Some courses are a hundred percent on-line others only twenty or fifty percent. Integrated learning creates a flexible learning culture for learners reducing required attendance on campus from five days a week to one or two.

TechBC recognizes that reduced on-campus attendance creates a social issue. For many learners university life is as much a social experience as a learning one. To address this issue TechBC has created a three dimensional VRML world that creates a virtual version of a physical campus for social interaction. To enter TechBC World students choose and customize an avatar identity for themselves through their web browser. Entering into the VRML world learners can walk or fly through the entry garden, central commons, and in and out of buildings. When other avatars are encountered, interaction can occur via chat, whiteboard, physical gesture, and voice. Private conversations between groups of three or four people can be held in specific areas of TechBC World by enclosing the group in a small dome. Extensions to this networked TechBC World will include links to a digital library, presentation theatres, and art exhibition spaces.

TechBC is committed to collaborative team based learning. Face-to-face learning sessions are structured to de-emphasize lecture and instead create small work groups where teams of learners engage in discussion, projects, and case studies. This culture carries over into the on-line environment through the use of synchronous and asynchronous discussion, lab simulations, and networked communities of learning.

A major social issue that emerged around this new form of learning was the need to educate faculty on how to change from being lecturers to facilitators and the need to evolve a new form of course production. To address these needs TechBC established a group called Educational Technology and Learning whose role is to:

- develop models of learning that map to course content
- test and select emerging web-based educational technologies
- develop technology templates for faculty to use for course content development
- provide faculty development workshops that provide guidance on the use of technology and their new face-to-face role
- devise and assist with assessment methodologies
- manage the production process and schedule of course and program development
- find existing learning resources and negotiate licensing and copyright
- provide a production facility to suport the creation of new media learning resources

The Educational Technology and Learning group has emerged as an important cultural element of TechBC.

One final aspect of TechBC's new university culture is Corporate Education and Training. The fastest growing sector of today's educational market is the working adult. In today's high tech world the need to learn continues throughout your entire professional career. In recognition of these social changes, TechBC is committing to provide learning for its students not just to completion of a degree but for their entire career. TechBC has broken every one of its three credit courses into one credit modules. This modular design allows for mix and match creation of custom, corporate learning solutions. Small chunks of continuous learning can be provided right to learner desktops in the workplace. TechBC is leveraging its investment in educational technology to support learning infrastructure needs of knowledge-based companies and the lifelong learning needs of workers.

The cultural and social issues TechBC has grappled with reflect the societal aspects of pioneering the creation of a new, technology-enabled university. In the process of questioning and resolving these issues TechBC is

creating a new model for higher education. To further explore the evolving world of TechBC, refer to our web site at: <http://www.techbc.ca>.

Asynchronous Brainstorm: An Intranet Application for Creativity

Abstract: Informed by field observations of how proposals are handled in an organisation and inspired by the theoretical framework of organisational learning, I argue in favour of, and present design implications for, a web-based tool that facilitates organisational creativity through asynchronicity, anonymity, and persistency. However, early user feedback indicates that reward mechanisms must be addressed alongside the introduction of such IT artefacts.

1. Introduction

Many organisations encourage their members to submit improvement proposals. Often, these proposals are submitted to local Proposal-Handling Committees (PHC) that review the ideas. Good suggestions are usually rewarded in some way, while not so good proposals are rejected. However, I have noticed a few serious shortcomings with this traditional way of handling suggestions. First, the suggestions are seldom communicated sufficiently within the organisation: good ideas may be implemented locally but never heard of in other parts of the organisation. Other ideas may be prematurely rejected due to the PHC's limited cognitive capacity, the proposer's poor communication skills, bad timing, or being proposed in the wrong context. These ideas, good and bad, could have started other creative ideas elsewhere in the organisation, had they only been made public. Second, many ideas are never proposed at all. We may feel that our idea is not worthy of being submitted as an official proposal, or we may be reluctant to present "silly" ideas if we risk losing face in front of our colleagues. Instead, we keep our potentially revolutionary ideas to ourselves.

I seek to develop mechanisms that better support organisational creativity, and this paper describes ongoing work with a web application that addresses the above shortcomings by enabling asynchronous brainstorming.

2. Related Theory

[March 1999] observes that most new ideas are actually bad ideas. Thus, to generate something useful, many suggestions must be encouraged. Further, inspiration should be gathered from a variety of disciplines. [Kanter 1996] refers to such cross fertilisation as kaleidoscopic thinking. This is exactly what happens in a brainstorm session, where people from cross-disciplinary fields interact. Though each idea in itself may not be so bright, the associative process that each idea feeds generates many and often creative results. Another success factor for creativity is the absence of early critique. New ideas must be given sufficient time to mature and to be explored, says [March 1999], since good ideas look identical to bad ideas until they are tried. New ideas should therefore be shielded from criticism during their early stages, and given sufficient time to linger after the brainstorming has finished.

Anonymity needs also to be considered. An authority, e.g. a manager or an expert, can kill an idea simply by contributing to the debate, explaining "how things are". This, sometimes old, wisdom is then never challenged. However, if there is no telling whom the proposer is, the suggestions are judged from their content only, without unnecessary prejudice or bias, giving new ideas a better chance of surviving. [Poole *et al.* 1988] have shown that anonymity also leads to better results since social barriers to contributing are lowered.

It seems to have been established that generating many ideas and letting these be visible, possibly inspiring further thoughts, has a positive influence on the generating of good ideas. Further, all these ideas should be allowed to mature and to be explored without initial criticism. They should be both submitted and approached with an open and unbiased mind, which can be achieved through anonymous submitting. Informed by these theories I worked out some design principles from which I implemented a prototype.

3. Design Principles

Brainstorm is a prototype system that mimics the creative atmosphere often found in brainstorm sessions, where no suggestions are turned down but used to spawn new and possibly even better ideas. Unlike ordinary, real life brainstorm meetings, the prototype supports asynchronous, networked "brainstorming", eliminating the time and space restrictions that otherwise exist. Ideas are, often only very briefly, sketched in an email and submitted to a SMTP mailbox, from which *Brainstorm* adds them to a web page. The web was chosen for several reasons: a) it is accessible from all platforms; b) there are many tools available to help users find information, e.g. search engines and agent-based applications; c) asynchronicity is added to the sharing process, i.e. users do not have to be active simultaneously which removes the temporal restriction present in e.g. chat forums; d) the persistent nature of the web page allows the idea to linger long enough for it to be found by many different people in different locations and contexts.

Brainstorm lacks the possibilities to add comments directly to the proposal, as is otherwise the case in Usenet Newsgroups. This helps shielding the idea from public negative critique. While *Brainstorm* allows for anonymity by withholding the return address of the proposer and not showing it on the web page, it is possible to contact the proposer either to ask for or to provide information. This is achieved by clicking a hypertext link next to the proposal and typing in a message. A CGI-script will forward the comment to the original proposer, who remains unknown. Though such comments may contain criticism, the original idea remains publicly available and can serve as a seed for others, while the critique is not displayed.

4. A Discussion Regarding Future Work

I have tested an early beta version of *Brainstorm* in a large organisation, and discussed the problems with proposal handling, and the suggested design of *Brainstorm*, with PHCs and individual members. One question raised was what will happen if an initial idea, proposed by A, inspires B to generate a better idea, which then is modified by C to the great IDEA that receives acknowledgement by the PHC and renders a gratification? Should not A and B have some credit? If not, they are instead encouraged to keep their ideas to themselves to try to develop them into what C managed to come up with. Such a behaviour would be very unfortunate, since chances are that neither A, B, nor C would managed to create the IDEA on their own. The IDEA was probably the result of the interaction of A, B, and C - a social knowledge creation process that required the input from all three parties. The question is thus legitimate because without proper incentive, technology, if ever so user-friendly, will not be used. The problem is how to create the incentive system because as [March 1999] points out, we do not want to reward mistakes but we should encourage the creativity that sometimes leads to them.

In the future, I intend to study conventional brainstorm sessions in more depth, and I further plan to implement a full version of *Brainstorm* to answer the above and other questions. Brainstorming is normally only one aspect of group creativity, and for the whole process to work, other factors such as shared knowledge, commitment to common goals, and mutual trust must also be established [Bennet & Karat 1994]. It can be argued that this cannot be accomplished in an anonymous environment. However, *Brainstorm* is intended for an intra-organisational web where a minimum level of common objectives may be assumed to be in place. Further, the objective of *Brainstorm* is not to deliver a full environment for collaboration and co-operation, but to serve as a catalyst for creativity. The purpose is only to get ideas out in the open for the community to share and move forward with whatever seems useful.

Architectural Detailing at Random. An Interactive Artist-Made Book On-Line

Starla Stensaas
School of Art and Design
Southern Illinois University
stensaas@siu.edu

Abstract: *Architectural Detailing at Random* is an interactive artist-made book that was first considered in 1986 after shooting Polaroids of "details" encountered doing renovations in a small Wisconsin town, Random Lake. Because local people talk about what goes on in this village as being "at Random," I imagined a book focused on architectural details of a house renovated "at Random." I loved moving the Polaroids into different visual combinations and wanted to design a book that invited viewers to devise their own variations. This sense of a book without finite limits is another play on the title "at Random."

It wasn't until I started working with web page design in 1995, however, that I found a form that would allow for the interactivity I imagined. It had taken nearly a decade for the Internet to develop to a place where I could realize my earlier concept in physical media.

In 1986 while working on my M.F.A., I renovated a house in Random Lake, a small town 45 miles north of Milwaukee, Wisconsin. During the renovation, I shot 26 Polaroid images which I intended to use in an artist-made book I planned to title "Architectural Detailing at Random." Local people living in Random Lake talked about what went on in this small village as being "at Random," and I used that idea in my titled; I imagined a book that focused on small, everyday architectural details of a house renovated "at Random."

I also loved moving these Polaroids around in different visual combinations and wanted to design a book that invited the viewers to devise their own variations. This sense of a book without finite limits was another play on the title concept of being "at Random." Because Polaroids are a one-of-a-kind medium, however, the design implications for creating such a book were formidable. I abandoned this book, despite the strong images and the playful combinations I repeatedly discovered, because in 1986, I could not design or imagine a form that would allow for interactivity with the viewer.

I first considered the possibilities of hypertext in a very general sort of way in 1991 when I attended a conference sponsored by Apple. Over time, it dawned on me that a hypertext environment is an ideal one for looking at images in a variety of combinations and for inviting viewers to participate in creating other variations, "at random" or deliberately. I imagined a "book" in which the on-line viewer could see my favorite combinations of image and then choose their own combinations. I also imagined the site growing over time as image sequences from people around the globe were included.

Once I was able to imagine an on-line form for the book, my creative process became one of primarily solving technological problems. First were the issues anyone new to designing web pages faces--how to control image quality in a format that is readable for a variety of monitor resolutions. The web is not yet an ideal place for an artist or designer to control color and image integrity. It wasn't until I was nearly finished with the project that I realized there are also issues related to crossing platforms to consider. Although I am moderately satisfied with this site viewing it in a Windows format, I am much more pleased with the result in a Macintosh environment.

Next were issues of site structure. How would the viewer navigate through the site and how could I control the rhythm of that movement without inhibiting the viewer from engaging in the interactive aspects of the work? Surfing the net introduced me to the ways in which others were presenting "gallery" images, usually with pages of thumbnail images that could be seen in a larger format if the surfer had the patience to wait. This however, did not serve to focus the viewer on a sequence of images, which was central to my design concept. Instead, I used an actual gallery wall as a metaphor and presented screens one after the other as one might walk through a gallery.

Finally, there was the issue of interactivity. How was I to create a "studio" space in which viewers could move the Polaroids around, see them next to each other, and decide on their own combinations? For this work, I turned to a college senior with some experience with Java. We collaborated over the course of a semester, discussing possibilities that he would then translate into code. When the day finally came that six page files were added to the site to give it interactivity, I was struck the ways in which that moment of realization brought our generational differences into focus. In 1986 when I first conceived of pages that any viewer could arrange and rearrange, the young man who wrote the code for me was in fourth grade learning his multiplication tables. It took nearly a decade for his math skills and the Internet to develop to a place where I could realize my earlier concept in physical media. What he takes for granted as a young person entering his 20's, I couldn't even imagine as a graduate student a decade ago in my 30's.

But what does it matter if one artist moves from using the computer and traditional media to produce illuminated texts in a book format to creating books designed to be read on the web? On one hand, this work is merely one example of a natural progression that is taking place in the culture at large--the move from print to digital culture. On the other hand, this work insists on its existence despite formidable resistance from those cultural norms that measure and put value on "art." Most cultural measures of "success" of either artist or artwork are related to exhibiting and selling a product. The more "important" the work, the more exclusive the venues for exhibition and the higher the price for the sale.

On the web, however, the venue for exhibiting work is democratic and, aside from the issue of computer access, for the viewer the work is free. To try and distribute this work in traditional fine art venues is extremely difficult. To begin with, the standard documentation for viewing artwork, whether gallery owner, curator, juror for an exhibition, or faculty search committee, is the 35mm slide. To strip a web site, no matter how traditional the site, down to a 35mm slide is to take away the very features that placed the art on the web in the first place. Secondly, should someone actually decide from a slide to delve deeper and go to the site, even if the work is accepted for exhibition, the issue of equipment in the gallery becomes another formidable hurdle--one not experienced by the painter or printmaker. Lastly, should the work, by some miracle, actually be shown in the gallery, there is no product to be purchased by the art patron, collector, or museum curator, and in the case of interactive works no one artist who can make claim to the work produced on the site. The work simply doesn't fit the profile.

Art has traditionally been a place where culture has pushed forward, where new ways of looking at the world and our experience in it have found form and expression. Artists have been our cultural prophets. But in this age, art as a discipline is uneasy and wary of the technology; college courses in computer fine art often focus on making two-dimensional images that fit comfortably in frames and document well in 35mm slide. And those most engaged by the technology, those who have been instrumental in moving the technology forward have often come out of math, science, engineering and industry and do not often have backgrounds in visual art. We must find ways to facilitate conversations and collaborations across these disciplines, and in doing so, create spaces for art on the web that don't just mirror "art-making" from a paint and canvas point of view. We have a stake in learning what artists might make in and of cyberspace, for what they make has the potential to change the space itself.

The Effect of Motive on Response Rates in Web-based Surveys: A Proposal based on the Heuristic-Systematic Processing Model

Tracy L. Tuten

Bandilla@zuma-mannheim.de Email

Abstract

The process by which individuals perceive and make decisions about information on the World Wide Web (WWW) is an underexplored topic. This project seeks to gain an understanding of the motivational processes, which underlie decisions of individuals processing information from the WWW, particularly in a survey context. Understanding these processes may allow for the prediction and explanation of non-response, drop-out effects, and why some context effects occur in web-based survey data.

Background

The heuristic-systematic processing model (Chaiken 1980, 1987) suggests that there are two concurrent modes by which people process information and reach decisions: the heuristic mode and the systematic mode. Which mode predominates in a given situation depends on the individual's motivation and capacity to process detailed information. An individual who is unable (due to distractions) or unwilling (not motivated) to think carefully about information in a message will be more likely to apply simple decision rules (e.g., I can trust an expert). However, an individual who is able and motivated to process details will tend to use more effort and the analytic systematic mode.

The heuristic-systematic processing model (Chaiken 1980) assumes three broad motives: accuracy, defense, and impression motivation. An accuracy motivation tends to foster systematic processing in order that the individual holds accurate attitudes and beliefs (Chaiken 1980, 1987). A defense motivation reinforces important self-related beliefs through selectively processing information in a way that meets this need. An impression motivated individual expresses judgments as called for by the social situations in which they find themselves (Chaiken 1996) and may utilize either the heuristic or systematic mode. The model also recognizes that some individuals may have an absence of motivation (Chaiken 1996). These motives represent possible sources of bias and context effects in survey data. In other words, individuals with an accuracy motive are likely to seek to answer questions in an accurate fashion while individuals with a defense or impression motive may respond with a response that they feel to be safe and non-threatening.

In addition to motivation, an individual must also have the capacity to process information systematically. Ultimately, these antecedent variables result in a broad motive (accuracy, defense, and impression) which determines in part whether an individual uses heuristic or systematic processing of information. The information processing results in an attitude towards the information, a behavioral intention, and ultimately a behavior. In a survey context, the behavior may be nonresponse, response with accuracy, or a response with poor data quality due either to the defense motive or the impression motive.

Overview of Research Questions and Methods

As described above, the model suggests that individuals may use heuristic and/or systematic processing of information to form attitudes and behavioral intentions. The processing used is determined in part by the individual's motivation. Accuracy motivation, defense motivation, or impression motivation may motivate an individual. Dependent variables will be 1) self-selection of two types (type 1: nonresponse and type 2: dropouts under various treatment conditions) and 2) context effects or judgmental biases.

Research Question 1: The heuristic-systematic processing model predicts that when accuracy motivation is induced, a respondent will elaborate on the presented material with greater intensity (systematic processing). The common experimental treatment is to vary the personal relevance of the task or implications without suggesting a particular response. A literature search suggests that this relationship has not been applied to survey research. The question, then, is what effect does accuracy motivation have on nonresponse, drop out effects, and context effects.

Research Question 2: As noted in the heuristic-systematic processing model, the capacity to process information is necessary to use the systematic mode of processing. This capacity to process information may be hindered by the vast amount of information including text, graphical images, and banner ads present on each web page viewed. Thus, this clutter, or information overload, may represent a distraction to potential respondents and may reduce their ability to process information and increase their use of selective exposure. The result may be nonresponse or a tendency to use heuristic processing rather than the systematic processing desired for accurate responses. This path will be examined in the same method as Path 1 above, but with an additional condition: distracters, such as additional tasks to complete.

Research Question 3: The heuristic-systematic processing model predicts that when defense motivation is induced, a respondent will elaborate on the presented material with selectivity. In other words, respondents will choose to process and respond to material in such a way as to protect themselves. Respondents may desire protection when asked about a sensitive topic, when they question the purpose of a survey, or when they feel their privacy may be invaded. The question then is what effect does defense motivation have on nonresponse, drop out effects, and context effects.

Research Question 4: This path addresses the effect of impression motivation on the dependent variables. An impression motive may be induced if the individual is influenced by a perceived "audience." Individuals with an impression motivation processes presented material in such a way as to promote social goals. Thus, the result may be the presence of context effects.

AVSC International, 440 Ninth Avenue, New York, NY USA
E-mail: pharper@avsc.org

Abstract: In 1998, AVSC International, a nonprofit reproductive health agency working in over 25 developing world countries, began a three-year pilot project to explore potential applications of computer-based clinical training in low-resource clinics and hospitals. This paper describes the project and defines the content, technical, and administrative problems faced in developing and field testing materials on infection prevention during the first and second years of the project.

Introduction

Staff training has continually been identified as a priority need in developing world health facilities. These institutions have a strong, on-going need to train more health care workers, to maximize scarce training resources, to cut down on classroom time that interferes with the provision of services, and to decrease the costs associated with centralized training. There is also a clear need for systems that allow practicing medical staff to obtain technical updates and continuing medical education, as well as for training opportunities that arise as needed ("just-in-time" training) as opposed to centralized training that is attended just in case it is needed.

Distance learning, delivered to health care workers through laptops, desktops, or over the Internet, has the potential to help meet these training needs in a way that is continuous, on-site, and interactive. However, because of the significant challenges posed by the limited computer availability and limited Internet access, very little has been done to attempt to reach this audience with computer-based training methods. Believing that CBT has enormous implications for the future reach of health education in the developing world, AVSC International has undertaken a three-year project to investigate the delivery of Internet- and CD-ROM-based health education in these settings. This paper describes the activities in the first year and a half of the project, which has focused on materials development and field testing, as well as on developing training approaches and forging partnerships with national and local health care institutions toward the institutionalization of technology-based approaches to training in these settings.

Materials Development and Training Approaches

Content Selection

There were three primary criteria in selecting the content for the first phase of the project: 1) that it be on a critical topic relevant and appropriate to a global audience of health providers in settings ranging from large urban hospitals to small, rural clinics; 2) that it be in an area that lends itself well to a self-instructional format; and 3) that it be on a topic on which paper-based training materials for this audience had already been prepared and field tested. The topic of infection prevention was selected as meeting all three requirements. Adequate infection prevention, which is crucial to the safety of all health workers and their clients, is a particularly important topic for the target audience: with limited staff, training, equipment, and funds, developing world health facilities are, unfortunately, ideal settings for transmission of deadly diseases, such as HIV and hepatitis B infection. This topic is particularly well-suited for self-instruction, since the content is largely knowledge-based, and most of the skills-based content (such as procedures for instrument processing, surgical scrub, and gloving) can be easily conveyed through video or still illustration. In addition, adequate material for repurposing was available: at the beginning of the project, AVSC had just completed field testing of a comprehensive, global curriculum on infection prevention in Africa and Asia.

Training Delivery Models and Course Design

While it can be said that the Internet is becoming truly global, connectivity and hardware in developing world health facilities range from state-of-the-art to nonexistent. While some countries maintain access to all Internet protocols, others are limited to e-

BEST COPY AVAILABLE

1468

mail only. In some countries, Internet connectivity can be achieved by telephone; in others, Internet users must rely on satellite or radio technology, bypassing unreliable or nonexistent telephone services. Although computers are slowly becoming more widely available, in many cases, access is limited to the "technological elite" of international corporations, governments, and universities. Even when computers and Internet connectivity are available, unreliable electricity or telephone services can render equipment and ISP services unusable for significant periods of time.

To meet these challenges and to accommodate the widest possible number of users demanded the development of highly flexible products and delivery models. AVSC developed four products (a CD-ROM, a reference booklet as a "leave-behind" for users who would have only temporary access to the CD-ROM, a Web-based course, and an instruction booklet with guidelines and training activities for online trainers) and four scenarios for training delivery: 1) instructor-led asynchronous Internet training for pre-defined groups of learners with individual e-mail accounts and fairly reliable Internet access; 2) self-instructional Web training for individual learners with occasional access to the Internet; 3) self-instructional CD-ROM (with reference booklet) for use on a trainer-supplied laptop while the trainer is conducting one-on-one clinical skills training with other staff; and 4) self-instructional CD-ROM (with reference booklet) for learners with access to a stand-alone computer.

Both the CD-ROM and the Web course have a simple, modular design, with content focused on low-cost strategies for assessing and improving existing infection prevention practices. The CD-ROM, which is designed to provide approximately two hours of instruction when used as part of a clinical training, presents a broad overview of infection prevention and presents training content in six critical areas. The Web-based course covers the same topics, but does so in much greater detail and is more centered on immediate and practical application of the material within a clinic setting. For example, in the Web course, each module is accompanied by a "Making It Work" section which contains a package of materials optimized for printing - including skills checklists, signs and posters, implementation guidelines, educational aids, practice surveys, and instructions for building devices such as an oil-drum incinerator or waste-disposal pit.

Because it was designed for users who do not regularly have access to a computer, the greatest design challenge for the CD-ROM was to develop a lively, interesting product with navigation simple enough for users with little or no computer experience which, at the same time, would not be tedious for more experienced users. In the Web course, the greatest challenge was to present interesting visual content and interactivity while adhering to universal accessibility standards.

Each of the four delivery scenarios has both advantages and drawbacks. For example, the asynchronous, instructor-led Web course allows the trainer to reach a far-flung group of learners, tailor the course to individual needs, facilitate group discussions and training activities, gauge knowledge transfer, and provide focused, individual attention to learners. However, the amount of individual instruction needed demands a small training group, and the requirements of an individual e-mail account and reliable internet connectivity are additional limiting factors. Although the CD-ROM product is more interactive, more visually stimulating, and easier to use than the Web course, it is also less comprehensive in scope and more expensive to produce.

Initial Field Testing and Evaluation

The diversity of training products and delivery models has also presented challenges for evaluation and field testing of the products. During field testing, the project's focus is on measuring knowledge transfer, user satisfaction, ease of use, and individual sites' current technical capacity to deliver computer-based instruction. Testing is being conducted through a combination of pre- and post-tests, electronic data collection, user surveys, direct observation, and interviews. Field tests of the CD-ROM product are being conducted in collaboration with in-country partner institutions during regular clinical training sessions with a goal of laying the groundwork for future collaborations regarding the use of instructional technology to enhance service delivery. At this point, mid-way through year two of the project, data from the first instructor-led Web course is being compiled, as is the data from the first field test of the CD-ROM product, which was conducted with doctors, nurses, and trainers from four institutions in Nepal (including a medical college, an association of private practice doctors, a group of medical trainers, and medical staff of a family planning clinic). Plans for additional testing of both products are currently underway.

For the online Web course, the initial group of participants was notable in that it consisted of 20 self-selected participants (15 doctors, three nurses, and two representatives of international health agencies) from 14 countries (Brazil, Colombia, Egypt, England, Republic of Georgia, India, Mexico, Nigeria, Pakistan, the Philippines, Tanzania, Thailand, United States, and Zambia) who responded to a request for beta testers for the site. It is also notable that five of these participants encountered serious technical problems with their Internet or telephone service during the first two weeks of the four-week course and were forced to drop out. During subsequent testing of the instructor-led course, participant groups will be more narrowly defined, and testing will be conducted in collaboration with in-country partner institutions.

The current explosion of information technology presents numerous challenges and possibilities for public health in the developing world. While the enormous growth in this technology in the developed world threatens to further deepen existing inequalities, it also holds out the promise of improved access to education, health care, and information.

Creating Multimedia Learning Environments for the World Wide Web Using SMIL Technology

Sebastian Uijtdehaage, Ph.D., Anju Relan, Ph.D.
Instructional Design & Technology Unit, UCLA School of Medicine, Los Angeles, CA, USA.
Email: bas@ucla.edu

Abstract: Synchronized Multimedia Integration Language (SMIL) became a W3C standard in 1998 and greatly facilitated the production of web-based multimedia applications. SMIL enables precise synchronization of streaming video, audio, text and images over the web, and streamlines the creation of effective multimedia learning environments. This paper presents and example of a web-based presentation made for a Neuroscience course and discusses production and implementation issues.

Introduction

This short paper describes a new technology that greatly facilitates creating multimedia learning environments for the World Wide Web: the Synchronized Multimedia Integration Language (SMIL). With escalating use of the WWW in education, instructors have been exploring the use of multimedia on the web to promote educational outcomes. Synchronized, hyperlinked multimedia ("hypermedia") could represent content in an engaging and meaningful way for students. Specifically, hypermedia could stress the conceptual inter-relatedness of ideas, provide multiple representations of the content, and could position the information in a real-life context (Hall, 1998, Jonassen, et al. 1997).

Until recently, creating web-based multimedia presentations was cumbersome. Synchronizing sound and images, for instance, required tedious editing and extensive JavaScript programming. This, however, has begun to change. During 1998, two industry standards were accepted that would open new avenues to effective multimedia development. First, the W3C approved SMIL (pronounced "smile") for multimedia integration and layout on the Web. Secondly, Real Time Streaming Protocol (RTSP) became the IETF standard for client-server transport of audio and video.

What is Synchronized Multimedia Integration Language (SMIL)?

With the introduction of SMIL a web developer can now become an effective "choreographer" of multimedia. SMIL gives a developer the ability to synchronize text, images, audio, and even video over the Web. A typical SMIL presentation consists of several components. Each component can be of a different media type and can be combined with simple HTML-like coding. Like an orchestra conductor, SMIL determines when each component starts and stops playing. For example, a particular image can be displayed only at the time during which the narrator in a video describes a certain topic.

One feature that makes a SMIL application particularly powerful is the ability to create hyperlinked hotspots on images, text and even on videos. These hyperlinks could launch a different SMIL presentation, jump forward or backward in the current presentation, or open a new website in the browser. For instance, by using hyperlinks, a video-on-demand interface can be created. Figure 1 illustrates a video-on-demand application developed at UCLA that includes video, images, text, and hyperlinks. SMIL documents are best displayed with Real-Time Streaming Protocol (RTSP), developed by Netscape®, RealNetworks®, and Columbia University. With client software such as the RealPlayer G2™ one can view a SMIL document using VCR-like controls ("play", "pause", "fast forward", and "rewind"). In addition, it is possible to embed a SMIL presentation in a webpage without the need of launching RealPlayer as a separate application.

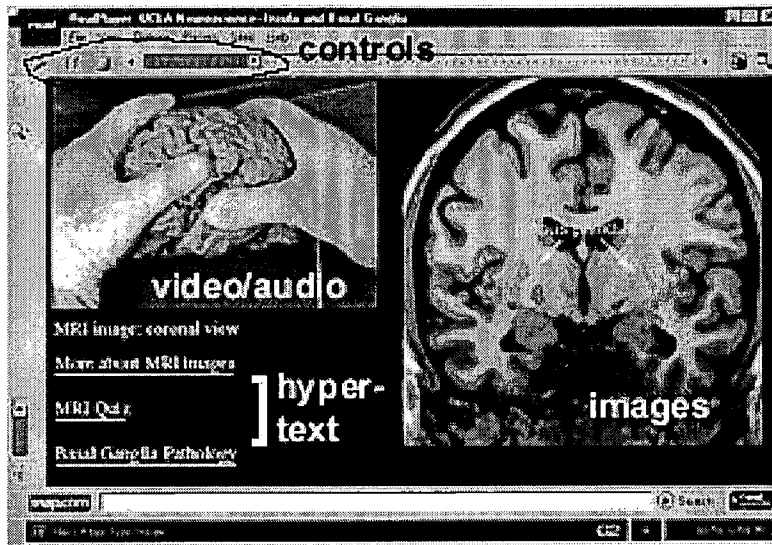

Figure 1: SMIL multimedia presentation including video, audio, images, hypertext and play controls.

How are SMIL presentations created?

SMIL is a straightforward, XML-based mark-up language, similar to HTML. Developers can use a simple text editor to write SMIL files or use specialized authoring programs. These authoring programs serve several purposes. First, they create the SMIL files in which the content, the layout, and sequencing of the multimedia components are coded. Secondly, these applications encode images, audio, video, and text in the appropriate format compatible with RTSP.

How are SMIL presentations implemented?

During this short paper presentation, an example SMIL application made for a Neuroscience course will be demonstrated. This application includes a video of a brain dissection, synchronized images and hypertext. The text and images appear and disappear depending upon the content of the video. We will address implementation issues, such as bandwidth issues, limitations, costs, and required programming expertise.

Conclusion

SMIL provides educational web developers with a powerful tool for creating effective multimedia learning environments. By virtue of the transparent nature of the SMIL language and of the relatively low start-up costs, web-based multimedia presentation can now be easily developed and implemented.

Tools for a Design, Development and Management of Multidisciplinary Multimedia Web-Based Courses

Vladimir Uskov and Maria Uskova
Department of Mathematics, Physics, and Computing Technology
OMI-College of Applied Science
University of Cincinnati, USA
Vladimir.Uskov@UC.edu, Maria.Uskova@UC.edu

Abstract: Web-Based Education (WBE) is a new teaching medium. This means learning new skills, new teaching methods and practices, and gaining a fresh outlook. Becoming familiar with a variety of tools for WBE (WBE tools) is a good first step for a design and development of Web-based curricula and courses. This paper 1) presents a list of several available WBE tools, and 2) describes the methodology and selection process of tools for a design and development of multidisciplinary multimedia WBE courses that provided best fit for instructors of the OMI College of Applied Science (OCAS), University of Cincinnati, OH, USA.

1. Introduction

WBE is the largest growing segment of higher and corporate education today. With the increasingly tight demands on people's schedules, and the need for continuing education to advance in the workplace, the ability to take courses via the Internet that fit into their lifestyle is attracting an unprecedented influx of students to colleges and universities worldwide. Experts say that 1) the number of WBE students will more than triple in the next three years, and 2) the cost of WBE may be as low as 25% of traditional classroom-based education. Studies show that "WBE students perform as well as, or better than, those in traditional classrooms" [<http://tenb.mta.ca/phenom/phenom.html>]. "Participation increases, retention is higher, and they're prone to express their ideas more often and in greater depth. WBE instructors are able to offer more personal and detailed guidance than in a traditional classroom, and they can do it unbound from a strict class schedule" [Martin 97].

2. Tools for Web-Based Education

Between April 1, 1998 and May 31, 1999, the members of the OCAS Distance Education Committee (OCAS DEC) and other OCAS computer professionals searched the Web, a huge number of periodicals, monographs, and conference proceedings in search of an application to deliver multidisciplinary multimedia Web-based courses to OCAS students in variety of technological areas such as Information Engineering Technology (IET), Mechanical Engineering Technology (MET), Chemical Technology (ChemT), Fire Science, and Humanities and Social Science.

The members of OCAS DEC performed a research on multiple features and capabilities of WBE tools that help to design, develop, maintain and manage multidisciplinary WBE curricula and courses. Vendors were contacted for demo versions of products. The members of OCAS DEC met regularly to discuss various WBE-related issues, and, specifically, advantages, disadvantages, features, and problems encountered during pilot course creation. More than twenty available WBE tools were selected for analysis on the first stage of research. They were ToolBook Assistant/Librarian [www.asymetrix.com], AuthorWare [www.macromedia.com], ClassWare [classware.uc.edu], Convene [www.convene.com], CourseInfo [www.blackboard.net/courseinfo], Director [www.macromedia.com], FirstClass Collaborative Classroom [www.education.softarc.com], Front Page'98 [www.microsoft.com], Intrakal [www.anlon.com], Learning Space [www.lotus.com/learningspace], MentorWare [www.mentorware.com], TopClass [www.wbtsystems.com/index.html], Virtual-U [virtual-u.cs.sfu.ca/vuweb], Web Course in a Box [www.madduck.com/wcbinfo.wcb.html], WebCT [www.webct.com], Webmentor Enterprise [avilar.adasoft.com], as well as Norton Connect, Allaire Forum, Team Wave, WebBoard, QuestionMark, and PlaceWare.

3. Selection Methodology

To analyze the above-mentioned WBE tools, OCAS DEC used a) available general [Gray 98] and b) additional particular criteria that are critical for the OCAS multidisciplinary multimedia Web-based courses. The list of criteria included but was not limited to

- 3.1. **WBE tools for various technological areas (or, in other words, multidisciplinary aspect of WBE tools)** such as Information Engineering Technology, Mechanical Engineering Technology, Chemical Technology, Electrical Engineering Technology, Fire Science, and Humanities and Social Science;
- 3.2. **WBE tools for instructors with variety of backgrounds** such as 1) with background in Computer Science , 2) with no computer background at all;
- 3.3. **WBE tool purpose:** 1) a tool for WBE course's design and development, 2) a tool for WBE courses' management, and 3) a tool for various types of WBE collaboration and communication;
- 3.4. **Instructor tools for WBE:** 1) course planning, 2) course managing, 3) rapid course revising and modification, 4) easy course monitoring, 5) course templates and tools for easy lesson design and development, 6) instructor-created sample courses, 7) tools for presentations, 8) variety of available libraries of icons, images, pictures, audio and video files, and 9) specific search engines;
- 3.5. **Student tools for WBE:** 1) self-assessing tools, 2) progress tracking, 3) motivation building tools (to build student own home pages without any HTML knowledge), and 4) tools for study skill building (i.e. grades online, change of passwords online, online note taking, study-guide generation of topics selected by student);
- 3.6. **WBE course communication features (or, in other words, multimedia aspect of WBE tools):** asynchronous sharing such as 1) email (one-to-one and one-to-many), 2) discussion facilities via searchable threaded bulletin board system (BBS), 3) newsgroup facility, and synchronous sharing such as 4) discussion facilities via electronic chat room, moderated online teamware, and group discussion board, 5) shared whiteboard, 6) video conferencing, 7) audio conferencing, 9) data conferencing or file sharing;
- 3.7. **WBE course management features:** 1) automated calendaring system and automated reminder system, 2) student online testing and automated grading, 3) student activity summary report and online gradebook, 4) timed quizzes/midterms/tests/final exams, 5) office hour facility, and 6) variety of class lists, 7) online student and instructor manuals, and online help system;
- 3.8. **WBE course administrative features:** 1) variety of levels of security, 2) online technical support, and 3) student honesty checking;
- 3.9. **WBE tools technical requirements:** 1) requirements for server platform (RAM, disk space, operating system, etc.), 2) requirements for client platform (minimal level), and 3) limitations of WBE tool;
- 3.10. **WBE tools pricing:** 1) prices, 2) number of student accounts per copy of WBE tool, 3) educational discounts, 4) availability of free demo version on the Web, and 5) extra considerations.

4. Findings

On a basis of results of performed research and completed search:

1. The OCAS DEC decided that currently there is no single WBE tool that is optimal for OCAS and meets all of OCAS above-mentioned criteria, requirements and expectations.
2. The great variety of available WBE tools was reduced to several tools for further careful in-depth consideration. The following WBE tools were recommended for utilization in OCAS WBE-related activities:
 - a) WBE tools for instructors with strong background in the Computer Science area and, specifically, for the newly established Information Engineering Technology (IET) degree program [Uskov&Saad&Uskova98]: WebCT, Asymetrix ToolBook II Librarian, and Macromedia Director tools;
 - b) WBE tools for instructors with no computer background: Macromedia AuthorWare, ClassWare, WebCT, and Asymetrix ToolBook II Assistant tools.

Integrating Administration with a Learning Environment on the Web – Case Study

Jari Vanha-Eskola, M.Sc.
Web Research and Development Team, Open University of Helsinki, Finland
E-mail: Jari.Vanha-Eskola@helsinki.fi, <http://www.avoin.helsinki.fi/>

Abstract: The Open University of Helsinki provides a learning environment and virtual courses as an alternative to traditional teaching. The project began as plain HTML pages in January 1998 and has gradually evolved into a comprehensive learning environment adapted to accommodate for our needs in course administration. This paper provides an overview of our learning environment and its uses.

Overview

Virtual courses and environments are becoming a necessity for all self-respecting educational institutions, and many already offer virtual courses as part of their repertoire. A lot has, and is, being said about how to design the courses and how they enhance (or hinder) the study process. New learning environments and applications, each better than the previous ones, are emerging on the market and promise integration of traditional teaching techniques with the Web.

However, ready-made applications and learning environments often have many kinds of restrictions on what can be done, and how. Indeed, organizations usually have to adapt their own process to that of the application software. Also, software is mostly centered on virtual courses, whereas other supplementary processes are often neglected.

The purpose of this paper is to promote integration of administrative processes with the learning environment, and present our solution as an example and basis for discussion. Instead of designing a virtual course, organizations could adapt the whole process to the Web, leading the student from idea to completion.

Student's View: Inside the Learning Environment

The open university is open to all, regardless of age and educational background. The teaching is equivalent to basic university teaching, and is offered at low cost by law. All goals of study are equal to universities and all study is part-time. The Open University of Helsinki has 25,000 students and 17 years of experience in distance education. It is not a separate educational organization, but part of the University of Helsinki which is the largest university in Finland.

Our Web service is a comprehensive environment that provides most of our basic services. Information is accessible anytime anywhere, and student counseling has actually been enriched by the Web: students can e-mail their questions or check our frequently asked questions lists to get answers. Tutoring pages offer information about the requirements for access to open universities and facts about assessment, virtual courses for improving study skills, and stories of experienced students. Even online counseling is possible at set hours.

Additional services are open for users who have joined in as members of our Web service. Membership is free and instantly available to everyone by filling in a registration form. Membership services center around the Student Club providing less formal services for students: local e-mail (inMail), student introductions, and discussion groups. Membership grants access to all exam results and various self-study materials. The purpose of the Web membership is to socialize students, encourage frequent use, and personalize our service.

Members can enroll on our virtual courses which are show-cased on the Web. Enrollment is possible through a Web form if there's room on the course (up-to-date status is displayed in the show-case; some course groups even allow queuing). After registration the student is informed of what steps to take next; whether she's to wait for an opening on the course or to pay the study fee. Currently study fees cannot be paid on the Web, but we have plans of including that option this year. When the study fee has been paid the student is granted access to the course and informed of the course details. If placed in the queue, the student will be notified automatically by e-mail when there's an opening on the course and provided with instructions on how to proceed.

In the beginning of 1999, we offered 20 virtual courses ranging from Computer Science to Theology. Some courses can take an unlimited number of participants, whereas others have a set number of students per group. Some can be studied all the time, while others have groups beginning at set intervals.

Because the study process is different on each virtual course, each course has been tailored individually to meet the pedagogical and didactical needs for the particular subject. Some of the courses are a combination of different forms; The Web, Classroom Teaching and Group Work. Sometimes the interactive part of learning is going on in discussion groups or study diaries, other courses lay stress on written materials and links, and some add audio/videoconferencing or face-to-face sessions.

Most courses still require a written test that cannot be taken on the Web (restriction set by university administration). Students have to sign up for tests, and for virtual courses that is done solely on the Web. Students post a pre-filled form and are then informed of their status, whether they can participate in the test or whether they'll have to pay a registration fee (some tests require an additional fee). When the student has successfully completed the course, the results are posted on the Web in the student club. After completing a virtual course the student is asked to fill out an evaluation form that is sent to our research team for analysis.

Administrative View: Interfacing with the System

All personnel interacts with the system through a Web browser with specific tools designed to manage the study process. InMail or Internet mail can be sent to certain subsets of our Web members (by course, group, test, payment status etc.). Naturally we also have tools for administering memberships (accounts, passwords, user information), course information, course enrollment, and exam sign-up. The system manages course dates, informing students about the date they'll be allowed access and warning them two weeks in advance about the expiration of their course access. The same process is applied to course and exam sign-up which expire if the student hasn't paid the study fee within two weeks of sign-up. Exam supervisors and teachers are automatically notified when exams are due for processing. And in addition to virtual course sign-up, it is also possible to sign-up for normal exams on the Web. However, at the moment only virtual courses are handled automatically.

All courses are individually tailored by our Web team, with a research team contributing to the course development process. Course design tools are not yet provided for the teachers since course production and updating usually requires programming or HTML coding. Pure text updates are actually quite rare, and teachers haven't expressed much interest in learning to design Web pages themselves. However, we are developing a course design package to combine course production unity, flexibility, and high class editing work with easy modification possibilities for the teachers.

Our course design team has several common tools at their disposal, e.g. inMail, notebook & study diary, discussion groups, and course calendar. In addition, different exercise applications have been developed for individual courses and can easily be adapted to other purposes (e.g. multiple choice tests, automatic feedback). For research purposes, we can obtain individual session paths from our Web server log to study individual students' actions anonymously. Other statistical data can also be computed from the log.

Conclusion

Instead of choosing from commercial applications, we decided to implement the learning environment ourselves. That enabled us to have total control of all the details, including system language, course design process, page layout and structure, and administrative processes. The main emphasis was on custom-tailoring, flexibility, and continuing development process. The learning environment development is done by a full-time, closely collaborating Web research and development team consisting of content specialists, researchers and experts in programming and systems design, Web design and layout, and Web-based learning processes.

The road that we have chosen may not be the easiest. Indeed, it does require a lot of work and involvement from the whole team. We need to have people working on Web projects full-time and a programmer / systems designer devoted to the project. But on the other hand, this process has taught us a lot about Web environments and made their use easier for our personnel since they get to participate in the process of implementing their work routines on the Web. The end result is a flexible environment that matches our needs and can easily be modified to include new cutting edge techniques, helps personnel do their work more effectively, and covers the whole process students need to go through for studying.

The CATCHUM Consortium: Developing a Cancer Prevention Curriculum using the World Wide Web

Introduction

A website can serve many functions for different organizations. Some will use it for publicity, some for commerce, some for learning and training and a few for all these purposes. The following case study shows how a statewide network of institutions has designed a website as a tool for collaborative efforts, for sharing of resources, and for dissemination of consortium-developed products.

Case study

The Cancer Teaching and Curriculum Enhancement in Undergraduate Medicine project (CATCHUM) is a grant funded effort with the goal of developing a cancer prevention curriculum for undergraduate medicine. To achieve this goal, CATCHUM activities are developed through a consortium consisting of eight medical institutions in the State of Texas. Faculty and staff from each of these eight medical institutions were nominated to the various task forces of CATCHUM depending on their area of expertise. CATCHUM is the only consortium-based project involving all the medical institutions in the state. Collaboration and resource sharing are the main key to the success of this project. To achieve project goals, faculty with multiple areas of expertise voluntarily joined their intellect and knowledge of content and technology to devise innovative approaches to advancing cancer prevention and control. Early on, the consortium saw the utility of the Internet and the World Wide Web as a means to publicize CATCHUM, to disseminate CATCHUM created products, and to collect data. Although the earlier website served these purposes, over time it became apparent that the basic structure of the site needed improvement.

The Educational Technology Task Force (ETTF) was charged with revising the website into one that was more interactive and user-friendly. The objectives of the website are to provide clinicians, faculty, and undergraduate medical students, with an easier access to information on cancer prevention and clinical screening. A professional web developer designed and developed the CATCHUM website in conjunction with the ETTF. The website (<http://www.catchum.utmb.edu>) contains background information on the project and explains the rationale and need for developing a cancer prevention curriculum in undergraduate medicine. It also provides information on the various task forces and educational resources.

The CATCHUM website has greatly assisted with collaboration and resource sharing. An important use of the website is to distribute Objective Structured Clinical Exam (OSCE) case studies. These are cancer-related case studies that have been developed by CATCHUM members to be used in teaching medical students. Having this information on the web makes it easy for any medical school, regardless of where they are located, to have access to it at any time. There is a concerted effort at present by all the medical schools in the consortium to incorporate some or all of these cases into their curriculum. The development of OSCEs has since been suspended temporarily and given way to the development of Problem Based Learning (PBL) cases that also will be available from the CATCHUM website. Some medical schools in the consortium are planning to incorporate the first four developed PBL cases into their curriculum in Fall 1999. Collaboration and resource sharing was facilitated by the CATCHUM website when developing Standardized Assessment Project (SAP) Exams. Students from all the medical schools in the consortium tested the exams on-line. Using the website to deliver and collect the exams held advantages over attempting to deliver and collect paper tests. The question bank has been updated and students from all the medical schools in the consortium can register on-line in order to take the original SAP exams. The newly developed exams are only available to faculty with prior approval at this time.

The website has proven to be helpful to instructors responsible for teaching medical students as it contains lectures and Power Point presentations on various topics related to cancer. Faculty from the medical schools in the consortium, are encouraged to look at other's lectures and to add their own to the CATCHUM website. There is also a Related Links page, which connects educators to a number of websites worldwide, related to cancer prevention and control. Other resources include the newly developed cancer education modules for the community preceptors, who are physicians in the community training medical students in their setting. These modules consist of cancer prevention and control information for physicians to educate and evaluate medical students under their supervision. These modules will be available for download in Fall 1999.

For the members of the various task forces, there are restricted areas on the website that provide them a place to communicate, to collaborate, and to post documents prior to making them publicly available on the website. Publicity on CATCHUM's website and its potential for students and faculty will be done through members of the Steering Committee, who will hold meetings with the faculty champions in their medical school. Faculty Champions are faculty who have been identified in each Texas medical school to promote an awareness in incorporating information related to cancer prevention and control into their curriculum. The faculty in turn will encourage their students to utilize the information found on the CATCHUM website to improve their knowledge base in cancer education.

Conclusion

In looking to the near future, CATCHUM envisions many possible uses for their website. One is to develop cancer related web-based clinical cases for students to review. The visual aspects and the interactive environment will enable students to show an active interest in cancer prevention and control. The other is to develop an interactive cancer risk assessment tool with a questionnaire for the students to complete and be reviewed instantly. Every effort will be made to make the modules interactive and user-friendly.

As Douglas Engelbart (1995) rightly pointed out that collaboration is the key to the success of any innovative undertaking because of the expertise that the members of a team bring to the table. No single person can hope to achieve the same degree of success as that of a team. Having said that, medical education is clearly catching onto this idea of a consortium-based environment for conducting projects, which will ultimately have an impact on the medical school curriculum. It is clear that the web will play a pivotal role in promoting CATCHUM's goals of developing a cancer prevention curriculum in undergraduate medicine, in the near future.

Knowledge Management in Education

Dr. M. Vernooy-Gerritsen
CPS, educational advisory center
Amersfoort, Netherlands
m.vernooy@cps.nl

Abstract: Knowledge Management is the set of practices and technology that leverages the value-added information that is mission-critical for organizations. Every school has a wealth of intellectual capital and experiences. Although it is of the highest value, this 'corporate asset' is also the most under-utilized. Teachers of different subject don't know the way of teaching of each other. Teachers can help teachers of their own school and of other schools. How can they exchange knowledge and best practices? How can they find the right information for their job in the right time? There is a growing need for an interactive knowledge bank for primary and secondary education, based on practical experiences.

Information

Primary schools in the Netherlands cater for children from four to twelve years of age. They are usually arranged into eight year-groups. Attainment targets have been formulated indicating the basic minimum that schools are required by law to teach their pupils in each area of the curriculum. However, schools have considerable freedom in the choice of course books and materials and they can also add their own emphases to the curriculum.

Secondary education changes from 1 August 1999. The main developments in secondary education relate to teaching itself. There are three interconnected aims: to further the broad personal development of all pupils, to promote an active and independent attitude towards learning and to cater for differences between pupils. These aims are the constant motif running through the recent reforms of the curriculum.

For each subject, the government has formulated new attainment targets defining the knowledge and skills which pupils must have acquired by the end of the period of basic secondary education. In these attainment targets, the emphasis is on coherence, particularly between the education provided and the pupil's own world. In addition, schools are given scope to cater for the differences between pupils. General educational objectives have also been formulated. These are not subject-based like the attainment targets but are cross-disciplinary objectives relating to social issues and skills. These general educational objectives are a compulsory aspect of basic secondary education, although how they can best be addressed is a matter, which is left to the subject departments in the individual school to agree amongst themselves.

All these reforms ask much of teachers and school heads. They are searching for any and all information that can help them get their jobs done and achieve their organizations' business objectives. Universities, national advisory centers, and other educational institutes give information, write papers, give courses, make lesson plans, and so on. But which course fits the lack of knowledge of a certain teacher in vocational secondary education teaching motor mechanics, caring occupations or commerce? A thematic interactive knowledge bank will help to find the way in the information rush. The interactive knowledge bank, accessible in several ways, will include questions, problems, traps, solutions, bench marks and best practices.

Knowledge

Information isn't knowledge until people add value to it, transforming raw data into advantages. Accessing and sharing information are only the beginning of the knowledge transformation process. Gradually, experience is growing in building knowledge systems to get improved achievements. Using ICT plays an important role in this. But, up to now, the role of ICT has been little more than a collection of electronic instruments for developing, establishing, and integrating knowledge and abilities within an organization. Many existing knowledge banks are therefore actually nothing more than automated filing cabinets. Knowledge and questions of people looking for answers themselves are not used. The results of these kinds of systems are disappointing. Modern knowledge systems, aimed at efficiency, take advantage of the practical expertise of professionals and of the questions they ask. A network of teachers or school managers, who are learning in an interactive way,

combines the learning opportunities of interaction in networks with the chances that ICT offers to make the knowledge of people explicit, as well as to record and to distribute it. In such a way, more aimed, better-equipped, and more effective networks can be established. A combination of physical and virtual networks, ranging the complete scale of necessary interactive knowledge activities: elucidating, making explicit, development, recording, filing, distribution and use.

New forms of learning in a school organization and an ever more critical environment ask for the development of learning networks. Networks of professionals who are to shape and give meaning to a new kind of learning. Much knowledge can be generated from the interaction among people with practical experiences. In these traditional networks the exchange and development of knowledge often remains among the participants. Another disadvantage is that the goals of these networks and with this the developed knowledge are often not connected with the goals and organization of the schools.

The success of personal (physical) networks of teachers and schools is indicative for the possible success of a virtual learning community.

Collaborative Knowledge Development

People taking action and working together to create projects, form teams, develop project deliverables, and manage projects and processes through their many stages and cycles. Capitalizing on your collective knowledge and intellectual assets takes more than a repository, some search and document management functionality. It takes collaborative knowledge management—a complete knowledge management system that addresses all elements of the knowledge process.

Coming years a knowledge management system for teachers in primary and secondary education in the Netherlands will be developed on Internet. It will be a portal to a mix of downloadable publications, courses, best practices, links to other web sites, theme discussion forums, all structured on a new way round profiles of functions and tasks. The Knowledge system for Education will be a thematic interactive knowledge bank, combined with other features as discussion groups on specific educational and organizational themes, coaching network members on the job by professional counselors, on-line fraternal consultation in a virtual staff room, and teleconferencing with experts on particular subject areas. The Knowledge system for Education will function as the carrier of a virtual work community through which teachers and school heads are to be given the opportunity to meet each other, to exchange thoughts, and where, on the basis of a personal knowledge and information profile, they can be referred to information and knowledge carriers, relevant to their work situation.

Applying the Hexa-C Metamodel of Instructional Theory and Design to Educational Web Applications

M.R. de Villiers

Department of Computer Science, University of South Africa, South Africa

E-mail: dvillmr@alpha.unisa.ac.za

Abstract: As the World Wide Web and Internet increasingly become delivery media and communication forums for educational purposes, guidelines for quality assurance of instructional sites should incorporate established principles of instructional theories, applied to these unique environments. Current directions and developments in learning theories and instructional design are overviewed and certain stances: cognitive science, constructivism, component-based instruction, customization, creativity, and collaboration, compositely called the Hexa-C Meta-model, are proposed as desirable characteristics of, and possible evaluation criteria for, educational web design.

1. Introduction

Developing materials for the World Wide Web (WWW) is fast and simple, bypassing the traditional processes of publishing and disseminating information. It is essential to maintain quality, particularly in sites and environments for teaching and learning. Instructional theories and instructional design were originated for text materials and later applied to computer-based products (de Villiers 1995; 1998). This paper relates such theories and practices to web-based applications, applying them to the specific characteristics of web-learning, but avoiding replication of print environments. The success of the WWW and Internet in education depends as much on instructional design as on technology (Cronje 1997). The paper overviews current instructional and learning theories, relates them to web design, and suggests six specific characteristics, compositely called the Hexa-C Metamodel, as desirable features of, and possible evaluation criteria for, instructional websites.

2. Learning Theories and Instructional Websites

Learning and instructional theories relate to the philosophy of education, whereas the discipline of instructional design (ID) defines characteristics of instructional products, aiming for optimal promotion of knowledge acquisition and skills in learners. ID proposes methodologies for the design and development of instructional media to make instruction effective, efficient and relevant. Various ID models exist (Reigeluth 1983; Wilson 1992; Merrill 1996), some being pragmatic definitions of instructional procedures, others based on instructional theory. Merrill (1996:6) defines instructional design as 'a technology for the development of learning experiences and environments which promote acquisition of specific knowledge and skills'. Reigeluth (1997) calls for clear links from learning theories to educational practice. There is increasing emphasis on instruction as the facilitation of learning, as well as imparting of knowledge - both roles in which the WWW can excel. Mehl (1993:13) states: 'The successful application of the computer in education is directly dependent upon instructional design ingenuity backed by a solid foundation in learning theory and learner research'. Judicious use of the WWW, based on relevant educational theories and appropriate ID principles, presents unique learning experiences.

3. The Hexa-C Metamodel of Instructional Theory and Design

The use of different theories in tandem is synergistic. This paper highlights six inter-related stances, referred to as the Hexa-C Metamodel, and discusses their impacts on instruction and learning. It is proposed that this model be applied, where appropriate, to provide guidelines for web-based learning sites and environments.

3.1 Cognitive science

Cognitive science relates to the reasoning and thinking processes as learners acquire knowledge and skills; it emphasizes active cognitive processing (Vockel 1989; Osman 1992). Perception and learning are viewed as reorganization of internal knowledge structures, as learners construct meaning by integrating new with existing knowledge (Inhelder & Piaget 1958) to facilitate comprehension and recall. Higher order thinking skills (HOTS) entail metacognition; critical and creative thinking; and the skills of classification, analysis and synthesis. In order to foster metacognition and facilitate active creation of schemata, cognitive features should be included in learning products. Particularly appropriate to web environments are chunking (classifying and linking information), concept-mapping (representations that show relationships), advance organizers (to introduce new material), bridging (linking from known information to new), rehearsal, graphic depictions, and mnemonics (to facilitate recall). Few traditional educational products emphasize cognitive strategies such as active planning and self-monitoring; instead, learners are viewed as passive participants under active instruction. Web-based learning, by contrast, fosters active, flexible learner-involvement.

3.2 Constructivism

Constructivism is based on learners actively constructing their own knowledge. Piaget was a constructivist! Key aspects (Dick 1991; 1996) are real-world situated learning, anchored instruction, discovery-learning, integrated testing, and transfer (applying known skills to new tasks). Constructivists object to criterion-referenced testing, preferring contextualized learning environments where learners set their own goals. The active learner participation required in constructivistic models can lead to long-term results and real-world performance. Grounded-constructivist learning environments (Hannafin 1997) are based on various theoretical frameworks, different learning contexts, and empirical research in human learning theory. Grounded design can be implemented in web-based learning, where heterogeneous learners navigate through links, reaching destinations via personal discovery voyages. Web-based teaching and training facilitate learner initiative, knowledge construction, and real-world exposure via browsing. Graphic representations on the Internet facilitate learning-by-visualization.

3.3 Customization

Design of learning materials must change to meet the information age (Reigeluth 1997). A learning-focused paradigm requires customization to individual profiles and facilitation of learning, as well as presentation of material. Instructional media should be flexible, characterized by individualization, adaptability, and interactivity, so that learners take the initiative, using technologies, choosing between methods, and selecting the level of support. Customized learning caters for varied learning styles, giving learners control over the time, place and speed of their learning experiences. It is user-centred, facilitating access to new information on a just-in-time, need-to-know basis. Customized learning via the Internet has the further advantage of information that is current.

3.4 Creativity

Instruction and learning can be dull, prescriptive and formal (Dick 1995). Despite sound objectives, learning materials, though instructionally effective, may bore learners. The design of many current instructional packages, however, is characterized by innovative features and learner-engagement. Creative design (Dick 1995) entails learner-analysis to match specific interests and an instructional strategy that motivates, for example, Keller's (1987) ARCS model which advocates gaining attention, demonstrating relevance, instilling confidence and providing satisfaction. Instructional designers in vocational business training (Caropreso 1996), are also aware of the value of creativity, novelty and innovation in their products. As adults are exposed to the paradigm (or the threat?) of life-long learning, such features in materials contribute towards positive attitudes.

3.5 Component display theory (CDT) and transaction theory

Component Display Theory (Merrill 1983;1996) is based on Gagné's conditions of learning (Gagné 1985) and proposes that different instructional strategies are required to achieve different instructional goals. CDT classifies the performance required and the content to be taught - the performance categories being *remember*, *use* and *find*; and content categories, *fact*, *concept*, *procedure* and *principle*. Each instructional objective is classified by performance (strategy) and content, and the corresponding instructional component is placed in Merrill's 2-D performance-content matrix to show the degree of coverage of the required content and outcomes. Learners choose components, selecting the instructional strategy and the content. In selecting strategy, they control the presentation method, degree of elaboration, and number of examples. For content, they choose material appropriate to their personal style or level of learning. CDT's deconstruction of a domain into

components is applicable to a variety of subjects and delivery media, but lends itself to computerized presentation of knowledge components. Computers should be used so as to capitalize on their unique capabilities, interaction and individualization, both of which are features of CDT, and can be effectively implemented in instruction and learning via the WWW and Internet.

3.6 Collaborative learning

Web pages are more static than CAI tutorials and simulations (coded in programming languages), and do not offer sensitive feedback and judgement. Yet the Internet holds great potential for interactivity of a different kind, namely collaborative learning, incorporating participative communication and spontaneous learner-input. Johnson (1991) proposes collaborative learning as a means of learning alone and together, with three prerequisites - a mutual goal, positive interdependence, and individual accountability. This entails a team approach where learners need each other's input to complete tasks, yet remain personally responsible and accountable. Schegel (1996) describes how the WWW presents a collaborative approach, yet without diminishing its potential for personalised, flexible learning. The Internet facilitates learner-learner and learner-facilitator communication, both in workstation teamwork and distributed virtual teams. Learners collaborate by e-mail, news groups, discussion boards, online conferencing, contributions to joint pages, and by editing peers' work. Appropriate design standards and ethics must, however, be upheld in all contributions. Collaborative learning is enriched by cross-discipline, cross-institution co-operation. Cronje (1997) describes Internet-based collaborative work, where distance-learners, geographically dispersed and communicating asynchronously, produce joint and individual products for assessment. Turoff (1995) describes the Virtual Class of the New Jersey Institute of Technology, where a remote degree programme is offered, replacing the physical class with an electronic virtual environment.

4. Conclusion

Teaching relates to the deconstruction of knowledge, and learning to the construction of knowledge. As instruction and learning migrate increasingly to the WWW and Internet, relevant aspects of expertise on human learning and ID models should be identified and applied to educational websites and Internet forums. The elements of the Hexa-C Metamodel: cognitive science, constructivism, customization, creativity, CDT and collaboration, are suggested as desirable characteristics for incorporation in the design and development of educational applications. Criteria for evaluation of electronic learning environments vary according to the nature and purpose of the application, and the Hexa-C Metamodel may be used, where appropriate, towards such quality assessment.

Online Experiments - Considerations and Possibilities

Morten Wagner, Allan M. Krebs, Christian Rothe, Lars Østrup Petersen and Jørgen Bøgh
([mw, amk, cr, lap, jb]@delta.dk), DELTA Danish Electronics, Light & Acoustics

Abstract: This paper describes work in progress in the area of connecting new, physical resources, like telescopes, cameras and other expensive (or rare) hardware to an online virtual shared environment. This paper is meant to inspire future developments and discusses design issues, both in terms of access control schemes and other CSCW aspects and in terms of software technologies like Java servlets and Java native interfaces.

1. Introduction

DELTA has, since 1995, been working with virtual classrooms and online learning and collaboration. Our virtual classroom is based on a college metaphor and is mostly centrally distributed, using web-technologies and mbone tools (see [1]).

We have integrated modular CSCW tools (shared whiteboard components, editor components, a virtual overhead projector etc.) in different virtual rooms to cater for different needs for asynchronous and synchronous CSCW (see [3]). Now, DELTA has embarked on a new area of research, namely methods and technologies for connecting new kinds of machines to the net. In terms of web-distributed teaching and learning, connecting different apparatus to the net gives the teacher the possibility to allow students to experiment with possibly quite expensive equipment, possibly very far away, in possibly very distributed groups. We have already seen telescopes - "wired" and remote controlled -monitored in virtual laboratories. So how about a remote controlled aquarium, with monitoring by mobile underwater webcams.

2. Connecting users to connected machines

In our design of web-connected apparatus, like a mobile camera and a shared web ISDN-Phone, several design issues have come up, which we want to share and discuss in this paragraph.

Traditionally, information sources on the web have been based on text and graphics. With the emergence of Internet CSCW tools, information sources can now be synchronous input from and collaboration with fellow students, teachers or co-workers. Now, technology furthermore allows us to put other sources of information on the net; cameras, instruments and even coffee-machines can be the originating source of information. The next step natural step - especially in the area of online education - is the sharing of and collaboration around these resources. Several issues for research and development must be addressed;

- implementation of coherent, usable virtual interface for "wired" machines
- collaboration in using and sharing of these machines
- design of software using good frameworks, to more easily address the "wiring" of new apparatus to the net

3. Interfaces for "wired apparatus"

Different applications of wired apparatus calls for different designs of interfaces to the apparatus.

Using web-technologies, we can limit and control exactly what information and what controls the user of a connected machine should have available. For instance, we have implemented simplified interfaces to both our web-connected phone and our moving web-camera. The web-camera, which is mounted with two separate servomotors allowing for two-dimensional panning, is controlled by simple mouse clicks on the image returned from the camera. The motors will then position the camera to focus on the spot where the user clicked. The web-phone is controlled by a simple html-based web-form.

Different design considerations should be applied when the purpose of the wired apparatus is to train the actual use of the camera; the interface should obviously be more representative of the real thing. Still, simplifications could allow for limited cognitive or perceptive "overhead" in the first phases of training.

A natural next step would be to create "meta-apparatus" or virtual machines. The same web technologies allowing us to join legacy software and database systems in unified web interfaces allows us to create actual collections of separate physical apparatus into coherent virtual machines. For instance, you could imagine a remote controlled aquarium in which you control both the dispensing of food, pumps for water flow and lighting - all through one, web-based interface.

4. Collaborative use of "wired apparatus"

Several issues come up when wiring apparatus for collaborative use - especially access schemes and access restrictions are of great concern. For most apparatus controlling it in a kind of "anarchy mode", where all users can "push" buttons as they like, is not a suitable solution.

The problems that arise using, for example, anarchy mode in control are not only because of situations where two users try to "pull" the apparatus in opposite directions, but are also due to delayed response. The delayed response is caused by two factors; first of all the transit time from client to apparatus and back, secondly the time passed from the apparatus gets the request to when it actually shows that something has happened. If we are controlling the apparatus in anarchy mode, users will sometimes see an old state of the apparatus, due to the delay, and therefore may act from wrong assumptions about the state of the machine. In most cases you therefore need some kind of restrictions of simultaneous access. On the other hand if a trainer is training somebody to use the apparatus, it is important that transfer of control can be transferred between trainer and trainee quick and easy. And in some situations it could also be of use if the trainer could break in and take control.

Another issue about access is who at all is allowed to access the apparatus; if you have an astronomical telescope, you are probably not interested in all Internet surfers having free access to control it. Therefore you need some authentication and access control.

Another area of interest is awareness of other users, either controlling or "watching" the apparatus. It is important that users can see if another user has the control and maybe also who the other user is. It is also nice for the user controlling the apparatus to be aware of other users watching.

Besides the control and view of the apparatus other tools for collaboration can be of interest in a wired apparatus application. E.g. tools for communication between the users, such as chat tools and videoconferencing tools.

5. Technologies used

This paragraph briefly describes the different technologies we see as operational in connection to putting new machines on the Internet.

DELTA's CSCW server and our CSCW tools are all implemented using Java (see [2]). Therefore, it was natural for us to concentrate on the use of Java (Applets, Servlets, etc.) in connection with "wiring" machines for use on the net.

Machine Layer: The software layer "closest" to the machine typically has to be written in C or C++. Using the Java Native Interface definition, we have developed an Java API for communication with an ISDN card. Control of servomotors for our webcam could be implemented using the standard Java communication extensions (javax.comm classes).

Server Layer: Java servlets allows us to program server functionality that is both easily developed and easily maintained. Servlets - in contrast to CGI-scripts for instance - can maintain a state, use several threads of execution, and be dynamically updated. A change in a utility or control class, can, due to Java's dynamic linking feature, be implemented just by uploading the new code. For creation of CSCW tools and "awareness" features, servlets also seems like a good technology, as they can continue to run between execution, and that new threads (that can be made to intercommunicate) are automatically being created for each new user invoking the servlet.

User layer: The user interface, naturally, is based on web-technologies like Java Applets, Javascript and HTML. The interface for our ISDN-phone is simply form-based, whereas our web-cam is far more advanced, and uses a combination of forms, javascript and a java applet.

6. Future developments

DELTA will continue to experiment with wiring apparatus for the net, seeking to enhance, communicate and standardise frameworks and technologies. Additionally, the area of human factors and usability tests of "virtual interfaces for physical machines" and mobile, connected machines will be subject for further study.

See <http://www.annecto.dk> and <http://www.delta.dk>

Busy City - On the Design of a Collaborative Learning Environment

Dr. Erik Wallin

Lund University, Dept of Informatics/Office for Distance Education
Ole Römers Väg 6, SE-223 63 Lund, Sweden
Tel: +46-46-222 8027, Fax: +46-46-222 4528, E-mail: erik.wallin@ics.lu.se

Abstract: This paper describes work in progress to establish a collaborative learning environment in the field of *eBusiness*, i.e. Electronic Commerce and some other fields of modern business informatics. The vision is for a virtual city with a community of citizens that inspires and mediates continuous learning and exchange of experience through hands-on training and field experiments in eBusiness. In this paper we will discuss some facilities and sets of rules for collaboration in this learning environment, which is called *Busy City*.

1. Introduction

Collaboration in *virtual* space necessitates an artificial, time-geographical *context*, such as a virtual classroom with meeting hours, to simulate a more conventional environment for working together. It is rather difficult to collaborate if you don't know *with whom, where, when, how* or *why* the collaboration should take place, especially if you don't even have a *sense of place*, or a mental map of your environment. This paper describes work in progress to construct different facilities and sets of rules for collaborative learning in the field of eBusiness based on *The City* as a metaphor for the context in which collaboration takes place.

2. Busy City - Learning eBusiness by Creating eBusiness

Busy City is a virtual city in formation, located nowhere and everywhere as a web-site under construction. It will be opened for "immigration" in January 2000 as an integrated learning environment for a set of courses currently running as separate distance courses at Lund University, e.g. General Business Informatics, Electronic Commerce and Business GIS. *Busy City* is based on a specific concept for distance learning developed by the author: the *Conversity*® concept, which is trademarked. It calls for an advanced learning environment on the Web with *The City* as a basic metaphor and guiding design principle [Wallin 1998]. The installation of *Busy City* as a *Conversity* in the field of eBusiness paves the road for a four-tier implementation, including the following facilities and support for collaboration [see Fig. 1]:

- **Campus:** collaboration in a *class* with virtual classroom facilities such as tools for online class meetings, threaded discussions, online lectures, bulletin boards etc
- **Business Research Park:** collaboration in a *project* with a project workplace for each team including tools for project administration, task assignments, project timetables, sharing of documents etc
- **Market:** collaboration in a *virtual company* with support for realistic eBusiness transactions including tools for web-site design, customer registration, payment services, delivery services etc.
- **City Hall:** collaboration in a *virtual community* with support for large meetings in a virtual conference room and with tools for member administration, voting, zoning and setting of access rights to different facilities and resources in the city, e.g. intellectual property rights etc.

The learning process in *Busy City* is designed to support and enhance actively a complete *learning cycle* in eBusiness [see Fig. 1], from the novice student to the president of a virtual company who uses eCommerce in his daily transactions with his customers. The student may enrol at the Campus (1) and take a course in eBusiness that has a number of group work assignments. One of these might need the laboratory facilities of a technology provider established at the Business Research Park (2). Here the student may engage in a project to set up a pilot application of a new business idea or a new technology, e.g. an Internet-Shop for virtual travels. The team has the option to transform itself into a management staff of a virtual company that is engaged in real eCommerce business on the virtual Market (3). The running of this virtual company may provide experiences that both the customers and the staff deem are relevant enough to feed back into *Busy City* as a new establishment, open also

for external customers (non-residents). The Community of Busy Citizens at the City Hall (4) must take such a decision as it might influence neighbours etc. The experience gained, the lessons learnt and the future potential of the virtual company, will be taken into consideration in the design of a new course at the Campus (1). In this way, we have a learning cycle that accumulates both theoretical knowledge and practical know-how into a common asset of immaterial, intellectual capital that can be used in new learning processes. During the cycle, Busy City evolves to better serve its purposes as a home for life-long learning in eBusiness.

A dedicated *graduation system* has been developed to integrate this learning process into the primary business process of Busy City to allow more formal careers within Busy City, e.g. a temporary visitor that transforms into a resident Busy Citizen [Wallin 1999]. From a business point of view, Busy City acts as a *factory of new virtual companies* with the Community of Busy Citizens as the first pilot market.

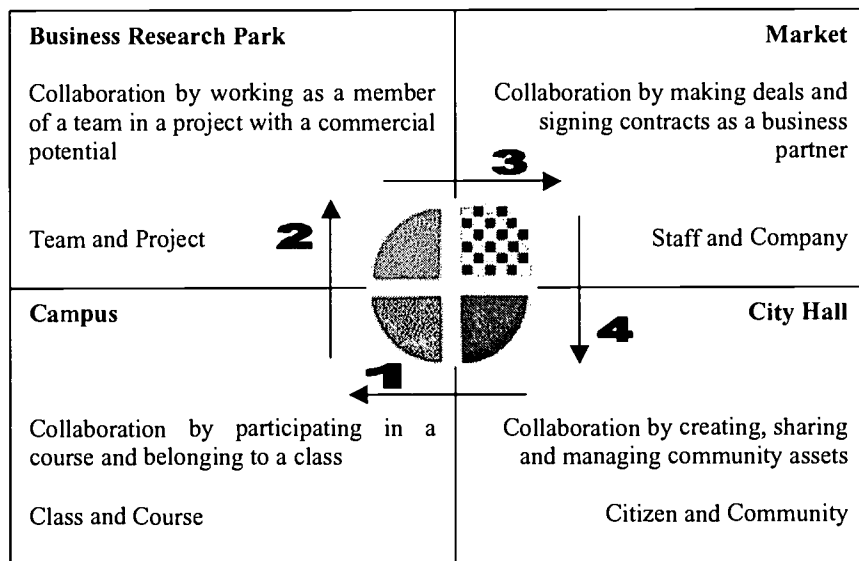

Figure 1: The learning process and the four areas of collaboration in Busy City.

3. Conclusions

To learn eBusiness in Busy City is to create and run eBusiness processes - but first experimentally! What makes Busy City unique from other virtual business schools and learning environments is that it goes beyond the traditional "academic" campus concept. It supports and integrates the student's development from being a novice eBusiness student to the launch of a full-scale eCommerce site for a new virtual company. There is no need to leave Busy City to be able to fulfil this development - on the contrary. In a similar situation, a traditional school will have a big loss in time, knowledge and human resources due to the fact that the students have to leave the school to be able to try out their commercial projects somewhere else. Due to the logic of the learning process in Busy City, there is a good chance that both the student and the new virtual company will be fully prepared for successful business operations in the next Millennium.

Using Online Collaborative Workspaces to Design Technology Integrated Instruction for Supporting K-12 Historical Thinking and Understanding

Beth Wellman, Office of Technology Projects, GSE&IS, UCLA, USA, ewellman@gseis.ucla.edu

Maya Creedman, Office of Technology Projects, GSE&IS, UCLA, USA, creedman@gseis.ucla.edu

Jana Flores, California History-Social Science Project, UCLA, USA, jsflores@ucla.edu

Abstract

In this professional development initiative, K-12 California history teachers developed instructional materials collaboratively to support historical thinking and understanding. First, participants examined the use of problem-based learning and technology to support their students' development of historical thinking and understandings in a two-day workshop at UCLA. Then, participants spent the next three months developing instruction in a collaborative online environment that reflected their examination at the workshop. The created instruction will be posted on the Internet.

1. The Project

Beyond Primary Sources: Using Technology in the K-12 History-Social Science Classroom project was conducted jointly by the California History-Social Science Project (CH-SSP) and the Office of Technology Projects in Center X at UCLA. K12 California teacher participants engaged in a guided inquiry to develop instruction focusing on the use of technology and constructivist learning approaches to solve shared instructional problems. Participants examined the use of problem-based learning and technology to support historical thinking and understanding in a two-day workshop at UCLA. In the three-month online follow-up, participants developed instructional materials for their classes reflecting their exploration in the workshop.

Using an online collaborative workspace (Milken Educators Virtual Workspace (MEVW), www.mevw.org), participants synchronously and asynchronously collaborated on their work in progress. Resources such as the State Board of Education Content Standards in History Social Sciences, case studies in history and social science, exercises and theoretical perspectives provided additional guidance. Teachers' questions and concerns about using technology in the history and social science classroom were addressed in the context of exemplary teaching and learning in their content area.

2. The Inquiry Model

Teachers rarely have the opportunity to experience good instruction as learners. As teachers often teach in the same way that they themselves are taught (Fosnot, 89), we believe it is important for professional development to model the teaching that we expect the participants to engage in. In this initiative, teacher participants were both recipients (learning how to develop instruction) and developers (developing the instruction for their students) of the same learning model. The model is composed of three elements: the acquisition of high level thinking skills, the optimal use of technology as an instructional tool and problem based learning as an instructional model.

As recipients, teacher participants engaged in constructivist, problem based inquiry and technology based collaboration to examine their practice. Problem-based inquiry required the teacher participant to identify and solve a "instructional problem" they encountered when teaching historical thinking and understanding. Through collaborative discussion, the participants used technology and problem-based learning to develop instructional solutions to the problem. Participants actively engaged in higher level thinking through continuous reflection on their own design process. They compared their own solutions with those of other participants, providing multiple perspectives and approaches to the problem. These instructional materials require students to engage in higher level thinking (specifically historical thinking and understanding), reflect on their own cognitive processes, solve a problem collaboratively and use technology to support their learning.

3. Historical Thinking and Understanding, Technology and Student Outcomes

Historical thinking and understanding skills essential for students to integrate, recount and analyze various aspects of human aspirations and strivings (State of California State Board of Education, 1999). Students need to be able to think historically in order to demonstrate these deeper understandings. These skills should be integrated into the content standards to produce student outcomes such as explaining, comparing, reconstructing, and analyzing, all of which are higher order thinking skills (Resnick 87). The teacher participants in this project focused on developing instructional materials that encourage student historical thinking and understanding.

This initiative gives teachers an opportunity to use technology to support instruction in a specific way. Exemplary technology integration involves constructivist learning approaches (Jonassen et al. 99). Teachers have many choices in determining how to use technology to encourage historical thinking and understanding. Students might develop their own instructional software or participate in international distance learning projects. By solving an instructional problem with technology and problem-based learning, teachers must think about how to integrate technology effectively. This project required teachers to determine how the use of technology in their instruction will help them attain their instructional goals

4. The Online Collaborative

An additional goal of this project was to explore the use of online collaborative workspaces as a tool both for collaborative work among teachers separated by geographic distance and as a tool for follow up for other professional development institutes. The MEVW space allowed participants to use the Internet to create and participate in collaborative online learning communities. Participants worked in small groups with a facilitator who helped maintain an environment conducive to communication, professional networking and the creation of exemplary instructional materials.

We believe this project illustrates a good professional development model. The problem-based learning model allows teachers to solve historical thinking and understanding problems in students by creating technology-integrated instruction. The combination of both offline and online activities enables teacher participants to establish professional relationships in a familiar and comfortable environment and then extend and utilize these relationships in an online environment. Without this online environment, it is difficult to maintain the relationships established in professional development institutes because of geographical and time constraints. This project explores the use of an online collaboration tool for developing and supporting statewide networking of teachers sustained over time.

Remote Manipulation of A Robot Arm Via The World Wide Web: Recycling Old Technology

Dr. Dawn E. Wilkins

Introduction

This paper describes a series of projects that allow remote users to control a robot arm via the world wide web. Remote manipulation and control of a device is sometimes called teleoperation or telerobotics. The National Aeronautics and Space Administration (NASA) has employed teleoperator devices on the moon. The successful Mars pathfinder mission with the Sojourner rover is an extension of teleoperation where the rover has some "intelligence" on-board which allows it to make some autonomous decisions, but the most critical decisions are made by a human operator on Earth [3].

There are many examples of Internet-controllable robots. These robots allow users to experience a variety of different virtual environments. For example, PumaPaint [2] allows users to create artwork, Carnegie Mellon's Robot Learning Laboratory houses several robots, including Xavier which was one of the earliest autonomous robots controllable via the Web [1], and Telegarden [4], originally developed at The University of Southern California, allows users to participate in gardening.

During the 1997-98 school year, the Department of Computer Science at University of Mississippi was awarded an NSF grant to work with middle school girls. The grant served girls in four remote locations, so activities were needed to encourage the girls to both interact with each other and to use the Web. We decided that if we could have a web site that allowed a girl at one location to play a game with a girl at another location then we would have accomplished both goals. This was the initial motivation behind the project.

Environment of the Robot Arm

Several years ago, we retired a TeachMover Robot Arm (from Microbot, Inc.). We retrieved the robot arm from storage and began the process of making this obsolete piece of hardware the centerpiece of a game that could be played on the Web from remote sites. This particular robot arm was originally distributed to engineering schools to encourage the development of courses in computer-aided design and manufacturing. It is a very simple mechanism that connects to a personal computer through a serial port. Movement of the arm is controlled by instructions given via commands to six stepper motors that control the three joints (shoulder, elbow and wrist), the rotation of the base, and the hand gripper. The motors are controlled by a card in the base that is connected directly to the serial port of the computer. The process of connecting the robot arm to a contemporary personal computer was non-trivial and required extensive web surfing and ultimately email to other users of the Teachmover Robot Arm. The driver code supplied by Brent Juelich and Dr. David Leech at Illinois State University was invaluable. The robot can only

connect to the serial port at a baud rate of 9600. Since all commands to the arm are given using ASCII text strings, once the robot was connected successfully, it was easy to use a scripting language to issue commands to it.

Previous Work

This project has been developed in stages. The initial work on the project was undertaken by Mr. Raghu Neelagiri, a Master's student in Computer Science at The University of Mississippi. In order for the robot arm to be used in such a way that the girls could interact with it remotely, three more parts had to be added, a web server, a video camera, and a web page with scripts that allowed a user to control the arm remotely. The web server used was Website by O'Reilly Software, but any web server would work. We chose a rather elaborate video camera (Winnov's Videum Conference Pro) because it came with a card that allowed for onboard compression which we hoped would speed up the video transmission. The scripting language used on the server side was Perl. While any scripting language could be used, Perl has strong text and file manipulation features and can be used to perform server side common gateway interface (CGI) tasks.

The first stage of the project allowed a remote user to perform each of the possible movements of the arm, such as rotate the arm about the base left or right, and move the shoulder up or down, by selecting actions from a web page (form). Each button on the Web page invoked a Perl program, which called a driver program (written in C), which sent the command to the robot arm. The camera was pointed toward the robot arm and captured an image every few seconds. The captured image was refreshed on the web page at a predefined interval, approximately every 10 seconds. A graphic of the command execution sequence can be found at: <http://www.cs.olemiss.edu/webnet/webimages.html>.

The second stage of the project was undertaken by Ms. Cindrika Arrington and Ms. Kathy Johnson, UM McNair Scholars in the summer of 1998. Their project involved actually setting up the game of Tic Tac Toe. Tic Tac Toe was selected because of its simplicity and the regularity of its movements. The game board was set up, the pieces were marked and then range of motion measurements were taken so that the game board and the game pieces could be placed within the reach of the arm. Care was taken to allow the arm to pick up all five pieces from each side ("X" and "O") randomly and without allowing any move to interfere with remaining game pieces. Colors of the game board and game pieces had to be chosen to ensure reasonable contrast in the images. Live streaming video software, EmuLive's Server/Producer suite, was added so that the site would have real-time update of the game board. A screen image can be found at: <http://www.cs.olemiss.edu/webnet/webimages.html>.

The game works well, but there are still improvements to be made. For example, there is no control over remote connections, therefore it is impossible to ensure that players are taking turns correctly. Similarly, the environment is stateless, so it is not possible to know whether one of the players has won the game, or whether moves indicated by the players are valid. One other technical difficulty is the sluggishness of the video.

Work in Progress

Currently, another Master's student is taking the project a step further. His goal is to correct the deficiencies described above by using a Java servlet on the backend, rather than CGI. The servlet can maintain state (so move validation, checking for a winner, a hall of fame, etc, can be included). Use of a servlet will also allow the option of single-user play against the machine controlled robot. The major bottleneck is still expected to be the video streaming software. TrueTech video software is currently being tested but the results are inconclusive at this time.

Prague, Czech Republic e-mail: {kolar, macek, mannova}@cslab.felk.cvut.cz

Abstract: We provide first year University students with an International Experience. The International Experience involves learning about a country and its people that are located on the other side of the world. Until recently, the countries had very different political systems. Students form friendships and talk with each other. Finally, they learn to work together on a team and jointly solve a challenging problem. The beauty is that there is no additional cost to the student in travel time or money. Students in the United States (Brooklyn Park, Minnesota) and the Czech Republic (Prague) weekly communicate about personal, societal, and course work topics. They use these tools of the internet and WWW: e-mail, NetMeeting for videoconferencing, chat board, and shared applications. Ultimately, global teams of members from both countries will solve computer-programming problems.

Introduction

In 1993 University teachers from North Hennepin Community College (NHCC), Brooklyn Park, Minnesota and Czech Technical University (CTU), Prague, Czech Republic participated in a teacher exchange with one teacher from each country living and teaching in the other country for a quarter. From this modest beginning grew our Global Cooperation Projects involving team teaching between the countries using the tools of the WWW and Internet. The project pairs computer science classes in both countries for meeting goals in two areas:

1. Promote international cooperation and understanding of diverse groups of people.
1. Promote the ability of students to work in teams, learn how to use correct programming techniques, and get used to the method of cooperation from a distance.

Initially the involvement was with the teachers although students were affected by having a teacher from another country. The teachers involved were galvanized by their exposure to a different culture and educational system. They realized there were substantial misunderstandings about each others' country on both sides. Yet there were also many similarities between the classes. Teachers in both countries had important contributions to make to the education of the computer scientist/engineer of the future. The experience so broadened the teachers' perspectives in the social as well as professional sense that they began to plan for their students to also have this experience. The teachers involved took some of their project philosophy from Vaclav Havel, President of the Czech Republic. In a speech in the United States when he was awarded the Liberty Medal in 1994, he challenged people to think about the world in a new way. He spoke of the necessity for people to see the mystery and poetry of life, not just its technical achievements. As Havel says, our civilization must offer something for the soul and the mind. It is our belief that understanding and respect for another's culture and life style is a noble goal and worth including with our subject matter goals. We decided we had the means to provide a meaningful educational experience for our students that in addition to the desired academic mastery in computer science also offered them 'something for the soul'.

After the teachers returned home from their exchange assignment they began talking with students about the other country and incorporating some of the different teaching techniques they had observed into their classes. The first step of the student involvement began when computer science classes in Minnesota and in Prague were paired. The teachers communicated by e-mail and had their classes do the same assignments. Both classes were aware of the class in the other country. The assignment problems were of a great variety. Some were interesting puzzle problems while others were practical applications. An interesting practical problem appeared one day when a businessman came to see the Minnesota teacher about a problem involving the most economical method of wrapping microwave popcorn. Students and faculty in both countries began a debate and proposed solutions to the problem. The communication was all done by e-mail through the teachers. The solution was not trivial and used advanced mathematics. Three quite different approaches yielded

approximately the same results. A summary of these solutions (from students in both countries) and a chart generated from a computer program were presented to the man with the problem. Interest was extremely high in both classes - students and teachers alike were excited to think that they were engaged in solving the same problem as counterparts across the ocean.

Global Cooperation Project

After initial explorations and detailed planning we were ready to begin our first Global Cooperation Project in spring quarter 1998. This was the first trial of forming teams and having students communicate directly with other students using a wide range of WWW and Internet tools. The students involved in the projects were the students of computer science courses. The NHCC students were from the "Algorithms and Data Structures" course. Those from CTU were students from the English language track of the "Introduction to Computer Programming" Course. One motivation for distance cooperation is the fact that so many companies are international in scope with offices in different countries. These companies have an option for employees to travel and then work locally. But this costs both time and money. Fortunately technology is now available that allows for effective cooperation from long distances. Team approaches can be used where the team consists of members working in different parts of the world. We wanted to have the students experience a situation which is close to real life. And in our quickly changing world, teamwork is the only way to be able to come out with new products and be competitive.

For many students the project is the first opportunity to have real working contact with a person from another country. They learn about differences in living styles, they get to know some current events in the other country, and also some personal interests of their team members. This social aspect of the project is mainly accomplished by personal e-mail communication and by using Microsoft NetMeeting and PC cameras for videoconferencing. The official "kick off" of the projects was done by the first videoconference with cameras. Excitement was great as we established contact with the schools. We introduced the teachers who gave an introduction to their respective schools and then the students were briefly introduced. Prior to this students had created their own web home pages and subscribed to e-mail lists that will provide important information about all aspects of the on-going projects

Students could decide to work on the project proposed by the teacher or they could propose their own projects that were posted on their web pages. Students could create a team by joining somebody who proposed an interesting project or who looked to be an interesting person. Each team had to have members from each country and were two to four individuals. After selecting a project manager the teams analyzed and wrote a detailed specification of the project. They also decided about distribution of the work among the team members. This was followed by analysis and decision making about the data representation and algorithms to be used. Next the algorithms were coded in a programming language (either Pascal or C). Then the students performed detailed testing of the product to prove it was without error. The last part of the project was documentation. The teams documented the projects and wrote a guide on how to use the product and presented this on the project WWW page. The culminating activity was a concluding videoconference between countries involving the entire classes. At this time short oral reports and summary results of the projects were presented.

Conclusions

At the conclusion of the first trial course all teachers were extremely satisfied with the results. We believe it was successful beyond our initial hopes. We discussed the project results with the students. Their conclusion was that even though the work on the global projects was harder compared to a conventional course, they were better motivated and extended their working practice to activities they would not have had a chance to try otherwise. They learned how to use some WWW and Internet tools that should be helpful in their future profession. And all appreciated the social dimension of the collaboration.

Clash of the Titans: Managing Conflict Online among Adult Distance Learners

Shahron Williams van Rooij, Ph.D., C.D.E.P.
Faculty-Facilitator, University of Phoenix Online Campus, USA
And
Academic Product Manager, Datatel, Inc., USA
E-mail: svr@datatel.com

Abstract: Unlike the traditional 18-21 year old college student, the adult learner approaches online distance learning with an existing set of communication styles honed in his/her respective work environment. Those diverse styles may lead to conflict. If not managed properly, conflict can adversely affect the learning experience for all members of the online course. The purpose of this paper is to offer some practical guidelines for managing conflict online among adult distance learners, with special emphasis on conflict prevention

Introduction

Faculty members approaching online teaching for the first time are faced with a variety of pedagogical as well as technology issues. A number of research studies have been conducted regarding instructional design and faculty development for distance education [Moore and Thompson 1990, Kinsey 1990]. When defining the areas of competence required for delivering instruction online, the ability to stimulate collaborative teamwork is almost always cited at the top of the list by researchers. This area of competence becomes particularly challenging when all aspects of the instruction – content delivery, communication, collaborative group work, individual and group assessment – occur in an asynchronous online environment with adult learners. For working adults who may be using electronic communication at work to supplement face-to-face contact, communicating with peers solely through asynchronous discussion groups can be challenging. Unlike the traditional 18-21 year old college student, the adult learner approaches online distance learning with an existing set of communication styles honed in his/her respective work environment.

The Instructor's Role

The role that the instructor chooses to adopt for participation in the discussion is a strong contributing factor to the success of the discussions. Basically, the instructor is expected to provide feedback and to facilitate the continuous flow of information that is useful in shaping the learning process while it is happening [Sherry, 1996]. Instructors who adopt the old "Sage on the Sage" paradigm may contribute to an online discussion characterized by surface thinking, unreflective personal reactions, or examination-style exposition. Conversely, the instructor-facilitator can stimulate adult distance learners into exploration, critical examination of their own thinking, and exploration of the complexities and unresolved issues in the subject area under study.

Preventive Measures

Rude, impulsive behavior, dubbed "flaming", is more common in electronic communication than in any other forum. Comparisons of face-to-face and electronic meetings have shown that group members tend to be argumentative and outspoken in electronic discussions, often leading to increased group conflict [Sproull & Kiesler 1991]. Group conflict may lead to personalization of perceived attacks, alienation of individual learners, and in the worst cases, withdrawal of individual learners from the group and/or course.

The instructor-facilitator must set the tone for communication in online discussions. To reduce the likelihood of conflict, the instructor may take the following preventive measures:

1. Clearly articulate the rules of engagement
2. Ask course members to describe their own style of written communication
3. Discussion room segmentation

Managing Conflict

While adult distance learners usually adhere to the rules of courtesy in online discussions, instructors should be watchful of conflicts that appear to be getting out of hand. Obvious signals are personal attacks on an individual's knowledge or experience, unacceptable language, or unsupported criticism. The instructor can prevent conflict from escalating while still remaining in the role of facilitator/guide. When an online communication displays flame characteristics, the instructor can send a message to the entire group reminding them of the rules of engagement online and re-stating the importance to the learning experience of a positive online environment. This helps to support the individual who was the target of the flame, while stressing to the writer that his/her communication was inconsistent with the code of conduct to which all course members agreed. If the writer again flames a course member, a private note from the instructor should remind the writer of the consequences of non-compliance with the stated rules of behavior. If the writer persists in flaming his/her peers, the instructor should keep copies of the messages as evidence to support punitive measures by the institution. Importantly, the instructor should be careful not to be drawn into a flaming response to the offending writer.

Summary

Fortunately, adult distance learners are usually able to manage conflict in online discussions on their own. Nevertheless, it is essential that the instructor set the stage for a healthy online environment by clearly stating learner and instructor roles and responsibilities and the online code of conduct. Only then can online discussions remain healthy exchanges of opinion among adults rather than a clash of titan egos.

Surviving Your First Web-Based Distance Education Course

Shahron Williams van Rooij, Ph.D., C.D.E.P.
Academic Product Manager, Datatel, Inc., USA

And

Faculty-Facilitator, University of Phoenix Online Campus, USA
E-mail: svr@datatel.com

Abstract: To the faculty member whose only teaching experience has been in the classroom, teaching at a distance via the Web seems like a daunting task. The purpose of this paper is to offer some practical tips on surviving the transition from physical to virtual classroom by: a) reviewing some instructional design basics; b) identifying some support and service issues; c) discussing some practical pointers for getting started, and d) looking at some tools to build a personal chest of resources for online instruction.

Introduction

To the faculty member whose only teaching experience has been in the classroom, teaching at a distance via the Web seems like a daunting task. On the one hand, the idea generates images of reading assignments and planning lessons in one's pajamas, free from the limitations imposed by classroom equipment, building ventilation, snarling traffic and the 50-minute lesson period. On the other hand, the task of stimulating students to explore the concepts and practical applications of your discipline solely by means of what you can fit on a 17 inch VGA monitor – 15 inches on some laptops – seems an impossible dream. Do you have the funding and resources of a small Hollywood production studio to convert your course content into a flashy multimedia show? Not very likely. The purpose of this paper is to offer some practical tips on surviving the transition from physical to virtual classroom.

Fleshing Out the Issues

Delivering all of your course content via the Web requires consciously stepping yourself through the basics of instructional design, summarized nicely in *The Communicators Handbook* [Maupin House 1996]: namely, goal statement; defining the learner; developing learner objectives; designing the evaluation; developing the content; selecting the instructional method and strategy, and ; selecting the delivery method

Once you've decided on your instructional design and formulated your strategy, a stream of issues that were "no-brainers" now become question marks. For instance, in addition to technical support, what about training students on how to navigate through the online course materials? Who is responsible for getting my materials onto the Web, for adding/modifying course content once its online? If I have to prepare my own materials, who's going to teach me how to use the authoring software? Online learners expect to have the same library, text and lab materials and resources as the classroom-based learner. How does the institution meet those expectations

Getting Started

Most faculty members already have some digitized materials: PowerPoint presentation slides, text prepared using some word processing software, access to free graphics, clipart and photos via the web. The very first step should be to take stock of the materials you've already accumulated over the years. The availability of high-quality, low cost scanners has allowed institutions with modest resources to acquire one or more of these units. Materials that may not yet be in digital form – articles, printed graphics and photos – may be scanned in for inclusion in your courseware package. Ideally, you would like to have a means of organizing your materials so that you can create content relatively easily, and re-cycle those materials for other courses you teach in the future.

Authoring Tools

Creating course materials is the most time consuming, resource-intensive portion of faculty workflow and there are a variety of shrink-wrap products for authoring. However, nearly all of the PC-based authoring programs require a fairly robust technology skill set to get beyond on-line page turning. Distance education course management systems such as CourseInfo, WebCT and Learning Space address web-based course administration and communication and have authoring tools that are relatively easy to use. However, they are not nearly as rich in functionality as the PC-based authoring tools.

Does ease of use always mean sacrificing authoring flexibility and functionality? A good authoring tool should provide step-by-step creation methods, templates, sample Web pages that can be adapted for individual use, automatic generation of CGI scripts, and basic instruction for creating standard components [Hansen and Frick 1997]. But the authoring tool should also be flexible enough to provide the functionality and the benefits of multimedia tools and integrate seamlessly into whichever course management system the institution has selected. MICROCOSM [HREF2] is an authoring tool that meets all three requirements: ease of use, rich in functionality, seamless integration. Created by a university consortium in the United Kingdom and winner of several international awards, MICROCOSM allows faculty to gather and organize multimedia materials to create courseware for on-line delivery without having to learn programming. Task cards and wizards in plain English step the faculty through the creation of the course, with lots of positive reinforcement along the way. Once the course is created, it can simply be “dropped” into the institution’s course management system via a Publish-&-Go wizard. Course content can be published to CD-ROM for large-scale local data storage for static and archived information, to save bandwidth for interactive components on the Web. Microcosm helps the faculty member build a chest of learning resources that is adaptable for various instruction delivery vehicles.

Summary

The key to becoming comfortable with web-based distance education is to experiment. Most software vendors will provide limited-time free copies of their authoring tools for faculty to try, so you can find the one that works for you with no financial risk. To be a novice is not an insult. Given the age of the Web, most faculty are just that. You can share ideas and experiences with fellow “newbies” and with the early adopters by joining listservs like ITFORUM, hosted by the University of Georgia, or WWWDEV, hosted by the University of New Brunswick. Importantly, your students are excellent resources, particularly when Web-research becomes part of the course work. After those first steps, you’ll thrive, not just survive.

Using E-Designed Courses to Enhance Teaching and Learning

Joan Wines, Associate Professor of English, California Lutheran University, USA wines@clunet.edu

Julius Bianchi, Associate Director of Information Systems and Services,
California Lutheran University, USA bianchi@clunet.edu

Abstract: California Lutheran University's Teaching, Technology, and Teamwork (TTT) faculty development program uses a team-based approach to help faculty members integrate technology into the curriculum. In creating and re-designing courses and course modules, teams build on and reinforce successful pedagogical practices and the one-on-one student interaction that is so valued by the University. Faculty from a range of disciplines are targeted in the TTT program.

Recognizing the importance of integrating technology into the University's teaching and learning environment, CLU faculty approved a set of revised criteria for hiring, promotion, tenure, and review that incorporates the use of technology as a key element in a faculty member's repertoire. CLU's administration has also made a significant commitment to integrating technology into the curriculum.

A major challenge now confronting CLU and other higher education institutions is how to support faculty members in improving their technology skills and applying those skills to their instructional methods on a routine basis (Candiotti and Clark 1998). At present, only 10% of CLU faculty employ at least five of the eight commonly used technologies: e-mail, newsgroups, web, chat, PowerPoint, video, teleconferencing, and 3D manipulation. Our early adopters are, to some degree, integrating these tools with the seven principles for good practice in undergraduate education: student-faculty contact, cooperation among students, active learning, prompt feedback, time on task, high expectations, and respect for diverse talents and ways of learning (Chickering and Gamson, 1987; Chickering and Ehrmann, 1996). Time and resource restraints have, however, made it difficult for faculty to add technology to their teaching.

According to the research (Shapiro and Cartwright 1998) and our own experience, creating quality instructional modules requires a team approach. We implemented our Teaching, Technology and Teamwork (TTT) project to incorporate these findings, and have subsequently found that working with colleagues in a university-supported Center for Teaching and Technology is an effective method for engaging faculty in course re-design.

Building on Successful Pedagogies One of the major goals of CLU's Strategic Plan (*CLU 2001*) has been to enhance the personalized, one-on-one teaching and learning approach so valued by the University. This approach, the first of the "Seven Good Practices" identified by Chickering and Gamson, has been favored by faculty who have worked in CLU's low teacher-student ratio classrooms. Many of the faculty have developed other successful and unique pedagogical strategies as well.

E-Design Process & Procedures CLU's TTT project teams e-design courses or develop course modules by combining good practices (Chickering and Gamson 1987; Chickering and Ehrmann, 1996) and the eight commonly used technologies. The cardinal attraction of our program and one that will affect the quality of the projects is that it can be customized for each faculty member. Each project will adhere to the following objectives: increase student achievement levels; enable faculty to use the tools of technology to support "good practices" and CLU's central value of one-on-one faculty-student instruction; effect a significant increase in the number of faculty members combining technology and pedagogy to improve their teaching; and provide a mechanism for the ongoing renewal and redesign of instruction at CLU and beyond.

The TTT Program is designed to provide the resources and support necessary for its success, including the CLUnet infrastructure and the University's Center for Teaching and Technology. Faculty are given the time needed to develop or re-design their courses and/or explore and incorporate new pedagogical methodologies into their teaching. Faculty submit proposals for specific projects to the Information Technology Advisory Committee (ITAC), who evaluate the proposals.

Faculty whose proposals are selected receive a stipend for the semester during which they work on the project. The instructional team supporting the work of each selected faculty member brings together the skill set appropriate to the proposed project. The purpose for using the team approach is to bring sufficient resources to the curriculum design process for the achievement of a quality product of high distinction (Kimber and McKay 1996; Horgan 1998; Peed-Neal 1998). Each of these team members will bring essential expertise to the course design and implementation process.

Faculty Member	Content expertise: subject matter and discipline, concept, and instructional plan
Librarian	Information literacy and resources expertise
Instructional Specialist	Expertise in project development; appropriate pedagogical and technological solutions
Student Intern	Responsible for technical expertise and for making a contribution based on personal knowledge and perspective
Evaluator	Assessment expertise: current teaching, student performance and student feedback

Table 1: Team Members and Their Roles

In conducting an on-going and comprehensive evaluation, the project teams draw from the tools and lessons learned in the body of research from the Flashlight Project (<http://www.tltgroup.org/programs/flashlight.html>). Since the proposed project relies on the seven principles of good instruction, using the survey items included in The Flashlight Project's Current Student Inventory (Ehrmann 1998) helps ensure that we are using validated items and that we will contribute to the ongoing collection of data on pedagogical change and outcomes using appropriate integration of technology.

Summary Richard Kimball, president of the Teagle Foundation, proposed in a letter to the editor of *The Chronicle of Higher Education* (11/19/97) that "Instead of viewing technology as a threat or a corrupting force, professors should regard it as offering extraordinary opportunities to make a difference in students' lives--and in their own." CLU supports this goal in its Strategic Plan and has made noteworthy progress in achieving it. Receiving the 1996 CAUSE Award for Excellence in Campus Networking marked a milestone in that effort. The Teaching, Technology, and Teamwork plan has the potential for making a major difference in the lives of those involved in both teaching and learning at CLU and beyond. Now fully launched, this program is to be incorporated into the University's long-term plan for faculty development.

Teaching Technology through Tradition: Native Access to Engineering at Concordia University

Dawn Wiseman

Native Access to Engineering Program, Concordia University, Montreal, Quebec (Canada)
dawn@encs.concordia.ca

Corinne Mount Pleasant - Jetté

Native Access to Engineering Program, Concordia University, Montreal, Quebec (Canada)
corinne@encs.concordia.ca

Abstract: The Native Access to Engineering Program addresses issues related to the under-representation of Aboriginal people within the science and engineering sectors in Canada. Because its target audience is widespread and largely remote, the program benefits from the Canadian government's commitment to national connectedness by distributing materials and developing initiatives via the World Wide Web (WWW).

Introduction

In 1993, the Faculty of Engineering and Computer Science at Concordia University entered into an agreement with l'Ordre des ingénieurs du Québec to develop concrete strategies to increase the representation of Aboriginal people within the engineering profession. Over six-years, the Native Access to Engineering program has evolved from a small operation aimed at Aboriginal high school students within the province of Quebec to a broad-audience, national project supported by the federal government, Aboriginal organizations, big business, academia, and the Canadian research establishment.

Concordia's Native Access to Engineering Program is unique in Canada. It is the only institution to address the long-term challenge of increasing the representation of Aboriginal people in science and technology sectors of the Canadian labour market. The focus is on the development and strengthening of technical skills, knowledge and expertise within the context of Native community needs and cultural identity.

Within Canada, delivery of national programs is complicated by challenges of geography and population distribution. The country measures 4634 km from north to south and 5,514 km from east to west. While the majority of the population lives in the south within 200 km of the US/Canadian border, there is still a significant percentage living in rural and remote communities. Aboriginal people constitute a majority of this rural/remote population. Communications technologies have historically played a significant role in addressing the challenges of geography and population. As such, Canada has been quick to embrace the Information Highway in all of its incarnations. In fact, several Canadian initiatives (SchoolNet and the Community Access Program to name a few) are international exemplars of connecting people and communities for life long learning.

This paper provides a brief background to the conjuncture of the Native Access to Engineering Program and Aboriginal issues in Canada, and examines the important role of WWW in taking the project to a national audience.

Native Peoples in Canada

According to the Department of Indian Affairs and Northern Development (DIAND), the current Aboriginal population is 1,333,700 people, or 4.4% of the Canadian population [DIAND November 1997]. It is a population growing at an unprecedented rate: the on-reserve birth rate is more than double that of the Canadian population as a whole. The 1991 Census/Aboriginal Peoples Survey conducted by Statistics Canada found that about 54% of Registered Indians living on reserves are under 25 years of age. In some communities, this percentage rises to in

excess of 50% under the age of 18. There is clear evidence that the explosion in birth rates is ongoing and consistent across all regions of Canada [Ibid.]. So, unlike the general Canadian population which is dominated by the concerns of aging baby boomers, many concerns within Aboriginal communities focus on youth and the young, education and training.

Additionally, there is an ongoing and evolving change in the relationship between Aboriginal peoples and the Canadian and provincial governments. Described in *Time* as "One of the boldest social-justice experiments in the country's history" [Purvis 1998], the goal is to "give native [sic] peoples land, money and political power." [Ibid.] This major shift in national policy is largely in response to the recommendations contained within the *Final Report of the Royal Commission on Aboriginal Peoples* a 5-year, multi-million dollar investigation into the strained relationship between the Government of Canada and its First Nations inhabitants. RCAP recommends fundamental changes in the relationship at all levels; the ultimate goal being the development - over a 20-year period - of self-government (within the confines of Canadian Confederation) for Aboriginal Nations.

Self-government, education, leadership and infrastructure

Despite Canada's consistently impressive showings in United Nations rankings, if the "on-reserve aboriginal population were viewed as a separate country ... it would fall somewhere below Mexico and Thailand and be on par with Brazil." [Ibid.] The fact is that many Aboriginal communities are essentially "developing;" there are large disparities between the on-reserve population and the larger Canadian population in terms of income, employment rates, infant mortality, suicide rates, basic infrastructure etc. [Ibid.]. Furthermore, the significant infrastructural, engineering and technical needs of Aboriginal communities are still primarily addressed by non-Native people. There are just not enough Aboriginal engineers and scientists to go around. This lack of trained community people means that huge sums of money leave Aboriginal communities and do not contribute to local economic development, thereby exacerbating existing conditions and maintaining "dependency" conditions.

For self-government to become a reality education is key. In 1979, less than 100 Aboriginal people were enrolled in post-secondary institutions across Canada [Munro 1979]. That number grew exponentially to 27,000 in 1994-95 [DIAND 1997]. While the trend is very encouraging, the reality is that in 1991 only 2.6% of the Aboriginal population over the age of 15 held university degrees (compared with 11.6% of the non-Aboriginal population) [RCAP 1996]. In addition, there is still tremendous dropout rate at the secondary level; the 1991 census indicated that less than half of Aboriginal people were completing high school [Ibid.]. The long-term goal of self-government requires that the pool of young Aboriginal people with the skills to fill leadership positions in all sectors must grow dramatically within the short- and medium-terms.

The Native Access to Engineering Program, First Nations SchoolNet and the WWW

The Native Access to Engineering Program was initially established to promote the engineering profession to Aboriginal high school students in Quebec. It began as a series of summer camps where Native students were invited into the university for a week to learn about engineering and its connection to their communities and traditions. Unfortunately, there was no follow-up support in community after the students returned home. The next step was to provide concrete support for teachers in schools so that they could connect engineering to the existing curriculum in a culturally relevant manner. This led to the ongoing development of a series of newsletters, worksheets and teacher's guides, which were - at first - distributed only in hard copy. As the project has evolved, it has become more and more focused on distance learning; connecting students, teachers and leaders from different and widespread First Nations communities together through information about science, engineering, tradition, leadership, sustainable community development and how they interact.

The costs associated with producing, printing and distributing curriculum materials are substantial; to extend the program across Canada, to 631 reserves (plus a number of urban schools) would be prohibitive without the use of a network like the WWW. Luckily, the Canadian Government has made a serious commitment to national connectedness, and particularly for connectedness of Aboriginal schools and communities. Through the First

Nations SchoolNet program run by Industry Canada, every Aboriginal school under federal jurisdiction will be connected to the Internet. The program is run in partnership with telecommunications companies in the Stentor Alliance. These companies absorb the cost of providing high speed Internet access to First Nations schools through Telesat's DirecPC satellite services [Industry Canada Summer '98]. Schools receive satellite terminals, computers, funding and technical support from SchoolNet; as of the fall of 1998 the project was 80% complete [Industry Canada Fall '98]. So, the network for distribution of the Native Access to Engineering Program's material exists.

The Native Access to Engineering web site (<http://www.nativeaccess.com>) allows teachers, students, parents and community leaders to access all of the program's materials in an on-line interactive format or to download it for classroom use in PDF format. It also provides teachers, who are generally young, non-Native and posted to isolated communities with few resources, with access to culturally relevant math and science teaching tools. Perhaps even more importantly, the WWW allows for the delivery of material in a highly visual format which matches the learning style of Aboriginal students. In the future, the site will be expanded to include interactive features where students on reserve can talk with engineering students at Concordia, connect with mentors, get online tutoring and consult advisors for education and career counseling.

Conclusion

Aboriginal communities in Canada have not generally been successful in producing large numbers of graduates. Thus far, delivery of education that has focused on western world views has proven inadequate. It is hoped that the combination of curriculum materials which incorporate and celebrate Native culture and wisdom with the interactivity and visual interface of the WWW will offer students a new way to look at the world, and a new way to see themselves which might encourage their exploration of and curiosity about math, science and engineering.

Incorporating Web-Based and Virtual Reality Instruction into a Distance Education Course Using the ADDIE Model of Instructional Design

Kelly Ann Yamashiro, Instructional Systems, The Pennsylvania State University, U.S.A., kxy125@psu.edu

Jack Lee, Workforce Education, The Pennsylvania State University, U.S.A., jtl106@psu.edu

Xun Ge, Instructional Systems, The Pennsylvania State University, U.S.A., xxg4@psu.edu

Abstract: The use of virtual reality (VR) applications in web-based distance education is still in its infancy. Instructors and instructional designers do not have specific models, let alone many case studies, upon which to design and implement web-based distance instruction using VR applications. Therefore, the purpose of this paper is to describe a case in which the well-known ADDIE model of instructional design was used to create the instruction for a one-hour web-based seminar using a VR application.

1. Introduction

Virtual reality (VR) is the ability to immerse the computer user, as an active participant as opposed to a passive viewer, in a computer-generated experience [Grimsdale 95]. The use of VR applications in web-based distance education is still in its infancy. Instructors and instructional designers do not have specific models, let alone many case studies, upon which to design and implement web-based distance instruction using VR applications. Therefore, the purpose of this paper is to describe a case in which the well-known ADDIE model of instructional design was used to create the instruction for a one-hour web-based seminar using a VR application.

2. Background

The virtual seminar was part of an advanced undergraduate communications course on computer-mediated communication (CMC) that was taught at a distance at a medium-sized American university during the fall of 1998. The VR application chosen for this seminar was The Palace, a web-based chat, client/server program that lets both the instructor and learners, who are represented by a creative avatar, go from room to room inside virtual worlds to chat, problem solve, collaborate, share, play, learn, explore, experience, and talk with other learners around the world. To design and develop the seminar instruction, the ADDIE model was used.

3. The ADDIE Model

ADDIE (Analysis, Design, Development, Implementation, and Evaluation) is an acronym for the basic phases one can follow in creating instruction [Rossett 87]. In the Analysis phase, one searches for and defines the problem and determines whether instruction is the appropriate intervention. If instruction can solve the problem, then information about the learners is sought and used in the Design phase in which the overall goal and specific learning objectives are created based on the desired learning outcomes, and the instructional strategies and delivery medium or media are selected. Once the instruction has been designed, the actual instructional product(s) (i.e., print materials, web pages, computer programs, etc.) are produced in the Development phase. The instruction is then tested during the Implementation phase. Finally, the success of the instruction is determined during the Evaluation phase.

4. Using the ADDIE Model in VR Distance Instruction

4.1 Analysis

During the Analysis phase, designers gathered information on the course goal and objectives, the types of CMC applications to be taught and used in the course, and the required course readings and assignments. Information about the learners was gleaned from an online student background survey, student homepages, and correspondence with the course instructor. Information about the learning environment, especially the technologies and Internet connection speeds particular to each student as well as to the campus computer labs to which students have access to, was provided by the instructor.

4.2 Design

Based upon the information gathered in the Analysis phase, the goal and learning objectives for the virtual seminar were decided upon and the instructional media were selected. The goal was to gain knowledge and skills on The Palace in order to comment upon its application in a learning environment. The Palace was selected as the instructional medium based upon such factors as availability of and access to the medium, cost of the medium, the amount of knowledge and skill required to operate in and communicate with the medium, the development time and complexity of programming needed to create the learning environment for the medium, and the availability of and access to the technologies needed to access the medium. The instructional products for the seminar were also decided upon, and specific instructional strategies, such as the use of role-playing in The Palace learning environment, the use and varying types of pre-seminar instruction, and the use of questions both during and after the seminar, were incorporated into the design of the instructional products.

4.3 Development

Besides the actual production of the instructional products during the Development phase, which included a lesson plan for the seminar, pre-seminar web-based instruction, pre-seminar email instruction, pre-seminar in-class, hands-on instruction, and The Palace learning environment itself, the use of VR required that the developer create the virtual tools, such as avatars and props, that the student would use during the seminar.

4.4 Implementation

While the virtual seminar was the core of the instruction, the implementation of instruction actually began with an in-class, hands-on orientation to The Palace, followed by further instruction delivered via the web and email. Once the pre-seminar instruction was implemented, the virtual Palace seminar took place for one hour with three groups, each consisting of three to five students.

4.5 Evaluation

As this is a work in-progress, the authors are still in the process of conducting both formative and summative evaluations of the distance instruction in order to refine the instruction and determine whether the goal of the instruction was achieved.

5. Conclusion

Positive post-seminar comments from the seminar participants, course instructor, moderators, and instructional designers seem to indicate that the ADDIE model can be a good general system to follow when trying to incorporate web-based and VR instruction into a distance education course.

Work-in-Progress Short Papers

Web Architectures for Database Access

Nicola Aloia, Cesare Concordia, Vittorio Miori
CNUCE – Istituto del Consiglio Nazionale delle Ricerche
Via S. Maria 36, 56126 Pisa - Italy
E-mail N.Aloia@cnuce.cnr.it

Abstract: Starting from may 1998 the “Istituto per lo Sviluppo della Formazione Professionale dei Lavoratori” (ISFOL), at the request of the Italian Ministry of the Environment, begins to render accessible via Web the results of a nation-wide census on the teaching and training activities pertaining to environmental themes carried out at Italian universities, secondary schools and professional training centres. The paper documents in brief the technical solutions adopted in implementing that part of the Web accessible information system relative to querying the database via the WWW. The system has been realised using currently available Java technologies such as applets and servlets interfaced to the database system through the JDBC. The paper also introduce the evolution of the system.

Introduction

The rapid growth of the Internet in recent years has brought about a considerable increase in the structural and organisational complexity of the data accessible and distributed via the Web, thus engendering a huge enriching of the information available. Great impetus towards a *global* information system came mainly through two factors: the integration of Web data with database management systems (DBMS) and the development of “*intelligent browsers*”, enabling local execution of *mobile code*. Nowadays, the combined exploitation of these two characteristics is ever more frequent in high information-content Web sites. The chance to test out the technologies for Web access to DBMS in actual use was afforded in the framework of the project “*Development and distribution of an information system on environmental training*” [Aloia et al. 98].

The ANFORA Information System

The project's ultimate aim was to render more accessible the results of a nation-wide census on the teaching and training activities pertaining to environmental themes. From the computer-science perspective, the goal we established for ourselves was to set up a system which would be independent

of the specific hardware or software characteristics. The architecture opted for was a three-tiered system. The interfaces for formulating data searches are made up of a number of Java applets that enable users to specify suitable filters in a friendly way. Interaction with the DBMS takes place on the server by means of servlets., which builds the queries and executes them through the JDBC driver [Hamilton et al. 98], then passes the results over to the Web Server, which formats and transmits them to the client. In order to improve server-side performance, we adopted a solution that consists of activating a pool of connections, each of which is managed by a single thread (connection broker). Because of the 'persistent' nature of the servlets, the connections will be shared by subsequent DBMS invocations. The system performed well in several tests using different DBMS, as well as different JDBC drivers, with no source code modifications whatever.

Next Step: INFEA an Open Hypermedia System

A new phase of the project, supported by the Italian Environment Ministry, is in progress and is named INFEA. The aim is the development of an Open Hypermedia System in which the users become actors in the management of the information related to environmental issues. The needs for co-operative work and distance learning are important requirements of the new system. Our main goal is the implementation of a Web Based Information System that integrates the DBMS technology with new tools available on the Web, such as those for the Computer Supported Co-operative Work (CSCW). The architecture of the system we adopt is multi-tier. Thin client realised by means of Java applets, and/or XML, communicates with the application server using CORBA and/or Java RMI [Orfali et al. 98]. The application server implements the business logic using the Enterprise Java Beans technology and manage the interaction with the DBMS..

WebQP : Web-based Teaching Assistant Quizzes Provider

Hiroyuki Anzai Takayuki Hirahara Keisuke Mori
Dept. of Engineering, Kyushu Kyoritsu Univ., Japan, IPERI, Kyushu Kyoritsu Univ., Japan
anzai@kyukyo-u.ac.jp hirahara@kyukyo-u.ac.jp kmori@kyukyo-u.ac.jp

Abstract : This paper reports a kind of web-based CAI server system called WebQP that has a database storing teaching materials for quizzes written by teachers or editors via www in support of WebQP and, when accessed from students or learners, sends them pages containing quizzes constructed from the database, making them learn by means of answering the quizzes and reading explanations sent after answered. For each learner and for each quiz, the learner's answer is recorded and used for selecting quizzes hereafter to be sent. WebQP has now three question types of quizzes: word-mean, multiple-choice, and matching. After teaching, WebQP serves to make students review and soon to know how much they learned.

1. Introduction

We have been developing a kind of web-based CAI server system that gives students or learners various types of quizzes related to contents of teaching courses. We call it WebQP and have used it on trial in a class for teaching C/C++ programming. This paper describes the WebQP, which is now working on our web-site.

Since 1997, we have tried to develop various applications as the university intranet information systems supporting education and researches, working on our web-site managed by IIS(Internet Information Server) on a Windows NT server and using a database Microsoft Access. They are systems for searching books, for seeking employment and for distributed data-input and automatic publishing of home pages with unified specification such as teaching staff information, syllabuses and so on. On the same web-site environment, WebQP has now been developing and working. They are shown (almost in Japanese) at <http://anzlabo.elec.kyukyo-u.ac.jp/>

2. Outline

This system WebQP is given as two sets of ASP files, HTML page files, image files and so on. One of the sets is for authoring and the other for learning. Namely, the former, *the authoring management part*, makes teachers or editors input teaching materials into the web database through intranet/internet from their web browsers on their machines. This part has a table called *Editor Table* used for managing editors or teachers registered. And the latter, *the learning management part*, makes students or learners learn by solving quizzes written in pages which are generated from the web-database and sent to web-browsers on their machines. And this part has also a table called *Learner Table* used for managing students or learners registered.

In the database, we have now three kinds of teaching material tables that each record in the tables has two fields such as a word or a term and its mean (*Type 1: Term dictionary*), a problem and solution candidates of which only one is correct (*Type 2: Quiz dictionary with solution candidates*), or a problem and all correct answers (*Type 3: Quiz dictionary with solutions*). From the record, a quiz page is generated and sent to learners. And furthermore, each record has a field containing a detailed explanation sent to the learners after answered, fields of evaluations obtained by analyzing answers of the learners, and fields describing information used to determine the timing of making a quiz to be sent.

These tables (i.e. dictionaries) are all managed in a table called *Dictionary Table*.

3. Quiz Tables And Quiz Pages

According to the above three types of tables, the following types of quiz pages are derived.

Quiz pages derived from the type 1 table are used for making users learn terminology in various fields. Each page contains a sentence, some terms and such a question which term has the sentence as its mean. The sentence that means a term has to be carefully described not so as to use the term itself. Of course, the detailed explanation sent after answered can fully use the term if necessary.

Each quiz page derived from the type 2 table contains a problem and its solution candidates which are all only copied directly from a record in the table. When one of the solution candidates is clicked, it is sent to WebQP as its answer.

Each quiz page derived from the type 3 table contains a problem and a text area where the answer has to be typed. And then the answer is sent to WebQP where it is compared with each one of the solutions.

4. WebQP Serves For Authoring And Learning

After a person is registered by the authoring management part as one of teaching material editors, the person is able to make the system create a table, insert records into the table and update the records from a web-browser on their machine. When creating a table, the editor has to attach a title to the table representing a branch concerned with contents that the editor wants to write in the table and to select the type out of the above mentioned three. The editor can make the system open or close the table to be used by the learning management part.

When accessed from a learner, the learning management part of our system makes the learner select one of the titles of tables related to such the branch that the learner needs or wants to learn. Then the system generates a page containing a quiz constructed by the system from the table according to the above-mentioned characteristic and sends it to the learner. When the learner sends back an answer to the system, the system at once returns a page that makes the learner know whether it is correct or not and describes the detailed explanation related to the quiz.

The order of getting quizzes out of a dictionary in the database is from the first to the last. However, it is locally randomized. Therefore, it is able to make orders of quiz sequences sending to client machines different each other but obtaining globally the property of the sequence from the basic to the higher. Furthermore, for each learner and for each quiz, the results of the answers are recorded and used for selecting the successive quizzes and for evaluating their achievement and the quiz itself.

As an option, a user can call out a Microsoft Agent which speaks various messages according to each stage of the learning process.

5. Remarks

Each ASP is written in JavaScript for client side scripting and in VBScript for server side scripting. In a page, places used for debugging is written in VBScript as client side scripting in order to find there easily.

Microsoft Access used as the web-database in WebQP is now working well. The speed of LAN may protect from over-accesses to it. The quiz tables (i.e. dictionaries) are independent each other and managed only in the Dictionary Table. Therefore it is easy that any one of the tables move into the other WebQP working on the other web-site.

After teaching a class, we have made students in the class review the lesson by using this system. In process of successively applying quizzes given by the system, we expected the students to effectively learn by carefully reading the explanation sent after answered. As result, we had been very pleased to find the students working earnestly with WebQP in spite of enriching the contents of the lessons.

Toward a Taxonomy of Risks to Human Subjects involved in Internet-based Research

Melinda C. Bier

Abstract: The practical application of research ethics must continually evolve to remain relevant as more research involves computer-mediated communication (CMC) and Internet-based research. There is a broad scope of harms to which subjects of research may be at risk. Physical harm, psychological abuse, loss of privacy, and unwanted public exposure are common research concerns that take on an added edge in research involving CMC. The permeability of the Net; the persistence of electronic data; and the electronic identification inherent in CMC all pose unique and far-reaching risks to subjects. The authors present a taxonomy of risks to human subjects organized by research intervention.

In June 1999 the AAAS (American Association for the Advancement of Science) and the OPRR (Office for Protection From Research Risks) sponsored an exploratory workshop on "Ethical and Legal Aspects of Human Subjects Research in Cyberspace" in Washington DC. The intent of this gathering was to reflect on ethical concerns emerging as research using the Internet and studies of the Internet and cybercommunities become common. As part of that workshop the authors presented a talk on the risks and benefits of research on the Internet. Building on this work the authors present a taxonomy of risks of Internet research organized by the type of research intervention.

There is a broad scope of harms to which subjects of research may be at risk. The extreme of that harm would be physical injury and death. More common concerns include psychological abuse, loss of privacy, and unwanted public exposure. Additional concerns include damage to interpersonal relationships, legal jeopardy, and threats to one's livelihood or career. Computer-mediated communications intensifies the historically identified risks of research articulated in both biomedical and social science literature. All of the above risks, including death, may come about as a consequence of public exposure or an undesired sharing of the information provided to researchers by, and about, subjects. The severity of this breach is, of course, dependent on a number of variables, such as the sensitivity of the information gathered, the vulnerability of the subjects, and to whom the information becomes available. Each of the above potential harms is made more likely, however, for subjects involved in research using the Internet because three features of computer-mediated communications (CMC) can contribute to just such a public exposure.

First, we discuss the risks inherent in the *permeability* of Net communications and suggest precautions that can be taken to minimize that risk. Second, we discuss the risks that accompany the *persistence* of electronic data, including storage mediums, and issues involving collecting such data into databases. Third, we review the potential risks of *electronic identification* inherent in computer-mediated communications. We discuss cases in which these risks have manifested in the harm of subjects.

There are many non-obvious implications of computer-mediated communication and several ways researchers can and should protect the subjects of their research. These questions are of interest to researchers, policy makers, commercial providers and the whole range of Internet users because given the permeability of the web, all users may be unwitting subjects of research and other forms of invasive data collection.

Establishment and Management of the Padua Astronomical Observatory Web Site www.pd.astro.it

Caterina Boccato, Astronomical Observatory of Padua, Italy, E.U.
boccato@pd.astro.it

Abstract: The Web Site of the Astronomical Observatory of Padua (Italy) has been one of the first sites of WWW in 1994. The increase in the volume of information and resources available on the Web for Astronomers required a complete revision of the Site organization and a new full time position for a person in charge of this project.

A new site capable of presenting the Observatory to the outside world and at the same time capable of supplying useful services for its employees has been created. Steps towards the realization of the new Web Site, problems encountered, adapted solutions and lessons learned are here described and discussed.

In 1994 the Astronomical Observatory of Padua created one of the first Web sites.

It is important to note that some of the pioneers of the Net are to be found within astronomical Institutes. The reasons being that the category of Astronomers consists of few people spread all over the World, and their work largely consists in elaborating large amounts of data (images) and in transmitting the results to other colleagues in a collaborative environment. In 5 years the site has provided different services that have been mainly aimed at researchers. The explosion of the World Wide Web has been fundamental to its growth: in fact astrophysical information, both the quantity and type of data, available on Internet has grown incredibly [Andernach H. (1998)].

Nowadays, the typical work cycle of an astronomer is almost all done on the Web.

The increase in the volume of information and resources available on the Web meant that the first site's organization had to be reviewed. Therefore, the Observatory decided to appoint a person who would be in charge of managing the Site.

My work as Webmaster began in March 1998. The results of a first careful analysis made it clear that the site had to be designed from "scratch", nothing could be gained by gathering more information and putting the existing material in order. There were 5 stages to the re-organization: *Planning, Revision, Establishing the prototype, Feedback from a chosen sample group of users* and *Publishing*. After publishing the 6th stage, *management*, is still in progress now. Planning and revision required the most work and time.

Planning

It was evident right from the beginning that the main problem was one connected to the *organization*, therefore, it was necessary to get right into the Observatory's work organization system.

Three principal aims were established during this stage:

1. The new site would have to have a *double use*: a) to offer important services for the benefit of the Observatory's personnel, both researchers and administrative staff (Intranet), b) to provide services for its external users, for example Astronomers of other Institutes, people interested in Astronomy, etc... It would have to act as an interface between the Observatory and the World outside.

Achieving this aim was made possible by choosing the right kind of *contents* that would be made available on the Net [Siegel D. (1997)].

2. The site would have to be organized so that it could be *visited by as many people as possible*, therefore, delivering quick and specific services. To reach this second aim the contents had to be *organized* in an efficient and effective manner, as well as having an appropriate graphic design.

3. The site would have to be organized in such a way to allow the Webmaster *constant supervision and updating* of both the contents and technology. Before this could be done precise rules had to be defined regarding who would supply the contents, which methods would be used, and what would be the limits of the Webmaster's responsibility. The latter regarded *choosing the kind of behaviour* to adopt in all the phases of the fine tuning of the new site.

Revision

The revision phase consisted in presenting the project to the Director of the Observatory, to people that supervise the project, and to several researchers who had been actively involved in realizing the first site. For 7 months the project was continually reviewed, revised and replanned, each time a more complete and correct project was proposed until eventually a scheme was defined and the prototype of the Web application could be developed.

Establishing the prototype

It took 6 months to realize the prototype, at the beginning this 3rd stage overlapped the planning and revision stages. The main tool used to manage and realize the application of the Web was MS Front Page '98.

Feedback

A sample group of users from the Observatory was chosen. Their different suggestions, ideas, problems they had encountered were all gathered and listened to and, the modifications were made accordingly.

Publishing

After the feedback stage the Site was published and the first one was then substituted.

Management

After the Site was published, it could be said that it was not only the start of the management stage but also the beginning of a new phase of feedback, which would provide useful information valuable for improving the Site. This was made possible by the flexible structure that had been chosen for its organization, more will be said about this in the description of the Site further on.

The actual management stage consists mainly in keeping the contents updated, in order to do this efficiently it is necessary to be fully involved in the organization of the work of a public Institute. It is essential to know who to ask for information regarding work and the people to address to about making certain information public or not.

Description of the Site

The new site was structured and organized in the following way in order to reach the three aims mentioned above:

1. The *contents* were chosen so that the Site would have a "double" use:

i) There is a section that is for Observatory employees only, which gives them the possibility to fill in administrative forms on-line. There are also other sections which are of interest not only for internal Observatory staff but also for external users, too.

ii) There is a section dedicated to scientific Research carried out at our Institute. This is of utmost importance for the external position of the Observatory, as unfortunately not all researchers present their work on the Web. This particular section was created with the aim of stimulating them to transfer their research and results on to the Web.

In the Web server of the Astronomical Observatory there is also an *education and outreach Web site of Astronomy* which is introduced during this conference in a Poster/Demonstration intitled: "*Catch the stars in the Net*" an *Astronomy educational and outreach project via the Web*.

2. *The organization of the contents and the specific techniques* of the site were planned in a logical structure so that the users can get exactly and quickly what they need without feeling frustrated by unnecessary complex operations. With this aim in mind we decided to choose a hierarchical structure.

Such a solution represents one of the best ways of organizing information for such a type of Web site [Lynch & Horton, 1999]. The site is, therefore, organized around a Home Page that acts as a point of entry into all the other pages. The information available through the Home Page is divided into 3 different levels of complexity and depth.

As well as having organized the contents according to the above-mentioned structure 2 other choices were made: a technological crossbrowser and simple graphics. The graphics were designed to create a visual hierarchy, which would accentuate the most important elements.

3. During the planning stage *the Webmaster's role was defined*. Once agreed that the principal task was to organize the contents present on the Web site, it was then decided who would supply them. It was also decided that all the documents regarding bureaucratic-administrative matters would be visioned by the Director of the Observatory before being made public.

The main information of the research section is supplied by the researchers, who have complete responsibility for the contents reported in it. In this case the service provided by the Webmaster concerns the final step of it being presented on the Net or the creation of specific links.

In *conclusion*, after a complete restructuring, I can say now that the new Site satisfy the users. This can be argued by the increased number of entries and by the positive feedback. The future development plans for the Site are the implementation of the Intranet side that will concern the administrative application forms that will become totally automatic. This, however, will be possible when there are specific laws regarding digital signatures. Future plans for Internet are mainly concerned with developing the Research section so that all the scientific results carried out at our Observatory are presented on the Web.

Abstract: The WWW represents a privileged environment when trainers want to extract information in order to produce hypermedia courses for Distance Education (DE). This paper presents research work in progress that aims to conceptualise an information retrieval method in this educational context. It is advisable to design trainers' features, to clarify how these features define trainers' needs and to study how this need expression is used in the information retrieval process.

1. Introduction

The huge documentary multimedia and educational data available on the WWW is increasingly used by Distance Education (DE) trainers in order to design hypermedia courses. The structure and navigation of educational materials must be planned in accordance with pedagogical goals and learners' features (knowledge, experience, skills and above all, isolation). Thus, information retrievals, which are done in order to exploit WWW data in this DE context, are fixed by criteria related to course conception, and they are bound by trainers' knowledge and skills.

However, the diversity of Web data and the escalating number of users, lead information search tools (such as Altavista,...) to implement a maximal standardised service. These tools are not adjusted to the trainers' features and trainers' needs and trainers have many problems in the interrogation step and results analysis step. Trainers must visit one site after the other because they can't target their information extraction and results are not necessarily relevant to pedagogical course goals.

This inability to adapt often discourages trainers causing them to abandon Web information exploitation [Wilkinson, 1999]. So, an interesting research problematic arises to study the possibilities to adjust information retrievals to suit trainers developing hypermedia courses for DE. This paper presents research work in progress that aims to conceptualise an information retrieval method in an educational context. This method seeks to give to trainers assistance at need expression step, results extraction step and results analysis step. The next paragraph describes the different points of view of this problematic.

2. A method of information retrieval dedicated to trainers properties

It seems essential to identify educational context particulars through trainers' specificities. For conceptualising trainers' features, we employ user model concept like Eklund and Zeiliger in [Eklund, Zeiliger, 1996]. Thus, the study of a trainers group and trainers' activity enable us to build the *trainer model* to define their main stereotypes. We assumed that in DE context, trainers' stereotype are related to educational materials, conception strategies, learning strategies and learners' features.

A fundamental first step is to define how information need is expressed according to Web sites or Web pages and to specify the relevance concept. Thus, we consider a site as an entity with a set of features, such as textual content, external hypertext links, internal hypertext links and ergonomics point of view, ... So, a relevant Web site

can be defined as an entity with a subset of these features each equal to a particular value. As result, defining a trainer's need is equivalent to identifying these features and assigning them a value. A set of reference criteria, called the *reference model*, must be designed according to trainers' features and DE context particularities.

Then, equivalence between all stereotypes intrinsic to the *trainer model* and all criteria pertaining to the *reference model* must be achieved. It is necessary to study how the pedagogical goals, trainers' knowledge and preferences determine document textual content, document organisation and document ergonomics. Moreover, it is indispensable to analyse what conditions related to Web sites features are implied by authoring course process. We realised a first empirical study with a trainer member of the DESS SIM (a post graduate diploma which provides an eight hundred hours specialised course in multimedia). It is a distant course and it will be reported in September 1999 at the University of Picardie and presented by Lecllet, in [Lecllet, 1999]. Realisations and perspectives of this study are described below.

Finally, comparison between the *reference model* and the Web site must be determined. Firstly a protocol allowing comparisons of Web sites features with criteria of the *reference model* must be designed. Then, the result of this comparison defines the *relevance indicator* that is presented to the trainers and estimates the correlation between Web sites and trainers' needs. However, a comparison between the *reference model* and the all Web sites is difficulty feasible. Consequently, it seems appropriate to use existing search engines, such as Altavista, and compare the *reference model* only with a subset of Web sites, which are extracted by "classic" keyword queries.

Experimental information retrievals were performed in order to build a Human Computer Interaction course, integrated to the DESS SIMAD. An information retrieval process, which can be composed in three steps, had permitted to valid results by trainers. The first concerns the production of a set of keyword queries for a same search session, according to the *reference model*. The second consists of setting these results in a corpus, which is filtered two times successively. The first filter level removes redundant and not valid links. The second eliminates Web sites that do not carry the features determined by the trainer. At this level, a filter is equivalent to the definition, for a feature F, of an only and necessary value V or a set of values V_i ($1 \leq i \leq n$, n is the number of values). All Web sites with the feature F not equal to V or to one of the set of values V_i are eliminated. Finally, the third step of the information retrieval process is composed by the relevance estimation of the results according to the trainers' expressed needs. Firstly, this estimation is made informally with the trainers' collaboration and would be developed when the experimental corpus gets bigger.

3. Conclusion and perspectives

This experimentation underlines that the trainers' need expression step and the results validation step must be formalised. We propose now a new experimental protocol with a group of DESS SIMAD trainers design hypermedia courses. Several steps make up this protocol. The first corresponds to an interview with each trainer in order to define their need and to identify their preferences, the pedagogical goals, the learning strategy and the characteristics of authoring process. The second aims to synthesise the interviews in order to design a questionnaire and consequently build the *reference model*. The third consists of perform customised information retrievals, according to the information retrieval process described above and the responses to the questionnaire. Results estimation and validation gather the last one. The results are submitted to the trainers together with a satisfaction rating. Questionnaire responses will allow us to verify the original hypothesis stated about the *trainer model* and the *reference model*, to upgrade those models and to achieve a first validation of our method.

Later, the method will be partially automated in order to achieve an information retrieval supporting tool adapted to trainers' features in DE context. The conception of this tool would be described in future communications.

Abstract: The Journal of High Energy Physics (JHEP) is a scientific journal written, run, and distributed by electronic means, the entire editorial work is carried out by means of a software. JHEP encompasses all areas of High Energy Physics, and is produced by ISAS (International School for Advanced Studies, Trieste-Italy) INFN (Italian Institute of Nuclear Physics, Italy), the CERN (European Laboratory for Particle Physics) and IOPP (Institute of Physics Publishing, UK), with the support of the scientific community. Born in July 1997, JHEP is now established as one of the leading journals in the field.

The Journal

The Journal of High Energy Physics (JHEP) is a scientific journal written, run and distributed by electronic means. In running such a journal the objective is to capitalize on the innovative advantages of the new media: rapidity of communication, broad diffusion and low costs.

First published in July 1997, JHEP was a natural outgrowth of the extensive use of electronic means by the community of physicists. Particularly remarkable are the electronic preprint archives (<http://xxx.lanl.gov/>) of the Los Alamos National Laboratory that have so successfully replaced the conventional system. JHEP is now an established publication and one of the leading journals in the field of High Energy Physics. At present it is produced and funded by ISAS (International School for Advanced Studies, Trieste-Italy), INFN (Italian Institute of Nuclear Physics, Italy), the CERN (European Laboratory for Particle Physics), and IOPP (Institute of Physics Publishing, UK), with the support of the scientific community. It is a truly not for profit enterprise, and the access to the journal is completely free of charge for all interested users.

The quality of the journal is guaranteed by the Advisory and Editorial Boards, composed by the most distinguished scientists in the field. Furthermore, JHEP has maintained the system of peer review, that constitutes the most remarkable difference between scientific journals and the online archives of papers [Boyce 1999, Harnad 1999 and references therein, Smith 1999]. Paper and CD-ROM versions of the electronic archive are published and distributed by the Institute of Physics Publishing (IOPP, UK).

Market Impact

Scientific communication has become instantaneous, with authors creating their personal library on their computers, thereby avoiding thousands of unnecessary pages. Retrieval and printing with book quality is possible at very low costs. At the same time, most libraries have been squeezed financially and archival space problems have become critical. As a consequence, over the past fifteen years most libraries have gone through the painful process of cutting subscriptions. The US Association of Research Libraries calculates that its 114 member libraries spent 142% more on journals in 1997 than 10 years before, but ordered 6% fewer titles. In

the same year Reed-Elsevier, the publisher of 1200 scientific journals, reported profits of 378 million US\$ on sales of 938 million US\$ in its scientific activities [Butler 1999]. Commercial publishers and learned societies have introduced electronic versions of their journals. However, they have linked their use to subscribing to paper versions or are reintroducing page charges (for a list of Physics online journals see <http://PhysicsWeb.org/>).

JHEP has proved to be an efficient and cheap alternative to conventional publishing that nevertheless maintains essential publishing features: scientific and editorial quality control, easy retrieval, and archival responsibility for the future. The costs of running such a journal can be easily supported by the scientific community, and funds thus saved that can be earmarked for other scientific purposes. JHEP could therefore be the right answer to the need for a new path for scientific communication. Although it is now produced for the High Energy Physics community, it could be considered as a model for developing other scientific journals in a number of disciplines.

How JHEP Works

The online publication of papers is made possible by the complete automation of the editorial work, that is carried out by means of a software robot, thereby reducing costs and speeding up the procedure. The software takes care of all stages of the editorial procedure: submission of papers, assignment of the papers to the appropriate editors, review by referees, communication between editors, referees and the Executive Office, revision, proof-reading and publication of papers, as well as the administration of the journal. Accepted papers are made available on the JHEP websites to all interested readers.

The JHEP software robot consists of three major families of programs. The first allows the interaction between JHEP and the scientific community, which is the section where papers are published and submitted by the authors. The second family runs the interface among editors, between editors and referees, and between editors and authors. The third family is in charge of the administration of the journal.

To assure reliability and fast connections, JHEP is a network of nodes. Currently active sites are:

<http://jhep.sissa.it> <http://jhep.cern.ch> <http://jhep.mse.jhu.edu> <http://jhep.weizmann.ac.il>
<http://jhep.jinr.ru> <http://jhep.yukawa.kyoto-u.ac.jp> <http://jhep.tifr.res.in> <http://jhep.ift.unesp.br>

All nodes are equivalent and kept synchronized. All events taking place at any of the nodes are immediately notified to the other nodes. On notification, the nodes execute the corresponding action and update themselves accordingly. All transactions are encrypted to protect the data.

Special multimedia facilities have been added to enhance the possibilities offered by the Web:

- Powerful search engines replace the table of contents and indexes used by paper journals
- Papers, which published in three different formats (PDF, PS, DVI), are hypertexts, with links within the article and to the papers quoted in the references
- The possibility for readers to post comments and ask questions to the authors of the published papers is currently being developed
- The possibility of using JAVA to view papers directly with a browser is currently being developed.

Mechanisms for Video Integration and Navigation on the Web

Teresa Chambel, Nuno Guimarães
DI-FCUL, Portugal, E-mail: tc@di.fc.ul.pt, nmg@di.fc.ul.pt

Abstract: This paper discusses the main issues and presents mechanisms for video integration and navigation on the Web.

There is an increasing interest in the use of video in hypermedia, and in particular on the Web. The motivation isn't new, but technological advances are making it more feasible, by reducing the limitations in cost, distribution and display. To provide video on the Web is a flexible way to publish and access video information. It simplifies the distribution process, and provides the user with the possibility to access it anywhere, anytime and at his own pace. Furthermore, in an hypermedia environment, video can be integrated with other information and tools in a seamless way, opening new dimensions not present in either medium by itself. In spite of its potential, video has been integrated in hypermedia, and the Web in particular, in a rather poor way. Until recently, when supported, video could only be manipulated in a way similar to a VCR, and links could only be made to or from video as a whole. True integration of video in hypermedia requires a more powerful model, defining the semantic of linking to other videos or other media, and an adequate navigation support.

To achieve video integration in hypermedia, there is a need for video hyperlinking support. In [Chambel 99], we define a model and tools for hypervideo on the Web. Besides from the basic linking mechanism in space and time, there are significant challenges to the navigation support, when this dynamic medium is involved. Link awareness is one such challenge: how link anchors should be represented in order to be perceived by the user? It is a particularly relevant issue, considering that: links may have duration; several links can coexist in time and space; and video changes in time, requiring a more permanent attention from the user. More information has to be provided, in a way that is not too distracting to the user, but helps in navigation. We identified five types of link awareness relevant in hypervideo: Where From: where is the link anchor or hot spot?; Where To: what is the destination of the link?; When: when do we have link opportunities?; When To: what is the destination sub-video?; For How Long: for how long will the links remain active? In that paper, we go into more detail in this respect and give some examples.

Being a dynamic medium, video content changes over time while presented. As such, the information space where it is integrated can also change somehow, reflecting new relations with it. An example of this is the integration of the video with some external information that acts as its index, referring to different portions of the video. This information can act as a map to the video, providing information about its content and assistance to its navigation, as orientation and direct access. For this purpose, we define a video index as a sequence of entries, relating time positions in the video with the information chosen to represent that part of the video. Indexes can be represented by text, images or video. For each entry, there are two states: *on* and *off*. An entry is *on*, while the cursor is over it, or when the video is playing on the time interval to which the entry corresponds. This is true, even when the current position on the video changes, in response to direct access through video controls, or after a follow link into the video. Entries are also defined as links to the corresponding moments on the video.

On and *off* states can be represented in different ways, depending on the type of the entry. For image entries, two different images are used. These typically correspond to different versions of the same image, with different highlights. Figure 2 (figures available at http://www.di.fc.ul.pt/~tc/webnet99_figures) exemplifies a video index where the index entries are images: the first frame of the video at the corresponding time. *On* state is represented by the flat frame image. *Off* state is represented by another version of the same image: embossed, shadowed and a little smaller. In this example, going from *off* to *on* state has a visual effect similar to a button click, also making the image clear and easily spotted, for orientation purposes. For text entries, *on* and *off* states can be represented by changes in text properties: color, font, size, style, etc., in isolation or combined. Figure 1 exemplifies a text index, where the status is differentiated by color (*on*: white, *off*: dark blue). Video entries can be small segments of the video, from the beginning of the video segment they are representing. *On* and *off* states can correspond to play and stop or pause video states. In this case, when the cursor is moved over an index entry, a small preview of the destination video is played.

A visual summary of the video can be constructed as a video index, based on the images that correspond to scene changes, and can be constructed with the aid of video processing techniques [Correia 96]. Using the visibility property for images *on/off* state, slide presentations can be synchronized with a video. More than one index can be associated with the same video. In this way, it is possible to have more than one type of additional information associated and

synchronized with the video. For example, an index representing the video table of contents, and another one showing the exercises relevant to the video topic being presented.

Indexes can also have the functionality of a play list. For this, index entries have a selected state and an order. Playing this kind of index has the effect of playing, in the specified order, the video segments corresponding to the selected index entries. The entries state and order can be changed interactively, and can be defined with an initial value by the page author. If defined invisible, a play list will just influence the way the video is played, with no interference from the user. The play list functionality is inspired in the audio and video editing equipment, and also extends to video the hypermedia concepts of path and guided tour. It is of particular interest in an environment where consumers are also authors, and the access to and reuse of information is very common. In this way, users can assemble video segments to make personalized versions of their favorite movies; and a teacher can make available portions of a video, in a particular order, to illustrate concepts in a context where the original video wouldn't be so efficient or concise. Note that these can act as views to information available elsewhere.

These mechanisms are implemented as extensions to HTML. New elements and attributes were defined and their functionality is supported by a set of scripts that are generic, reusable, and almost transparent to the author of the hyperdocument. The authoring process is done in a declarative way in "extended" HTML. The current prototype is based on Dynamic HTML and uses VBScript language and ActiveMovie technology.

Approaches to the integration of video with other media in different environments include [Liestøl 94, Sawhney 96]. SMIL [W3C 98] addresses the integration of video, as a synchronizable media type, on the Web. Video can participate in links, and it can be synchronized with other media elements. It provides for the basic hypervideo and synchronization mechanisms, but does not explore richer solutions for navigation support, and is not supported by common browsers. HTML+TIME [HTML+Time 98] builds upon the SMIL recommendation to extend its concepts into HTML and web browsers, but it is still a proposition. A less general approach was made for Sync-o-matic 3000 [Sync-url], a product that integrates Powerpoint and RealVideo/RealAudio to make on-line lectures. It synchronizes the slides being presented with the video of the corresponding lecture. There are similar applications that use MS NetShow/WindowsMedia technology [Media-url] instead. Markers are defined for the video and associated with the URL to be presented at each of those moments. Links to those markers can also be defined.

The mechanisms and tools presented are being tested and validated in the context of a project [Chambel 98] on interactive multimedia for open and distance learning, where video plays a central role, but was traditionally used in isolation from other materials. In the future, we will extend these and explore new ways to support video integration and navigation in hypermedia environments, with the goal of making our interaction with information and knowledge more efficient, flexible and rich.

Learning in the Information Age

Lih-Juan ChanLin, Associate Professor
Fu-Jen Catholic University, Taiwan
E-mail: lins1005@mails.fju.edu

Abstract: Through the integration of WWW (World Wide Web) in learning various subject areas, the typical classroom is no longer bound by four walls; it is open to include students, experts, and learning experiences from the world. WWW is changing the way students learn. However, information resources available through WWW is overwhelming and sometimes, difficult for some individuals to explore. Integrating information literacy into curriculum or problem-solving tasks is important for promoting active learning and the development of critical thinking skills among various learners.

1. Learning and WWW

Technology can be used as a vehicle to change the roles of both students and teachers in the classroom. Recently years, World Wide Web (WWW) has been widely used with various subject areas. With this vehicle, teachers can learn how to incorporate technology into their everyday teaching styles in a meaningful manner, whereas students can manage the problem individually and cooperated with their peers (Halpin & Kossegi, 1996). As the Web-based learning has been integrated in various subject areas, how to help students to develop broad skill experience and encourage motivation for learning become an important issue (Barron & Ivers, 1998). In a school-reform effort all over the world, school libraries have changed in focus from collections to learning. Academic libraries have pivotal roles in creating a culture in the school that is learner-centered (Stripling, 1996). Along with the progress of technology, adapting knowledge and experiences from learning theories is essential to encourage active and self-directed learning, and to achieve a life-long learning purpose.

In teaching, the WWW promotes the delivery of computer-aided instruction (CAI) for various instructions. Integrating the WWW in instruction involves finding and retrieving resources on the Web, communicating, publishing, and developing teaching and learning activities using the Web. Many cases indicate that the WWW is an ideal tool for providing different levels of distant education. Relating Web resources with learning contents and developing instructional activities on the Web has become an effective learning model for encouraging active participating in learning.

The ideal WWW learning environment combines electronic and human resources to create autonomous, lifelong learners. Instruction provided through WWW should incorporate active learning model to facilitate students to take an active role in their learning. The use of technology has great impact on schools and libraries. As stated by Weinberger (1997, p624) "Students need to experience the joys of free-form learning and self-guided discovery rather than being tethered by the constraints of outdated tomes, overcrowded classroom, and information overload".

Information skills are needed for problem solving, and that related information skills should be developed within the context of real need and the overall information problem-solving process. Research and practice suggest that people learn better when learning information literacy is related to their needs. Students will eagerly participate in learning and internalize the information skills if they realize how these skills relate to their school assignments and the problem-solving tasks (Warmkessel & McCade, 1997).

2. Active Learning

As constructivist-cognitive movement thrives in recent education reform, the emphasis of learning are changed from a teacher-center to learner-center. In this transition, students become active learners. Instead of passively receiving information from classroom, students are invited to explore the world of knowledge. Learning occurs when students are actively involved in the learning process. To learn actively is important in every educational environment, especially for WWW. Learning means understanding. It means that learners

have been confronted with new idea and have changed and reconstructed their previous understanding to incorporate those new ideas.

The power of digital libraries and new media technologies can provide the passion of learning, and a reward for seeking (Weinberger, 1997). In the new age of learning, students enjoy themselves in a context rich with resources and strategy-building activities to assist them in developing their skills as researchers or explorers in specific knowledge area.

3. Problem Solving and Information Literacy

In order to integrate scaffold learning, students need opportunities to engage in autonomous learning strategies, such as linking ideas, comparing alternatives, reflecting on progress, or critiquing ideas with support and guidance. In the Information Age, how to help students develop information skills to explore the world of knowledge becomes an important issue. Schools and libraries should take a more active role in creating a learner-centered environment that allows sharing of resources and communication of ideas to facilitate the active construction of knowledge among learners.

The library literature emphasizes the use of information, and defines information literacy as the ability to recognize an information need and to locate, understand, evaluate and use the needed information. The information literacy is important to help people successfully solve problems and make decisions. Research and practice suggest that people learn better when learning information literacy is related to their needs. Students will eagerly participate in learning and internalize the information skills if they realize how these skills relate to their school assignments and the problem-solving tasks (Warmkessel & McCade, 1997). If information literacy is integrated into problem solving activities in the earliest stages of students' educational careers, it will provide potential impact on students' life-long learning, and skills of thinking and evaluating. Students will be also encouraged to be self-directive and to work collaboratively with others.

4. Implications for Instruction

In the WWW learning, the skills used for problem solving and relating and evaluating information become important. Information literacy among learners is the key to their life-long learning. The skills are needed for problem solving in the real world. Since information literacy stresses the universal skills such as developing good research strategies, applying critical thinking in approaching information is important. By promoting the process of interactive and expressive nature of learning through WWW, the social construction of knowledge is held. More meaningful learning will be fostered.

Rather than restructuring the instructional program predominantly to the learning of a fixed body of knowledge, it is important to improve the use of instructional methods that encourage the utilization of information resources. To promote thinking skills and active learning, placing the student in the center of the teaching/learning process to reflect the use of information in the real world in solving every-day problems is essential. Since information literacy is critical in solving problems, creating an instructional environment that encourages the use of information skills in the problem scenarios should be an effective way to reflect active learning and thinking.

Abstract: Since summer 1998 a medical knowledge base server is available at URL <http://medexpert.imc.akh-wien.ac.at> considering the importance of decision support systems in health care based on Internet technology. The available systems on this server are (1) HEPAXPERT-III/WWW, an expert system that interprets the results of qualitative and quantitative routine serologic tests for infection with hepatitis A and B, (2) ToxoNet, a knowledge-based system intended to provide automated decision support to the clinician about a possible affection of a pregnant woman with toxoplasmosis and, thus, a probable threat for the unborn, (3) JAWS-ABC, a system that supports classification for early diagnosis, diagnosis and progress evaluation of craniomandibular malfunction, and (4) LARSEN, a system for computer-assisted scoring of radiographic abnormalities in rheumatoid arthritis. This paper presents a summary about these systems.

Background

Knowledge-based decision support systems will become more and more important in health care. Based on Internet technology such systems perfectly match the requirements (such as access from every computer, ease of use, ...) to work in clinical infrastructures for the next century.

Objective

Since summer 1998 a medical knowledge base server is available at URL <http://medexpert.imc.akh-wien.ac.at> in the World Wide Web. Users of this server have the possibility to access several knowledge-based systems for decision support in medicine.

The following systems - developed at our section - are in operation at present:

(1) HEPAXPERT-III/WWW is an expert system that interprets the results of qualitative and quantitative routine serologic tests for infection with hepatitis A and B. The fully interactive system based on *Cold Fusion Application Server* is the successor of an off-line HEPAXPERT/WWW [Chizzali-Bonfadin et al. 1997] that returned the results by e-mail up to 24 hours after request. The system automatically provides and interprets the result of the laboratory tests measuring antigens and antibodies, without the use of additional biochemical or clinical data, and thus helps physicians to understand complex serologic findings. To deal with all possible combinations of findings, the knowledge base of HEPAXPERT-III/WWW contains 16 rules for hepatitis A and 131 rules for hepatitis B interpretation. In analyzing serologic test results, the program compares the constellation of serologic

findings with constellations that may occur in the course of hepatitis A or B infection. Possible active or passive immunization is taken into account as well. However, there are several possible sources of misinterpretation, such as deviations in the course of the disease from the assumed courses, as well as falsely positive and falsely negative findings. Therefore, in each case the program's conclusions have to be correlated with the patient's overall clinical picture. Serologic test results can be entered and will be interpreted immediately. The reports that HEPAXPERT-III/WWW automatically generates include (a) the entered results of the tests, and (b) a detailed analysis of the results, including virus exposure, immunity, stage of illness, prognosis, infectiousness, and vaccination recommendation. It is possible to interpret incomplete and uncertain results as well as prototypical results. Furthermore, as a check on the laboratory results, any inconsistent combinations of findings are identified.

(2) ToxoNet is a knowledge-based system intended to provide automated decision support to the clinician about a possible affection of a pregnant woman with toxoplasmosis and, thus, a probable threat for the unborn. The results are derived from analyzing the outcome of SFT (Sabin-Feldman dye test) and IgM ISAGA (Immunosorbent agglutination assay) tests performed in terms of the obligatory serological screening program of pregnant women in Austria. ToxoNet is accessible from within a World Wide Web browser located on any computer equipped with a connection to the Internet. Apart from the possibility to investigate a patient's state resulting in an interpretation consisting of a diagnosis and a therapy recommendation, the system also enables the physician to modify the inference mechanism by adjusting the underlying knowledge base to new needs.

(3) JAWS-ABC is a system that supports classification for early diagnosis, diagnosis and progress evaluation of craniomandibular malfunction. The ABC staging rate (= subjective complaints; temporal suffering) contains the specification as a result of patient history and palpation. After classification of the patient into a specific state (A, B, C, or no designation), an analysis table is used to get the diagnosis and a view of the stage of illness. The progress of a malfunction is determined by the JAWS-grading (= objective complaints).

(4) LARSEN is a system for computer-assisted scoring of radiographic abnormalities in rheumatoid arthritis. Evaluating radiographs of rheumatoid arthritis by scoring systems is internationally established. An accurate quantification of erosive diseases gives an appropriate assessment of the disease status at a given time, serial measurement of radiographic damage provides a view of the disease course and the essential data for calculating a progression rate. We have developed a computer program that allows a fast, accurate, and reliable documentation of erosive and degenerative changes on radiographs of hands, wrists, and feet in rheumatoid arthritis. The program is able to calculate the score (currently we are using the Larsen Score but the software is able to support other scoring systems as well) and to deliver diagnostic hints based on the pattern and types of morphologic changes.

Technical Specification

MedExpert/WWW is based on *Microsoft Internet Information Server*. The operating system of the Dual-Pentium-II personal computer is *Microsoft Windows NT*. The web server is extended by *Allaire Cold Fusion Application Server*. MedExpert/WWW can be accessed from any state-of-the-art WWW browser. Some applications are developed using Java and/or JavaScript. Therefore these features have to be enabled in the configuration of the browser.

Conclusion

Additional systems are under development and will be offered soon. Because of the rapidly growing importance of the Internet and of medical knowledge, interactive medical knowledge-based systems which are based on Internet and World Wide Web technology will become most important in the future.

Wireless Internet In Education In Developing Countries

Gideon Hayford Chonia
e-mail: gideon@ghana.net
k042240@rzu.unizh.ch

Abstract: This project report describes a Wireless WAN technology used by Chonia Informatica in the project Ghana SchoolNET for providing a direct Internet access to various University, Schools, NGO's, departments and other establishments scattered around the city of Accra, Ghana with a diameter of approximately 25km. A packet-based 2Mb/s Wireless Metropolitan Area Network solutions for Internet Access to link point-to-multipoint access servers.

Introduction

New developments in the use of the WWW and of multimedia materials in education like:

- Web-based technology to improve student academic,
- Online tutor or online professor,
- Virtual classroom,
- Distance learning,
- Virtual lecturing hall

increase the demand of bandwidth in delivering courses to Schools and adding new courseware on School servers. Modems don't have anywhere near sufficient bandwidth to allow entire schools to access the Internet at instructionally useful speeds. Leased T1 lines do offer enough speed 1.54 million bits per second (Mbps)--to connect schools to each other and to the Internet, even for heavy-duty multimedia use, but the lines are far too costly for most schools.

Wireless is a first real competition in developing countries, and I hope it's going to force ISP's to become more responsive to bandwidth demands.

We used wireless solutions over a two-month test period to connect an Academic Computing Center office with the University of Ghana, Legon.

Requirements for a Wireless WAN Network

The intended WAN imposes that the following requirements be satisfied with the following characteristics.

- Licensing *Frequency license for 2.4 GHz transmission*
- Highest Visible Point. *Territory survey to install Base Station*
- Farthest Access point

The first requirement is particularly important if the country need frequency license before operation.

Wireless - Basic Functionality

The FCC in 1985 approved (47 Sec.15.257) three so called Industry, Medical & Science (ISM) bands for license free use:

- 902-928MHz,
- 2.400-2.4835GHz,
- 5.725-5.850GHz.

These bands are used by microwave ovens, garage door openers, and also spread spectrum radios. Current FCC regulations limit spread-spectrum radios to a meager 1-watt of power and confine their transmissions to so-called ISM bands. Yet despite these regulatory limitations, the inherent superiority of the technology allows the radios to cover 15km distances at speeds up to 2 Mbps. The radios can reach as far as 45km (with direct line of sight) and with the use of additional radios as relays, the range can be extended even farther. In part because spread-spectrum radios cause less interference, the FCC requires no license for their operation.

Configuration Overview

A dedicated PC based router running JNOS was used, keyboard and screen from this PC was removed when it was configured No hard disk required in this PC - DOS, JNOS and configuration file will fit on floppy disk. Cables, connectors, antennas, and amplifiers for installation

Aironet 2.4 GHz Direct Sequence Spread Spectrum Wireless Access Point and Client Adapters were used. To set up the ARLAN network, we used ARLAN 630 Access Point for the central site (Access Point is a "transparent" device that connects two media's: wireless LAN and wired Ethernet)

ARLAN 655 ISA adapters is mounted in PC routers for the client sites ARLAN 655 ISA adapters normally do not communicate directly, but all communication between ISA adapters goes through the central ARLAN 630 Access Point.

BEST COPY AVAILABLE

1523

The distinct property of ARLAN is that several Access Points can be used to cover larger area; the Access Points themselves can be interconnected through wired Ethernet interfaces, or over radio, if one Access Point can "see" another Access Point. In this way it is possible to use an Access Point as a radio repeater to extend the range of wireless communication.

Point-to-Multipoint usable bandwidth measurements

In case of wireless LAN, one central node can "talk" to numerous "client" nodes simultaneously, thus requiring only one wireless adapter per connected client site.

The project implies the exchange of large amount of data over the network. It is therefore necessary to ensure that the network - and the supporting applications - is providing the performance required. Several services have therefore been evaluated:

- Ordinary TCP/IP links
- File transfer FTP
- WEB Browsing

The Client - Server Wireless Link

A series of measures have been performed to evaluate the behavior of these applications, comparing their respective performances. In all cases, the tests were performed between a Unix Server (ACC) and 14 PC's workstations networked at the University. The workstations are linked to the server through a wireless network 15km away from the Base Station

The Server machine

The server machine stored small, medium and large files for FTP tests and gave access to files through a WWW server and through the simplified file-sharing protocol. The server machine used is a Unix server. This choice was made considering all functions it has to fulfill: WWW server, file server, etc. Such a machine is versatile enough to cope with all functions at the same time.

Communication Performance of Wireless and Ethernet LANs

The TCP/IP basic tests showed quite promising performances for the wireless link: up to 200kbps over TCP was reached in this configuration, which is fairly good considering that the additional bytes due to TCP/IP headers that are not counted in. The file transfers also benefited from the increase of bandwidth. Small, medium and large files were transferred across Ethernet and wireless, either one at a time or 4 at a time. After these promising results, we looked at one of the most used services between workstations, *Web browsing*. Again the test were performed with files on a server at the Academic Computing Center.

To summarize

We have seen that a high speed Wireless network delivers the expected bandwidth. However, depending on how the applications transferring data are conceived, this improvement can be counterbalanced by protocols not designed for higher speed networks. According to our measurements direct TCP/IP have an adequate behavior while the current Browser versions doesn't bring the expected performance increase. It is clear that due to the different nature of the information transfers, the problems are not the same.

Future direction:

The system is still running and gaining acceptance in most African Countries, but some directions for future can be already be drawn up. There is a clear demand for an increased bandwidth, in order to allow multimedia applications like videoconferencing, access to multimedia data, etc. to be really usable.

The most important development will address the support for a Backbone system to remove backlog...

Conclusion

As the successful completion of our project has shown, wireless network will transmit signals with any bandwidth required, file transfer protocols will deliver requested data where needed.

There are political decisions that will shape the future. An example will be ISM frequency licensing.

Acknowledgements:

I gratefully acknowledge the support of Mikrotkls, which share some of these visions and showed a keen interest and provided solutions. The importance of support from Mr. Amis is gratefully recognized. Finally, it was a pleasure to work with Mr. Tetteh jnr. and the staff of Chonia Informatica without whose hard work, none of this would have been possible.

NETEST: A Significant Change in Internet Software

stacieg@cc.usu.edu

Abstract: For the past three years, student programmers have developed a program called Netest. This software package consists of 30,000 lines of JAVA code. It has all of the capabilities of a multi-user system, network interface software, test generation package and statistical software.. Netest is accessed through the Internet so people with accounts can use it anywhere in the world. It is currently being used at Utah State University to help implement the Computer and Information Literacy exams, a new requirement for all state institutions of higher learning.

Acknowledgments

We would like to thank NFS and FIPSE for their grants in making Netest possible. This project began three years ago in connection with these grants and we have been going strong since!

Overview

As the demand for technology increases, so does the demand for college graduates to be computer literate. A few years ago, it became evident the graduates from state funded universities in Utah were not as computer literate as one would hope. To address this issue, the Computer and Information Literacy requirement was implemented. The Computer and Information Literacy (CIL) requirement obligates students to show competency in six areas of Information Technology:

1. Public Networks and Electronic-mail
2. Computer Ethics
3. Computer Operating Systems
4. Document Processing
5. Use of Spreadsheets for Data Presentation and Visualization
6. Information Access via the Internet.

Utah State University's CIL Implementation

In 1994, Utah State University formed a CIL committee consisting of at least one faculty representative from each college. This committee established the six competency areas. Students could take these tests until 70% competency was shown and would do so during their Freshman year. It was a great idea, but making it happen was the real challenge.

The committee decided to establish a testing facility where students could come in during the day, evening, or Saturdays and take the CIL tests. A computer testing system would need to be developed to store the data for each student, store the individual tests, administer the tests, correct the tests, score the tests and send the score in the student database, and gather statistics for each test and test question. It was also decided to use the Internet as the means to deliver this software environment to the students. Therefore, this huge testing program had to be accessible via the Internet.

In the Beginning

NSF and FIPSE grants assisted in funding the development. Student programmers were hired to develop the testing software, each working on separate tasks. The program was written in JAVA, the most logical high level language to be used because of its Internet capabilities. One of the tasks at hand was to develop a tool which would allow an Instructor to create a test. The test would be based on concepts and could consist of true/false questions, multiple choice questions, fill-in-the-blank questions, matching questions, multiple answer questions, short answer questions and/or essay questions. The questions must be able to be randomized as well as the answer choices for the multiple choice questions. The test should be automatically graded with the ability to post a percentage score as well as a passing or non passing status.

Another task was to develop software allowing an instructor to make a performance based test. This is a test for which the student

actually performs a task using a software tool, i.e. developing a document in a word processor or calculating statistics using a spreadsheet. The goal would be for the instructor to develop two files, one consisting of instructions or tasks for the student to perform and one being the initial file for the student to load and perform the tasks outlined in the instruction file. When the student finishes the test, the completed file is copied to a directory on the server where the instructor can grade it and manually enter a score for the student. Instructors would have a choice for tests to be always available for students to take anywhere, at anytime or to control the time and location at which a specific test is available. Also, a test can be "unlocked" for a specific amount of time for a particular student or class.

Additionally, statistics would need to be gathered. The system would produce information about each individual test (how many times it was passed the first time, the second time, etc.) and each individual test question (how many times each question was answered correct, incorrect or skipped.) These statistics may indicate a poorly written question, or perhaps one where the given answer was incorrect. Thus, allowing the instructor to make the necessary changes.

Once the ideas for the tests were complete, it was necessary to establish a student database to store all of the necessary information. This database would consist of names, student identification numbers, username and password used to enter the system, e-mail address and individual test statistics (i.e. which tests have been taken, passed, failed, still being corrected, etc.).

The next task at hand was to develop an environment which would control of the necessary processes. Three levels of access would be available — Manager, Instructor and Student. Managers could add, edit or delete Managers, Instructors and Students. They could unlock specific tests at the request of an instructor or student (depending on protocol). Instructors could develop, change and delete tests they "owned". They could manually grade the performance tests and update a student's test score. Students could take tests and be able to view their personal statistics.

An overall paradigm was established to help this process become useful in other testing environments. The model of a "class" was developed. Classes were made up of students. Tests belonged to classes. When a student viewed his/her statistics, the test scores were shown for the classes in which the student was enrolled. This allowed many tests to be developed for several classes and students would only be able to access the information belonging to their classes.

Final Product

Because of the flexibility of this program and the fact it was able to run on the Internet, other areas of the university became interested in using this product. Netest, the adopted name of this program, is now being used to administer tests for the CIL requirement as well as the History CLEP test and several other History and Engineering tests.

As the CIL requirement was implemented, it became necessary to develop interactive teaching modules for students to go through allowing them to "brush up" their technical skills. Again, these interactive tutorials, must be available via the Internet so students may use them at their leisure. Additional programmers were hired to develop these on-line tutorials.

CIL and Netest Today

A CIL lab was constructed, consisting of 24 Pentium based computers using the Windows 95 operating system. The software on these machines include the Corel Suite and Office 97. Each computer has access to the Internet and the University VMS system. The lab is staffed with consultants who unlock tests and answer CIL related questions, and technicians who set up the students accounts and maintain the computers in the lab. The lab is open from 7:30 a.m.- 10:00 p.m. Monday through Friday and 12:30 p.m. - 5:00 p.m. on Saturday.

The CIL requirement is outlined on a CIL Web Page (<http://cilserver.ser.usu.edu/cil.html>) as well as procedures for taking each CIL test. This web page links to teaching modules and other necessary information for students to pass the CIL tests. Students can study this information from anywhere and then come into the lab to take the tests. The lab is used to ensure test security and to eliminate cheating.

As far as the Netest system is concerned, to meet the demands of the CIL requirement several tests have been developed for each category so students do not take the same tests. Students come in at take tests at their leisure. The system keeps track of all the data associated with each student's tests.

Utah State University has several extension sites throughout the state. Some of them are more than 200 miles away. The students who attend school at these sites also need to take the CIL tests. Since the Internet is the means where these tests are given, it is very easy to have these centers implement procedures to give the CIL tests through the Netest system.

Netest is still being improved as well as the processes involved. It has been an incredible achievement to develop the Netest program — a program which administers accounts, tests, and people, and provides global access to all of this via the Internet. It is difficult to put into words the capability of this program. A demonstration would be more appropriate. Netest is definitely worthy of being shared with others.

Retro-Engineering Medium Scale Client-Server Applications

Peter A. Cooper, Ph.D.

Jamie L. Hebert, Ph.D.
Sam Houston State University

Abstract

It is easier to impose a coherent organizational structure on an application when the user requirements for the development are both well understood and relatively stable through the life of the project. This paper describes an experience of retro-engineering an application in which the user specifications were not well defined and were relatively unstable. The resulting application, while functional suffered from a number of problems, not the least of which was the difficulty in extending the application. The application was a web-based, client server application written using Java™ 1.02. With the rapid development of both Java and the browsers that support web-based applications, it became clear that the application would require re-engineering in order to remain function in the current environment. This paper describes the purpose and characteristics of the original application and results of the restructuring process and offers some comments concerning the benefits of the retro-engineering the application.

Introduction

Web Imaging and Remote Sensing (WIARS) is a web-based, client-server application providing large image analysis facilities integrating tools for boundary, cluster and change detection supporting image comparisons and change assessment. The application was developed as part of a SERDEP funded project supporting the monitoring of threatened and endangered species habitat on Department of Defense installations. For fiscal year 1999, the research team, including new team members, was presented with the task of rationalizing the interface, integrating an image registration module, and rewriting some problematic SAS routines in either C or FORTRAN. A surface examination of the existing code uncovered the need to perform a complete re-engineering of the application.

Analysis phase

The analysis phase involved a number of components. First an examination of the existing code was performed in order to determine a number of attributes including the functional structure of the code and the data structures employed. Data flow diagrams were developed to identify data flow and data storage requirements. Analysis of the communications requirements was also performed. The analysis phase provided the researchers with a clear picture of the original project as one that employed traditional functional decomposition, minimal data structures and data storage mechanisms, with a simple communications mechanism. The project consisted of a client and a server module implemented using Java™ 1.02 communicating through the socket and DataInput and PrintStream abstractions. The client functional and procedural structure consisted primarily of a single class with a large number of supporting methods enabled through one comprehensive event handler. The server module comprised a master process, distributing clients to slave processes. The slave process handled incoming data and processing requests and provided data storage functions. The primary function of the slave threads was to spawn external processes, typically SAS, MATLAB, FORTRAN and C routines that performed mathematical and statistical functions on large-scale graphical images. The second component involved the user interface. The interface consisted of a series of panels displayed in a main browser window, together with a large set

of supporting frames. As a result of shifting user requirements over the life of the original project there was a lack of consistency in the organization, structure and presentation of each of the supporting frames. The limitations of the application development and client deployment environments were evident in the lack of coherence of the interface. The third component of the analysis phase involved examining the communications flow. Two forms of communication were identified, string communication, and image communication. The URL class was the primary vehicle for image communication. User identified images are identified through publicly accessible URL's and then ftp'ed to the server for processing. The final component of the analysis consisted of identifying the data storage requirements of the project. Data storage was performed only on the server. User and project information is stored at the server site in sequential files for user/password lists and project status reports. Direct access files are used to store project state information so users can resume projects without having to restart.

Object Modeling

Having completed the analysis phase and given the current project requirements, a decision was made to utilize the data flow information and data storage requirements from the original project but completely redesign the user interface, data communications and data storage mechanisms. Central to the redesign was the utilization of a coherent object model that encompassed all three areas and allowed for rapid extension of the project functionality. The design of the object model reflected the major areas of concern. Independent class structures were developed for the user interface, for communication and for data storage.

The GUI was designed with three main requirements; first, all the main controls for the interface had to be available within a few clicks or key presses from any other point in the project, second, the controls should be consistent across all segments of the interface and intuitive for the user, and third, the interface should be contained within a single frame to reduce the complexity of the presentation.

The client side can be structured into a sequence of tasks; login, project and image management, GIS attribute specification, process specification and output specification. As a result the GUI was constructed with major controls for accessing. Accessibility to the later controls is managed by a login mechanism. After successful login, existing or new projects can be managed. Image attributes can be set, analyses performed and output requirements specified. A status screen displays the current project state and logs project activities.

Within each tabbed panel, an indeterminate number of screens may be required in order to capture all the data required by one segment of the application. To accommodate this each tabbed panel acts as a container for a wizard object. The wizard, selected because it is a familiar mechanism to many users, provides a framework for display, controlling and navigating through multiple panels. The final component of the interface is the Panel extended to provide title and placeholder components and to provide consistency across all Panels in the interface. Much of the development process of the user interface consists of designing appropriate panels and the sequencing of the panels within the framework.

Three primary data classes were identified, a user class, a project class and an image class. Each of the classes functions as a data storage module with facilities for controlled retrieval of the data. The user class contains basic user data to allow login and project management. Typically the user class is used to retrieve information about current projects. The project class manages project status information. The project class includes owner information, image information and status information on the project. The project class allows a partially completed project to be stored. The image class contained information concerning the location, type and attributes of images used within a project.

All three data classes are communicated between client and server at intervals through the processing of a project. For example during the login phase, a user object is populated with login information and then passed to the server for verification along with a processing request. The server responds with potentially additional user information, project information and other control information. The primary medium for communication is the `ObjectInputStream` and `ObjectOutputStream`. To allow objects to be sent though a socket both client and server need at least a common object prototype. A communication object was designed comprising service request information and a generic object container that utilized polymorphic capabilities to allow user, project and image objects to be passed within the same communications object. This approach allowed the researchers to consolidate all communication on a single port. The generic `Object` class provides facilities for interrogating an incoming object to determine its source class for appropriate casting.

Building an Internet Knowledge Support System for Nurses

Janet Curran-Smith

Halifax, Nova Scotia, Canada
mwhite@iwkgrace.ns.ca

Our journey in developing the **Internet Knowledge Support System (IKSS)** began with our quest to improve the delivery of distance education to practicing nurses enrolled in the undergraduate program at Dalhousie University School of Nursing in Nova Scotia, Canada. The School of Nursing was challenged to provide university education to nurses who were employed full time, had primary family responsibilities and limited access to academic resources. At first glance, quality distance education systems are more complicated than face-to-face learning systems because of time and geographic variation and the lack of mental models for faculty, administrators and students. The IKSS provides a model of delivery which responds to the demographics of this unique population and values interactivity in the learning process. World-wide experiences with distance delivery of education have shown that effective learning occurs when methodologies are chosen to fit the content but also provide opportunities for interactivity and learner independence. Traditional distance education strategies usually focus on only one of these factors. However, our experiences with **web-based learning** technologies have shown ways to ensure mastery of content while encouraging both interactivity and learner independence.

The IKSS is based on principles which arise from the constructivist paradigm. The notion of the constructivist theory is that people learn best by actively constructing their own knowledge. This paradigm is well suited to Nursing which values a holistic, experiential model. The key principles of IKSS are:

1. Learner Focus

The system is flexible in approaches to course content and assignments with recognition of diversity in student learning styles and the students previous knowledge and experience. Learners identify gaps in knowledge and seek relevant resources to fill gaps.

2. Interactivity

The expectation is that students are accountable for their own learning. They must be active in the process by contributing to the

learning environment, interacting with their peers and resources (content experts, literature, web resources).

3. Context of the learner

The Constructivist's view is that learning is affected by the context of the learner. The model provides learners with the opportunity to construct new knowledge from the context of their personal clinical/learning experiences.

The relationship between these three principles is the value placed on each individual student's contribution to the learning environment and their ability to fit new information with what they already know.

The IKSS model provides a collaborative web-based learning environment where nurses interact with a variety of information resources using multiple pathways. Examples of the web-based environment include: case study activities or short tutorials with content experts in real time through chat rooms, bulletin board or email opportunities for asynchronous discussions with peers and content experts, and links with relevant web sites and online journals. Assessment of student progress occurs using multiple strategies such as online quizzes and presentations, participation in bulletin board discussions and chat rooms, and submission of scholarly papers. Students are also able to monitor their own progress throughout the course.

To date we have offered 7 different web based courses to approximately 100 nursing students using the IKSS principles. Evaluation data related to access, active participation, student learning and support have been collected from students and faculty. Overall student and faculty feedback has been positive and

instrumental in building the Internet Knowledge Support System.

University of Western Sydney, Australia

Abstract. Currently at UWSM, an in-house developed, web based teaching delivery infrastructure called PlatformWeb is being developed. In the current teaching semester there are over 3,000 students across 200 subjects using it in conjunction with traditional teaching methods. PlatformWeb has modules for various online assessments including online quizzes in a variety of delivery modes; and online uploading and marking of student work, along with the automatic display of progression to students. This paper presents methodologies and issues relating to the needs, management, implementation and operation of conducting a range of online assessment activities with large subjects.

Introduction

Because of the raw number of students and the associated supporting staff, large subjects have particular problems relating to consistency and equity of assessment, administration and coordination and the handling of student problems, needs, concerns and arbitration (such as issues of cheating, absence, lateness and disputes). When moving to online web based assessment, the issues of student access, network reliability and performance, off campus verses on campus supervision, feedback to students, logging, issuing of receipts, the timing of progression results to students and other related activities need to be addressed.

The PlatformWeb Project

The PlatformWeb project was introduced to the University of Western Sydney Macarthur in 1998. This project aims at providing a complete Web Information System for teaching delivery. It integrates with the student administration system to provide a single entry point for all staff and students to access their subjects. PlatformWeb has been designed along user-orientated design principles [Hansen, 1999], with its specifications and functionality developed from staff perceived needs, feedback and experience. Besides providing various content delivery and messaging functions, it also provides a range of online quizzes, student uploading of assignments and online automatic progression modules. The user orientated design has been receptive, in particular, to the needs of large subjects (excess of 300 students). Also drawing on previous LAN based work with paperless subjects, various features and logistics for large subject online and web based assessment have now been included. Many others have been identified and will be incorporated.

From a study of staff perceptions of needs and problems with teaching delivery in the educational environment. The major (70+%) of problems related to the lack of administrative support. For large subjects, moving onto the web has made some of these support functions even more important. For example, with 900 students, without an accurate and timely provision of student enrollment data, a web based delivery system with logons will have constant problems of student access and staff management. From staff surveys, there can be a considerable loss of teaching time (up to 4 weeks) at the start of a teaching period in addressing these problems.

The PlatformWeb project, from the beginning, integrated with the administration information systems, making it a possible platform for staff in bulk (rather than just the "innovators") to make use of the Web medium. In particular, the integration allows many problem areas in teaching delivery in large student subjects to be addressed. Two such areas are given in this paper, namely online submission of assignments and online quizzes.

Web based assessment submissions with large subjects

The PlatformWeb project enables an instructor to set various assessment items and include them in the subject delivery. The submission modes, in keeping with the PlatformWeb design, have been developed from staff experiences and perceived needs. With large subjects, the management and verification of student submission by traditional paper means has typically involved problems of late submissions, lost or misplaced material, disputes over submission, lateness of marking, returning material to students and coordination and consistency of marking. Increasingly students are now preparing work that is web based and this has also meant setting up complex link tables and logons to web sites for staff review and marking, along with the logistics of adding comments and feedback to students. Based on these concerns, the PlatformWeb submission module has two submission modes. An instructor can either set an assessment item for students to upload a file or files (of any format except for executables and the like) or to upload a link or links to an associated web site. For the submission of files, the number of files, overwriting and viewing of the submitted material can be set. For all student submissions, every upload is time stamped, logged and an online receipt is given. This enables an orderly management of student queries and submission problems. The inbuilt progression module of PlatformWeb allows the marker to view the student files or links, add marks and comments that appears on the student progression area. In addition the display of the marks can be disabled, allowing for all markers to complete marking and a comparison of the marking scales used, before becoming available for student viewing (inevitably with large subjects some revision of marking scales is needed, with online automatic progression students do not appreciate seeing a given mark changing). Another area being addressed is the partitioning of student progression and marking, not only into groups (horizontal) but also into various vertical modes. With a large subject of say 900 students, the actual download of the data can take considerable time.

In addition, from staff usage, with large subjects, the need for a variety of reports has been flagged (and will shortly be implemented). These reports cover the status of submission, the allocation of groups to different markers and various statistics to assist an equitable marking.

Web based quizzes with large subjects

Similarly, applying the user orientated design approach, the quiz module in PlatformWeb has particular emphasis on the management of quizzes in addition to the delivery modes. The general philosophy is to upload question banks and then form quizzes from the banks. A variety of delivery modes have been developed to cater for enabling, reviewing and repeating quizzes. Quizzes can be formed either as a fixed sequence of questions, a randomised set from a bank and for large classes with multiple groups, a randomised per session mode. This mode sets the same set of questions for a "session" but a different selection for another session (there may be 20-30 sessions in some large subjects). This allows a set of questions to be reviewed on a class basis, which is not possible if every student has a different random selection. Also a variety of delivery modes are available giving password quiz enabling, time window enabling, time windowing for reviewing, options for recording marks or repeated quizzes and similar. Needs for large subjects include the ability for a marker to actually review the quiz of any student including a timestamp of when a question was answered, the actual answer and the number of attempts. In addition is the ability of a marker to reset individual student quizzes. This becomes particularly important when there are many hundreds of simultaneous users with various internet response times and variable network performance. All of the above has been incorporated into PlatformWeb and a variety of staff and student feedback is now being collected for incorporation into the system

Conclusions

This paper presents various issues that can take on special importance with web based delivery for large subjects, particularly if the web delivery is being used in conjunction with traditional teaching modes.

Intrinsic Human Interest in Internet Use

Dineh M. Davis
Department of Communication
University of Hawaii at Manoa
Honolulu, Hawaii, U.S.A.

Abstract: The numerous advantages of the Web for delivering distance education have overshadowed issues of student learning preferences. While some individuals who have no access to computers and web technologies report an intrinsic readiness to participate in Web-based courses, others who have computer and network access and are familiar with the Web express a strong unwillingness to take (or to continue to take) Web-classes. Preliminary analysis of longitudinal data points to a refinement of self-reporting on nonuse from the more generalized categorizations of "values & principles" and "anxieties and phobias" toward a more specifically articulated but broader range of intuitive reasons for non-participation in a primarily asynchronous learning environment. This shift has occurred even as their primary computer use has shifted dramatically from word processing to e-mail and Net-based activities, while the number of those "ready and willing" to take Web-based courses has dropped from over 55% to under 40%.

Background

Discourse about cyberspace, including its use in education, is generally framed within the context of the technology itself rather than as a part of a larger universe that includes non-user populations. Even the most conscientious members of the debate focus on non-users primarily in the context of universal access, the digital divide, or haves and have-nots, in effect placing all non-users in a single category of "wanting to, but being unable to" participate in this digital universe. Clearly, within the nonuser population there is great and growing demand to obtain access to the technology and it is not my intention to downplay the immense need for opening the network to those whose access is blocked by economic or technical bottlenecks. This study augments the already-well-covered tangible domains of non-use by focusing on a smaller, but still significant, portion of our population who have identified shortcomings in the current system that are incompatible with their personal learning and or communication styles. In other words, rather than view the non-user in terms of how we can "get them on board" as consumers, this study articulates some of the most commonly voiced concerns that tend to preclude certain individuals from participating in Web-based, asynchronous educational programs. The primary goal of this study is to legitimize the values embodied in the non-user population response to the Web vis-a-vis education and learning; and in turn remain open to the possibility that such valid issues may form the basis for a different and as yet unexplored alternative to our current models for Web-based learning.

Sample Population and Methodology

My studies of low-use to non-use populations have been conducted through surveys as well as one-on-one and small group informal interviews in educational, private, and public settings in Hawaii. The time frame encompasses the life span of the World Wide Web with a comparative study of two similar groups of undergraduate cohorts in 1996 and 1999 used for statistical analysis. The latter group represents students registered to take the introductory course in Communication during Fall semesters of 1996 (N=99) and 1999 [N=88] who responded to an identical set of questions, with an additional refinement of a question in 1999. (In 1999 in addition to being asked if they felt they were "ready and willing to take a full college course taught primarily through e-mail and the World Wide Web, they were also asked if they were "ready for a course ENTIRELY on the Net.") During the past two years similar methods involving informal interviews were used to extend the study in the Continental United States, as well as several European and Asian countries and Eastern Canada. All such interviews were conducted in English and were

a part of a much larger effort to gather data on everyday uses of new communication technologies. This is a preliminary report on an ongoing synthesis and analysis of this aggregate data, with specific statistical focus on student surveys at the University of Hawaii at Manoa.

Preliminary Results in Context of Current Literature

Adoption of new media for educational purposes can be studied from the perspective of educational institutions delivering the service or they can be viewed through the eyes of the potential user population. Clearly, without service providers' taking the first step to take advantage of new communication technologies and to create these innovative learning environments, students would not even face a choice in alternative modes of learning. Once such services become universally available, however, we can begin to assess their outcome and future direction. Models for assessment may be located within the educational framework [for example, Houle, 1996; De Diana & van der Heiden 1994]; focus on the technology [as in Lin, 1998; Atkin, 1995]; take a particular social construction approach - for example, reasoning that economic status is the only determining cause of non-use of technology [Greenstein, 1998]; or take a meta-perspective [such as Rogers, 1995] in anticipating trends for the adoption and diffusion of such new delivery mechanisms.

The current study addresses compatibility issues between technological innovations and pre-existing human values, learning styles, personal traits, characteristics, and predispositions that affect or inhibit what some students refer to as "peak" learning experiences. In other words, there is little debate that, given no alternatives, students are quite able to learn through a variety of remote, asynchronous, and self-paced methods of instruction. But given a choice, what is the learner's intuitive experience in peak learning experiences? Preliminary results from this study indicate that individuals are capable of articulating these nuances in a variety of ways that can be categorized in the following overlapping yet distinct domains of personality and physiological traits, attitudes & perceptions, and circumstantial, environmental or peripheral concerns: (1) *personality traits* (such as not having enough patience, self-discipline, structure, or intrinsic motivation for Web-based learning or simply not having an inherent interest in the medium, thus getting bored); (2) *physiological traits* (such as getting sleepy in front of a computer screen or having more reading difficulties or experiencing disorientation; or needing the multi-sensory, three-dimensional stimulation of a live classroom setting for optimum learning); (3) *perceptions of needs* in communication environments (such as equating face-to-face interactions with "personal" and "animated" satisfaction while considering any form of computer-mediated interaction as "impersonal" and inanimate); (4) *mis/perceptions of technology* (as lacking real interactivity or as being impersonal, incomplete, or complex beyond personal grasp); and (5) *circumstantial, peripheral, or environmental* concerns (such as lack of control, lack of immediate access to faculty, distrust in the remote evaluation and assessment process or quality control). To these can be added a palpable sense of loss felt by many: a loss of intimate feedback, relationships, and necessary social experience.

In-Service On-Line: 'Computers for Lunch!'

Suzanne de Castell & Jennifer Jenson, Simon Fraser University, Canada

Objectives:

Based on a need identified in the conduct of field research with the GenTech (gender/equity/technology) project (<http://www.educ.sfu.ca/gentech/>) on the equitable implementation of new information technologies in classroom learning activities, the present project's goal has been to design a "deep" website, a maximally interactive, richly scaffolded, activity-based instructional resource for teachers wishing to learn about computer fundamentals. Utilizing the WWWeb's "anytime, anywhere" accessibility allowed us to respond to teachers' concerns about already over-burdened work schedules, by creating a web-based program, "Computers for Lunch," designed in 20-minute instructional segments which learners can access at home, at school, or anywhere else there's an internet connection.

The program itself is free and its instructional activities all use either "shareware" programs, or programs (such as "Clarisworks") which are widely available in public school computer sites. A subsidiary goal of this project was the field-testing and modification of the program, based on user feedback.

Because the site is extremely large, we will show segments of it in relation to two themes which have emerged for us in thinking about how to create better educational software. They are (1) community and (2) interactivity, specifically, for us, *educative* or *pedagogical* interactivity.

1) Community, and questions of audience

As educators our task is a pedagogical one, a task of forming relationships of a specific kind, relationships which are educational ones, first and foremost. In this work we follow the insights of cultural activist and popular education pioneer, Paulo Freire, who advised that we must be learners in order to be teachers, and before embarking on any educational project, you have to find out what it is in your particular local cultural context that people already know, what their daily lives are like, their systems of value, their affections and interrelations, local threats and dangers, and the like.

And that's how we ended up with the core concept and the site name, "Computers for Lunch." The **teachers** told us that they had no time at all for professional development or inservice, no time for anything which wasn't very practical and directly relevant to their teaching, and that their existing commitments meant that if workshops were offered **after** school, they simply would not be able to attend them. Remember that our audience here is elementary teachers, a 97% female workforce, so most of these women have children of their own to get home for, and their evenings are fully taken up with childcare, shopping, cooking, dishes, their own kids homework and only then, the most essential classroom preparation, marking etc---They opted for lunch hour workshops one day a week, and they told us "the secret of success here is if you want teachers to come to a workshop, provide food." So here we have a lunch-hour workshop, designed in 20-minute segments to be done once a week, which provides virtual food. And of course a way to introduce the idea of selecting computer based activities from a menu becomes a familiar one with this metaphor of a diner menu, in which each activity is a different virtually edible dish.

The program is based in activities which fit into existing curriculum contexts, and represent the range of computer-facilitated practices prescribed by Ministries of Education in BC and in Canada more generally. This activity-based approach to instruction is starkly contrasted with the kinds of programs currently available which try to achieve the same goals--and we will show some of these-- using basically pages and pages of text with far too much useless information, lots of alienating language, and no context, in particular no obvious classroom application.

2) Interactivity, specifically pedagogical interactivity

One of the most crucial considerations of this project, we've tried to indicate, was the question of audience - and not only in terms of what technologies that audience did or did not have access to. Avoiding the impulse to "address everyone"-- because in doing so it's all too easy to end up speaking to no one--we've focussed much of our attention on the question of audience, so when we think about interactivity we think about both about how to "address" this particular audience and also, just as importantly, about the kind of audience we are going to construct. Decisions about content and presentation, we think, have to do with how we fashion a particular kind of audience, and cultivate particular ways of knowing and learning. Questions of addressivity and audience, then, shape our

understanding of interactivity, especially of what we call **pedagogic interactivity**, interactivity driven by questions of how human subjects are constructed in and through ways of knowing and learning. We wanted to, as much as possible, move away from more machine-based conceptions of interactivity whereby the user does something, the machine records it and then reacts to the user, doing something back to her. In educational technology, this is one of the most familiar and pedantic forms of interactivity, where the user is asked to demonstrate competency at a particular skill before she can move to the next skill; her "progress" through the program is recorded and then used as proof of competence or incompetence of that skill. We tried to think of types of interactivity that invoked a different set of relations, relations which maximized learner agency. By scaffolding activity-based learning, and we sought to enable performance before competence, to assist users to succeed at computer-based practices as a means to learning how to do them. The interactivity in this program, then, is then less about a machine or software reacting in sequenced and structured ways to what the user is doing and more about maximizing learners' freedom to determine what they want to learn, with the program guiding their activity, sometimes simply by "modeling" a particular skill which the user can then imitate. This way of understanding interactivity meant figuring out ways of scaffolding learning such that successful activity could be co-produced by the learner and the content, making one of our tasks that of imagining possible ways of learning about software that did not presume user-identification with a pre-existing technicist discourse. So the content we created, for example, did not take for granted familiarity with terms like tool bars, menus, a desktop and so on. Instead, we tried to find a way of executing technical skills that recognized that for these users, technicist discourse is far from transparent. Rather than interactivity being a kind of entertaining add-on, then, we have tried to make the content itself, in effect, "always already" an interactive response to the users we are addressing. The point here is just to acknowledge a significant difference between what counts *intechinical* terms as interactivity, and what might count **pedagogically** as such.

Outcomes

The easiest way to assess this project's outcomes is to go to <http://www.sfu.ca/~cfl>, where the program is presently on-line. There are two sections (graphics and video), which will be on-line very soon. If a user "logs on" as "cfl", s/he will however be able to see some of the graphics section--not yet available to outside users. Users could also go to a section under development at http://www.sfu.ca/~cfl/dw_index.html.

Conclusion

We'd like to conclude by coming back to the inter-related issues of communities and audiences, and specifically to the ongoing debates about the perils of confusing so-called "real" and so-called "virtual" communities. There is a great deal of talk about the need (depending upon one's "social orientation") either to create spaces, environments, a "home" in *virtual* communities; or else, from those on the other side of the issue, about the need to inhabit and to be a full and engaged participant within, *actual*, 'enfleshed' local human communities.

For us, however, the work we have been doing illustrates ways in which these two kinds of community might be optimized only to the extent that they can become conjoined, hybridized new forms of community. We are finding that we need to build a resource addressed to the specific people, and the specific capacities and constraints, of our intended user-communities, in order to create an on-line environment in which spatially and temporally dispersed users **could** form an on-line community. But this is itself only viable as a community of practice to the extent that the virtual relationships and exchanges "pay off", i.e. have a real application and use in the actual world of real teachers and students in particular local, face-to-face classroom communities.

Evolution of Strategic Web-based Communication in Organizations: Webmaster Survey

Sjef van den Berg (Asst. Professor, Department of Communication Sciences, University of Connecticut, USA) vandenb@uconnvm.uconn.edu

James Watt (Professor, Department of Communication Sciences, University of Connecticut, USA) watt@uconnvm.uconn.edu

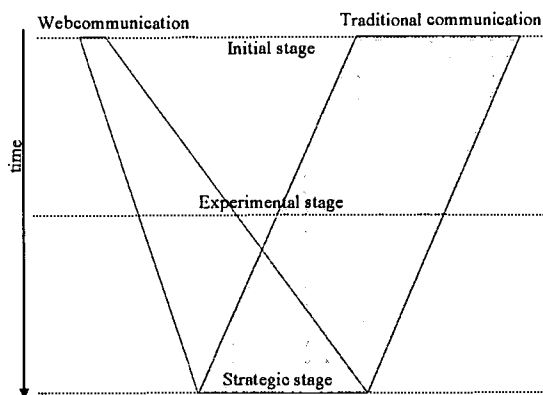

Abstract: The focus of this research is to obtain insight in way that organizations apply Web communication in the integration in their overall communication strategy. It is hypothesized that as an organizational site develops along the continuum from promotional (in which the site primarily replaces print communications) to transactional (in which the site is fully integrated in the organization's strategy) different organizational structures and personnel skill sets are needed. A Web-delivered questionnaire to investigate the evolution of Web sites, their organizational centrality, and the changing roles and qualifications of communication professionals responsible for the sites is described. Data from Webmasters around the world is currently being collected on-line, and preliminary results will be presented.

An integrated research program focusing on Web communications was begun in September 1998 as a joint effort between the Communication Research Laboratory in the Department of Communication Sciences at the University of Connecticut and the Research and Development Institute for Information Technology and Communications at Fontys University in the Netherlands. The overall research program has these objectives:

- Describe the basic taxonomy of Web sites, based on their strategic uses in different organizations.
- Develop a measurement instrument based on the characteristics of sites and their host organization that can be used to classify sites according to the site's strategic position in the organization.
- Chart and predict the evolution of sites from one strategic position to another.
- Determine the personnel skills and characteristics necessary to establish and operate each type of Web site.

A primary question involves the progression of an organizational Web site from one type into another. Each type of site requires a different composition of skills and leadership. We propose that as the site develops along the continuum from promotional to transactional different organizational structures and personnel skill sets are needed. During the initial site implementation, the company typically is unsure about how to exploit the Internet. The implementation team is usually part of public relations, marketing, or information technology, and may be housed in any of these organizational locations.

As the site becomes more central to the core business of the company, the Web team moves to a more central position in the

organizational structure, and Web communication is integrated with traditional communications, as illustrated in the accompanying diagram. The identity of those responsible for site operation is likely to change as a consequence. It is hypothesized that promotional sites move to being customer relationship or business-to-business sites. A single promotional site may evolve into either type, or may combine types in a single site, or may bifurcate into two sites, one customer relationship and the other a supplier network or other business-to-business site.

At the transactional phase, the site and functions are reintegrated, and the management team moves to a finance or operations position in the organization. The site becomes central to the strategic plan of the organization and it is again likely that different educational/skill requirements for Web managers will emerge. The evolution of pure portal sites is not clearly understood. They are essentially independent organizations, rather than operational parts of a larger organization. They may represent an immediate establishment of a transactional site type, bypassing the preceding evolutionary phases. Congruent with the evolution of the Web sites it is the expectation that the use of the communicative possibilities of the Web will increasingly be integrated with non-Web business communication.

The research in progress investigates the evolution of sites at a large number of organizations. To do this, an efficient method of characterizing the developmental phase of a site is being developed. Therefore, much of the research currently focuses on developing and validating a classification instrument. This instrument will be used to characterize the stages of development of existing organizational Web sites. It will also be used to study the transition of sites from their prior phase, and to predict their transition to future phases.

As the position in the organizational structure of the Web site changes, we propose that differing skills and educational backgrounds will be required of Web site team members. The research will investigate the organizational titles and desired team member skills reported by Webmasters in sites at each phase of development.

A Web-delivered questionnaire has been developed and is currently being used to gather information from a large number of organizational sites. The World Organization of Webmasters (WOW) has placed a banner on their site for respondent recruitment. This will provide access to Webmasters in a wide range of organizations in the U.S. and other countries. In addition, an international sample of Webmasters from a commercial e-mail list organization is being recruited by e-mail. The questionnaire is being hosted by the Web survey research organization Swift Interactive Technologies (Hopkinton, MA). The database of responses will be used for the statistical description and analyses required by the research questions.

The questionnaire collects information from three time periods, corresponding to the past, present, and future organization of the site. A series of questions follows this general form:

- (1) In the past, what was your Web site like (e.g. "How many persons devoted full time to the Web site before your last Web team reorganization?").
- (2) What is the Web site currently like? (e.g. "How many persons currently devote full time to the Web site?").
- (3) What are future plans for the site? (e.g. "How many persons do you expect to devote full time to the Web site when you next reorganize the Web team?").

The same three-part approach is utilized in a series of questions about the skills and training required and/or desired of Web site team members. The questionnaire also contains items about the organization's size, primary business, organizational structure, etc.

The comparison of the answers to each set of questions will give:

- A description of the current state of development of Web sites in differing organizations. Organizational type information from the questionnaire will be used to break down the site types by industry (e.g. manufacturing vs. information sector), size of organization, etc.
- The frequencies of transition from one phase to the next. This will confirm or disconfirm our hypothesized sequence of development of strategic Web sites.
- The description of both the changes in the degree of integration between Web communication and regular ways of communication and the departments or people involved with the management of the company.
- A prediction of the types of Web sites likely to operating in the near future.
- A description of the skills and training likely to be in demand for Web team members in the near future, and how these differ from the skill sets required in the past and those currently defined.

Cultural, Ethical and Technical Considerations in Leaver vs. Taker Communities: Incentives and Barriers to Providing Universal Internet Access

Jim Demmers
Georgia Tech Research Institute
Atlanta, Georgia USA
jim.demmers@gtri.gatech.edu

Dara O'Neil
Georgia Tech Research Institute
Atlanta, Georgia USA
dara.oneil@gtri.gatech.edu

Abstract: There is currently underway a concerted effort on the part of industrialized nations to bring both the traditionally disadvantaged citizens within their borders as well as citizens of developing nations into the online fold. The work outlined in this short paper addresses this universal access phenomenon by considering the growth of the Internet in terms of *Leaver* and *Taker* users—idioms usually associated with a culture's interactions with its environment. Leaver cultures interact with their surroundings in a sustainable manner while Taker cultures produce in excess and tend towards imposing their ways upon others. The Internet is explored as a community of users, which in its current state is dominated by Takers. However, realizing the need for a more heterogeneous Internet community, this paper explores incentives for Leaver cultures to participate in the development of online content and methods for improving interface designs to be more intuitive to Leaver communities. Through their participation, it is hoped that an impending "tragedy of the commons" can be avoided with regard to the current exploitation of Internet resources as more Leavers become involved in nurturing the Internet as a valuable tool for all communities.

Whether you agree that access to technology in developing nations is detrimental to the maintenance of their cultural heritage, the reality in the world today is that a predominantly Western approach to the use of technology is subverting these cultures at an accelerating rate. A new form of cultural imperialism is emerging as tribal communities become wired to the Internet, gain access to satellite television, and begin using global positioning systems to enhance their agricultural productivity. Many Westerners who favor the preservation of traditional, indigenous cultures tend to take a negative view of this phenomenon. Yet, if there is money to be made in the process, it is inevitable that some multinational corporation will find a way to bridge the divide that separates first and third tier cultures for the purpose of opening new markets for their high-tech wares. It is essential, then, that we think critically about the role that the tools and interfaces we create play in human evolution and everyday life.

Ever since the dawn of the agricultural revolution 10,000 years ago, humankind has embarked on a split cultural path. Daniel Quinn's book *Ishmael* explores this diversion of Leaver and Taker cultures to show how the dominating *Mother Culture* in Taker societies is devouring Leaver cultures at the expense of a sustainable environment. Traditionally, Leavers see immediate resources as necessary for survival whereas Takers see resources as a commodity to be exploited. Similarly, the Internet, while once a more balanced community of Leavers and Takers, is becoming a more uniform clique of Taker users. In the guise of "progress," developing nations and tribal cultures (i.e. Leavers) are dying out as broadcast telecommunications saturate the airwaves with what is primarily a Western worldview. It was perhaps inevitable that the "network of networks" that is the Internet would again take on some of the attributes of the Taker culture that spawned it as an ever increasing number of users migrate online intent only on searching for information relevant to their specific interests. Unbridled growth tends to destabilize any system and the Internet is no exception to this rule.

But how does one address the issue of communication with people from extremely disparate cultural backgrounds? When the medium of communication involves technology, the key is a well-designed user interface. A technology that is both transparent and complementary to a given culture's existing tools will almost certainly be the most effective. In other words, the best technologies are intuitive and the procedures for learning how to use them are deeply ingrained within a society's cultural practices. If an individual from a given background can interact with a technology with little or no effort devoted to navigating the space that separates his or her five senses from the task to be accomplished, then the interface is successful. By subtly stepping out of the way and removing itself from the process, the interface is doing its job efficiently by not interfering with the experience. In order to make this happen however, one must build interfaces to technologies that are meaningful to those that use them so as to enable the users to freely express themselves and engage in a synergistic exchange of information with the rest of humankind. If Taker cultures simply school Leavers on the Taker approach to interacting with technology, the best that can be hoped for, in the way of meaningful output, is a slightly morphed version of the Taker perspective—an echo. What we need are fresh perspectives, not more redundant information.

The perfect interface alone, however, will not eliminate all barriers to the adoption of new technology. Many primitive cultures use literal versus symbolic representations to transmit a particular message. For millennia, the Aborigine of Australia have used rock painting as a way of communicating with each other over great expanses of space and time. An interface consisting of the standard keyboard and mouse may well prove awkward for an Aborigine to master whereas a large format, pressure sensitive flat panel display that could be hung vertically and painted upon by hand might provide a more intuitive means of expression. Neoteric interfaces such as this and those being developed at MIT and the University of Washington's HITLab could enable cultures unfamiliar with Western symbolic representations to express themselves fluently in the new medium. Perhaps a design team consisting of an anthropologist, Aborigine, graphic designer, and user interface designer would be better equipped to design a "One World" graphical user interface. Such a team could incorporate their unique combination of technical and cultural perspectives to create a context-based system where the user model becomes identical with what is displayed onscreen.

It seems a bit patronizing and paternalistic for those of us accustomed to the widespread use of technology in our everyday lives to conclude that traditional cultures are too inexperienced to cope with the negative influences that technology is certain to have on their cultural character. The authors are not advocating the assimilation of indigenous cultures but are attempting to adopt a realist perspective towards the problem of technological encroachment. Given that the adoption of First World telecommunications technologies by tribal communities is an unavoidable fact in today's modern world, the authors seek ways to ameliorate the negative influences that these technologies may have on the unique aspects of indigenous cultures. Encouraging tribal cultures to participate in the development of Internet content and new interface designs can only reduce that impact. Our work in this area is an attempt to open discussion, provide some cultural context, and initiate a dialogue with Leaver communities based on mutual trust, respect, and a sincere desire to imbue humankind's digital archive with multiple perspectives.

Building Web-Based Technology Training for Teachers: A Case Study

Mr. Timothy Dirks, Manager of Online Courses and Training
The Institute of Computer Technology, 589 W. Fremont Ave., Sunnyvale, CA 94087
(408) 736-4291, (408) 735-6059 (fax), e-mail: tdirks@ict.org

Abstract: Since 1992, the Institute of Computer Technology (ICT) has offered a Technology in Education Certificate program in partnership with the University of California, Santa Cruz Extension, to train thousands of teachers in using and integrating technology into instructional programs. In a cooperative arrangement, the University offers quarter units of credit for classes, and ICT provides the copyrighted curriculum and teachers. This paper describes the collaborative efforts of three partners (the University of California, Santa Cruz Extension, the Institute of Computer Technology, and Kaleidoscope Software), beginning in 1998, to adapt and develop the Certificate program to offer technology teacher training via the World Wide Web.

1. Introduction

The Institute of Computer Technology (ICT) is a non-profit public agency that provides technology training and planning services to both schools and industry. Authorized by an act of the California State Legislature in 1982, ICT's primary mission is to improve the technological capability of public schools and the training of teachers. Since its founding, the Institute of Computer Technology has partnered with school districts, the State of California, and a number of local Silicon Valley high-tech companies (e.g., Hewlett-Packard, Intel, Microsoft, and 3Com). A Board of Directors that is composed of three elected representatives from education and four appointed representatives from Silicon Valley high tech companies governs the Institute. Currently, ICT is operating technology-training programs at various sites including California, Texas, Oregon, Washington, Massachusetts, Arizona, New Mexico, Georgia, and Washington, D.C.

Additionally, ICT offers over 60 courses covering a broad range of Windows and Macintosh applications and computer programming; customized training programs (one-hour workshops to multi-year programs) for teachers, administrators, and support personnel; customized curriculum development, training manuals, and instructional materials; assistance in preparing/updating school technology plans, district and school technology audits, and technology courses for K-12 students; assistance in establishing student and teacher technology standards; assessment of classified and certificated personnel computer skills; and piloting of new instructional technologies.

2. Early Development of the Technology in Education Certificate Program

In 1992, a partnership was established between the Institute of Computer Technology and the University of California, Santa Cruz Extension to develop a Technology in Education Certificate Program. Completion of the Technology in Education Certificate Program (10 required units and 5 elective units, totaling 150 hours of instruction) would provide a systematic, sequential learning approach toward the use and integration of technology into instructional programs, teaching, and administrative assignments. The classes were held in ICT's facilities utilizing their computer equipment and copyrighted curriculum, and taught by experienced and qualified classroom instructors. The main goals of the program were to: (1) prepare teachers to teach in a subject area, and (2) prepare teachers to teach using technology in the classroom. Each class would include hands-on training and a usable classroom activity to integrate computers and other educational technologies into an ongoing curriculum. Various electives would offer hands-on experiences using technology to enhance learning in specific curricular areas.

Advantages and incentives for teachers taking the program include: (1) possible reimbursement and advancement on pay scales, (2) fulfillment of the requirements for a supplemental authorization in Computer Concepts and Applications for the Multiple and Single Subject Teaching Credential, (3) promotion of personal achievement, (4) options to clear one's credential, and (5) fulfillment of professional growth requirements. An online catalog of the current classroom-based teacher training courses is available at two Web addresses: <http://www.ict.org/fall99/teachertrain.htm> and

3. Development of Online Technology Training for Teachers

Efforts to offer classroom-based teacher training to an ever-increasing number of teachers became circumscribed by geographic limitations and marketing considerations. Increasingly, students/teachers couldn't commit to a standard schedule of courses or enroll in traditional classroom-based courses at a specific site. Beginning in early 1998, ICT decided to extend the scope and delivery of teacher training to under-served segments of the adult education market by developing online courses as an additional component of the Technology in Education certificate program. ICT partnered with Kaleidoscope Software, an online educational service with expertise in web-delivered instructional design, and an international corporation committed to global education. Online training would utilize state-of-the-art Web technology from the corporate world, expand the opportunities provided by the teacher training program, allow students to mix and match classroom and online courses, and refresh curriculum content.

Beta testing of a pilot course (one of the required, existing classroom-based courses) was determined to be the best means to understand the different needs of online learners, transform classroom instruction to a distance-learning format, set parameters and standards for future courses, and create a template. It was determined that each self-paced course would remain instructor-led, cross-platform transparent (when possible), and feature the same content as the classroom courses. Online course units and fees would be consistent with the classroom courses.

4. Results of Technology Training Pilot Course

As a result of the pilot course, it was found that time was a critical component - the teacher in fact spent more time with individuals in an online format and the time management of student e-mail became a major issue. Additionally, there needed to be a better means for interactivity between class members. Although it was important for the class instructor to be an experienced teacher, more often they would function as a facilitator and manager of learning, rather than as the fount of knowledge. Obstacles to be overcome included student's frustrations with technology and difficulties with coordinating synchronized chat rooms. Online learning also required the development of new paradigms: the length of the course, student response time, lesson re-purposing, and the challenging coordination of inter-relationships between partners with differing 'cultural' orientations. A team approach was required for online course development, involving such diverse roles as an online manager, instructional designer, online instructor, and course author.

5. Further Online Course Development

The results of the pilot course were analyzed and taken into account for future course development. Specific hardware and software requirements were to be kept to a minimum level. Online students would be required to have basic prerequisite technology skills. The content was made truly 'anytime, anywhere' without required chat times - this made the learning a more global experience. Curriculum content was revised to follow a simplified, instructionally sound modular template - a pattern or design model to be utilized for all future classes. Links to subject-related Web sites supplied some of the course content for the self-paced materials, and hands-on activities/exercises and assignments provided the avenues for students to communicate with the teacher and each other. Instructor-led interactivity would remain at the forefront. Two means of asynchronous class communication were provided to every online student: a Virtual Classroom environment with a threaded bulletin-board message system, and Web-based email (offered to students if requested). A customized assignment calendar, an electronic self-assessment of computer skills and class evaluation form were also developed. Advanced administrative functions included grade retrieval, online course editing, and overall course monitoring. Detailed responses from electronic evaluation data collected from student participants are available.

An online catalog of *current* online teacher training courses (with sample lessons) can be viewed at the following Web site: <http://www.eduniverse.com/edu/ictcatalog.asp>

National Library of Virtual Manipulatives for Elementary and Middle Level Mathematics

Jim Dorward, Ph.D.
Department of Elementary Education
Utah State University
jimd@coe.usu.edu

Robert Heal, Ph.D.
Department of Mathematics and Statistics
Utah State University
heal@math.usu.edu

Efforts to increase and expand the interoperability of web-based instructional tools are receiving increased emphasis from university faculty, commercial vendors, and public and private funding agencies. Few can argue the enormous potential for providing low cost, interactive manipulatives with associated curriculum and resource connections, in an easily accessible, open-ended format.

This paper describes initial development and dissemination efforts of a National Science Foundation funded project (ESI-9819107). The project establishes a library of uniquely interactive, web-based manipulatives or concept tutorials, mostly in the form of Java applets, to teach mathematics with a high degree of engagement. All materials created to date are freely available through the Internet (www.math.usu.edu/matti), creating a national resource from which teachers and students anywhere may draw to enrich their classroom experience.

A recent review of research located five dissertation studies and four research articles from 1989-1999 where computer software was used to simulate or model physical manipulatives. In three studies (Kieran, C & Hillel, J., 1990; Smith, J, 1995; Thompson, P., 1992), students using computer-simulated manipulatives experienced higher achievement than students using associated physical manipulatives or no manipulatives. In two studies (Ball, S., 1988; Terry, M., 1996), students using a combination of computer-simulated and physical manipulatives showed higher achievement than students using no manipulatives. The remaining four studies (Berlin, D. & White, A., 1986; Kim, S., 1993; Nute, N., 1997; Pleet, L., 1990) reported no statistically significant differences between students who used computer-simulated or physical manipulatives and those students who used no manipulatives.

Due to an insufficient amount of research and the variability of research characteristics, we concluded that findings from the research review were inadequate to establish a thorough understanding of the value of computer-simulated manipulatives. Variability associated with grade level, school type, prior experience with manipulatives and computers, sample size, dependent measures, study design, treatment length, and software design must be considered as researchers continue to investigate the value of computer-simulations in mathematics instruction.

The Java-based mathematical tools and editors are designed to increase conceptual understanding of mathematical content and to link these electronic tutorials to companion content instruction for parents and teachers. While appropriate use of good physical manipulatives has been shown to increase conceptual understanding, these 'virtual manipulatives' directly link iconic and symbolic notations, highlight important instructional aspects or features of individual manipulatives, provide links to related web-based resources, and have the potential to record user movements through stored procedures within each application. In addition, virtual manipulatives are very cost effective, versatile, and provide at least as much engagement as physical manipulatives.

Development of each manipulative and tutorial is a collaborative effort between a team of elementary classroom teachers, mathematics educators, mathematicians, and software programmers. Typically, team members use teacher resources to identify physical manipulatives and associated concepts appropriate for development into an

electronic counterpart. Associated curricular activities are linked to specific standards proposed in the Draft Principles and Standards for School Mathematics (National Council of Teachers of Mathematics, 1999). Initial versions of the applets are placed on the webpage (www.math.usu.edu/matti) and comments are solicited from users and national consultants.

There are several technological issues that have had significant impact on the software development process. These issues include specification of minimum hardware and software capabilities. For now, we are requiring a monitor resolution of at least 800 x 600, Windows 9x or NT 4.0, and a browser that is fully Java 1.1 enabled (Internet Explorer 4.0 or Netscape 4.5). There have been several browser difficulties using Mac operating systems running internet security software designed to screen teacher and student access to Java-based programs. Currently, the newer browsers on Mac operating systems 8.1 or higher will run any of our Java applets. We are planning to release a significant subset of our library that will require only Java 1.0 functionality.

The AWT for Java 1.1 is limited with respect to graphical tools. We constructed our own buttons, sliders, and graph windows that focus on math functionality. We now have a code base that includes a library of classes specifically designed to construct graphical user interfaces for interactive mathematics.

Initial evaluation and research efforts have focused on analysis of instructional design features that enable applet users to increase their understanding of mathematics concepts and incorporate applet use in their math curriculum. Currently, researchers are conducting a quantitative investigation on the effects of using the Geoboard, Tangram, and Pentomino applets on geometric concept acquisition among students in grades six through eight.

France
Email: patricia.plenacoste@univ-lille1.fr ; dumas@lifl.fr

Abstract

We have elaborated a new 3D virtual workspace for distant meetings. 2D/3D documents can be integrated. The interaction must be generic so that the users can manipulate all documents in the same way. From real-time computer graphics techniques and users' abilities in a 3D virtual environment, we have defined a model on interaction together with the spatial organisation of the workspace. We emphasize the interaction based on two-handed direct manipulation, the use of two 3D input devices, simple metaphors, suggestive visual cues. Three experimentation tested our model. The first concerned the structure of the visual field and motor performances. The results show the latter is influenced by the visual context. The second one studies what are the relevant perceptive hints to enhance the pointing task performance according to the kind of input device used. The results show that isotonic devices are superior and that shadows are helpful to guide the action. The last one investigates the effect of shape of the shadow. The results suggest that the shape shadow was processing as a action's affordance.

A 3D INTERACTION MODEL

We define navigation as changes in the user's point of view. Interaction refers to how the user acts in the scene: the user manipulates objects without changing his overall point of view of the scene. Navigation and interaction are intrinsically linked; in order to interact with the interface the user has to be able to move within the interface. Unfortunately, the existence of a third dimension creates new problems with positioning and with user orientation (Hinckley, 1994); these need to be dealt with in order to avoid disorienting the user. This is especially true for our interface, where the main objective is not to navigate within the interface, but rather to act on the interface. This entails designing a coordinate frame where navigation within a restricted space is adequate and easy. With an 3D isotonic input device (Zhai, 1998) like Ascension™ trackers, translation of the dominant hand's movement is immediately reflected in the interface by the pointer (figure 1). In a real life situation, users cannot go search for documents or tools without getting up from the table. With our room metaphor, the user does not have to navigate to find objects, he can select them directly with the pointer, it can be moved throughout the entire meeting room. Although the appropriate input device is available to the user he may still lose his pointer when moving around in the interface. There are several ways of dealing with this problem. First, pointer orientation is used to indicate any change in direction and to enhance the impression of movement. Secondly, we use shading effects and the pointer's shadow is projected onto the floor. This helps the user to perceive meeting room depth accurately and to get his bearings quickly and easily (Kersten, 1997).

Figure 1: pointer on an H₂O molecule, with progressive bounding-boxes surrounding objects

Our model uses visual cues to show that an object has been selected or that it can be selected (figure 1): a graphical representation of a box appears progressively around the object. The closer the pointer is to the object,

the more the surrounding box is visible and closer to the object. This progressive bounding box system greatly simplifies the manipulation of the pointer.

Once an object is selected, the user may want to manipulate it. In order to maintain direct manipulation and to avoid widgets, we use an isometric device, a 3D trackball, in the non-dominant hand to apply actions to the object (like rotation, etc.). So, our model uses bimanual interaction (Kabbash, 1994), because the user has more interaction possibilities and it simulates reality. It should reduce dominant hand movement and thus increase precision for object manipulation (with the isometric device).

EVALUATION

We show here the first experimentation but the poster will give the three experimentations that have tested our model at different levels of the conception. Recent developments for a 3D interactions showed that people had trouble in identifying the depth of a visual scene (Wanger & al, 1992; Carr & England, 1995) when using 3D input devices. The shadow enables users to infer both the position and the location of an object. The gap between an object and its shadow indicates the object's height above the ground plane. The location of a shadow on the ground plane indicates the object's distance. We hypothesize that shadow cues provided by objects and the dynamic shadow cues provide by the pointer influence the access to the depth and distance perception. They enhance the guidance for pointing an object in 3D scene and the pointing performance. The user is enabled to use static shadow and dynamic shadow information to guide actions, to achieve a particular goal and make decisions in a three-dimensional world.

The aim of this first experimentation was to analyse the effects of manipulating the contextual cues of depth on the accuracy of an aiming task. Expert and Novice subjects performed a pointing task in a three-dimensional environment. For this task, we used two kind of input devices : a combinaison mouse and keyboard, and isotonic device. The target was a cube presented in a 3D room. The 3D context is configured by three factors which are texture, dynamic shadow or no shadow to the pointer and static shadow to the target. The pointer shadow is considered as the shadow follows the pointer moves. These three variables were allowed to build eight experimental conditions. The results have shown the superiority of using isotonic input device and the usefulness of the shadow for a guidance in a 3D computer environment.

CONCLUSION

Our interaction model is able to exploit the advantages of two sorts of devices (isotonic and isometric). We can manipulate easily 3D documents. We plan to further evaluate our model, especially with two-handed manipulation.

Modeling Effective Use of the Internet to Teacher Candidates

Karen M. Dutt-Doner
University of Southern Maine
Department of Teacher Education
USA
Karendd@usm.maine.edu

Abstract: It is clear to all teacher educators that prospective teachers need to become prepared to implement technology into their classroom practices and teaching. The TEAMS (Teachers for Elementary and Middle School) Program is an undergraduate teacher preparation with integrated course work and field experiences. In addition, technology is woven as a strand in the program, with requirements integrated into all coursework. Our ultimate goal of integrating technology into the curriculum is to model best practices as we teach necessary knowledge and skills. This paper explores our first year's experiences in trying to implement these requirements and model technology integration into our teaching.

In Fall 1998, the University of Southern Maine (USM) admitted its first students in the Teachers for Elementary and Middle School (TEAMS) Program. TEAMS students are admitted as a cohort, a group of entering students who plan to pursue teaching in elementary or middle schools as a career, of no more than twenty-five candidates. This four and a half year program highlights field experiences each semester along with a seminar. Seminars include experienced educators from partner schools and from USM. Each semester the students take thematically based coursework in which class requirements connect course concepts to practices in the field settings.

Another unique feature of the program is the dedicated curriculum strands including: technology, art, multiculturalism, and literacy. Rather than requiring students to take just one or two courses in these areas, the program expectations span the four and a half years of the program. In addition, students are expected to not only know skills and concepts in these areas, but demonstrate their application in school settings. Aspects of the technology strand are the focus of this paper.

It is clear to all teacher educators that prospective teachers need to become prepared to implement technology into their classroom practices and teaching. In the development of the TEAMS Program, an Ad Hoc Technology Committee was formed which included faculty from the Teacher Education Department, The College of Arts and Sciences, the School of Technology, and three Professional Development School sites. This committee's work included: identifying the key technology knowledge base for prospective students in the program, identifying the method for delivering the technology training, and identifying the ways that this new knowledge could be extended into the Professional Development School sites. And, using the Internet is one aspect of this technology implementation that our teacher education program had to address. Below are the essential knowledge pieces from this committee's work related to Internet use:

Demonstrate skills using e-mail communication tools. TEAMS students are required to participate in a Web Board conference and/or listserv during the program. TEAMS students must demonstrate their ability to ethically and appropriately participate in an electronic discussion group.

Demonstrate an ability to access and use the World Wide Web. TEAMS students are required to use the Internet as a research tool for seminar sessions and bring the results of their searches for discussion. In addition, TEAMS students develop and maintain a TEAMS Program webpage. (<http://www.usm.maine.edu/~karendd/teams/>)

As the coordinator of this new undergraduate teacher certification program, I will share my experience in trying to implement the recommendations of the Technology Committee specific to the areas of Internet and web use.

In the first semester of the program, students began with learning the basic skills of using e-mail, accessing website information, and participating on a class listserv. This listserv proved to be an effective way for the students to communicate with each and discuss important issues and experiences outside of class discussions. The TEAMS students primarily used the listserv as a way of communicating information to each other and supporting each other.

But, in some cases it provided a forum in which students could reflect on experiences in their field. At the end of the semester, we agreed as a group, that we should continue to use some form of electronic discussion group in order to stay connected outside of class meetings. While the students felt that the listserv provided a valuable vehicle for debriefing, reflecting and discussing critical issues in education, we decided that using Web Board conferencing would better allow us to see the connection between on-going conversations without overwhelming students' e-mail. In addition, the Web Board will provide a better visual organization of messages by topic/theme.

Once students became proficient in those areas, they then worked as a team to develop a website for the TEAMS Program. Because some students had more experience developing websites than others and because we were approaching the task as a group, this process was a bit complicated. First, we needed to decide as a group what would be included on the webpage. Then we had to learn the skills to develop the webpage. And, finally we had to decide how we would break up the tasks so that the students could work in pairs on different aspects of the webpage. Overall, the process took approximately three weeks. And, the finished product needed major polishing. In developing the webpage, some students seemed more concerned with the content than the visual affect while others were more concerned with how the webpage looked than what it contained. So, the pairs were each assigned a two week period in which they continued to "clean up" the webpage and make any necessary revisions/additions. We continue to work on the webpage, always updating our work, and applying our deeper level of sophistication about developing webpages and adding new information about the program.

Since our ultimate goal of integrating technology into the curriculum is to model best practices as we teach necessary knowledge and skills, utilizing the Internet in a variety of ways becomes necessary. During this second year in the program we have decided to use two anchoring Internet resources in order to "force" students to learn how to use the Internet as a teaching tool: 1) all course materials have been put up on the web using CourseInfo and 2) students will participate in an electronic discussion using a Web Board Conference. Using these two resources will provide students in the program an opportunity to have greater exposure to the Internet as a learning tool as well as require them to use the resources available on Internet for their learning. These Internet tools allow me, as the instructor, to better incorporate using the web as a research tool as well. The students have a forum for which they can share the results of their Internet searches, commenting and responding to each other's findings.

Through this journey, I have learned a great deal about how to use technology as well as how to implement it into my own teaching practices. First, I have learned that many of my students know much more than I do about the using the Internet. Since I am supposed to be modeling for my students how to effectively use the Internet in a teaching situation, this creates some dilemmas for me. But, in reflecting on the discomfort I felt at times, it became apparent to me that it is more important that I continue to model ways to implement technology rather than be so concerned about whether I know as much about as my students. Second, I am becoming more aware of how important it is to have a background in teaching/curriculum as I work to integrate new technologies into my courses. Learning the technology is only part of the battle. Once I have learned the technology I need to consider in what ways will it be incorporated into and change the way I teach. In this way, I must give my teacher candidates the opportunity to learn the technologies, but also learn how to make it a part of their teaching in the classroom. Third, I am becoming more aware of how critical it is to reflect and debrief with my teacher candidates about the teaching decisions I am making about integrating technology. The true "teachable moments" happen when we spend time as a group thinking about what we did, how it worked and what can we learn that will make our learning more meaningful.

Ultimately integrating technology is just as much a teaching issue as it is a technology issue. It is true that you need to know the technology in order to use it, but it is also true that if you know the technology but not how to integrate it, then it has no meaning. The focus of technology integration for teacher candidates lies in the modeling of strategies as well as an opportunity to try.

Creating Optimized Learning Environments II: Pedagogy and an Interactive Web Interface

Abstract: Students in the course described in this paper are active participants in their learning rather than passive recipients. They are given opportunities to learn via the following Web-based functions: (a) an interactive syllabus; (b) a series of Web Quizzes prepared by the instructor on course topics, including the instructor's Power Point presentations with notes and Web links embedded; (c) a threaded discussion group; (d) a private electronic journal; (e) web sites particular to the course linked from the course home page, including a publisher provided textbook Web page; (f) an interactive, dynamic, and organized set of Web links arranged according to content area of emphasis, to which students can suggest additions; (g) a large number of archived Web quizzes that students in former sections of the course have designed for their own and others' use; and (h) a form for submitting questions to the instructor.

1. Introduction

Potential educational opportunities and pedagogical flexibility that are available in Web-Centered instruction provided the impetus for the revision of a graduate course that has been taught for over 26 years. In the belief that the most appropriate role of a professor is to help students complete activities designed to enhance their learning, the role of the professor in this course changed dramatically as the potential of the web was brought into play. Gone forever is the "jug to mug" model of lecture, listen, and test. The efficiency given by technology now allows a different professor to student relationship. The constructivist approach of moving students from passive recipients to active designers of their own systems of learning coincides directly with the "learning to read – reading to learn" theme that guides the "Content Area Reading" course

2. Course Components

2.1 The Syllabus

The syllabus of "Content Area Reading" explains the requirements and contents of the course, and provides several Web links. Within the syllabus students also find a link that allows them to create a profile of themselves, and thus to "register" themselves for the interactive elements of the course. Once they do this, they can participate in the course discussion and electronic journal features of the course.

2.2 The Discussion Group

The discussion group is an online threaded discussion in which all students participate. Though the professor does not usually contribute to this, he is able to monitor the discussion and respond to individuals or the group via the discussion or in class. Students choose the topics of their discussion. As a starter for the semester, each student is asked to make a first entry on the topic, "Why I am taking this course." From that point onward, the discussion meanders as most discussions do, taking on a life of its own.

2.3 The Journals

Students are required to make entries to their journals once or twice a week. They are instructed to use the journal as a record of reflections and reactions to the course that only they and the professor can access. When a student posts an entry, the professor receives an automatically generated e-mail message that notifies him of the post. Within 24 hours, he opens the student's journal, reads the latest post, and replies via the email note. This ensures a continuous flow of feedback and response between professor and student. The final journal entry for each student is a required self-evaluation in terms of the individual's goals in taking the course.

2.4 Course Websites

An index of course Web sites, including a) the web site for the textbook, b) Kathy Schrock's home page, and c) a locally maintained site called The Content Literacy Information Coalition (CLIC), with hundreds of content-specific, on-line resources, as well as professional organizations, journal articles, and various other instructional artifacts. The latter is a site that allows students and other users to add resources as they find them and wish to share with others.

2.5 Class Notes

These notes are given as a series of Web Quests prepared by the instructor on course topics, or the instructor's Power Point presentations saved in HTML format, including notes on each slide. Slides often contain hypertext links related to the topic and links to electronic reserves placed on line by the instructor. The class meets in a computer lab where at the beginning of each class session, students access the course Web page, turn to class notes, and open the notes for the day. They then use a process of think, pair, and share to think about each Web Quest or slide/notes combination. They pair up with a partner to compare their own notes about the information presented and then share that information with the class. The class discussion centers on the questions and comments of the students in response to the notes.

2.6 Web Quests

Web quests are created by the students based on the model and template provided by Bernie Dodge (the creator of Web Quests). Each student creates a professional web quest for teachers and a student web quest on a topic of their own choice for classroom use. These are posted on the class Web page as they are completed, usually near the end of the semester, and each semester's work is archived and accessible for later use.

3.0 Support and Maintenance Issues

Issues of access, expertise, availability, and ease-of-use are still common and serve as barriers to some students and faculty. The current course is run on locally generated perl scripts so maintenance is high and changes are approached gingerly. The current Web structure has worked well for over four years. However, difficulty in making changes to the course and modifying basic structure of the course is a task that is both time consuming and expertise intense. Efforts have been started to produce a course Web structure that will be both flexible and easy to maintain. A number of options are under test, including selected commercial products and a locally generated course authoring and maintenance system.

Identification of the critical pedagogical issues in using the Web in graduate education has a direct bearing of the type of software that can be used to ease the burden on the instructor for development and maintenance of a course. Experience gleaned in the attempts to modify the structure of this Web course will be shared and suggestions for better solutions will be sought.

Management techniques and software quality for small scale Web project developers.

Ken Eustace
School of Information Studies
Charles Sturt University
Australia
keustace@csu.edu.au

Abstract: Computer project management techniques that are taught to information technology students concentrate on the theory and practice of information systems development (the traditional systems development cycle and object-oriented modelling techniques), as well as on the industrial project management techniques, common to most organisations [Bennatan, 1995; Ince, 1995]. However information technology students (undergraduate or postgraduate) are faced with developing projects in their course, on a much smaller scale, requiring abridged management techniques. Many information technology students are normally involved with small scale project teams of 2 or 3 students. In many cases, students are required to develop computer software projects alone. Students often find it difficult to translate the theories of computer project management into practice and require a practical set of activities which demonstrate the principles of larger system development, but at the same time, allows for effective understanding and application of sound computer management techniques on a smaller scale.

1 Introduction

The most common form of small scale computer project management, used by information technology students is Web site development, as the technical environment is easy to develop and popular with all organisations. As a project manager, the computing professional is required to express the skill and knowledge acquired from all experiences in programming, systems development and object modelling. This paper examines how such skills and knowledge can be strategically adapted for Web site project design and management on a small scale by individuals or small group developers. One method of *user-centred design* [Abels, White & Hahn 1998] sets out to identify and implement user based criteria and developed a four stage process based upon the users' task related information seeking/Use behaviour. The alternative approach to user-centred design proposed by [Abels, White & Hahn 1998] consists of four traditional software engineering stages: information gathering, development, evaluation and implementation.

2 Forming the Web project management team

Before development, set up a *Web Project Design Studio* as a Web page where you can design and monitor the development of your Web project. Your new design studio (a metaWeb site!) can be linked from your other Web pages. The exact form and content is left to you, but it is a "*show and tell*" site where you can experiment with, and share with others, the Web publishing techniques to be used on your Web site. Here is a simple layout for such a *Design Studio*:

- a small resume and project description
- contact details and an e-mail link
- up-to-date information about your project using project management techniques
- a link to your developing Web site
- resource collection
- documentation of the project including User Guides and References Manuals if needed.
- prototyping - samples of your publishing skills
- "other" - these are sections and links to anything that you determine such as site evaluation forms.

The Web project management team is responsible for setting policy, allocating roles for team members, template construction for the Web site and the formation of sub groups. Formation of the Web site development team is usually part of a formal process for larger project development, but for small scale projects, some members of the team may be required to take on several roles, so care should be taken that regular communication is made and that the roles do not cause conflict. As an individual developer, at least one other person should be assigned the *quality assurance role*, while several other roles can be enlisted by the single developer. For small groups, all members form the *Web Project Management Team* [Charles Sturt University, 1998]. Two main sub-groups are required:

1. *Web development (devel) sub-group*: responsible for sourcing, editing and migration of Web site files to the quality assurance (*qa*) area.

2. *Web quality assurance (qa) sub-group*: responsible for quality assurance team tests and evaluation of all files according to the quality assurance policies and migration of successful files to the online production site.

The Web site files have three possible status codes: *devel*, *qa* and *prod*, as defined in [Tab. 1]. These file status codes are used to identify and track the development of the files within the Network Publishing System (NPS) in [Fig. 1].

Production area	Characteristics of each production area
Development <i>devel</i>	The development group of people, hardware, software and processes for sourcing and editing files. This can be on a local computer or offline Web server. The <i>devel</i> team can receive files for updating from the <i>qa</i> or the production site. All files sourced or existing as <i>qa</i> or <i>prod</i> files in this area are marked as <i>devel</i> files, before sending to the <i>qa</i> area.
Quality Assurance <i>qa</i>	The quality assurance group of people and procedures for testing, proofing and evaluating <i>devel</i> files. If a <i>devel</i> file passes all tests, the file status is changed to <i>prod</i> and sent to the production Web site. If a <i>devel</i> file fails a test, its status is changed to <i>qa</i> and sent back to the <i>devel</i> team.
Production <i>prod</i>	This is the main Web site and server area where the final product resides. Only files from the <i>qa</i> area can be received, but files can be sent to the <i>devel</i> area for updating.

Table 1: Status codes for files flowing through the Web publishing production areas of the NPS

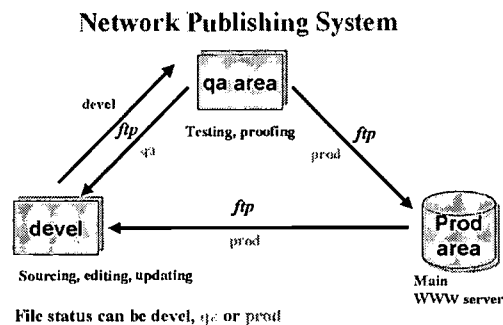

Figure 1: The Network Publishing System (NPS).

The Web site management team should decide all issues concerning the context, technical environment, communications (via meetings and e-mail) and template construction, before dividing up into sub-groups. On the smallest scale, a Web developer must have at least one other person to act in the *qa* area, as only the *qa* area can send approved files to the production Web site. If however, you are still working alone, you must "swap roles" and still function in the *qa* area, perform the tests and proofing activities, before sending the file to the production site. Using a colleague to help with a peer review *qa* process, however is a better option than trying to do it alone. Web system development can be broken down into a version with eight steps for system development and testing of small scale Web projects. The activities in each step are used to help focus ideas and to track the project using project management tools and techniques as described by [McLeod & Smith 1996] and [Gido & Clements 1999].

Conclusion

Management techniques for small scale Web projects, contain many of the features of object modelling and the systems development life cycle for students to employ. The skills and knowledge constructed from previous studies are used to development the student's own project management style. User-centred design methods, as shown by the Silo case study, assist with the evolving conceptual design of a Web site and the work in [De Troyer & Leune 1998] provides a Web site design method (WDSM) that supports the inclusion of object modelling techniques and the description of user classes. Setting up a *Web Project Design Studio* as a Web page where you can design and monitor the development of your Web project is essential.

The Web site development team structure for larger projects can be harnessed to fit the needs of a smaller team. Suggested strategies for small teams included dealing with issues such as multiple roles and reduction of conflict by regular communication. For an individual developer at least one other person should be assigned the quality assurance role as the best option or as a fallback option, several roles can be enlisted by the single developer by "swapping roles". The Network Publishing Model in [Fig. 1] further extended management techniques by providing a simple structure and labelling of sections and assigning file status codes as *devel*, *qa* and *prod* to support quality production of Web site files by small teams.

Applying a New Model: Moving a Course from the Classroom to the Web via the SUNY Learning Network

Patricia C. Franks, Chairperson, Business Information Technology Department
Broome Community College, Binghamton, NY, US
Email: franks_p@mail.sunybroome.edu

Abstract: During the Fall of 1998, a new course designed for Communications majors was offered on campus. It provided an introduction to information technology including the Internet, web page creation, desktop publishing, and computer graphics. This course was a success as evidenced by student comments and grades earned. The challenge for the Spring 1999 semester was to offer it in an asynchronous format using Lotus Notes via the SUNY Learning Network with similar results. This short paper will compare and contrast both methods of delivery. Student success and satisfaction data as well as improvements to the online course planned for Fall 1999 will be shared.

Traditional Model

A text, *Information Technology: The Breaking Wave*, was selected. A companion CD containing multimedia presentations supplemented the text. The students met 3 hours a week for fifteen weeks in a computer lab. They had access to the lab during hours when classes were not in session. Students used IBM PCs, a SONY Digital Camera and Scanner, and an HP Color Scanner. They also had a computer account with 40 MB of space and access to ZIP drives for storage. Students kept abreast of recent advances in technology through research in newspapers, magazines, and on the Internet.

The software packages available including Microsoft Office 97, Netscape Communicator 4, Internet Explorer 4, PageMaker 6.5, PhotoShop 5, Illustrator 7, and PageMill 3. An electronic mailing list was created for the class, and the instructor used it to communicate with the members of the class at least once a week. Students used the mailing list to communicate with each other. A companion web site was created for the course, and materials such as the course syllabus and instructions for completing class projects were posted.

Students worked individually or in teams to create their final project, a web site, which was stored in their own computer accounts or at a free web-hosting site. The projects were demonstrated during the final class, so all students had the opportunity to view each other's work. In addition to submitting their project for a grade, two groups of four students linked together the web sites they created for the Communications Club and the Communications Department and entered a contest for the best student-created web site on campus. They won first prize, \$500, to be used for a Communications Club field trip.

A New Model

The next question was, "Could this course be delivered online with similar results?" A decision was made to offer the course online through the SUNY Learning Network for the Spring semester. The same instructor, this author, attended three one-day training sessions, received a course template, and developed the course using Lotus Notes. The same textbook and companion CD were used. Based upon student feedback from the first course, a second CD that introduced the concepts of the Internet and taught students how to create a simple web page using the Hypertext Markup Language became an added requirement.

Lotus Notes provided a course map, which allowed the instructor to post modules containing lectures, written exercises, activities, and discussion threads. The lectures provided hotlinks to web sites containing information to supplement the textbook. An area for students to "Meet their Classmates" was used, as was

a Bulletin Board for posting messages. The instructor communicated with individual students regarding issues not related to their coursework through an email account provided by SLN. Students were instructed to read the chapters in the textbook, complete all of the assignments, review the chapters by completing the practice quizzes on the companion CD, and demonstrate mastery of each chapter by completing an online objective quiz.

Instructions were posted for students to complete assignments using Microsoft Office 97, which was the software package identified in the course requirements. However, not all students had that software on their systems. The instructor, therefore, obtained copies of almost all of the software used by the students and spent many extra hours providing individual assistance to those students.

Students were required to post their final project on the server provided by their Internet Service Provider or at a free site. Again, individual assistance was necessary. The projects were graded. The URLs of all sites were made available to students so that they could see what their colleagues had accomplished.

Student Success Rates/Satisfaction with Course

Nineteen students registered for the traditional course but one withdrew; the remaining eighteen students satisfactorily completed the course. Seventeen students registered for the online course the following semester, but one of those did not complete the course and received an F. The following table shows a comparison of the letter grades earned.

Traditional Course taught on campus Fall 1998			Online course taught via SLN Spring 1999		
Grade	# of Students	% of Students	Grade	# of Students	% of Students
A	10	55.6%	A	13	76.4%
A-	1	5.6%	A-	2	11.8%
B+	0	0.0%	B+	1	5.9%
B	3	16.7%	B	0	0.0%
B-	2	11.1%	B-	0	0.0%
C+	2	11.1%	C+	0	0.0%
F	0	0.0%	F	1	5.9%
Totals	18	100.0%	Totals	17	100.0%

Table 1: Comparison of grades earned Fall 1998 and Spring 1999

The same satisfaction survey was provided to students each semester. Student taking the course on campus appreciated the fact that the skills they obtained were "useful" and they were now "computer literate." Several students simply said, "Thanks a lot!" and "Enjoyed this class." One student appreciated the fact that the instructor "smiled a lot." Although the students in the online course couldn't "see" the instructor, similar comments were noted including: "Excellent class and teacher," "Questions were answered quickly," "Learned a lot," "Great course," "Great Job."

It was apparent that students appreciated the course because the skills and knowledge they gained were "relevant" and the instructor provided a great deal of individual attention regardless of method of delivery. This course, whether taught on campus or online, was a success!

Improvements for Fall 1999

The requirement to use Microsoft Office 97 will be enforced, and more detailed instructions for assignments requiring the use of computer software will be provided. In addition, activities providing the opportunity for teamwork will be explored.

Fast Start for Web Accessibility

Deanie French, Ph.D.
Department of Health Services and Research
Southwest Texas State University
San Marcos, Texas, USA
elearn@Deanie.org

Mette Schafer, graduate student
Department of Health Services and Research
Southwest Texas State University
San Marcos, Texas, USA
ms52129@swt.edu

Abstract. The Internet is revolutionizing business, education, and healthcare due to the explosion of technology for worldwide communication. In the USA, one person in 10 has a severe disability. (Microsoft, 1999). USA law requires federally supported agencies and programs to develop Web sites accessible for physically challenged individuals. Even if not required by law, smart business will want expand their consumer base. "Computers and cyberspace are far from the exclusive province of younger generations. Based on research, the fastest growing demographic group using high tech and the information highway is mature adults, age 50-75." (Hansen, 1999). Many seniors will not need any special assistance; however, there are selected accommodations such as size of type, which will enhance the electronic experience. The Fast Start Guide helps to address this issue now by adding alternative text links to current sites to obtain "Bobby approved" recognition, (which is the standard indicating universal accessibility). Over 3 million web pages are tested per month, and only 650 sites have been approved. (Cast, 1999)

Introduction

The FAST START Guide to be published by the Institute for Quality Improvement in Long Term Health Care is being developed to enable quick conversions of complex web sites to accessible "text only" sites using any popular "What you see...is...What you get" web page composer. There are also several immediate effects of transforming complex web sites with beautiful graphics and **wonderful eye candy to primarily text-based web sites**. The download time is faster. The loss of eye candy does not effect the information conveyed. When pictures or images are needed, a clear description of that image provide the same effect for the viewer as reading a book. *The FAST START Guide* avoids the use of tables, without the loss of information.

More information about Fast Start can be found at the Internet site.

<http://www.swt.edu/~df12/Fast/OVERVIEW.HTM>

Selected Key Players

The World Wide Web Consortium (W3C), was created to lead the Web to its full potential by developing common protocols that promote its evolution and ensure its interoperability among different types of computers. This international industry consortium is run jointly by the MIT Laboratory for Computer Science (MIT LCS) in the USA, the National Institute for Research in Computer Science and Control (INRIA) in France, and Keio University in Japan. The guidelines developed as part of the W3C Initiative program are a model for HTML programmers to develop accessible sites based on a series of priorities. W3C is to be applauded for their leadership role; however, many individuals want Bobby approved sites without having to learn HTML coding. Information about the W3C

BEST COPY AVAILABLE

1555

can be found at:

<http://www.w3.org/Consortium/>

Another organization, the **Center for Applied Special Technology, (CAST)** is an educational, not-for-profit organization, which uses technology to expand Internet opportunities for all people, including those with disabilities. In addition it includes assistance for obtaining Bobby Approval (a software program from CAST, which determines if a web page is disability accessible). Over 3 million web pages are tested per month, and only 650 sites have been approved. "CAST is committed to providing Bobby as a free public service in order to benefit the greatest number of people throughout the world." (Cast, 1999)

Overall Conclusion

The use of the Internet can provide an effective source of information for all business, education and healthcare organizations. The Fast Start Guide allows very quick "what you see...is what you get" transformation of complex sites to Bobby approved sites (the standard of measurement to indicate universal accessibility). The guide should help you obtain approval within one to three tries. All of the sites, which we have personally transformed, that were not approved the first time, did obtain approval after the second try. Examples of complex sites with alternative text sites that have earned Bobby approved status include:

Developing Standards-based “Technology Intensive” Courses

Catherine P. Fulford, Ph.D., Associate Professor
Department of Educational Technology, University of Hawaii, USA
Email: fulford@hawaii.edu

Abstract A systematic process was used for developing a new designation of “technology intensive” courses including course standards and guidelines. The standards include six categories based on: ethics, operations, analysis, retrieval, application, and attitudes. Among the categories are there 33 specific standards. Faculty in the project have been provided with ongoing professional development to effectively integrate technology into their courses. Most sessions provided faculty with hands-on practice with the technology. In a three-year project 35 courses in a variety of disciplines were developed.

Purpose

Technology is already an integral part of modern life and increasingly demands are being placed on educational institutions to prepare students to live in this high tech world. Vast resources of information are available. As future workers, students will need to have the skills to access and manage these resources, ask pertinent questions, and draw logical conclusions. Technology offers a wider variety of learning and communication styles than traditional education and allows students to use tools relevant to the workplace.

The purpose of the project was to develop a general designation of “technology intensive” courses that could be used university-wide. “Writing intensive” courses were used as a model for development for the project. Three grants over a three-year period have been received for this effort. Each project had two major components: faculty professional development and course development.

Technology Intensive Standards

The type of impact desired called for an expansive, long-term project thinking through “what should our graduates know?” A committee of 16 faculty members from a broad range of subject areas in 14 departments met to develop a set of “technology intensive” standards and guidelines for the development of the courses. The standards include six categories based on: ethics, operations, analysis, retrieval, application, and attitudes. Among the categories are there 33 specific standards.

Technology Intensive Guidelines

The following excerpts are from the technology intensive guidelines that provide information for faculty on course development.

The course subject matter should remain the priority for technology intensive courses. The technology should help facilitate communication, problem solving, analysis, research, and presentation. It is highly recommended that faculty planning technology intensive courses develop curriculum that utilizes at least one standard from each category. No single course can cover all of these standards. The idea is that among the variety of courses students take, they will upon graduation have mastered these standards.

Technology intensive instructors should serve as exemplary role models for the use of technology. ... Instructors should model good ethical standards when using technology, such as, adhering to copyright laws. Good instructional and visual design are fundamental to learning with technology. Technology intensive courses must have the essential component of student involvement. Students not only need to see technology used by a good role model; they need to use it themselves. ... Students should have opportunities to create course projects that include technologies such as multi-media, web pages, videos, and electronic slide-shows. ...

Discussing the use of technology frankly with the students is highly recommended. It is expected that the instructors will need to acknowledge issues of access, skill level, and anxiety. Helping students understand the need for growth in the area of technology is an important part of the process.

Course Development

Faculty in the project have been provided with ongoing professional development to effectively integrate technology into their courses. Most sessions provided faculty with hands-on practice with the technology. Faculty professional development has included topics such as: course design, visual design, electronic conferences, web page design, multi-media and video production, electronic presentations, technology ethics and copyright, assessment of technology projects, one computer classroom strategies, and the use of and science probe software. Each course developed during this project needed to undergo considerable curriculum restructuring to meet the standards for technology intensive courses. Faculty had to reevaluate their teaching methods so that they demonstrate effective technology use. Thirty-five "technology intensive" course have been or are being developed. These are some of the courses.

Japanese 202: Intermediate Japanese, is supported by multimedia technology. Students experience real-life communications with students in Japan through email and enjoy first-hand information on the Web. Students learn to use essential software and, the video camera and editor for class projects.

Speech 251: Principles of Effective Speaking, models technology by using electronic slide presentations, pictures from digital cameras, and electronic mail. Students use a variety of technologies to search for and present information. They videotape their speeches to evaluate their performance. To respond to guidelines on ethics, students spend one full day in class discussing ethical issues in public speaking.

Botany 456: Plant-Animal Interactions has a class web page that includes the syllabus, assignments, practice exam quizzes and links to other sites relating to lecture topics. All class lectures are delivered with presentation software to allow for seamless incorporation of sound, color photos, and video into lectures. Students participate in and lead online discussions and use a graphical software package to simulate interactions between plants and herbivores over space and time.

Family Resources 230: Human Development students use multimedia to learn about human development over a lifespan. They use the course web site to participate in chat room exchanges and conduct searches. Students have the opportunity to practice with computerized self-exams and then take computerized tests.

Math 206L, students use calculus software for computing and graphing in order to understand course concepts better. They use computer graphics to interpret problems and make approximations. The algebra features allow them compute exact solutions that then can be compared with the graphical approach. Modeling physical systems using both graphics and exact formulas will be done in the context of population growth and other differential equations.

Arts & Sciences 101/102 students are involved in an international project on the Internet called collaboratory, a theme-based research project. This project is a partnership among universities, schools, museums and corporations worldwide. They work on collaborative projects, share these with students around the world who are part of this initiative, and display their work locally at the end of the year.

Teacher Education and Curriculum Studies 439: Office and Marketing Technology. This course provides vocational education preservice teachers with an understanding of technology's impact on curricula and its use as a teaching tool in preparing youngsters for the highly technological workplace of the 21st century. Preservice teachers have the opportunity to explore and experiment with various technologies available in the classroom and in business and industry. They use desktop publishing to create brochures, newsletters, signs, and multimedia software to create electronic research papers.

Didactic Model of Internet Application in Education

Dr. Ivan Gerlič, assistant profesor
Centre for Computers, Informatics and Multimedia in Education
Faculty of Education Maribor, University of Maribor
Koroška 160, 2000 Maribor, Slovenia
E-mail: ivan.gerlic@uni-mb.si

Abstract: This paper reports how the Faculty of Education – University of Maribor and Board of Education Slovenia is infusing technology into its education courses, in order that its students will be better prepared to use modern informatic technology in the schools.

In modelling computer application in the Slovene educational system, we proceed from the definitions of computer application, various Slovene and foreign authors have put forward in their works; yet, we basically proceed from the actual position and actual possibilities offered within the Slovene educational system. Among the points that concern the definition of computer's function and role in education, we considered those where the authors stuck to the *informal determination* (of computer's function and role in education); the authors show differences in the number of these possibilities of computer application they deal with, what naturally results in differences among these authors in the level of generalisation of individual possibilities. In our model, we distinguish globally among the following three fields of computer application in education:

- The *primary field*, - the field of computer science education; it comprises activities the aim of which is to make the participants in the educational process (the students), as future users of computers, familiar with the functioning and the use of computers (the field of general education), or to make them enthusiastic about work with computers, so that they decide for a professional career dealing with computers (special professional field).
- The *secondary field*, - the field of computer application in the educational process; here belong all the activities that are closely related to the frontal (direct) educational process in any subject area in elementary schools. In this case the computer serves as a teaching tool or aid in the traditional forms of computer-assisted learning systems (monomedia- or multimedia systems) on one hand, or in the systems supported by artificial intelligence (AI), - the so called expert learning systems.
- The *tertiary field*, - the field of activities that accompany the educational process; here belong various research activities, as well as school administration and management of the educational system, the latter thus being integrated into the educational informational system at the school, communal, regional, and state level, or at the international co-operation level.

The education benefits mostly from the *secondary field*; here belong the use of computer in e.g. teaching mathematics, physics, Slovene, science, sociology, music, etc. In all these cases computer serves as a teaching aid or tool, which is fully or partially involved in the teaching and learning course. If computer is fully involved, this means that it is part of every single phase of the teaching and learning process and that it interferes with the entire regulative teaching course, and that it is actively involved in all procedures - students' preparation for educational work, learning and work with new learning contents, practice, revision, checking what and how the students have learned in order to ascertain their knowledge and plan further work, etc. In the second case, computer is part of only some of the phases of the teaching and learning process (course), such as practice, revision, checking the

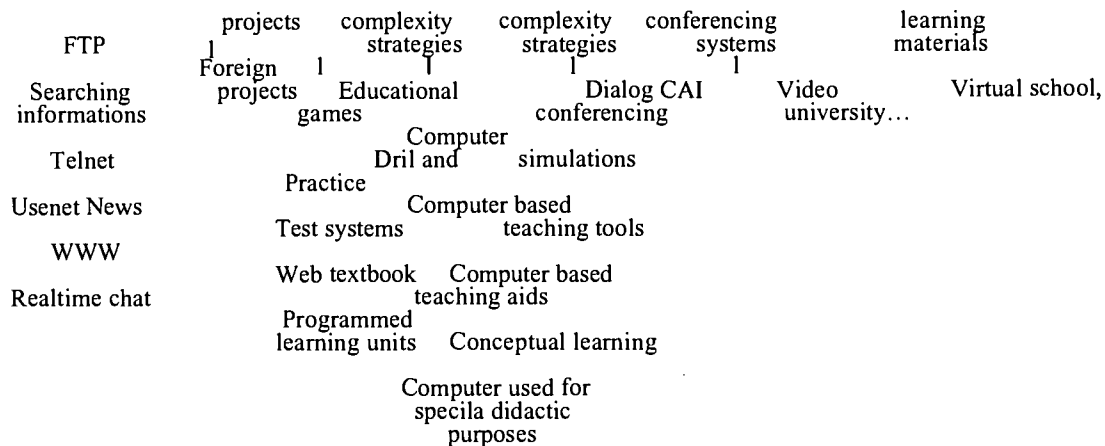

Figure 1: Didactic model of Internet – educational network application in education

students' knowledge, presentations of new learning contents in individual steps or in the form of whole activities as units, etc.

As we can see, *educational networks* are increasingly making their influence felt in the lessons in monomedia- as well as multimedia-based approach. The educational networks bear all the characteristics of monomedia and multimedia systems. In the year 1995 we established in Slovenia the Slovene Educational Network, where an increasing number of our schools have access through Internet and Intranet to various projects home and abroad. Figure 2 shows didactic model of Internet – educational network application in our educational system.

Web Sites Lost in Cyberspace: How to Ensure your Web Site is Found

Brenda J. Gerth
Computing User Services
University of Victoria, Canada
bgerth@uvic.ca

Abstract: A significant number of resources are expended on developing and maintaining University of Victoria web sites. As student recruitment initiatives become increasingly more competitive, the ability for potential students and associates to locate departmental, faculty and staff web sites becomes critical. The emphasis of developing a University Web presence began by "getting the site published" and progressed to improving the design and usability of the site. However, a critical question remained unanswered, "What initiatives can be implemented to assist potential students and associates find the information they seek on University web sites?" The focus of this paper details the design techniques and strategies that organizations can employ to help ensure their web site is found by people searching the Internet using the Web's free search services.

Finding Your Web Page on the Internet

The main purpose of creating a web page is to publish information on the Internet for others to read. Effective design techniques and strategies can be implemented to help ensure that search engines will find and improve the site ranking results of your web page when users search the Internet for information contained on your web site:

- Prepare Your Web Page with Appropriate HTML Tags
- Avoid Features that Hinder Search Engine Indexing
- Register your Web Page with Search Engines

Prepare Your Web Page with Appropriate HTML Tags

Summary Paragraph To optimize the ranking results of your web page by search engines, the content must be carefully and succinctly written. Search engines index and rank the text placed at the beginning of the page. Write short pages containing substantive content, choosing keywords and keyword phrases that reflect the content of the web page. Position the most discriminating keywords at the beginning of the web page and within HTML tags to improve the search engine's ranking of your web page.

HTML Title Tag The title is the most important element indexed by search engines and is the first line of information displayed by a search engine in the listing of pages found. The title must engage the viewer's interest and encourage the viewer to read the description, and the description should compel the viewer to click on the link that loads the web page. `<TITLE>Finding Web Pages using Search Engines</TITLE>`

HTML Comment Tag Search engines that do not recognize META tags often use the comment tag description in the listing of search engine results. `<!--Use the text from the META Description tag.-->`

HTML ALT Tag Attribute Search engines will not index graphic images. Use the ALT attribute to provide a method for search engines to index the graphic image and provide a text description of what the image represents for browsers that do not display graphic images. ``

Descriptive URL Choose a descriptive URL when naming the web page. For example, in a document containing year 2000 information, the URL `/y2000/y2kinfo.htm` will more likely be found and receive a higher rating from search engines than `/web/info.htm`.

HTML META Tags Many search engines use META tags to index web pages and respond to a searcher's query. Their purpose is to provide information about a web page without the search engine scanning the entire document. The *description* element defines the summary that some search engines display after the web page has been selected by a keyword search. The description should be brief and describe what is found on the web page, as well as encourage the searcher to click on the link that loads the web page. The *keywords* element includes the carefully selected keywords that reflect the content of the web page. Specify keywords and keyword phrases you anticipate the user would choose, including common misspellings. Separate each keyword or phrase with a comma.

```
<META NAME="DESCRIPTION" CONTENT="Finding Web Pages using Search Engines. The main purpose of creating a Web page is to publish information on the Internet for others to read. What can you do to ensure search engines will find your web page when users search the Internet?">
```

```
<META NAME="KEYWORDS" CONTENT="promoting web sites,finding web sites,finding pages,searching internet,web page promotion,promote your web site,marketing,finding sites,search engines,directories,promo,finding information,register,locate,web development,hits,internet,searching sites,marketing,marketing web sites,marketing web pages,increase hits,locating pages,submitting web sites,internet promotion">
```

Avoid Features that Hinder Search Engine Indexing

Some design features will hinder the ability of search engines to index web pages. Without special consideration, search engines cannot index web pages that contain frames, image maps, Java and Perl scripts and CGI directories. The use of invisible or tiny text, pages with a high META fresh rate or words repeated excessively on a page will be recognized as *spamming* (falsely improving the ranking position of the page) and will not be indexed.

Register your Web Page with Search Engines

It is a good idea to register your web pages with search engines because non-submitted web pages may take several months to be indexed and not all search engines use robots to automatically find and index web pages. Unless you submit your key web pages with the popular search engines and directories, it is unlikely that search engines will find your web page. For best results, register web pages manually or use an automated submission service. Resubmit the web page if the original submission was not accepted. To prolong the listing of your web site in search engine databases, frequently update the content of your web page and the corresponding *last updated* date.

Manual Web Page Registration

Before registering web pages, determine how each search engine displays its found listings and read the Help pages to confirm your submission adheres to the criteria for each search engine. Search engine robots require the web page URL. Directories require more information such as the URL, title, description, subject category and keywords.

Automated Submission Services

Free submission services are available to automate web page registration. Some search engines will not accept registration by a submission service and registration may take much longer.

The Integration of Web-based Learning with the "Real" Classroom: An Art Education Paradigm

Donna Gesualdo, Education department, New Museum of Contemporary Art, US, gesualdo@newmuseum.org

Abstract: The New Museum of Contemporary Art's *Visible Knowledge Program* Web site, based on cold fusion programming, is both dynamic and interactive. Complementing the Education department's outreach efforts to high school students, the site provides a forum for educators, artists, students and museum staff to share ideas, engage in dialogue and work towards "real" and Web-based projects in both the physical and online classrooms. As with any new concept for a traditional practice, there is need for continual reevaluation and modification of the vision by its creators and participants.

The New Museum of Contemporary Art's Education department has been working with alternative high schools and at-risk students in the New York area since 1984 as part of the *Visible Knowledge Program* (VKP). Pairing artist-instructors with classroom teachers on a semester or year-long basis, the Education department provides professional development and technological support to VKP participants collaborating on the integration of contemporary art with core high school curricula (Social Studies, English, Science) and the development of online Classrooms and Studios. In liaison with museum staff, the teachers and artist-instructors develop and teach weekly lessons that explore the connections between contemporary art practice and current cultural and social issues introduced in the different subject areas. The program encourages critical thinking about these issues and various interpretations of art through a multicultural and interdisciplinary team-teaching approach. It also empowers student expression by drawing upon their diverse personal values and interests.

Launched in March 1999, the *Visible Knowledge Program* Web site (www.vkp.org) uses cold fusion programming to provide an interactive and continually expanding resource and work space for educators, artists and students. The site complements the practical in-class learning experience by providing a cyber learning environment consisting of four areas—Classrooms, Studios, Galleries and a Library. The Classroom and Studio spaces offer participants individual or group work areas to upload images of student and artists' work, personal statements and lesson plans in progress. Both the Curriculum Units, which may be downloaded, and the Classrooms are linked to Forums where visitors and registered users, who gain sign-in access by applying to the site administrator, may participate in dialogue and offer feedback on the lesson plans and posted work.

The eventual goal of the VKP Web site is to reach and support educators worldwide. As the site is still quite new, the activity online consists only of the teachers and students from the schools with which the museum has established collaborative programs. Even at that, the use of the site has been sporadic. The challenge the department now faces is how to fully incorporate the site into the classroom learning process and then extend it in an organic manner specific to each unique group of students. Measures have recently been taken to ensure that the site will be used more consistently, eventually drawing in participants from outside the core group of collaborating schools in the New York area.

The first step was to make inclusion and use of the VKP site and training with the site administrator mandatory for all teachers and artist-instructors who wish to participate in the program. Before the start of the school year, both artists and teachers are required to attend a training session with the site administrator in how to use the site and access and maintain the areas for which they are responsible: classrooms and studios. The museum has no binding contracts with the teachers, as it is the participating schools' responsibility to reimburse their teachers for time spent in professional development and training workshops. They are, however, still required to fulfill the expectations and adhere to the deadlines presented at the outset of the program. As for the artists with whom the museum does have contracts, there are very specific requirements that must be met as outlined in their agreements, like the monthly submission of lesson plans and updating of online classrooms.

In addition to training the adults, the site administrator also goes into the schools to do a training session with the students, provided the school is equipped with Internet access, on how to open and maintain their individual studios. If the school is not online, the students are encouraged to go to the museum, where the site administrator can work

with them on the work stations in the education seminar room. High school interns are appointed from all the collaborating schools and act as liaisons between the museum and the "real" classroom. They will also be carefully trained on the Web site, so they may offer technical support to their class when the site administrator is unavailable to go out to the school.

Beyond technology training, the use of the Web site and its integration into the *Visible Knowledge Program* will be addressed at professional development meetings, of which there are twelve throughout the school year. Time has been scheduled for discussion among participants and museum staff about ways of including the site into the curricula and ideas for new media and Web-based projects. Of course, as with any addition to a class lesson, standards and measures of evaluation must be considered and employed to assess the technology-based work. Teachers will need to decide, with the help of artists and staff, how much of the class grade the technology and art aspects will constitute and how much class time will be devoted to these components.

After an initial lack of valuable responses in the Forum section of the site, the department's aim this year is to create a structure that facilitates more regular and evocative discussion in the Forums. In response to this need, time is being planned into the professional development meetings for teachers, artists and museum staff to engage in Forum discussions online and respond to comments and questions from browsers and other participants. It is also our hope that time will be allotted during the class period for students in one classroom to respond to feedback from students in another, so that there is continual dialogue among the youths as well. It will be interesting to see how teachers and students incorporate this feedback into the development and eventual outcome of the project. The use of the Web site will naturally emphasize the importance of process to both students and teachers, as they will have regular opportunity for reflection and reevaluation of their choices and the directions in which their projects are going, especially in the Forums.

The education staff acknowledges that the long-term success of the Web site depends on this type of dedicated participation by all members of the program and its consequential benefit to the students. Taking this one step further, the department is working on creating incentive for the students to sustain participation on the site by having the school and/or teachers offer some type of class credit for their involvement. Independent of credit, however, the museum builds in its own incentive for teachers, artists and students by offering them a space to exhibit their work either at the museum or at an off site venue.

At the end of each collaboration (usually coinciding with the academic year), there is an exhibition of the students' final projects, which express an idea or concept resulting from what they learned through the intersection of contemporary art with the class subject. Sometimes a third component is added when the students' work is displayed in conjunction with an exhibition at the museum. From experience, this opportunity to display a work in a well-established art institution has been the most effective incentive yet.

After a full academic year with the Web site functioning and integrated into the VKP, the staff will be able to assess its effectiveness and future potential. For now, though, the long-range objective of the museum is to have an international network of educators using the site as a work space and sounding board for current museum and art education practices. The New Museum aims to promote replication of the *Visible Knowledge Program*, either in its existing form or in modified versions appropriate to particular learning institutions. To that end, the site strongly encourages open communication about the program, the lesson plans and the pedagogical philosophy of the Education department. With classroom teachers and museum educators worldwide participating in this dialogue, schools without art programs and museums with few educational resources will benefit from the fruits of the VKP's collaborative efforts.

Acknowledgements

The Visible Knowledge Web Site is supported by generous grants from the Albert A. List Foundation and the National Endowment for the Arts to provide educators and students nationwide with the curricula and teaching methods of the New Museum's high school outreach program.

Efficient Search Methods for Database Backed Web Applications

Karl M. Goeschka, Juergen Falb, and Christian Halter
Vienna University of Technology, Institute of Computer Technology, Austria
goeschka@ict.tuwien.ac.at

Abstract: Searching database backed Web applications with dynamically generated HTML pages differs considerably from searching static document trees or databases directly. Universal relations and natural language interfaces known from database theory are combined with keyword searches known from the Web to define a metadata model for searching a database backed Web application. The key idea here is the separation of structural and contextual meaning of words. Based on this idea, natural language interfaces, and generic interfaces for both Intelligent Software Agents and robots from search engines have been implemented. This short presentation will give an overview of the status quo of this ongoing research and will show future directions.

Search Methods on the Web and in Relational Databases

Searching database backed Web applications with dynamically generated HTML pages differs considerably from searching static document trees [<http://www.sci.ouc.bc.ca/libr/connect96/search.htm>] or databases directly. However, the disadvantage with relational query languages is that one has to know the exact names, relational topology and the semantic meaning of this structure (e.g. entity relationship diagram) to formulate a useful query to the database. An interesting approach to overcome some of these deficiencies are 'Universal Relation' query languages. Although universal relations are not the best solution for searching in database backed Web applications, the idea of a path through the database will be used for the approach proposed here. On the Web - and hence also for database backed Web applications - only two methods of querying are realistic - keywords and natural language interfaces NLI's [Trost & Buchegger 1990]. Nobody would expect the average Web user first to learn the scheme of the underlying database and then to formulate a proper query directly with SQL. Keywords are the usual method of searching today, but more recently Altavista has started a pilot with short NLI queries.

A Natural Language Interface for Database Backed Web Applications

The key idea is to differentiate between the structural and contextual meaning of keywords. The structural keywords are used to select a path within the database topology (i.e. a particular attribute of a table or a whole SQL statement). A full-text search then detects the occurrence of the contents keywords within the pre-selected path. Similar ideas - called 'keyword separation' - can also be found to search static hypertext systems. Other papers suggest rich links [Oinas-Kukkonen 1998] or meta-level links [Takahashi 1998] for better navigation and queries. Yet compared with linked hypertext structures, the structure of a relational database (and especially the semantically richer ER description) contains even more information. The basis is a configuration repository (stored as relational data structure) which defines a semantic metadata model of the database.

The algorithm: First, the starting phrase and uninteresting 'filling' words of natural language utterances are eliminated. Then the query input is searched for structural keywords. For each keyword found, the other keywords are treated as content keywords and the parametrized SQL statement is then filled with the content attributes and executed as often as necessary. The results are formatted according to the presentation rules of the respective path. These results are links, the anchor tags are built from the URL definitions filled with the names and values of the attributes found. A click on one of these results brings the user directly to a point within the database application that reflects the query results.

Again, we are searching database backed applications with dynamically generated HTML pages, but neither static documents nor databases directly. Here the task of the search interface is to bring the user into the right starting point within the application rather than giving him a perfectly precise search result: The user can then - with the possibilities of the application itself - proceed further to the desired information. Hence it is only important to place the user somewhere near the desired results within the application.

Agents, Robots and Search Engines

The key idea in providing an agent [Kiniry & Zimmerman 1998], [Chorafas 1998], interface for a database backed Web application is to encapsulate the search functionality described in the previous section within an agent called 'database guardian'. It is able to talk to other agents, either with short messages, or with an intelligent language like KQML (Knowledge Query and Manipulation Language) [Chorafas 1998] or ACL (Agent Communication Language). From the other agent's view this version of the natural language interface would look as if the guardian knows the database application and can hence communicate it to others. A personalized agent with a particular task can now migrate on its own through the Web and eventually find our database, communicate with our guardian and -- in the case of success -- report back home on what it has found. The prototype has been implemented using IBM's Aglets [<http://www.trl.ibm.co.jp/aglets/>]. One obvious enhancement of this agent approach is to let the database itself send out agents - either to provide the contained information actively, e.g. to meet information seeking agents at virtual marketplaces, or to seek new information to be stored in the database.

Search engines use programs - called robots, wanderers, or spiders - to index the whole Web [<http://www.ouc.bc.ca/libr/connect96/search.htm>]. The problem with search engines and database backed Web applications is that the latter need links with lots of parameters in their URLs, which the former sometimes ignore. Hence we need static pages which the search engines can bookmark. The first straight-forward approach is to generate one large static page. The disadvantage, however, is that for a very large database this would mean loading the textual representation of the whole database over the Web. The alternative is to repetitively build a static hypertext tree from the database, following the entity relationship structure. An algorithm can be applied using graph theory [Goeschka 1998]. The contents of the generated pages is derived from the same repository as described earlier, especially from the part, where the entry points for single tables are defined. This method enables the bookmarking of the whole database contents by any search engine with reasonably small pages and the possibility to jump into the dynamic application. This method can also be applied with intelligent agents, that expect a static hypertext tree to traverse. In fact, the static tree is not really built, but rather dynamically simulated from virtual extra paths by the static tree engine.

Web Utilization of Relational Databases with Dynamically Generated HTML

Karl M. Goeschka and Juergen Falb
Vienna University of Technology, Institute of Computer Technology, Austria
goeschka@ict.tuwien.ac.at

Abstract: While databases store information and the Web is the place for the gathering and distribution of information, there are inherent difficulties in linking them together. Often proprietary methods compromise Web compatibility. This paper presents a design methodology to use groups of pure HTML hyper-links for sophisticated user interaction with relational databases. The key idea is to use a Finite State Machine model. A Web based toolset has been implemented to generate the different applications thereby also fostering unlimited Web collaboration. Using this technique, complete real-life information systems have been built. The proposed techniques will also help to provide new ways to integrate legacy systems.

Web Information Systems

While databases process and store information and the Web has turned out to be the place for gathering and distributing of information [Isakowitz et al. 1998], integrating them is quite difficult. However, it soon turned out that most real-life applications need an underlying database on the server side and many legacy database systems need to be connected to the Web [Adida, 1997].

If the user interface has to work with any browser and should not depend on proprietary non-standard extensions like Plug--Ins, Active--X, VBScript or JavaScript then the user interface is restricted to the possibilities of pure HTML (Hypertext Markup Language). This concerns the representation, but the user interaction even more so - the only functional elements are following a link, pressing a submit button of a form or clicking on an image or imagemap. They always result in an HTTP (Hypertext Transfer Protocol) connection. Hence, any functionality resides on the server side.

Another problem arises due to the different nature of databases and the Web: The HTTP is stateless and the browser does not store its user interface state but connection orientation is inevitable for real-life database transactions. To overcome this deficiency, we use Short URL (Uniform Resource Locator) encoding: A short session identifier, called a handle, is passed back and forth between client and server with every HTTP connection. The complete session state information (database transaction state and user interface state) is kept on the server side, usually in a database. This approach scales well to complex state information and it can also be used with frames.

Architectural Model

Being limited to an HTML-only user interface, we are confronted with a disadvantage with HTML forms: no functional dependencies between different input fields of a form can be implemented. An HTTP session has to be performed before functional dependencies or restrictions can affect other inputs. To achieve this HTTP session, a submit button has to be explicitly pressed. It is not usually enough to fill in an input field or make a selection. The key idea of this approach therefore is to use links to solicit user selections. Control elements are thus constructed of sets of links grouped together. These links are a means of user interaction, no cross-references or links for navigation! This approach is reasonable for a typical Web application where most user

interactions consist of browsing, selecting and collecting information from the database. The possible values for user input are predefined in these cases.

The general idea of modeling hypertext documents as Finite State Machines is well proven [Stotts et al. 1998]: It is proposed to view a document as an abstract automaton that specifies the process of browsing within it. The linked structure of a document can usually be thought of as the state transition diagram of a FSM. Hence each document defines a state (i.e. the state that this document is displayed in with only one document being displayed at a time) and the state transitions are provided by the hyperlinks. Clearly this describes a FSM with a finite set of pages (states) and a finite set of links per page. The most important difference between a database backed Web application and a static document tree is the number of pages: In the latter case this number is well defined, whereas in the first case the number of dynamically generated pages is potentially infinite due to the arbitrary nature of the Turing machine which is formed by the database application. Nevertheless, the theory of FSMs can still be applied [Goeschka, 1998].

The strict separation between state transition and output generation is a key feature of this model to achieve stable and robust Web applications: It is necessary to guarantee a deterministic generation of the dynamic HTML pages independently from the last user interaction. Hence, as long as the affiliated state information is not changed, a dynamically generated Web page will always look the same, regardless of which user interactions have taken place in the meantime. Web applications which ignore this rule can easily produce unpredictable results and a corrupted output. Again, the two reasons for this are the stateless nature of the HTTP protocol and the browser. Hence, if a user interaction has to produce a different output, it first has to change the session state information, making it possible to generate the new output from the changed session state information afterwards.

Implementation and Conclusion

Whereas the advantages of a client/server model are exploited for design, in the case of pure HTML the final implementation of a PHC is done on the server side. Every Web page, including all links, is dynamically generated from the database. The hyper-reference URL of every link contains parameters for the global session handle and state transition information. The lifetime-problem of state information is overcome by a time-out mechanism. The problem with the browser cache that every URL-based state maintenance mechanism has to face can be overcome by setting the HTTP response header field 'Expires' to a date in the past.

Evaluation of the design and generation methods has been done by two sophisticated, multi-lingual, real-life implementations. A product marketing and tourism information system (<http://land.ict.tuwien.ac.at/>) and a Web based interactive database training server (<http://aki.ict.tuwien.ac.at/>) for a graduate course with 90 students per year. Hence it is proven, that the approach scales to larger systems. Despite the limits of pure HTML, sophisticated user interfaces could be designed. With the Web based tools, a novel design and implementation technique for complete Web based information systems was implemented. This development framework can also provide new ways to integrate legacy systems.

Abstract: Using hypertext to support work, learning and research, has have increasingly popular. The user can arbitrarily navigate in the information space. Yet many approaches do not consider the aims, interests and the knowledge of the user. This paper introduces a method for the intelligent and dynamic generation of hypertexts from an information space, and for the support of navigation in large, complex hyper documents, which is based on the modelling of the application domain. Intelligent generation of hypertext is based on different inference strategies, for horn clause resolution. The generated hypertext is problem-oriented and presented in a context sensitive manner. Furthermore, the structure of the hypertext is presented graphically and serves as a navigation support for the user. All tools related to this work are implemented in Java.

1 Introduction

The deployment of hypertext to represent knowledge and information has gained popularity over the last years, not least due to the WWW. Hypertext allow a non-linear representation of knowledge and information. The user can move freely within the information space. Unfortunately, this flexibility has its drawbacks. Big hypertext systems quickly leads to user disorientation. The user is lost in the web of links. When hypertext is used for learning, teaching and working, this phenomenon will occur very soon. Many solutions have been proposed to deal with this problem, but none of the suggestions really appreciate the aims and the interests of the user.

This work introduces an approach to solve this problem. Our approach support, the intelligent generation of new hypertext from an information space and a proper navigation help in complex hyperdocuments. To support the user during learning, researching and working with big information spaces the approach generates an appropriate hypertext, to bring into account the interests, the knowledge and the aims of the user. Thus the generated

hypertext is extremely problem-oriented and context-sensitive, and will be presented in an appropriate manner. These properties qualify our approach for the area of teaching and learning especially in intranets and the internet.

2 Approach

Rule interpreter can be used to find answers to the users's questions. They use a dedicated knowledge base, which describes the basic knowledge of the system. Additionally, they accept input from the user, which will be interpreted as a question. Using the knowledge base the interpreter tries to find an answer to those questions. Regardless whether or not a clear answer can be found, it establishes a solution path.

The quality of the generated hypertext depends on this solution path. The clearer it is, the better the quality of the generated hypertext. The measure of the quality is described through the information pieces in the generated hypertext which are related to the question.

The tree, which is built at run time, has different kinds of nodes, which serve different purposes. The first kind of nodes is the *root* of the tree, which represents a global target. The root also has the properties of the inner nodes. They are the second kind of nodes, representing the derivation of the solution, i.e. the rule of the knowledge base. The inner nodes also have additional references to contents, which are related to the subject of the rule. The content might be text, audio, video or other multimedia data. A node may have several references with different types. The third kind of nodes are the *leafs*, which represent the input of the user, consisting of prescribed facts.

There are two different ways to build up a tree. Both cases need a root and the leafs, the user has to supply the input. The difference is the starting point of the algorithm, which may start of the root and tries to get the leafs or vice versa, i.e. starting with the leafs and getting the root.

These schemes are realized in two different interpreters. The first is realized in an interpreter like PROLOG, i.e. it works backward chained. The second scheme works the opposite way and is realized in an interpreter that works forward chained.

At interpretation time the interpreter generates a tree, the solution path. The nodes of the tree represent an ordering of the information space. When considering the tree the choice of a node of the next level, depends on the nodes of the prior level. Following this scheme to the start of the algorithm, one obtains the input of the user. The difference to other systems is that the users input is not limited to keywords. Like to the rules in the inner nodes they have explicit references to the information space and are prescribed by the system.

3 Discussion

In this paper we have introduced an approach for the intelligent generation of hypertext which is context-sensitive and problem-oriented. The approach supplies a method to support the user in a context-sensitive and problem-oriented way at his work, learning and research. Additionally, a navigation support, which is based on the same method, are also been introduced it handles large, complex hyperdocuments. All tools related to this work are implemented in Java as applets and applications. Thus, they can be used within web-pages and as standalone applications. The tools can be used in the internet and also in intranets like in big clinics, firms and schools or universities. All tools are integrated in the HTML-Version of the DSM-IV[1].

The Importance of Link-Transformation and Link-Proposals for Hyperlink-Management Systems

E.-G. Haffner, Andreas Heuer, Uwe Roth, Thomas Engel, Christoph Meinel
Institute of Telematics, Bahnhofstr. 30-32, D-54292 Trier, Germany
Tel: +49 (0)651 97551-0, Fax: +49 (0)651 97551-12
E-mail: {haffner | heuer | roth | engel | meinel}@ti.fhg.de

Abstract: This short paper emphasizes on a special aspect of hyperlink-management systems as part of online authoring systems. The transforming and adopting of links in HTML-files is very important. This can be done only if there are relationships between the corresponding documents. Another aspect is strongly related to the first one: the generation of link proposals for new documents. Both ideas together lead to a very efficient and user friendly management of hyperlinks.

Link management in general

The Internet, especially the World Wide Web (WWW), is growing very fast. There are millions of documents retrievable from the net. One main reason for the success of the WWW is the possibility to connect HTML-files via hyperlinks. The idea is to improve the quality and usability of documents while offering additional information within the reach of a single mouse click.

Hyperlinks are one of the most important ways to find an HTML file on the Internet. Unfortunately they are also very hard to manage. Due to the structure of the HTML code, the renaming or moving of a file requires several changes within the hyperlinks of the concerned documents. Improper handling of the hyperlink-management may result in broken links or unsuitable references.

There is another aspect that is gaining more and more importance as well: For multilingual web-sites, a relation has to be established between documents of the same content which exist in different language-versions. If there is a change in one document, all other language-versions of the same document-content should be altered accordingly. It is important that the language-specific links of the original document do not get copied with a "one-to-one ratio" into a document that has the same content but is written in a different language. Rather, the "transformation" of the link should take place as follows (figure 1):

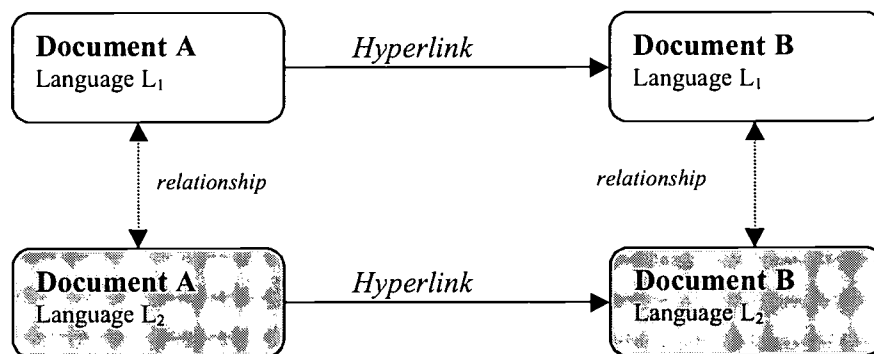

Figure 1: The relationship between documents

In the scenario described above, the transformation of a link into another language is quite straightforward. But there are also many situations where the finding of suitable links turns out to be a very hard job. How can one make a proposal for hyperlinks in a document A in general?

The idea of this short paper is to find the most *similar document* *S* to *A* and to take the hyperlinks of *S* as proposals for *A*. The calculation of the similarity is a complex process, because there are some inherent difficulties in the definition of the similarity itself [Tverski77].

A practical example

In a hyperlink-management system devised by the Institute of Telematics, we have used five different kinds of partial similarities between HTML-documents for calculating their total similarities:

- (1) evaluation of the similarity “MK” between the weighted, normalized (meta)-keywords
- (2) evaluation of the similarity “MD” between the (meta)-descriptions (on the basis of a pure word-check)
- (3) degree “MA” of correspondence between the authors (with regard to the ranking of the authors)
- (4) comparison of the document-validation and the expiration time “MT” (creation and expiration time are considered)
- (5) comparison of all document catchwords “MC” (analogous to the meta-keywords)

According to the normalization of the keywords and catchwords (1),(5) it must be taken into account that there are not only grammatically variants but also different languages.

All results MK, MD, MA, MT and MC may have values between 0 and 1, where 0 means “no similarity” and 1 means “identity”. Each partial similarity is weighted by a system- dependant, constant, positive value (WMK, WMD, WMA, WMT and WMC respectively) with no further restrictions.

Thus, the total similarity TS between two documents is calculated by dividing the weighted partial similarities through the sum of the weights [1]:

$$TS = \frac{MK \cdot WMK + MD \cdot WMD + MA \cdot WMA + MT \cdot WMT + MC \cdot WMC}{WMK + WMD + WMA + WMT + WMC} \quad [1]$$

The total similarity between two documents must exceed a reasonable threshold-delta (e.g. delta > 0.75) to be an indicator of a candidate for link-proposals.

The research in this field is still in progress and we hope to get valuable results about this approach soon.

The Take-Up of Web Technology:- Adoption & Diffusion into Mainstream Teaching

Steve Hansen, s.hansen@uws.edu.au

Graeme Salter, g.salter@uws.edu.au

Paul Davies, p.davies@uws.edu.au

Centre for the Enhancement of Learning and Teaching and the
Department of Computing & Information Systems,
University of Western Sydney, Australia

Abstract. In 1998, at the the University of Western Sydney Macarthur, a project called PlatformWeb was introduced to enable a "bulk" movement of teaching staff to make use of the Web medium for teaching delivery. From a comparison of models of adoption of teaching innovations, it was decided to approach this project by making use of the Burkman "User Instructional Orientated Development" model. Instead of simply adopting an off the shelf web delivery package, from surveying staff perceptions of needs, a fully integrated Web Information System incorporating the Student Administration System was developed. Using this adoption model, within two teaching semesters, there has been a voluntary movement of about 200 staff and subjects into making use of PlatformWeb. This involves about 3,000 active student users and up to 6,000 students with access. The daily usage being 40,000 to 60,000 items accessed via the web. This paper outlines the adoption model and the development of the Web Delivery System.

Introduction

The adoption of web based education represents an example of Instructional Technology Diffusion as part of the standard Innovation Decision Process theory [Rogers, 1995], with the prediction that individuals who are predisposed to being innovative will adapt an innovation earlier than those who are less predisposed. On one extreme of the distribution are the "Innovators" On the other extreme are the "Laggards" who resist adopting an innovation until rather late in the diffusion process, if ever. The diffusion process following an "S" curve. The PlatformWeb project aims at moving the rate of adoption of the web medium in education along the "S" curve as quickly as possible.

Applying the Burkman Model

In particular the approach of Burkman's [Burkman, 1987] theory of user-orientated instructional development (UOID) was used. This model sees the needs, and perceptions of the potential adopters as being the primary forces that influence adoption. The UOID process consists of 5 steps, each of which is concerned about the characteristics of the individual adopter: namely, (1) Identify the potential adopter, (2) Measure the relevant potential adopter perceptions, (3) Design and develop a user-friendly product, (4) Inform the potential adopter (of the user-friendliness), and (5) Provide post adoption support .

Preliminary Work

The adopters were identified as primarily (at this stage) the teaching staff, as without them there would be no web based delivery to students, with the University management and students as secondary. It was recognised, as the project developed, that the primary adopters would shift towards the students as staff came "online". Adopter (staff) perceptions were sampled in terms of real or perceived problems firstly in existing traditional teaching delivery and secondly in moving to web based teaching.

Real or Perceived Problems with Traditional Teaching Delivery (as seen by staff)

Staff were surveyed on their perceptions to traditional teaching in the broadest scope (not just of their perceptions inside the lecture room). The main concerns were grouped into three main areas. These are in order

of importance were (1) General administration problems in subject delivery dealing with student enrolment, timetabling, and resource availability. (2) General and specific communication to/from students resulting in student (and staff) confusion of procedures, requirements and where to obtain needed information (3) Student participation and attitudes towards attendance at lectures and submission of assignment work

From this survey work, there emerged a prime importance of the administration information systems in supporting existing traditional teaching methods (for the bulk of staff). The survey also indicated that some (if not many) of the attitudes students develop regarding their learning experiences (particularly in large subjects) are influenced by the administration related problems encountered in the first few weeks of their studies, particularly regarding communication with the staff and administration.

From an examination of a number of commercial teaching delivery packages, there is currently a lack of administration integration due to either proprietary backend databases and lack of data "gateways" [Sawers and Alexander, 1998 make interesting and candid comments of these types of problems with a major university implementation].

Real or Perceived Problems with moving to web based teaching delivery

The main concerns for this area were grouped into three main areas. (1) Developing and learning web technology. Except for a few "trend setters" the bulk of the teaching staff had reservations on spending the time and effort in learning how to produce and author web based material. Also put forward was the concern of "locking in" to vendor specific methods if a commercial web delivery product were to be used. (2) Making use of existing materials and resources. Since most staff had developed over the years, considerable amount of material in traditional form (typically quizzes, notes and slide presentations), a major concern was how these could be easily incorporated into web delivery. (3) Technology and network issues. The typical concerns being student access, bandwidths, multiple passwords to access various websites and available computer facilities.

Design of PlatformWeb

The PlatformWeb project started with a bare bones implementation, integrating the Student Enrolment system for automatic daily updates with simple uploading management structures that can include almost all forms of legacy material, and supplying a online student messaging system. Students and staff access the system from one entry point, which lists the subjects relevant to the user. Later added were online quizzes, student upload modules for assignments, online marking, online discussion groups and various administrative functions. Specifications for these being generated from staff perceived needs, experience and feedback.

Results and Conclusions

From the original trial with 800 students and 19 subjects, The PlatformWeb project has become a "teaching companion" for not just the innovators but also for the "bulk" staff population. There are currently about 200 subjects and staff using the system with about 3,000 active students (once a day access). This has resulted from staff demand rather from management directives. Further details on the pilot study in [Hansen,1999]

Agents in Digital Libraries and Electronic Publication: An Architecture Proposal

Pedro T. Isaias

Department of Organization and Enterprise Management (Information Systems and Management Group - CENEGE), Universidade Aberta (Portuguese Open University), Lisbon, Portugal
pisaia@acm.org

Abstract: Intelligent agents can be effectively used to structure a whole digital library and play an active role in the electronic publishing process. In this work, a Virtual Research Digital Library (VRDL) based on an architecture of agents is presented, with the roles of each agent explained and their interactions shown.

Keywords: Digital libraries; Software Agents; Electronic Commerce; Electronic Publishing

1. Introduction

Agents have been in the past and are currently being used in several areas. One of the areas where they can have an important role is the digital library area, in general, and more specifically, the electronic publishing process. In fact, agents can help to structure a Virtual Research Digital Library (VRDL) and help each of the participants to fulfil its goals. In this work this idea is developed through section two where the agents role in electronic publishing and digital libraries is presented, and section three where an architecture to achieve this is proposed.

2. Agents Role in Electronic Publishing and Digital Libraries

A possible and original digital library definition is the following [Gladney 1994]:

"A digital library is an assemblage of digital computing, storage and communications machinery together with the content and software needed to reproduce, emulate, and extend the services provided by conventional libraries based on paper and other material means of collecting, cataloguing, finding and disseminating information. A full service digital library must accomplish all essential services of traditional libraries and also exploit the well-known advantages of digital storage, searching, and communication."

From the given definition, one may conclude that digital libraries are a set of well organised technologies and, above all, a very important source of structured, well organised and well stored information. It is clear that digital libraries can help to store and even organise the results from an electronic publication process: authors works (i.e. a paper).

The above described can be accomplished through the use of agents. In fact, we can conclude that agents, besides their expected roles (i.e. information location), can host an architecture (contributing to the concept of an organised technology) and play important roles within that architecture in order to establish a digital library. By playing these roles, agents are not only intermediaries between the parties but also actors in the process (solving the structure, organisation and storage information requirement).

Moreover, agents can also have an active role in the electronic publishing process (i.e. of a paper) where we can consider that there are up to four phases (modified from original phases of the traditional publication process - see [Denning & Rous 1995]): Preparation, review and revision, publication processing, and archiving and indexing. The agent architecture described can play a key role in all the phases:

- by helping the author to submit his work to several editors;
- by helping out editors to forward the work to the right reviewers;
- by forwarding it to an on-line journal;
- and finally by archiving and indexing it on a WWW repository (an on-line database or a digital library).

Through the above-described agents can effectively help to bridge the gap between information producers (i.e. authors), publishers and information consumers.

3. Architecture proposal for the VRDL

In the proposed agent architecture, which basically is an information distributed service over the Internet, each type of agent has a specific role. The architecture is composed of the following eight different types of agents:

- *User interface agents (for consumers)* - agents responsible to interact between the information consumer and the rest of the system. Each user has one of these agents;
- *User interface agents (for authors)* - agents responsible to interact between the author of an information work (i.e. article, thesis) and the publishers or the consumers. Each author has one of these agents;
- *Publisher agent* - agents responsible to interact between the publisher and the authors or the consumers. Each publisher has one of these agents;
- *Information retrieval agents* - agents responsible for finding the required information for a consumer. Each consumer has one of these agents. They interact mostly with the directory and publishers agents through the broker agent;
- *Broker agent* - central agent responsible to receive and send information (i.e. journal title, abstract, number of pages, price) between participants. It has the responsibility of interacting with all agents;
- *Directory agent* - this is an agent that has lists of publishers and authors. It is contacted by the information retrieval agents and contacts publishers agents regularly to have updated lists (all this through the broker agent);
- *Quantity agent* - this is an agent that can get several requests for the same article and then negotiate a lower price (because buying in bulk quantity) for each information consumer requesting it (through the broker agent);
- *Referee agent* - agent that represents accredited referees. It is responsible for finding specific information works (i.e. article) to be referred and presenting it to the referee person and after, to communicate the results from the referring to the publisher agent (through the broker agent).

The proposed architecture is currently being developed with the ZEUS agent system (<http://www.labs.bt.com/projects/agents/index.htm>) from British Telecom. This agent development environment has a very important characteristic: The agents are produced in the Java language, which is very important for platform independence and communication between all party systems.

4. Conclusions

It was argued in this paper that agents could be used to specify a digital library, and also play an important role in the electronic publishing process. An architecture for these purposes was presented with eight types of agents specified and described. In the future, this architecture, which is being implemented at the moment, will be tested and its results evaluated in order to conclude or not for the validity of this approach in practical terms.

Abstract: Since 1995, the Windows to the Universe web site (www.windows.umich.edu) has been presenting Earth and space science content to the general public and the science and education communities. Windows to the Universe has been widely acclaimed and has seen exponential growth in users of the site. As might be expected, we learned a number of lessons that would have been more convenient to have known at project inception.

Introduction

The highly acclaimed Windows to the Universe web site (www.windows.umich.edu) is now in its fourth year of development. This site provides public access to interdisciplinary Earth and space science information, data, and educational resources in home, classroom, library and museum settings over the internet. The site consists of ~5200 html files, ~5300 image files, and ~400 image maps which span concepts in the Earth and space sciences, ranging from the Earth as a planet to astrophysics. Windows to the Universe has experienced dramatic user growth over the past four years, reflecting the growth in internet use by the public as well as the growing use of internet technology in the classroom (Figure 1). Over the past year, the site was visited by 2.5 million users, serving 15.3 million pages and corresponding to ~60.2 million hits on the site.

Figure 1: Number of User Sessions per Year

Users of the Windows to the Universe project range from 5 to 85, and include a large number of students and teachers. The success of the project and extensive dissemination efforts have succeeded in attracting the attention of users from around the world, many who are using the site in support of their classroom Earth and space science

education program from elementary school through the undergraduate level. Unique aspects of the project include the three levels of content development, that allow users of all grade levels to access content appropriate to their reading level, as well as the availability of a supplementary CD that allows users to rapidly access images integrated into the web site from their local drive, conserving download time. These features have been very popular with our users in the precollege education setting. Windows to the Universe provides excellent, comprehensive science content presented at the level of their students and integrated into an interdisciplinary and attractive presentation format.

Lessons Learned

Our project was initiated in 1995. Much of the knowledge and many of the tools web developers now have at their disposal were not yet available. Similarly, although our development team included a wide array of individual expertises, including Earth and space scientists, precollege educators, programmers, artists, and outreach specialists from the museum and library community, we did not have extensive experience in web site development when our project was initiated. As a result, our project developed, along with our expertise in web site development, while riding the wave of expanding internet technologies and use.

Several aspects of the project can be identified that allowed us to succeed in this environment. A key factor was the inclusion, from the beginning of the project, of an on-going evaluation effort. This includes analysis of user interaction of the site through log analysis as well as on-line and hard-copy surveys. Through these evaluation efforts, we collect information about the design of the overall site and the perceived impact of the site content on the understanding of the Earth and space sciences by students, teachers and the general public. Another key factor at the beginning of the project was the adoption of a rapid-prototyping development cycle that allowed us to plan, develop, implement, evaluate, and revise rapidly enough that we could modify plans for the project to accommodate to the changing technological environment as well as to developments in computer-based science education. The coupled effect of these two factors has been to allow us to use our user audience, in part, as co-designers of the site.

Although our initial team included much of the expertise required to accomplish the goals of the project, we discovered along the way that several additional skills were needed. These included the skills of a legal advisor, copyright specialists, and translators, in addition to the administrative assistance that is so easily underestimated for a project of this size. As we developed our project to our rapid-prototyping schedule in a university environment, interesting cultural issues developed that required team members to adopt new modes of working. Working on a product-based development cycle is not common in a university or research institution, and team members had a difficult time adjusting to this schedule, and balancing project requirements against their research activities. All team members brought their own quite different cultures to the project, requiring adjustment from all members in order for the project to be successful.

As might be expected, we learned a number of lessons that would have been more convenient to have known at project inception. As the project developed, it became clear that methods for automatic updating of pages on the web site were necessary, and this needed to be implemented while the project was already underway. Similarly, after the project was initiated, we discovered the need to develop a number of search capabilities, including searches based on keywords, which required implementation after the site already consisted of more than 1000 html documents. Finally, we underestimated the staff-time required to support new functionalities on the site in the "Ask-A-Scientist" and "Headline News" areas.

Abstract: Web-based courses at university level provide several advantages and flexibility for students and educators. Presenting course material in such a fashion is a relatively new challenge to educators. Rapid developments in Internet technology has spurred developments in web-based applications and authorware, leading to the feasibility of developing multimedia courseware without having thorough training in the use of hardware and protocols. This paper presents an argument about the importance of cultural issues in a web-based course in a multicultural university. This paper identifies significant cultural issues and discusses studies in progress about students from different cultural backgrounds using web-based courses. The study attempts to define web-based system components from the perspective of effectiveness of course delivery in a multicultural university.

1. Introduction

It is generally accepted that contact curriculum delivery at universities will not cease in the near future. Courseware delivery through hypermedia has had some impact on traditional academic practices. Because of their non-contact nature and associated flexibility, web-based courseware provides several advantages for course delivery. Courseware delivered through web-based hypermedia applications is inherently multi-user and multi-site in nature. Many users can work on a web interface at the same time and in different locations - day or night. Moreover, popularity and economics of the Internet is increasingly making it feasible for educational institutions to consider course delivery through a web-based system, at least in parts.

Web-based delivery systems can promote change in the student-trainee/teacher relationship compare to the traditional teaching system. The trainer/teacher shifts his/her role as initiator, motivator and educator and educationalist towards being a sporadic expert, indirect motivator, planner and facilitator [Sherry & Wilson, 1997]. Part of the teacher's traditional tasks are passed to the students, the course group or the system [Ringsted, 1992]. However, new tasks are added to the role of the teacher. These include media description, development of distance learning methodology, coordination and organisation and participation in a production team for authoring tasks. These roles complement differential learning styles and cognitive patterns used by on-line learners.

On-line learners work in a collaborative, social structure where they and their teacher/facilitator generate knowledge and interact [Palloff & Pratt, 1998]. It is argued that a web-based course delivery system is an ideal environment for completing lessons for all students, as they can pace themselves [Duchastel, 1997]. Recent work by Slay (1998) and Bauer (1998) suggest that on-line learning can be especially important in case of students from non-English speaking backgrounds.

The quality of teaching and learning on the web-based system encourages students to take the advantage of interactive learning and learning through a process of trial and error. This approach of interactivity, discovery learning and graphical interaction, creates a particularly favourable environment of this type of learning [Revel & Bessiere, 1992]. Human ability to visualise parts such diagrams leads to relating to similar experiences that were faced previously and somehow has relevance to the present moment. This leads to the availability of a large amount of visual metaphores that can be used for precise expression within a knowledge domain. Graphical interaction provides a powerful principle of representation, analysis and action based on the individual students' personal experiences. In a multicultural university environment, design of courseware delivery systems supporting information can use a number of tools including graphical icons, colours, representation of information in more than one format to generate effective learning [Revel & Bessiere, 1992]. However, there is a

need to redress the differential learning patterns imposed by culture and the way knowledge is socially constructed by individuals from different cultural contexts.

2. Importance of the study cultural factors

Building on the seminal work of Hofstede (1991), there is agreement amongst web-based course developers that culture has a definite and very strong influence on the design and use of information, communication and learning systems [Henderson et. al, 1996]. The perspective on individual differences has to do with cultural, ethnic, racial, or linguistic background [Fernandes, 1995]. Most of the existing web-based tertiary courses are currently designed such that the developer assumes that the user demography pertains to a single culture background (usually English speaking). Perceptions due to cultural influences are two way processes. Not only the learners are effected by their cultural backgrounds, but also the designers express their ideas, influenced by their cultural background [Wild & Henderson, 1998]. Creating an effective multi-cultural leaning environment remains a challenge of on-line learning and teaching.

3. Future investigation

Culture is a culmination of ways in which an identifiable group adapts to its environment. Hence, Learners/Teachers often belong to more than a single cultural group embodying a subset rather than totality of a culture's identifiable characteristics and they may not maintain their cultural characteristics to their birth culture [Scheel & Branch, 1993]. Humans evolve due to their changing environment and adaptive nature. This study is investigating design and development of components of web-based tertiary courses for multi-culture background learners. The by product of this study will be expectations from web-based learning apart from more information about learners' and teachers' cultural backgrounds. The study will yield information about how learners from different culture background effectively learn and how university course structure can be improved by web-based delivery.

Electronic Commerce in Australia – Trends and Challenges

Nitya L. Karmakar, Ph.D.
Faculty of Management
University of Western Sydney, Hawkesbury
Richmond NSW 2753 Australia
e.mail: n.karmakar@uws.edu.au

Abstract: The growth of electronic commerce (e-commerce) is a phenomenon, primarily in the USA. The Australian position in the era of e-commerce is promising and improving rapidly. The digital economy based on globalization and Information Technology is influencing Australian Government to take greater role in shaping blueprint for e-commerce. It is very interesting to note that Australia embraces new technology very quickly. For example, Australia has the 3rd position in the percentage of Internet use just after the USA. As revealed in a recent survey, many potential customers in Australia are reluctant to do business on the Internet due to security concerns on online payment systems. The paper outlines the recent development of e-commerce in Australia and identifies major trends and challenges concerning this online business. The author also provides a snapshot of the current status of e-commerce globally.

1. Introduction

The Internet is driving economic growth at an unprecedented rate in the USA. Australia along with many other western countries is also enjoying the benefit of the explosion of Internet use. It is creating a huge market in cyberspace and carry valuable information to a large number of people all over the globe. Telecommunications technology has turned the world into a global village. The entire world is getting networked. Furthermore, the individuals and organizations will become more and more location-independent for their information needs and performing their roles in the society and economy.

2. The World Wide Web & E-Commerce

With the emergence of the World Wide Web (WWW), totally new global business culture and environment are emerging. The new way of doing business across the globe is called Electronic Commerce (E-Commerce) or Online or Internet Commerce [Roth 1998]. E-commerce is accelerating the growth of digital economy. 'The Age of Networked Intelligence is an age of promise' as predicted by Tapscott [Tapscott 1996]. E-commerce is a technological wonder for benchmarking and productivity improvement [Karmakar 1999]. It helps to achieve greater production and distribution efficiencies. All contemporary production methodologies are dependent upon highly dynamic information flows in supply chains. E-commerce also helps to keep reduced inventory and thus lowering operating costs for the company [Mougayar 1998].

3. Current Status of E-Commerce: a global overview

E-commerce is growing dramatically. It was approximately US\$43 billion last year, but it is estimated that online business may soar to US\$1.4 trillion by 2003 [Los Angeles Times 1999]. It promises to radically redesign business processes to do business in the connected world [Kambil 1997]. E-Commerce still represents a relatively small percentage of the total commerce market, but it is significant and growing exponentially. With the growth in Internet usage, there is a corresponding increase in E-Commerce. The USA is the leader in driving E-commerce due to its dominance on the Internet. Currently over 80% E-Business is taking place in the USA.

Information Technology (IT) is key challenge to the world economies in regards to the network infrastructure and the way in which it is effectively utilised by an economically leading age industries and government to have effective global markets. According to a recent report (July 29, 1999) by GartnerGroup¹ – IT spending will increase to \$3.3 trillion worldwide by 2002 driven by E-business initiatives. It also predicts that 60% of IT spending and decision-making will originate within business units and away from the traditional IS function. Electronic Commerce will be crucial for IT spending as corporations aspire to thoroughly re-engineer their business processes.

4. E-Commerce and Australia

Australian businesses are moving rapidly to participate in electronic commerce activity-as providers of goods or services. The strong growth in the use of e-commerce by Australian consumers could be attributed mainly to the following factors:

- High percentage of Internet use,
- Easy to use,
- Widespread acceptance of credit cards,
- User-friendliness.

Australia's Internet users are expected to be 5.8 million by 2002, according to International Data Corporation [Manktelow 1998]. The most recent data² concerning Australian Internet User Population are as follows:

Regular Internet Users (access at least weekly):	1.8 million
Casual Users :	1.5 million

There are more male users (68%) than female users (32%). The majority of Internet users live in New South Wales (37%) and Victoria (22%). Internet use varies among age groups - the people from 20 to 39 years are the most frequent users.

Dr. Paul Twomey, the Head of the National Office for the Information Economy (NOIE) in Australia, said billions of dollars could be saved by adopting e-commerce [Lynch 1999]. The priority industry sectors for the impact of e-commerce are banks, communications, government, education, transport, health & professional services. Internet penetration is reaching a point where e-commerce applications like banking and share trading are accelerating quickly (Tebbutt 1999).

Australian Internet Service Providers would be in a strong position to act as supplier hubs for small and medium sized businesses. Australia also has the potential to be an Asia Pacific regional hub due to its strong skills base and high quality telecommunications infrastructure.

The digital economy based on globalization and Information Technology is influencing Australian Government to take greater role in shaping blueprint for e-commerce. Australia's information economy policy, Investing for Growth was released by the Prime Minister, Hon'able John Howard

¹ http://gartner5.gartnerweb.com/public/static/aboutgg/pressrel/07299e_bus.html

² http://www.consult.com.au/reports/aus_internet_user_population.html

in December 1997. The Government is committed to providing a light-handed regulatory framework to support and encourage the development of electronic commerce.³

5. Trends & Challenges

The Internet and related markets are growing exponentially. Electronic commerce provides consumers with convenient shopping methods, from online catalogue ordering to phone banking, both of which eliminate the costs of expensive retail branches [Kalakota & Whinston 1997]. Electronic commerce is now a valuable business tool to run business in a cost-effective way and thus providing consumers goods at home at a reduced price. Now there is a true convergence of computers, communications businesses. Electronic commerce presents ongoing challenge to the international legal systems. It represents major threats concerning privacy and security. It is a business without a boundary, so concerns are the collection of the sales and other taxes and secured electronic transactions.

Australian trend to e-commerce is exciting. A recent study by GartnerGroup has found that online spending by Australian consumers has reached \$US1 billion for the first time and will grow to \$US7.6 billion within five years [Grayson 1999]. The GartnerGroup research also found that annual business-to-business e-commerce spending had reached \$US3.6 billion and would rise to around \$US44.8 billion by 2003.⁴ This is compared with annual business-to-business e-commerce spending of \$US12 billion for the Asia Pacific region in 1999. This was the forecast to explode to \$US280 billion by 2003.

Australia is facing a number of challenges. The foremost among them is the shortage of meeting the Digital Workforce. A report recently released by the Australian IT & T industry Skills Taskforce has estimated that around 30,000 additional IT employees will be required over the next 12 months, 88,000 over the next three years, and more than 169,000 by 2004. Tertiary institutions are graduating only about 10,000 students annually (Williams, 1999). Most traditional Australian firms do not have a culture of competing on price or of really letting the savings flow through to the consumers. There will be tremendous competition for product markets and firms need to exhibit flexibility to cope with those challenges.

Electronic commerce presents fundamental challenge to the law. The suitable law should tackle the threat of security and privacy when we do business online in the digital economy [Karmakar & Fertuck 1998]. As revealed in a recent survey, many potential customers in Australia are reluctant to do business on the Internet due to security concerns on online payment systems. But for anyone to benefit from E-Commerce, electronic payment mechanisms must be reliable, secure and easy to use [Clarkson 1998].

6. Conclusions

Global information infrastructures are rapidly becoming a reality to run business electronically. Australia can overcome its isolation to take part effectively in electronic commerce. The Web is the key player in bringing e-commerce which will create true network economy. Selling the products of many firms on the Web is growing exponentially. Doing business on the Internet should be easier, fairer, safer and legal. For most end users, the convenience and benefits of electronic commerce will soon outweigh risks, thus giving rise to an Internet commercial explosion [Lane 1998].

Talking Through the Web: Finding Your Voice Online

Do you remember the movie *Aliens*, and the catch phrase was, "In space, no one can hear you scream"? That same horror is invoked in many instructors when they learn that their institution wants them to teach a class online. The fear may grow deeper when they are writing instructors. What about my voice? What about my students' voices? In cyberspace, no one can hear you scream—or otherwise.

As a writing instructor, this was indeed a huge concern of mine when I was faced with teaching an English composition class online. Even though the concept of voice is one we speak of when we are talking about writing skills, it seemed to me that the concept still needed to be vocalized somehow—through lectures, reading out loud, etc. Furthermore, I was scared that my personality in the classroom would be lost in the online forum; and I had always felt that my in-class presence was one of my strongest teaching skills.

The obvious didn't occur to me, though, until well into my first semester of teaching online.

The fact that students (and instructors) are forced to conduct almost all of their communication in writing inherently lends itself to a productive writing class (whether it be creative writing or research writing). The old adage rings true: you can only learn how to write through the very act of writing. This is also true, I found, with the concept of voice.

Whether or not students had previously talked about (or had been lectured on) this concept, after a few weeks, I was able to discern many of their personalities through only their emails and threaded discussion responses. Most of them already knew the concept of voice. They just didn't know that they knew.

I still had quite a time trying to explain this concept to students when it came to more formal types of writing. In informal communication, their voices were often very evident—their writing through email was usually bold, bright, and full of personality! All of a sudden, though, it was gone when I received one of their formal essays. Gone without a hint.

Had this occurred in the traditional classroom, where the bulk of the writing I received was in the form of the more formal research essays, I may never have seen that many of my students' had voices at all. Within the online forum, though, I had other correspondence to show students and say, "Like this! Your voice comes through here..."

What teaching writing online showed me about the concept of voice is that it is not exactly a teachable skill; in fact, it already exists in every writer. The challenge is in trying to teach students to not turn it off. It can be modified as necessary—for the more formal assignments—but formal writing doesn't have to mean boring, faceless writing.

Over the three semesters of instructing a research writing course online, I saw this interesting phenomenon take place repeatedly. We would come to the unit on Voice—which came pretty late in the semester—and when asked, very few students were able to articulate the concept of voice in writing. However, all along, much of their informal correspondence with me and with other students was full of *voice*. Enough so that I felt I could say I knew them, even though I'd never spoken with many of them on the phone or met them face-to-face. That *is* the concept of voice.

But now that I knew about this wonderful, yet hard to describe, occurrence, the question became: how do I incorporate this knowledge into a more effective writing class, both online and in the traditional classroom?

Web-Distributed Change Evaluation and Management

Teemu.Riipinen@nokia.com

Abstract: Change evaluation and management deal with the analysis, design and implementation of new versions and variants of engineering systems according to requested changes. New systems should satisfy the requirements of cost-effectiveness, time to market, architectural robustness and other applicable criteria. The international project SACHER delivers a methodology and web-based tools for effective change evaluation and management. Web distribution is supported with dedicated tools and the Integration Layer. New web distribution policies are introduced following a specific node type (A, B, and C nodes) and node service classification. In connection with these functions, the project makes extensive use of XML, XSL and meta-modelling technology.

Model-Based Change Management

Change management is a fundamental part of systems engineering. It deals with the analysis, design and implementation of new versions and variants of engineering systems according to requested changes. The SACHER project [SACHER 1998] uses a model-based approach to change management. The methodology includes the following models: a workflow model for managing the change requests, and a process-and-product model of developing and implementing system changes corresponding to the indicated change requests. The workflow model includes a number of roles such as change request analysts, designers implementers, etc. The process-and-product model includes an artefact part specifying all critical products of the target system development and implementation process, and a traceability part that indicates how the changes propagate between the artefacts and related activities. It is assumed that all artefacts and activities may be distributed among change management and system development environments, which may use different methods and tools. SACHER intends to provide appropriate integration of the resulting distributed change process. There are two basic functions of the change process: change evaluation and change management. Change evaluation provides online assessment of the change requests and the planned alternative system changes. Change management uses the assessments to take appropriate informed decisions about change contracts, applicable change process and about the management of the corresponding system development and implementation. A number of change management criteria may be used in the evaluation including change management cost, time to market, risk, architectural assessment [Bass et al. 1998], etc.

Toolset and Integration Layer

SACHER provides the methodology as well as tools supporting the various roles of change management. The SACHER Toolset, built on a requirement traceability platform, supports the change management functionality. The supported interactive user activities include: process and product modelling, metrics modelling, synchronisation of models, change request editing, change engineering, impact analysis and modelling, impact tuning, etc. The Integration Layer (a part of the Toolset) supports the web distribution by introducing a common data representation for the change management and engineering process [SACHER 1999]. The common data representation is based on a common vocabulary introduced by the methodology and supports the defined models. The representation leaves enough freedom for a very broad variety of change management approaches, e.g., the feature-oriented approach. The representation uses XML for data interchange.

The Integration Layer also includes a number of tools to generate and operate on the change management data. The supported functions include export, import, refresh, and translation between different models and presentation of the data. The data should be representation-conformant. While for operation of the full SACHER Toolset a suitable traceability platform is necessary, a simplified but most often satisfactory presentation of the representation-conformant data can be done with much simpler presentation and, where necessary, translation tools. The presentation tools are based on common XML-sensitive browsers. The translation tools use XML metalevel technology to provide adequate translations between representation-conformant data associated with different change management and engineering models. The presentation tools of SACHER use XSL and can define a broad variety of presentation scenarios for various types of change management processes.

Importance of the Web

The ability to share and co-ordinate data generated in different environments associated with an engineering project (including specialised environments for change procurement, implementation, marketing, etc.) is a critical issue of change evaluation and management. The Web is a suitable media for interchange of such data. Another critical issue is the ability to reuse experience and data assets across different instances of the same process or product type.

Node Types, Services, and Web Distribution

Web distributed change evaluation and management is implemented with three types of user nodes. An advanced change management node (A-node) has full access to SACHER Toolset and the respective traceability platform. It supports advanced change evaluation and management processes. Another type of user node, a browser node (B-node) offers a set of simplified change evaluation and management functions based on presentation and translation facilities of the Integration Layer. The name is connected with the fact that B-nodes run appropriately equipped but otherwise regular XML-sensitive browsers. B-nodes use services provided by A-nodes. Still another type of a user node is the C-node, which, through the use of various XML-sensitive tools (e.g., CASE tools) can produce or consume change-related XML data though it does not cover all the change evaluation and management functions of the B-nodes. In particular, they may need to obtain the translation services from A or B nodes.

In SACHER, web distributed change management is implemented by allocating appropriate types of nodes and establishing a policy of exchanging services between the nodes. The policy should reflect the actual needs and technical capabilities of the nodes. The SACHER approach supports an integrated approach allowing for evaluating the entire change management process. Apart from evaluating and managing changes and the changed systems, it is suitable for performing evaluations and managing web distribution policies, for instance from the viewpoint of their architectural robustness.

Conclusions

The SACHER project delivers a methodology and web-based tools for effective change evaluation and management. New web distribution policies are introduced following a specific node type (A, B, and C nodes) and node service classification. In connection with these functions, the project makes extensive use of XML, XSL and meta-modelling technology.

Supporting the Ephemeral

Paul Lambert

Faculty of Education, The University of Sydney, 2006. Australia
p.lambert@edfac.usyd.edu.au

Abstract: This paper introduces the notion of a *Community of Learners* as a teaching and learning model that addresses the education needs of contemporary society. This model can be used to inform the design of online learning environments, and this is illustrated in the HENRE online environment. HENRE, like most online learning environments, has been designed to support learning in institutionally organised groups, however many of the learning needs of contemporary society may be effectively met through more spontaneous learning communities which emerge through an aggregation of people with shared interests and goals. A technology to support such communities could be developed from the existing HENRE learning environment.

Communities of Learners

The notion of a community of learners encapsulates a socially oriented approach to learning, where collaboration, social knowledge construction and discourse contribute to effective learning [Collins, 1996]. Such approaches are believed by many to be more responsive to the needs of contemporary society [Scardamalia & Berietter, 1997; Brown, Ellery, & Campione, 1996; Rogoff, 1994]. Supporting and facilitating communities of learners within virtual environments has been explored in the HENRE project (<http://henre.edfac.usyd.edu.au>) with promising outcomes [Lambert, 1999]. However HENRE, like most online learning initiatives, has been concerned with providing opportunities within established educational institutions and its communities of learners have been formed from virtual class mates.

Changes in contemporary society bring into question whether an institutional model of learning is one which will address many the population's emerging learning needs [Twigg, 1994]. Long duration courses may not be effective in a society where the half-life of information is rapidly falling, where workers are involved in increasingly varied tasks, and where specific knowledge may be required quickly. The World Wide Web provides an information medium to meet some of these needs, however richer learning outcomes might be achieved from socially-oriented learning experiences within communities of learners. In accord with this the notion of Spontaneous Learning Communities is presented as model in which ephemeral learning organisations engage in socially-oriented knowledge-building activities.

Spontaneous Learning Communities

Spontaneous learning communities arise organically from a coming together of people with complimentary interests and needs, and while the internet provides the possibilities for this occurrence, it does not currently provide the means to support, in an integrated manner, a rich community of learners in which,

- learners are mutually involved in activities which have brought them together
- a community of discourse is established
- learners own and use the information and knowledge artefacts of the community
- learners are involved in the authentic activities of the community
- learners are able to participate at personally appropriate levels

For such activities to be facilitated and supported requires an environment where community resources can be collected, organised and made widely available, members can interact but maintain privacy if needed, artefacts can be collectively constructed, shared, and published, the community can establish and project a collective identity, and a pervasive communication system supports discourse between individuals and at a whole group level.

In addition to these characteristic, a spontaneous learning community needs mechanisms which support their casual and potentially ephemeral existence. Without organising institutions, for example, learners need effective mechanisms for finding community members, and joining existing communities or forming new ones. Communities need a technological infrastructure which allows for their automatic establishment and eventual disestablishment. In addition, as many people may be members of more than one community they need the means to manage their involvement and access to these communities.

Building on HENRE

The development of such a technological infrastructure could be based on an existing online social learning environment. For example the HENRE. learning environment, which provides a non-domain specific collaborative environment for learners, could be enhanced with the functionalities listed above to provide an enabling technology for spontaneous learning communities. HENRE, which has been in use since 1995, has been informed by socially-oriented approaches to learning, and research has shown it to be successful in supporting online communities of learners [Lambert, 1999].

However, HENRE has been designed to support learning communities which are peopled from a pre-defined student population. Typically, these communities are class members concurrently studying the same subject, and as a result, HENRE has no functionalities to enable communities to spontaneously form via mechanisms which aggregate people with shared goals or interests. Internet news groups provide an example of spontaneous communities with effective mechanisms to support their existence, however these communities are not provided with rich collaborative environments that facilitate the socially-oriented activities listed above. In response, the HENRE II project in the Faculty of Education at the University of Sydney is currently exploring the design of a technological model for an extended HENRE which can provide the means to examine the potentials of spontaneous learning communities.

How do firms leverage differently a homogeneous physical resource in different industries?

- Using Resource Based View to examine the strategic value of the Web site resource in three industries

Introduction:

Whilst Electronic Commerce has been a hot topic in the press and the consultant literature, the strategic management has not yet examined systematically the strategic value of Web sites. By viewing Web site as a physical resource, this paper intends to respond to the call of Wernerfelt (WERNERFELT 1995) for building Resources Based View (RBV) by advancing our knowledge in 1) mapping the space (or identifying the profile) of specific resources in more detail both in theory and measurement 2) investigating empirically the duality between markets and resources 3) collecting more empirical evidence about how firms leverage differently the homogeneous resource¹. Aiming to examine Web sites under the light of RBV, we begin this task by asking following two research questions:

If we see Web site as a physical resource to firms, then

1. How differently are firms among various industries exploiting Web sites, an initially homogenous (physical) resource?
2. Do market conditions mediate the strategic value of Web sites? If market conditions do play a mediating role on the value of Web resources, what are the contingencies between market conditions and firm's exploitation of Web resources?

To answer the first questions we use a list of 50 distribution channel functions summarized from previous Channel Distribution, Consumer Behavior and Electronic Commerce literatures to examine the functions of Web sites. To answer the second question, we examine 60 web sites in three industries: travel agent, book sale and the automobile industry to test our hypothesis. These three industries are selected according to Phelan's Internet selling matrix (PHELAN 1996). Our proposition is that the less perceived risk and channel costs of products in a industry, the more functions Web sites in that industry will have. The testable hypothesis is that numbers of functions of Web sites in travel industry, book industry and automobile industry will be descending order.

Results:

Our results partially validate Phelan's internet selling matrix that two market conditions: channel cost and perceived risk do influence the number of the Web site functions but we

¹ We consider Web sites as homogeneous (physical) resources to firms, in the sense of their technical similarity.

find discrepancy in the Automobile industry. Our explanation, based on the empirical evidence in this paper, is that the Automobile industry use Web sites also as 'Relation Development' device (contrast previous suggestions of 'cost saving' and 'revenue generating').

The Academic Implications

- (1) Together, the functional list, the industry-wide functions and the unique-industry-wide function can be a tool for mapping Web sites as strategic resources in two levels: within-industry and inter-industries.
- (2) The unique-industry-wide functions can be used as the first step for further identifying potential mediating market conditions. As in the case of the automobile industry, the 5 Unique-Industry-Wide Functions related to 'relationship development functions' leads us to hypothesize that the 'value' dimension might mediate the number of functions of Web sites in the automobile industry.

The Managerial Implications

- 1) This research also has following managerial implications. We propose our functional list can be a cookbook guide for managers in dealing with two issues: 'Web channel design' (i.e., what functions they can put in the Web site) and 'dis/reintermediation' (i.e., what functions be carried out by traditional intermediaries like car dealers) issues.
- 2) The list of Industry-wide functions can be also a strategic necessity guide for managers in thinking about competitive issues. For example, since these functions represent theoretically functions which can be the most efficiently carried out by Web sites in different industries. For Web-based firms competing on a 'cost strategy', these industry-wide functions represents a basic functions they can/or must adopt into their sites to be as efficient as their competitors. On the other hand, for Web-based firms adopting a 'value strategy', they probably need to focus either to do better in these functions or do other functions (to differentiate from these industry-wide functions) to be competitive.

Abstract: Using the Web to enhance or as the sole medium for teaching has produced a new range of problems and opportunities. Tools that facilitate such teaching are appearing and enhancing the delivery and activities of these courses. Studies have been made on how readers (usually students) use such material and tools. Systems have been developed that analyze the student profile, adapting both the pages and the navigation. This paper explores the other side of these issues: the perspective from the author (usually an instructor). ReCourse, the Retargetable Course Generation system, has had the instructor as a focus from inception.

Keywords: authoring, adaptive hypertext, dynamic hypertext, web-based course management systems, distance education

1. Introduction

WebReCourse [5], the Retargetable Course Generator enables creation and reuse of Web courses. It is a secure software system for online course management, allowing instructors to increase the accessibility of online course material and to create a convenient means of communication between instructors and students. It provides many of the enhancements missing in the World Wide Web implementation of hypertext.

ReCourse allows an author to write a single document which can dynamically choose its content when a reader selects a particular topic.

We call this *Retargeting*, because the information is retargeted to different readers and different audiences. Such retargeting is a staple among course instructors who teach similar courses to different audiences, or teach the same course multiple times under different circumstances.

Previous papers [6,7] have analyzed student use and response to these tools.

Despite what appears to be an overwhelmingly positive response by students, tools such as ReCourse have not become commonplace in the web-enhanced classroom. In our experience, instructors either shy away from even trying it, use such tools once and not again (thus, for us, defeating the whole Retargeting philosophy!) or use such tools in such a minimal way as to have little impact on the students.

For us, this was particularly frustrating because of all the similar systems, ReCourse was designed to enhance instructor use. The student tools are fairly standard.

Since we knew these tools are viewed positively by students [6,7], we decided to find out why instructors are not as enthusiastic, and to discover what we can do to encourage them to use web tools to enhance their classes. In particular, we wanted to discover what changes need to be made for effective use. We generalize this to the problem of authoring and using integrated tools for World Wide Web courses.

2. Instructor Assessments

Because we had discovered how useful the tools were for us as instructors, we only waited until we felt the tools were robust enough before making them available to other instructors. A ReCourse "team" consisting of both undergraduates and graduate students prepared to monitor their use. We began with a few carefully selected instructors within the Computer Science Department.

Ultimately, this became two instructors, one teaching an undergraduate course and one teaching a graduate course.

The instructor teaching the graduate course found that entering the class members by hand was quite tedious - he

had no TA. Group observation showed that he did use the Grading Sheet, but that there were no postings other than our own on the bulletin board, and no indication that the chat room was ever used. The instructor teaching the undergraduate course had a TA, so only the TA complained about entering the students by hand. Nevertheless, we realized that this must be changed and we changed the ReCourse User function to allow students to enter themselves.

The following term we went outside the computer science department and "invited" a few instructors who, we felt, had positive attitudes towards teaching to try ReCourse. One was reasonably computer literate (he had created his own web pages) while the other found computers generally frustrating and had had her pages created by a school web master who does this as a service to faculty members. We also assigned one member of the ReCourse team to work with each instructor.

Because we had not prepared the same level of questionnaire for instructors as for students, we relied on their feedback both to me and to the ReCourse team member. We are currently testing a new group and changing our questionnaire as well.

We have some clear results, however. We characterize them below:

1. *Faculty Status (!)* When the ReCourse team (students) sent an email invitation to faculty, inviting them to try out and then use the system, there was virtually zero response. When the author (faculty) sent the same message, many people responded.
2. *Faculty Chaos & Inertia* Of those faculty who did respond and declined to use the system, no one had time to even look at it. All mentioned wanting to use it "in the future." All appeared overworked - one mentioned being overwhelmed that term.
3. *Missing functionality* One faculty used it for one term and did not choose to use it again. She wanted a feature not yet available (the grading system does not operate with full spreadsheet features yet).
4. *No instructor help* One factor is that some instructors do not have teaching assistants to help them.

3. Author Characteristics

Although we continue to gather information and statistics, we know the following:

1. The more computer literate an instructor/author is, the more apt they are to use the system, and the more apt they are to use more of the available tools.
2. The more helpful the assigned ReCourse team member is, the more apt the author/instructor is to use the tool in its entirety.
3. Newer faculty are much more apt to respond to the invitation, to use more of the tools, and to return to use it again. This is due to more experienced instructors having (existing, but not as appropriate) tools they are used to using and the general chaos that surrounds faculty members as they find themselves with more service activities. The ReCourse team believes as they hear that the tool is an asset, they will make the (small) effort to use it.

4. Conclusions

ReCourse is documentably popular and useful for web courses. Students like it. But students have grown up in a computer world and, now, even in a web world. Instructor/authors have more inertia. We are continuing to gather statistics from both the users and non-users in an attempt to encourage use of a system which improves the delivery of web courses. It is likely that a new type of education is needed to create the appropriate mindset for using tools for web-enhanced courses.

3D-, Digital Environments for Social Contact in Distance Work

Sören Lenman
Centre for User-Oriented IT-Design (CID)
Royal Institute of Technology
100 44, Stockholm, Sweden
lenman@nada.kth.se

Abstract: Shared 3D environments are investigated as a means of providing information for supporting awareness and the feeling of co-presence in distance work. The aim of this work-in-progress is to develop work environments for distance work that satisfy both social and ergonomic demands in order to reduce social isolation and stress and increase work efficiency when working at a distance.

Introduction

In traditional workplaces there is continual, mutual awareness of co-workers' activities as well as rich opportunities for informal communication and spontaneous meetings. This contributes both to productivity and to well being because of better coordination of work activities and support of social processes in the workplace. In distance work, however, these dimensions are largely missing, which contributes to social isolation, increased stress and reduced efficiency. The aim of the current project, which is in its initial stage, is to develop work environments for distance work that satisfy both social and ergonomic demands.

Providing Information for Awareness and Co-presence

A basic problem is to identify information that supports awareness [Dourish & Belotti 1992] and co-presence: the feeling of mutual, social presence, of simultaneously being in the same place, and to provide that information so that it does not intrude on foreground tasks, but serves as a background and a context. It must be sufficiently rich, but at the same time not violate privacy. A straightforward approach is to provide open video- and/or sound channels between participants. However, there are a number of disadvantages for continual use, such as high bandwidth requirements and violation of privacy. An opposite approach is to provide symbolic information, e.g., ambientROOM [Ishii et al. 1998]. However, the mapping of information is arbitrary and representations could become too artificial. Both approaches also lack the important notion of a common place. A third possibility, then, that has only recently begun to be investigated for this purpose, e.g., [Broll et. al 1999], is to use a shared 3D-, digital environment (DE) for supporting awareness and co-presence.

3D-, Shared Digital Environments

3D-, shared DEs, which are currently available over the Internet, can provide rich information without the surveillance aspect of desktop video. Rendered, but possibly realistic, avatar representations of participants provide a straightforward mechanism for action filtering, representing only relevant information. Because all participants are represented in the same environment a natural shared space for co-presence as well as for exchanging task-related information is provided. However, unlike most approaches to shared DEs, here the DE is not intended to provide the primary means for task-oriented, focused communication and collaboration, but to be a complement to other means.

Early User Studies

The Active Worlds technology [Active Worlds, 1999] was used for the initial mock-ups. A first informal study took place as part of a course requirement, where students' were building a shared DE for a virtual exhibition and meeting place. A group of three students were working together at a distant location and the tutors' task was to

give advice, when requested, by means of the built-in text chat, or by telephone. Initially the tutor, using a 17" screen, experienced problems with screen estate and found the DE intrusive. A portable computer with a 12" screen was then added, placed on the side and used for presenting the DE (fig.1). Students who needed help could simply "walk up" to the tutors' avatar in the DE, filling the tutors' screen with their own avatar.

Figure 1: In the picture to the left a prototype workplace setup is shown. The picture to the right shows one participants' view of an interior of a DE with two other participants, represented by personal Avatars.

This type of setup was found to provide a natural, efficient and non-disruptive way of keeping in touch and initiating communication. An informal evaluation showed that the DE induced a strong feeling of co-presence, but that awareness of actual activities at the distant site was lacking, due to limitations of the technology. The same observation was made in another study, where five informal text-chat meetings between three to four participants, and lasting between 15 and 30 minutes, were held in a DE. A short questionnaire was issued to the participants. They all agreed that the feeling of co-presence in the DE was high, but that there was a lack of information in the DE about real-world events.

Future Work

The concept obviously requires an efficient coupling from events in the real world to the DE. Video image analysis and sensors are being investigated for this purpose. A related question concerns avatar design: how should users be represented and what do avatars need to express? A flexible, ergonomic workplace along the lines of the simple prototype shown in fig. 1 is being developed in collaboration with the TCO, using multiple flat-panel displays. Large-scale projections will also be investigated. Long-term user testing with at least three functional prototypes will be performed.

Introduction

The WWW is fast growing as the new medium in academic institutions for organising and delivering subject material to students. This paper focuses on the lack of structure and foresight in preparing and supporting academics in this new teaching environment.

Perceived benefits

The justifications for utilising, where feasible, this new technological learning support (or teaching-aid, depending on perspective) are many. There are of course disadvantages, however due to the continuing enthusiasm in higher education for computer assisted learning/teaching we must assume that the positive aspects of this medium eminently outweigh the negative ones. Staff in institutions of higher learning are therefore being encouraged, and often expected, to give their full support to the development of such methods. While most agree that there are obvious benefits, in practice the reality needs further scrutiny.

The reality

Although during the last decade many initiatives have been launched [2] & [3], the situation in several HE institutions, is to petition *academics* to convert their existing course material into computer supported learning (CSL) sites. Many, of course, feel inadequate in this new environment through lack of relevant training.

Purely from a design point of view can we reasonably expect academics to be skilled sufficiently in developing Web based course material to an acceptable standard? Do we have a standard? More importantly is how effective the site is as a teaching/learning tool. The expertise of our teaching staff is normally in a subject area befitting the school in which they teach. Few have teaching qualifications, (and have therefore not necessarily studied learning styles, etc.), and even fewer have degrees in any form of computer mediated teaching/learning. It appears that some on-line courses, not surprisingly, do not address the phases of the learning process correctly. Although this medium is touted as being highly interactive, the lack of expertise on the part of the developer often hinders interaction and learning.

The required pace of the change, coupled with the lack of skills and training, is understandably dampening staff's enthusiasm for this transition. The task is proving to be stressful for many staff members according to a national survey [7], and without their very positive efforts in this direction the processes and pace of change will be hindered. If everyone is thrown in at the deep end, some will swim, but some will sink. We may well lose some of our most experienced and competent teaching staff without good cause. "Since over 70% of HE Institution expenditure is on staff, there is an axiomatic need to make optimal use of our human resources...., academic staff need to be qualified not just in their knowledge domain but also in the skills of teaching". [2]

Consideration for our students

Apart from questioning the skills of our teaching staff, do we as developers need to consider whether these

new courses are being properly tested and evaluated before going on-line? If these questions are not being asked, and answered positively, then the quality of our courses must be in question. Are we using our students as guinea pigs while we "try to get it right?" This is a difficult period of transition however, it is an important area for consideration and should currently be under major scrutiny. My intention is to look into the current practices of other Universities, to assess whether students and teachers feel that the quality of courses are being compromised by the haste for change. Whether all are in favour of change is another issue.

Important practice issues

Firstly, if we are to use academic staff to facilitate the change then we must encourage suitable and willing candidates as developers. At the same time we need to ensure that early adopters are not inadvertently exploited. The staff concerned should be seconded from their normal duties in order to allow them the necessary time to become competent in the use of this new medium. For the efficient development of quality computer supported material, it is essential to identify the specific training requirements. Training should also be undertaken when it is likely to be most effective, i.e. when they are able to continue work on a project. We undoubtedly need the provision of competent and responsive technical staff to support implementation (5). Lastly, but of major importance, is the need to identify evaluation criteria that can provide us with reliable evidence of the effectiveness of these new developments.

The options

An alternative to that of using existing teaching staff alone, is to employ consultant educationalists (experienced in electronic delivery of course material) to work alongside academics in house. Another alternative may be to use external developers such as "Blackboard" [3] & [4].

Some have criticised the use of external sources, and tools such as Lotus Learning Space because of the rigidity in the delivery template. Staff are not convinced that the course material they have developed will not be compromised by the tools and the medium itself.

Conclusion

Attitudes towards current practice need to change swiftly if we are to avoid an erosion of standards in courseware during this period of transition. Students will demand quality, they will be paying. We must be confident that we are able to deliver what is expected. Staff and students alike must feel empowered in this new environment if we are to reap the benefits that on-line education has to offer.

Web Radio Sites: An (Overlooked) Opportunity for Broadcasters

Norman J. Medoff, Northern Arizona University
&
Rebecca Ann Lind, University of Illinois at Chicago

New technology available from the information superhighway has brought forth the possibility that the radio industry is facing a potential revolution. Technological advances have made Web radio an exciting new development in the industry. What is it now? What can it become?

The present research is designed to provide information regarding the extent of Web radio broadcasting in the U.S., briefly describe the range of content and types of graphic devices currently used by Web radio broadcasters as well as the types of changes Web broadcasters anticipate making, discuss the advantages and opportunities presented when employing this new technology, and warn broadcasters of the lessons learned by those already on the Web.

This research, then, is focused upon the Web radio broadcaster and is guided by the following research questions:

- RQ 1. To what extent is Web radio used by radio broadcasters?
- RQ 2. What is the range of content offered on radio stations' websites?
- RQ 3. What changes in the content of Websites do radio broadcasters plan to implement?
- RQ 4. What benefits have broadcasters realized as a result of having a Website?
- RQ 5. What problems have radio broadcasters encountered with their Websites?

The present research relied on interview and survey data, and content analysis of websites. The research was conducted in three phases: (1) Station Interviews: In-depth interviews with 19 Web radio broadcasters in Chicago, Los Angeles, Minneapolis, and Phoenix; (2) Station Survey: 419 stations completed a questionnaire about their Web radio experiences; and (3) Radio Station Web Site Coding: We conducted a content analysis of 791 radio station websites.

A general conclusion of this study is that broadcasters are underutilizing the Web and their Web sites. Since studies are beginning to show that people who are using the Internet more are using traditional media less (Arbitron, 1999), broadcasters should seriously look to the Web to capture audience attention – and once captured, to hold it by providing sufficient relevant and interesting material. To do this will require goals, a vision, and a commitment of resources.

The World Wide Web and Teacher Education

Edmundo F. Litton

Loyola Marymount University, School of Education

7900 Loyola Boulevard, Los Angeles, California 90045-8425 USA

elitton@lmumail.lmu.edu

Computers are increasingly being used in educational settings. Are new teachers being adequately prepared to use technology to enhance learning? A review of the literature shows that technology is used more and more in teacher preparation classes. However, there are obstacles that still prevent teacher educators from harnessing the power of educational technology. The author presents lessons that illustrates how technology can be integrated in a course on cultural diversity in education. The lessons allow students to experience a new way of teaching and learning that encourages them to construct their understanding of the world.

Teachers are constantly striving to become more technologically literate. Pepi and Scheurman (1996) state that computer technology has a mystical power to “loosen the grip of tight-fisted board members, help principals to find time to work with teachers, get grant money flowing, bring colleagues to presentations, and imbue college administrators with enthusiasm for projects.” (p. 229). However, despite all the advances in technology and its power, many teachers are still not using computers in their classroom. Those educators that use computers, do very little to alter the traditional teacher centered classroom.

The purpose of this paper is to explore how the World Wide Web is used in teacher education programs. What obstacles prevent teacher educators from using technology in the preparation of teachers? A review of the literature will show that technology is being used in teacher education. However, it is also clear that in order for new teachers to begin using technology to enhance learning in their own classrooms, they must experience a different way of teaching that allows them to “construct their own knowledge, acquire new models of teaching, and analyze the teaching and learning process” (Hatfield, 1996, p. 223). This paper will contain a number of lessons that illustrate how the World Wide Web is used in a course on cultural diversity in education.

Examples of Using the World Wide Web for Integrating Technology in Teacher Education

“Sociocultural Analysis of Education” or EDUCATION 500 is a required course in the teaching credential program at Loyola Marymount University. For many of the students, EDUCATION 500 is their first course in their education program. The main purpose of the technology assignments is to explore cultural diversity through the use of technology. Specifically, students will gather information on the World Wide Web and they will use software, such as PowerPoint and ClarisWorks, to present information to the class. The class projects will be used as a starting point for the discussions on the different topics used to explore diversity in educational settings.

Lesson # 1: Exploring Issues of Gender and Lifestyle

This technology activity will be used in the lesson on gender and lifestyle issues. At this point in the course, the students have already learned that culture is more than just ethnicity. At the end of this lesson, the students will know how to use a drawing software. Furthermore, they will learn that gender discrimination is prevalent in schools and sexism and homophobia are harmful to everyone.

Procedure: 1. Provide a brief overview to the class and explain that the microculture that will be discussed today will be gender and lifestyles. 2. Provide a quick demonstration of the drawing program in ClarisWorks. Tell the students that they will be asked to create their own picture using ClarisWorks. Highlight the use of clip art and also show the students how they can cut and paste pictures from the internet. 3. Divide the class into 8 groups. 4. Give the groups the following assignment: Draw a picture showing the characteristics that society has on one of the following groups of people: straight men, straight women, gay men, lesbians. Encourage the students to draw their characters in a setting (such as a workplace, a social gathering, etc.) 5. When the group has finished drawing the pictures, each group will be asked to present their pictures using the projector attached to a computer. The students will be asked to explain the stereotypes that may surface. 6. Connect the lesson with the reading assignments. Discuss how boys and girls are stereotypes in schools and how teachers treat boys differently from girls. Discuss how homosexuals are typecast in society. How does locking people into gender specific roles hurt all people? Discuss the research that shows how girls are harmed because of the differential treatment they receive in math and science classes.

Lesson # 2: Constructivism through Technology

This technology activity will be used to learn about Sociocultural theory. The main point of the theory is learning is done through social interaction and not transmission. The lesson also demonstrates why it is important for teachers to see their students' prior knowledge as a resource rather than as a liability. This is an important concept to learn especially when teaching students of culturally diverse backgrounds. Through this lesson, the students will experience the theory in a real lesson. The students will also learn how to use PowerPoint.

Procedure: 1. Provide a brief overview of the lesson. Ask the students to remember that they have just learned the different aspects of culture and we have been stressing that culture affect they way students learn. 2. Divide the class into 6 groups. Ask the students who are experts in PowerPoint to raise their hands. These students should be in separate groups. 3. Provide a brief overview of PowerPoint. Using a pre-formatted disk, demonstrate some of the features of PowerPoint. Highlight how to create new slides, change colors, and animation. Tell the students they each group will make a presentation using PowerPoint and all groups will be required to use animation in their presentations. 4. Tell the students that they will be creating a presentation on an aspect of Sociocultural Theory. The six terms that the class will explore are: Lev Vygotsky, Sociocultural Theory, Schema Theory, Cooperative Learning, Zone of Proximal Development, and Constructivism. Each of these terms will be given to a group in a disk. They will need to perform a search on the web on the term that is given to their groups. 5. Give the students ample time to complete their presentations. Stress to the class that they need to work cooperatively in groups and as a class. If one group finds information that they feel another group should be given, then they should pass on that information. Remind the class that there are PowerPoint experts in the groups and they should rely on these experts to help make the presentations attractive. 6. After the students have created their presentations, ask the groups to present their slide shows. The professor should help the students make the connections between each term in between presentations.

7. At the end of the lesson, the teacher will ask the students to talk about the practical applications of Sociocultural theory to teaching.

Abstract

The present paper presents the Learn&Web Project that has the objective of being an integrated environment for the cooperative learning in Internet; a place for the intimacy and the exchange of experiences, where the knowledge can be shared among the peers. The major compromise of Learn&Web is the creation of an on line community, active, reflexive and ready to collaborate within an innovative way so that it becomes an useful, qualitative and adequate educational environment to the Brazilian reality and on a continuous improvement.

Introduction

The Internet with all its technologies on information, communication and cooperation provides great opportunities for the Education. The navigation through the Internet can promote the incidental learning which is quite advisable and useful but it is necessary and feasible to provide an organized environment where the learning process is not submitted to the contingencies of the fortuity. However, how to learn within an organized way not only the curriculum and extracurricular contents but also to develop cognitive meta-skills such as decision making, formulation of hypotheses, analysis, synthesis and evaluation? How to learn to interact, to communicate and to cooperate on distance? How to learn to participate as a contemporaneous citizen of a virtual community in the new Information Society? Some of such questions have already answers. During year 1998, it was developed an experimental and testing site, based on DCL - Distance Cooperative Learning [1] that inspired the actual Learn@Web Project.

Summary Environment Description

Learn&Web is an integrated and opened environment for the cooperative learning and a space for the companionship and exchange of experiences where the knowledges can be shared among the peers in the social-historical-cultural Brazilian content. This environment is a place for the collective and cooperative work based in Vigotsky's social-historical-cultural theory [1], and has some goals: a) to apply the information, communication and cooperative technologies available in the Internet to the process of teaching and learning within a consistent and innovative way for both pedagogical and technological aspects, b) to develop courses on distance supported by the Internet, applying new methodologies of learning that meet different users, c) to create a Brazilian multicultural community whose interest is driven to the segment of the Internet in the Education, d) to create the culture of the collective and cooperative of the learning construction among the environment participants and e) to evaluate the results obtained during this process of teaching and learning. The environment follows a line of action, which concentrates its development in new paradigms addressed to the improvement of the Brazilian educational system. It also provides updating and improvement of first and second grades teachers of the public and private schools network that offers a renovation of curricular contents and pedagogical procedures such as courses of Education on distance and the use of the Internet resources and setting and diffusion of the tech-educational materials for the dichotic planning that support the docent practices linked to cooperative projects.

Conclusions

Learn&Web is presently in the phase of setting up its visual identity and is being as far as possible developed based on the Places Theory [2]. This theory is based in a special metaphor to situate actions and interactions occurred inside an integrated work context. Therefore, each space is constituted by a virtual space parameter that will provide

the interaction places. The navigation in the environment is being modeled as a hypertext, however close to the linear with the objective of guaranteeing the participant' self-orientation and to avoid the cognitive overload that normally occurs in sites organized in knob networks. It is expected that Learn&Web opens a differential and innovative space in the Brazilian Educational System to provide a paradigm change as regards the attitude in relation to what is to learn and teach in Internet, to permit the development of a critical and reflexive conscience of the virtual community that will be being formed with the participation of children, young persons and adults, including teachers and to prepare participate citizens subject and transformers to act in the Information Society.

Implementing an Automated Real-Time Test of Computers Connected to Both an Intranet and the Internet with PUSH Technology

Brian G Mackie
Saint Ambrose University
USA
Bmackie@sau.edu

Gary Parker
John Deere Corporation
USA
ParkerGaryL@JDCORP.deere.com

Abstract

We have been studying Network Design for the last three years. We have developed an interesting algorithm to development a simulation model of a network. To test the model we developed a real-time test for any network that would allow the algorithm to be implemented and the effects on the network to be evaluated. Thus the simulation model could be compared to the real network. We found that the real-time test not only was able to show that the simulation model worked but it took on a life of it's own. It was able to show problems that the simulation model could not show. Problems caused by the type of hard drive used. Problems caused by the interaction of different applications acting across the Intranet and/or the Internet. The software used to control each workstation was Automate. Automate was invoked by the Automate Enterprise server. Unisyn Corporation developed both products.

Real-Time Testing

The purpose of this testing was to improve the arduous task of real-time testing by the use of new tools and refined methodologies. This testing was a second phase of a previous project, which used real-time testing to validate a network-simulation model. Robert Buchanan, author of *The Art of Testing Network Systems*, offers ten primary test objectives for a network system, and each with a specific methodology and approach [Buchanam 99]. These testing objectives are *application response time testing*, *application feature/function testing*, *regression testing*, *throughput testing*, *acceptance*, *configuration sizing*, *reliability*, *product evaluation*, *capacity planning*, *bottleneck identification* and *problem isolation*. To learn more about how others are using real-time testing, please see the references. In this paper, we emphasize application response time testing which is probably the most prevalent type of testing. Application response time testing is the measure of how long it takes an application to complete a series of tasks, and best represents network performance from a user's perspective. Tests are run at various loads, with a number of real or emulated users [Buchanam 99].

Real-time tests were performed at three different locations. Two of the testing sites consisted of thirty-two workstations and one server. The third facility contained twenty-four workstations and one server.

Testing was performed using scripts that when invoked would automatically run applications including Internet Explorer, an FTP client, Word and Excel. The frequency of application requests was set to a given level but using the scripts the applications were invoked randomly. Also the size of files requested was set to a given range depending on the application selected, but the actual size was selected randomly.

The product that was used to setup the scenarios implemented by each workstation was Automate. Automate is developed by Unisyn Corporation. The product includes a scripting language that is very similar to visual basic. In fact, in the scripting language you can invoke visual basic programs. Automate now allows the script to be pushed to the workstation and invoked, thereby eliminating the need to work at each machine. The only requirement is to install the Automate client on each machine.

The tests executed at the first two locations were used to verify that a general network-simulation model was in fact valid. The tests run at the third location were used specifically to address two issues, first, of which was the growth and increased dependence on the Internet and its impact on network performance. Second, was to better prepare the organization for an enterprise migration from Windows 95 and NT Workstation 4.0 to Windows 2000. As part of that preparation this test was hoped to show if in fact the machines running WIN 95 should be upgraded to WIN 4.0 at this time.

The machines were configured very similarly at all three locations. The biggest difference was the number of workstations evaluated. In the first two locations there were thirty-two workstations whereas at the third location there were only twenty-four workstations. The description of the environment at the third location helps one understand how a test was setup.

Environment setup and Preparation for Testing at John Deere

For this real-time test, twenty-four workstations were used to allow twenty to be available for any given test scenario. The test bed environment was a 10MB 10BASET switched Ethernet subnet. The server and all workstations had processors that were at least 200MHz. The server and workstations all had a minimum of 128 MB of RAM and all were running the TCP/IP protocol. The server was running Windows NT 4.0 and included, IIS (web server), and Perfmon, which was used for performance monitoring. Twelve workstations in the test bed were running Windows 95 and twelve were running Windows NT 4.0 Workstation. Other than the difference in operating systems, each set of twelve workstations had a common software load.

In preparation for testing, a fresh "control" software load was installed onto each set of homogeneous workstations to minimize some of the problems which were encountered during previous testing. Both software loads included the Microsoft Office 97 suite, and Netscape browser (version 4.04). All applications, which are used in these tests, were the same across all of the workstations in the test bed. In addition to the core loads, WinFTP was installed on (copied to) each workstation, as well as the AutoMate client from Unisyn Corporation, which was installed on each workstation for automation scripting. Automation scripts were written for AutoMate in "Saxan Basic" and were edited for each of the different test variations. To aid in the timing of the test all workstations were time synced to the test server

Difficulties encountered

At each location, when the machines were being prepared to run the tests and/or the machines were running the tests, many interesting issues were brought to the surface. A few of these issues were:

- A Server configured with an EIDE hard drive would only support up to fifteen workstations whereas a server configured with a SCSI hard drive would handle thirty-two workstations.
- Windows 95 was more likely to lockup during the testing phase.
- Excel had major problems if two machines tried to access the same document
- Many machines were missing applications
- Hardware frequently was found to be faulty

At the end of testing at each location it was found that the machines were in better working order. Fewer employees complained of problems with the machines after the tests than before the tests.

In summary real-time testing helps show how your network will react under different loads and/or when modifications are made.

We would like to do real-time testing on larger and more diverse networks. The product we are using to run the workstations, Automate Enterprise, has a new version out and many new features that would be useful in running real-time tests. Therefore on the next tests we run we will implement the new version of Automate Enterprise.

Nurses' Use of Online Communication Tools: Critical Indicators of Use

Margaret Ann MacQuarrie, RN, MN
Distance Nursing Programs
Extension Department
St. Francis Xavier University
Canada
mmacquar@stfx.ca

Abstract Although many factors influence students' use of online tools, nurses face additional deterrents to active participation in online courses. Some factors include the traditional reliance on communicating through clients' charts and careplans, as well as face-to-face dialogue or telephones as primary communication vehicles. Trends have emerged, based on post-RN nursing students' reluctance to use online communication options such as posting narrative comments in threaded discussions or having critical exchanges in real-time forums.

The StFX Post-RN BScN Program

St. Francis Xavier University has offered a part-time baccalaureate nursing degree to registered nurses since 1988, enabling more than 600 nurses to complete degrees while living and working in their own communities. Based on a distance education model that combines local resource centres, audiovisual and supplementary resources, local mentors, and regular toll-free telephone access to course professors, this program ensures that students are supported throughout their educational career and are able to communicate with other students in their local area.

Although the traditional delivery format is print-based, StFX offers a number of core and elective courses for nurses in an online or CD-ROM format. Students may select the delivery format that best meets their needs. Online courses feature synchronous and asynchronous discussion forums, while CD-ROM formats include a link to the web also offering comparable forums. Both digital formats offer rich, non-linear learning environments and intuitive interface design.

St. FX Post-RN Students

Student profiles in the St. Francis Xavier University Post-RN BScN Program reveal a majority of women (97%), who are married (88%), and have dependent children (60%). The majority of students range in age from 25 to 44 (88%). Most students are employed in acute care institutions, with work schedules comprised of a series of 12-hour shifts on a rotational basis. Most students have a minimum of 8-10 years experience in professional nursing practice, and have commenced the Post-RN BScN Program to develop their practice and progress professionally.

Among students enrolled in the Post-RN BScN Program, less than 50% have experience using computers, either in their work or at home. Of those students with experience, only a small percentage would describe themselves as "intermediate" or "high" in terms of computer competency.

The Online Course

Students are accustomed to discussing course topics in local face to face groups, which is comparable to the types of communication occurring in the workplace. They are, however, much more reluctant to communicate using online tools. This trend has been observed since online courses have been available through the BScN Program, and while exceptions occur, silent observation or "lurking" has been prevalent in the past.

Upon interview, students report a number of barriers commonly identified in the literature, which include a lack of computer skills, fear of writing a comment in a public place that has the potential for criticism, and a perceived lack of importance related to overall course evaluation (see Moore & Kearsley, 1996; Haughey & Anderson, 1998; Harasim, Hiltz, Teles, & Turoff, 1997).

In addition, post-RN students cited the following factors as barriers to engaging fully in online communication: 1) limited writing skills, associated with mainly documenting specific points of clinical data rather than narrative or scholarly writing, 2) difficulty accessing threaded discussions due to employment schedules and twelve-hour shifts, 3) lack of access to home computers, related to competing demands for computer access in the family, and 4) small class sizes in online courses intimidated students, resulting in the feeling of close scrutiny and the obligation of having to respond to every comment. In addition, it was observed that the course professor's ability to coordinate interaction and weave previous comments together to stimulate further discourse were critical.

Several strategies have been developed to nurture student participation and develop competency and confidence. The primary strategies that are being implemented include assigning a value to online participation, identifying basic expectations regarding the frequency and quality of participation, coordinating a guest online moderator to facilitate discussion of a specific aspect of course content, creating collaborative assignment which necessitate the online interaction among students, the use of online case studies, establishing the online communication environment as a constructive and supportive place to offers critical opinions, theories, and compare perceptions, and supporting the development of writing skills in students through additional resources and assistive personnel (see Moore & Kearsley, 1996; Harasim, Hiltz, Teles, & Turoff, 1997; Haughey & Anderson, 1998).

Faculty development was identified as a significant issue, resulting in the development of a document guiding initial faculty activities in moderating online courses. Additionally, assistive personnel will be available for technical and course delivery guidance.

These strategies will be implemented Fall 1999 and will be evaluated in early Spring 2000 through the use of focus groups and individuals interviews.

The myths and realities of using IT in education: A Hong Kong case report

Dr. Stephen Mak
Department of Building and Real Estate
Hong Kong Polytechnic University
Hung Hom, Kowloon, Hong Kong
E-mail: bssmak@polyu.edu.hk

Abstract: To maintain its competitive edge, the Hong Kong SAR government has decided to invest heavily on information technology in education. This paper will briefly describe the networking environment in Hong Kong. It will also look at what is being done and what has been neglected.

1. Introduction

Education and information technology has become top priorities in Hong Kong political agenda. Special funds have been set aside for development and deployment of information technology (IT) and IT in education. In 1997, 10 primary and 10 secondary schools were selected and given a huge sum of money for them to set up showcase for using IT so that others can follow. From 1999, each of the 1100 plus school was given a sum of money to set up IT infrastructure, network classrooms and connection to the Internet. It is argued that while the IT infrastructure is essential, it is more important to note that contents, software, IT management and people's mind-sets are indispensable for IT in education to be successfully carried out.

2. IT in education: Myths and Realities

The proliferation of the Internet and the WWW provides new channels and modes of delivery of information, the quality of which, however, varies. The unprecedented speed of information processing poses us with these opportunities: (i) IT itself is a motivator. (ii) IT changes the mode human interacts and increases the intensity of interactions. (iii) IT allows connectivity anywhere and anytime; the boundary of time and space becomes blur. (iv) Information accumulation and spoon-feeding is over and so is the "storage" function of students. (v) Teachers' roles are to guide students in information processing, and help them develop knowledge and wisdom.

3. What the government is doing

3.1 Pilot Schools

In 1997, 10 primary and 10 secondary schools were selected and given a huge sum of money for them to set up show cases for using IT so that others to follow. They have finished spending their money in equipping their schools with leading edge hardware and software.

3.2 Quality Education Fund

The Quality Education Fund (QEF) was set up in 1997 to finance projects for the promotion of quality education in Hong Kong, as a result of the Education Commission Report No.7. HK\$5 billion was allocated to provide an effective channel for worthwhile projects from the school education sector to be funded of the following types:

3.3 Teacher Training

Training the 43,000 working force of teachers is a major task the government is to achieve in the next 3 years. Four levels of achievement have been established each having specific targets.

4. What have been neglected

4.1 Establishing an IT Culture

There is a need to demystify the perception that IT means high-tech. It is true that IT uses high-tech; however, using IT does not necessarily involve high-tech. It is important to distinguish between using IT as a tool and IT itself (while IT uses high-tech, using IT does not constitute using high-tech). We are talking about learning *using*, **not about**, computers. IT-culture necessitates people's ability and willingness to extend beyond their physical capacities to acquire information and cope with the vast community beyond space and membership.

4.2 Initiating a re-engineering process

A lot of attention and resources have been put in the network connection and hardware set up. However, there was no re-engineering process to raise the quality of teaching and learning.

4.3 Specific training and support for teachers

We need to help teachers overcome the doubts that IT may replace them and spend time to discuss issues such as (i) How can teachers make good use of IT in teaching? (ii) How to make use of the face-to-face interactions, or are they required any more? (iii) How can we ensure individualised learning? (iv) Internet access is of prime importance but when and how can this be achieved in ALL schools and at home?

4.4 Support for learners/students/parents

Students are still primarily examination oriented. At Grades 5 and 6 students spend most of their time doing repetitive drilling exercise for the Aptitude Test. At Grades 10 and 11 they need to do the O-levels; after which is a two-year intensive study for the A-level. To allow the greatest extent of "learning", these examinations have to be addressed. Parent participation is another important issue.

5. Conclusion

As Warschauer (1999) pointed out, literacy and language skills are changing in the 21st century. It is not so much a matter of using computers to teach the same things more efficiently, but rather to teach the new kinds of literacy, communication, and language skills needed for success in the 21st century. The bottom line, however, lies in the understanding of both the benefit and the costs of these new learning technologies.

Towards a Walloon Virtual Campus

Poumay Marianne, Demily Fabian, Georges François, Jans Véronique, Leclercq Dieudonné

University of Liège, Department of Educational Technology, Belgium

E-mail : m.poumay@ulg.ac.be

Abstract : This “work in progress” paper presents the results of a study conducted in Belgium, proposing the deployment of a virtual campus through a call for tenders selecting SMEs and organizations to be trained and accompanied in the development of their own distributed learning project. From the needs analysis, an important focus on quality all along the process will control the decisions, actions, plans and measures, forcing the regulation and preventing the projects from being too technology centered.

The context

Wallonia, a French speaking region of 3,5 inhabitants located south of Belgium, is presently investing in a wide fiber optic infrastructure along the highways with local loops to private organizations and public institutions. Electronic commerce, tele-business and distance learning are then considered as main issues to generate traffic on the new fibers.

Our study

In this context, in 1998-99, the Walloon Region has asked the Department of Educational Technologies of the University of Liège to conduct a study advising the Walloon stakeholders on the choices and steps to make towards a Walloon Virtual Campus¹.

The study ended in June '99, proposing :

- a common platform for distributed learning respecting the emerging international standards ;
- a strategic plan to unfold an efficient distributed learning system over the whole region in the next 4 years, to start in 1999.

This study and the strategy proposed for 1999-2003 could inspire other regions or countries wanting to develop distributed learning. Its focus on quality will allow an emergence of “examples of good practice”, transferable to new contexts.

Deployment

Regional information events including many “hands-on” demonstrations will be organized in order to highlight the added-value of distributed learning. The WebCT platform will serve as common tool for a deployment in two phases from 1999 to 2003 :

- In phase 1, a call for tenders will be launched to select 20 projects to be closely coached. The selection criteria will guarantee the representation of diverse target publics (age, socio-economic origin), types, status and activity sectors of organizations, types of objectives, sizes, main focus and contents of the foreseen services, etc.
In addition to the variety, those criteria will also largely focus on the quality of the proposed methodology (priority given to activities, problem solving, case studies, dialectics,...), the

¹ Poumay & al (1999), *Vers un Campus Virtuel Wallon*, Rapport à Technifutur

“demultiplicative” aspects of the new services, the quality and originality of the contents and the motivation of the candidates.

A training, provided half at a distance, both in Technology and in Pedagogy (programs of 70 hours and 90 hours already available), will be offered to two persons in each selected organization. Depending of their quality (criteria to be refined in September'99), the new distributed learning services will be certified by the Walloon Region of Belgium and information on those services will be linked to the Region's Web site ;

- In phase 2, one hundred projects will be coached from 2000 to 2002. The same training will be proposed (but not anymore completely free of charge) and the same quality control applied. We should end up in 2002 with a wide covering of the Region and a quality increase of the available services.

The budget, piloting structure and coaching of those actions have of course been detailed, but, most important, a series of educational models serve as references to the development plan. Funding will be obtained before the end of '99.

Website Redesign: The long and winding road!

David Matusow
NASA / GSFC
david.matusow@gsfc.nasa.gov

Abstract: If the Internet is the Information Super-Highway, then redesigning your website has to be the long and winding road! Because the World Wide Web (WWW) has been around for a while now, many sites are on their third, fourth and even fifth generation or more. The process of taking a current website and redesigning it (especially on a large site) can be an overwhelming, daunting task. This is the story of one such (painful) experience.

The Integrated Financial Management Program (IFMP) is a very large project currently in motion at the National Aeronautics and Space Administration (NASA). This program will be responsible for overhauling NASA's current financial systems. The Technical and Contracts Office (TACO) is a sub-unit of IFMP responsible for managing the technical work and the main contract associated with the project. One small responsibility also falling on the TACO is the development and maintenance of the IFMP website. When the project started in 1996, there was not a lot of information available, but a website was created in the hopes that it would mature to be a great communication tool, both for project personnel and for the public at large. In the next year, the project started to grow, and with it so did the website. By 1998, the site had been stretched to its limit, and it was time for a change. A great deal of the content was out of date, the user interface was inconsistent, and current web technology was not being used.

This paper will discuss the story of how IFMP went about redesigning their website, the problems and pitfalls they encountered, and the current status of the site. Lessons learned will be shared on do's and don'ts of website redesign for a large site, as well as a look into the hazards of having multiple groups plan and implement a redesign effort.

Introduction

Website redesign. The words invoke a dreaded feeling, one of duplicating effort or worse yet, doing something again while the original still works. Yet, every day, thousands of websites are in the process of being redesigned, costing millions of dollars. Why are these businesses spending all this money doing something to a website that is probably just fine as it is? The answer lies in the fact that the World Wide Web (WWW) is a relatively new technology. As with all new technologies, they evolve. As the web evolves, techniques change and more capability exists all the time. Because of this, companies with websites want to have their best foot forward, thus always wanting the latest capabilities on their website. To accomplish this, those companies need to go through the process of website redesign, taking the information on their current site, and re-mapping it into a newer site, probably consisting of a new user interface, a new look and feel, and possibly new data availability.

Although this re-mapping activity might not sound bad, it can be quite problematic. First, the new website must be laid out and developed. This involves trying to understand who the "customer" or main focus is for the website, and tailoring the site to them. Then a "look and feel" must be created for the target customer. Probably, this involves implementing some of the latest website techniques such as graphic rollovers or JavaScripting. After that, the website must be populated with good data. The old data might or might not fit into the new website, so the team might need to develop new material. Finally, it all has to come together into a nice, neat package that works! If you are lucky, this activity didn't take forever to do, didn't cost an arm and a leg to develop and implement, and the site isn't outdated the minute it is unveiled!

Background

The Integrated Financial Management Program (IFMP) is a large, Agency-wide project currently in motion at the National Aeronautics and Space Administration (NASA). The goal of IFMP is to revamp the Agency's financial systems, providing an integrated approach using the latest technologies and new business practices. The Technical and Contracts Office (TACO) is the part of IFMP which is in charge of monitoring the main contractor for the project, as well as being the head office for technical issues. One of the many activities that the TACO leads is the IFMP website. When the project started out in 1996, there was not a lot of information available about the project, so it was decided that the website would be established, and grow with the project. The initial hope was that the website would serve as source of information and communication for internal project personnel, NASA employees, and the public at large. In the next few years, the project started to grow, and as it did, so did the website. Finally, by 1998, the site had been stretched and stretched to the point of breaking, so it was time for a change. A large amount of content was out of date, and current web technology was not being used. Yes, the dreaded re-design was afoot!

The Redesign Effort

To redesign the IFMP website, a team comprised of multiple entities was created. This included government civil servants and multiple contractors. One of the early decisions made was that the design of the website and the implementation would be split between different contractors. It was hoped that the design team (with its expertise in design) could work on that part of the website, and then hand over the design materials to the implementation team (with its expertise in implementation) to create and maintain the actual site. This is a bad idea because when split, the design team does not take the difficulty to implement the design into consideration. If the design team and implementation teams are comprised of different contractors as they were in this situation, they might use different, non-compatible tools

which will also make the work slower and more painful. Furthermore, the implementation team will not be able to give as much input into the design, which can also weaken the overall product. Another problem with this approach is that it adds more personnel to the overall project. More opinions get considered, and while that can be a good thing, if there are too many inputs, it is easy to get bogged down coming to a consensus. It is hard to please everyone, and the more people you are trying to please, the harder your job will be.

Next, a schedule was developed to create the necessary graphics to develop a prototype, create the design for the entire site, and then hand over those materials to the implementation team. One big problem was that it wasn't taken into account how difficult it would be to get the content out of project personnel. As stated earlier, the site was full of out of date material. So, in order to populate the new site with useful information, someone or some group had to actively seek out project personnel to retrieve the information necessary to populate the website.

During the design phase, it was also decided that the website should take a three-tier approach to satisfying its customers. In other words, there were three basic groups of people whom the website would cater to. The first group would be project personnel. The second group was the NASA community at large. The third group would be the general public. It was hoped that by creating the appropriate design, the needs of all these groups could be satisfied, eliminating the need for multiple sites. This is a very wise thing to do, because it can save the organization a lot of money. The organization will not have to develop multiple sites for the different groups, and the web team will not have to maintain as many different pages. Furthermore, if the website is designed to please all the people the organization most desires, then clearly the website will be accomplishing its goals.

By July of 1999, 13 months after the start of the website redesign, the site was still not completed. The big thing that was missing was new website content. Although some new content was created, it was still very under populated, and therefore unable to be made public. A decision was made to go ahead with the new site anyway, populating it with old website data until the new data could be developed and placed on the site. This turned out to be a very good idea, because when the new site was released, it made everyone even more anxious to have a well-populated new site, and new content started flowing. Although a schedule was created from the initial project conception, it was not followed very closely. This is a major problem! Although things can happen to throw off schedules, it is very important to try and keep to your schedule, because as long as the schedule slips, more money is being spent on the redesign, and the end goal is delayed.

Current Status

As of September 1999, the IFMP website is in pretty good shape. The site has a considerable amount of new, relevant data, and is organized in an appropriate, helpful manner. The graphics are sharp and attractive, intermixing simplicity and new technology to achieve a modern, classy look. On the horizon for the IFMP website is the development of an area being called the "virtual office." This will be an area on the website tailored towards helping communication of project personnel. First priority for this area will be a document management system. This system will allow for project personnel to create and store documents on the web. It is hoped that having a virtual office will further enhance the IFMP website, and make it a more useful tool for project personnel.

Lessons Learned

As you might have already known, website redesign is no easy task. Whether you are a small company looking to expand or a large organization with an already huge website wanting a new look, you have a lot of work to do! Although there are a lot of mistakes you can make, here are the key points to keep in mind:

1. Know who your audience is. It is very important to know right from the beginning whom you are redesigning the site for. It is not helpful to think you are designing the site for the general public, and then only have information that is useful to your local project. Likewise, you probably would not put the same kind of look and feel on your site if you are redesigning it for a small organization, than if you were advertising something to the world. If you are trying to accommodate multiple "customers", then you better make sure you consider both needs in the design.
2. Too many cooks spoil the soup! This is true in cooking and it is true in website redesign. The more players you have giving you input, and the more people you have helping make decisions, the more time you will waste, the more money you will spend, and in the end, you will get a site that isn't what anyone wants, and therefore makes no one happy. Although you might need a large team to actually do the work, it is better to have a very small group of people making decisions.
3. Follow your schedule. Create a detailed schedule, monitor it closely, and try to stick to it. It is very easy to get lost or sidetracked in some obscure design issue or implementation feature. Look at the big picture, get the redesign implemented, and touch it up from there.
4. Do not separate the design team and the implementation team. Better yet, have one team that does both. These two facets of development are both very important, and you will find that having experts in one discipline can help with the other discipline and vice-versa. An integrated team will produce a better, cheaper product in less time.

Conclusions

As you have read in this paper, there can be a lot of pain in a website redesign. It doesn't have to go that way – there are a lot of success stories out there as well. If you can avoid the pitfalls and stay focused on what the goal is, you can redesign your website to be a better one. Make sure you focus on your audience. Make sure you use the latest technology with your latest information so you will not have to redesign so soon in the future. Finally, make sure your redesign team doesn't get lost...down the long and winding road!

Integrated Online Learning Environments

Rory McGreal, TeleEducation NB
New Brunswick, Canada
rory@teleeducation.nb.ca

Abstract:

Integrated online learning environments (IOLE's) have emerged with the internet itself. They are based more on a collaborative learning instructional paradigm than the self-instructional paradigm of the multimedia authoring systems and as such, make extensive use of the asynchronous and synchronous collaborative tools available via the internet. IOLE's are client/server applications using standard internet protocols. They have been designed specifically for educational applications. They have taken the stand alone synchronous and asynchronous collaboration capabilities of the internet and integrated them within a tool that mirrors the instructional process.

Because they have been built around the bandwidth limitations of the internet, they do not have the same sophistication of authoring logic built into them as traditional authoring tools. IOLE's are not multimedia development tools although some of them have been developed as enhancements to such tools. They are client/server applications using standard internet protocols. Although some have proprietary client side applications, almost all now have enabled their software to be accessible via common Web browsers.

Given the number of development and delivery tools available to educators to support Internet-based education and the wide variety of approaches to using the internet and WWW for educational purposes, making the right software choices can be a daunting task. Of course there is no one "right" answer. There are simply better or poorer choices based on how well tools are selected to match both organisational and technical requirements.

When organisations embark on a selection process for these types of tools the decision criteria often comes down to getting the tools with the most technical capabilities within some kind of cost or budget limitations. However, software tools can serve different needs just as organisations will have different requirements that need to be met. Educational, organisational and technical considerations need to play a part in the decision.

Education goals can exist at a number of levels. An institution may have an objective to distribute learning via distance education and is looking for a powerful tool with sophisticated administration and user capacity to help them do just that. On the other hand, a single professor may be looking for a tool to support or improve his/her class. These two situations might point to different software tools to meet each goal.

The tools needed for Internet-based, individualized self-instructional modules are different than those that would support a collaborative learning approach requiring high levels of electronic communication between students and instructors. A mixed approach might require a combination of software tools or a product that has the most flexibility to accommodate both approaches to learning.

The technology in place or planned within an organisation will play a large part in the types of development and delivery tools. Institutions with a mix of server and client platforms will place cross-platform versatility high on their list as will institutions wishing to deliver distance education to remote students. Other organisations may have a more homogenized user base which could affect their choice.

Network bandwidth and speed, as well as the power/capability of end user platforms will also play a role. High media content is not well suited to delivery over slow networks with low end PC user platforms.

All organisations have cost and budget limitations. Some of the tools are expensive even though they may be highly appropriate to certain instructional goals. There are low cost alternatives that might meet the same need in a somewhat less integrated way.

Instructional new media development requires expertise. At the very least it requires media creation expertise and should also include professional instructional design support. When organisations do not have this expertise available to them (or have decided not to acquire it), the quality and speed of projects is limited. There are a number of very simple low- end media creation tools available to educators who are "on their own" when it comes to developing Internet-based learning. Professional instructional designers and media developers will need higher end tools.

Another way organisational expertise can affect software selection is simply the preferences and experience of those who are to use the tools. For example, many of the authoring tools are similar in price and functionality, but some multi media developers simply prefer one tool over another or have more experience with one over another. Since the learning curves on some of these tools is high, it often makes sense to stick with what is familiar and effective.

Prioritized organisational needs make wading through technical criteria much easier because it acts as a filter by which to assess the importance of the many features and capabilities of each software tool. Technical evaluation should not be as basic as determining the presence or absence of certain features/capabilities. Two software tools may do the same thing, but one may do it better, more intuitively, faster or more aesthetically than the other. So software evaluations that simply list the presence or absence of features can be deceiving. At the very least, features should be weighted and ranked. Technical criteria should also include measures of usability such as ease of learning, ease of use and flexibility from both an authors and users point of view.

Multimedia authoring tools offer the capability to develop highly modularized and media rich self instruction. Bandwidth limitations of the Internet simply do not yet allow the highly interactive multimedia these same tools can develop for CD-ROM delivery, but that will change soon enough. In the meantime, experiments with browser plug-ins will help define the best use of these authoring environments for Internet based education. The most effective uses of authoring tools for the Internet at this time are for short animations and simple interactive sequences that do not demand much bandwidth, typically embedded in native HTML. Sites that have experimented with this approach have produced easy to use, fast and effective instructional sequences.

The self-instructional model associated with authoring tools break down the "course" structure so common in university education. This model has found greater acceptance in workplace training where more flexible delivery structures are the norm. Many IOLE's are modelled more on the "course" structure found in university and higher education settings. Because they have emerged with the Internet itself, they take better advantage of the collaborative learning possibilities the Internet provides. Many IOLE's cannot accommodate the self-instructional logic that is built in to different authoring systems tools.

The two approaches both have useful pieces to offer Internet-based education. The best solutions will ultimately be some combination of both environments. The importance of bringing a structured instructional design approach to the use of these tools cannot be overstated. All the tools described in this survey can be used to develop very good or very poor instruction via the Internet. The variable that defines quality and instructional effectiveness is instructional design. A much stronger team approach to instructional design involving media experts, instructional design experts, project managers and professors/instructors, than is currently used in higher education, will have to be employed if Internet-based education is going to be a success in the long run.

Abstract:

As samples for Web applications we present in this paper a lecture information system and a student learning tool. The technological concept of both is similar. The information is directly published out of a database integrating multimedia data on the fly.

The Multimedia Center was established in November 1998 to moderate and integrate all multimedia activities in the university. Beyond the basic services like media production and running appropriate servers for media streaming and the web it was intended to support the university staff with competent assistance in producing media based materials for lectures and lessons. One of our ongoing tasks is preparing the ground for lectures on demand and the virtual university.

A major amount of these issues is targeted to the web, intranet or public. Therefore we aim to integrate the multimedia based activities and the work of building web applications, where we gathered a lot of experiences in the recent years. Out of our current projects and development we like to pick up two applications. Both can be considered as good examples stressing this goal, having exceptional semantical aspects and different usage scenarios.

They are based on the same technological platform and software. The institute staff responsible for the content is accessing the database by an Microsoft Access front end database application providing forms for data input and update. The Microsoft Access back end database is located on a web-server running IIS 4.0. On server site the databases are accessed and published via ASP (Active Server Pages).

The first application can be considered as information system containing all lectures, lessons and seminars of the institute of General Practice (see Author 2). Lectures, lessons and seminars can be divided into semantically independent learning units – further on abbreviated as LU - labeled with a theme. To the respective LU the information, when and where it will take place and which teacher will do the task, is linked by using the appropriate form fields of the front end application.

The web application offers several possibilities of publishing the information stored in the database:

List of teachers with phone number, email account, room number etc., list of LUs, weekly time table of all LUs or for a teacher and search forms for LUs, filtered by themes or teachers. For each LU one can get detailed information about time, teacher and content.

Moreover we added references to the LUs to integrate full text explanations, literature references and multimedia data for the distinct themes of the lessons especially video clips streamed by a Real G2 Server for this purpose.

Starting with a traditional data management tool we expanded this application to a framework hosting multimedia data for lectures and lessons.

As an experiment we added a discussion forum for patient case studies.

The concept and coding of this application was done in consideration of serving as a general template, so that any other institute can use it.

The second application is a web based student learning tool, which was developed in cooperation with the institute of Orthodontics (see Author 3). For each patient test case the staff fill in forms with general data and references to image data. Additionally there can be one or more forms where the correct answers for the questions are filled in, the student has to answer. Each case is assigned a complexity degree. As image data for each case we have jpeg-files for intraoral pictures, models and x-rays so far.

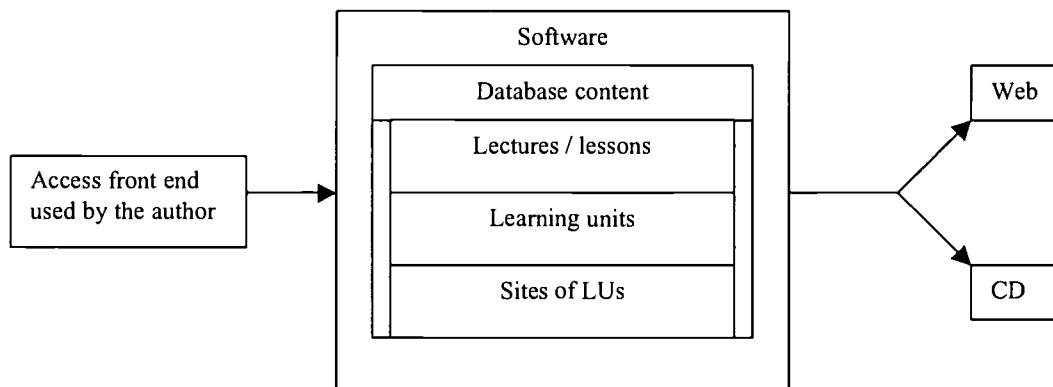

Accessing the application in the internet the student has the choice which question set of complexity degree he wants to work out. Then he can navigate thru the cases, access the image data and zoom them. The questions are presented in HTML-Forms with an embedded rule-driven Java application for marking invalid input. After completing the question forms the student can access an online form comparing his answers with the correct ones.

Again this application can be considered as a general template that can be reused in different fields. Of course one can replace the static images references by video clips.

The first mentioned application you can visit at <http://www.med.uni-duesseldorf.de/AllgMed>, the second at <http://www.med.uni-duesseldorf.de/KieferOrtho>.

Strategic concepts and solutions for multimedia based lectures and lessons:

For a university wide software solution we consider the following aspects to be most critical: ease of use, flexibility, productivity factor and the possibility of tailoring on customer's demand. So far we have not found a software on the market really meeting our requirements. So we took the challenge and now we are in the process of developing a solution by ourselves.

Using access forms the author structures his lecture / lesson into LUs containing content sites. Each site is filled with objects like text, interactive buttons, multimedial objects etc. There is a property form for each object type. The software generates the complete html web site with embedded java script and dhtml which is used extensively. Our first tests showed that the generated Web/CD application is capable of playing all known media types by using the appropriate java scripting. The productivity factor on the author site is still a challenge. For further information about the ongoing process do not hesitate to contact me by email.

Collaborative Knowledge-based Learning Environments and Applications

Abstract: Our work discusses the prospects of building training systems integrating collaborative and knowledge-based capabilities. We present an example of an educational application build under this capabilities. This application is designed to help in developing procedural skills about OOP in object oriented programming for University and College.

1. Introduction

Many researchers/developers of computer-based instructional systems had considered Intelligent Tutoring Systems (ITS) and Learning Environments (LEs) as different and even contradictory ways of using computers in education. Recent success of such well-known ILE showed that these ways are not contradictory. ITSs are able to control learning adaptively on various levels, but generally do not provide tools to support free exploration. LEs and microworlds support exploratory learning, but they lack the control of an intelligent tutor without such control the student often works inefficiently and may never discover important features of the subject.

Another component that can be added to instructional applications is the collaborative one. This can be defined as the instructional use of small and medium-sized groups through which students work together to improve their results.

Another methodology of approach in computer assisted instruction systems can be used. This consist of three components: learning environment, collaborative / co-operative environment and intelligent tutoring. We present the general structure of such systems and one application designed to help learners in developing procedural skills in object oriented programming

This educational applications may help teachers and learners in the learning of concepts relayed with OOP, such as instances, abstract classes, inheritance relationships between them, interface and implementations.

In this work, we address the problem of presenting and teaching a general framework where a group of learners may learn concepts relayed with OOP. This paper is organising as follows, the following sections present the characteristics and associated problems with the intelligent and collaboration learning environment components of our educational applications, then present an example of this kind of applications, and our future works. Finally, the last section is the conclusions.

2. Educational applications ´s knowledge-based component

Intelligent Tutoring Systems (ITIs) appeared in middle 70's as a reaction to the limitations of earlier CAI systems. Their idea is to apply AI methods and techniques to CAI systems, yielding the term ICAI (another name for ITSs) **Error! Unknown switch argument.** Such an integrated system can support the learning of both procedural and declarative knowledge and provide both system-controlled and student-controlled styles of learning.

Our main objective is developing integrated systems can support the learning of procedural knowledge. We understand that training is not the same as teaching or tutoring **Error! Unknown switch argument.** These differences are important in the design of an architecture for an ITS.

3. Collaborative and learning environment

Collaboration environments support groups of people who work on a common task by providing and interface to a shared environment collaboration support in a interface to a shared environment **Error! Unknown switch**

argument. Collaboration support in a co-operative environment usually requires **Error! Unknown switch argument.**

- Management of shared data objects
- Management of shared user interfaces
- Support for group awareness
- Support for co-ordination
- Support for communications

Learning environment allows the user to play and experiment with concepts of a given subject. Collaborative tasks reinforce learning, Learners's thoughts may be verified and with answering, discussing and sharing information during a resolution problem process.

Collaboration in computer instructional tools search to provide a framework where the users may develop their own and each other's learning/skills. Collaborative learning methods are more effective than traditional methods.

4. An example of collaborative intelligent environment application

In this work we address the problem of assisting the learner in knowledge acquisition **Error! Unknown switch argument.** and develop of procedural skills in the building of class hierarchies. So learner may eliminate misconceptions and clarify ideas about this subject.

Class hierarchies is an important concept in any object-oriented programming language. This kind of language and his principles is massively important in today's world.

The developed tool is a complement in methodology to teach concepts as instances, abstract classes, interface and the relationship between them (inheritance and implement). This concepts are presented to learners in the class room by the teacher and then learners can practice in the develop of class hierarchies in a collaborative computer assisted environment. Learners are helped mutually and the communication and discussion is facilitated by the interface application.

Learners do not work alone. They have a virtual trainer-friend that appears to inform and advice about errors or misconceptions are introduced, like multiple inheritance or when erroneous inheritance relationship are defined in the class hierarchy.

5. Conclusions and future works

This tool is part of a more ambitious project that we are developing to introduce and reinforcement relayed with OOP concepts and so learn some bases of any powerful object-oriented programming language.

Our work aims to eliminate spurious concepts of inheritance, to provide a framework where students may 'learn by doing' and may acquire skills building class hierarchies.

Under the same considerations we are developing more applications. These tools may help to acquire procedural skills in mathematical calculus at University and High School levels.

Images of Japan – It's Framework and Evaluation

Y. Nakanishi L. Tatsuta M. Ohnishi G. Tomizawa K. Gunji
 Dokkyo Univ. Dokkyo Univ. Dokkyo Univ. Science Univ. of Tokyo Uiv. of Illinois
 ynakanis@dokkyo.ac.jp tatsuta@dokkyo.ac.jp kimiko@uiuc.edu

Abstract:

In the past two years, we have been developing "Images of Japan," a collaborative learning system for Japanese and Japanese culture. We present herewith ways to evaluate its framework and the content along with the results of its experimental evaluation.

1. Introduction

The purpose of a collaborative learning system, "Images of Japan," is to develop a network-based learning environment to promote the interactive learning between Japanese and non-Japanese students. In order to achieve this purpose, the theme of Japanese culture and language is chosen. In determining the specific content, a survey was carried out on a total of 302 Japanese and foreign students at Dokkyo University, Science University of Tokyo and University of Illinois, and over 300 items were collected. The followings are the themes that Japanese students want to introduce, and which most interest the foreign students.

	Japanese	Non-Japanese		Japanese	Non-Japanese
Eating habit and food	51%	25%	Traffic and trains	6%	9%
Sports	12%	14%	Daily lives	36%	32%
Ways of thinking	8%	18%	Music and arts	22%	12%
Religion	5%	37%	Movies and TV	12%	14%
Marriage	1%	1%	Books, hobbies and crafts	35%	35%
Education	5%	14%	Traditional events	26%	12%
Student's life	13%	12%	Geography and region	9%	6%
Language and communication	9%	15%	Nature	7%	3%
Clothing and trains	22%	11%	Others	7%	48%

The diversity of the items selected by the students is far exceeded our expectation. More than 300 items have been collected. The table reveals that there is a wide gap in their perception of Japanese culture, particularly between Japanese and non-Japanese students. We expect that this perceptual gap between the Japanese and foreign students will serve to facilitate a cooperative and collaborative learning and a sharing of knowledge among the students and to lead to their active participation in the program.

2. Evaluation

Other than the number of hits, we believe that the assessment of the web pages can be determined by analyzing the extent to which this perceptual gap among students is filled through the interactive communication on the "Bulletin Board" as well as the content of "e-mails" received by the provider. An evaluation based on those means should be carried out through a long span of time, however. In the meantime, therefore, we have decided to perform an experimental assessment in the form of a questionnaire. The number of responses collected was 63 in total (51 Japanese and 12 foreign students). Questions focus on these themes: (1) The overall framework, (2) Introduction of the Japanese Cultural items, and (3) Japanese Language Learning Program. The data collected by means of the questionnaire will help us to study necessary changes to be made.

2.1 Framework

The framework of this home page is primarily designed to show the diversity of Japanese society and to encourage users to exchange opinions and to share their knowledge on Japanese culture. In addition to the "Bulletin Board," other devices to evaluate the program are installed. One is a "Voting." Users are encouraged to vote for the items in which they are interested. Users can also add new items of their own choice in the existing page. In the evaluation of the overall framework, the following issues were asked. The responses obtained from those 61 participants are basically positive.

	good	bad		Very interesting	Interest ing	Not interesting
Accessibility of items	78%	22%	Photo picture	8%	78%	16%

Layout	92%	8%	Illustration	14%	53%	33%
Linking	98%	2%	Animation	20%	68%	12%

	very good	Good	not good	bad
Size of the letter and presentation	12%	80%	6%	2%
Screen presentation	12%	80%	8%	0%
Control of Screen	8%	80%	10%	2%

As for the accessibility of items, however, the response is not sufficiently positive. There could be a few reasons; the list of items introduced may be too many for participants to screen them thoroughly; some students could not see the page because of plug in software, the instructions on how to use the page may be inadequate.

2.2 Japanese cultural items

Each one of these over 300 items is presented with visual and written information. It consists of at least two visual screens either in the form of photos, and/or illustrations, or animations. The written information is the one provided by the students who participated in the original survey.

The responses are not as positive as in the evaluation of the framework, due in part to the lack of sufficient information on each item. Particularly, the responses from Japanese students are much less positive than those from foreign students, while the ones from foreign students are much more positive. Additional comments given by those foreign students are quite favorable; saying, for example, "This is a fascinating resource to learn more about Japanese culture," "I think the items introduced here are very thorough, everything from traditional to modern culture.

Japanese St. Foreign St

(1) Could you understand the ways young students grasp Japanese culture? Yes 76% 100%

(2) Have your ideas towards Japanese culture changed? Yes 37% 100%

(3) What do you think of this home page on Japanese culture introduced by students?

Japanese students Useful 55% Not useful 6% Interesting 31% No Answer 8%

Foreign students Useful 75% Not useful 0% Interesting 25% No answer 0%

2.3 Collaboration

In order to investigate a possibility of encouraging collaboration on this web pages, we asked a few questions such as the one shown below. The response from foreign students is quite affirmative comparing to the one from Japanese students.

Japanese St. Foreign St

(1) Do you want to exchange your ideas with others on the "Bulletin Board?" Yes 71% 100%

3. Conclusions

The results of the present experimental evaluation suggest that this home page could be a good source of information on Japanese culture and collaboration in general. After implementing further improvements and having obtained sufficient number of responses, we will re-evaluate the home page.

Universal Ecommerce Currency Breakthrough

Martin Nemzow, President
Network Performance Institute
United States of America
www.networkperf.com

Abstract: The handling methods for money suppress the advancement of Internet business. We need to simplify data processing operations to make more money through E-commerce and appeal to an international customer base. Specifically, we traditionally see money as a numeric field with added currency symbol and punctuation set by language and culture. Rather, a "normalization" of the money structure transforms it into any other world currency, scales its value over time, or adds many currency bases to generate a single total in any chosen basis. One system thus can handle all world currencies at the same time and display them in any chosen formats. This enables one computer system to consolidate assets of different types, unify accounts from the past, present, and future into something that actually makes sense, or sell products or services around the world to people in any country in their own currency particularly over the Internet. In financial and practical terms, this new currency paradigm lowers the costs for multiple currency accounting, centralizes and simplifies work flows, and automates a complex, error-prone, and time-intensive series of steps with a codified method. Although other solutions even current manual or automated methods exist, the paradigm yields economies-of-scale, efficiencies, and accuracy not currently available.

The Monetary Paradigm

Currency is a field variable of a special format. The configuration for a computer system defines exactly what that single property is for each system. It is different for the U.S., for Germany, for China, and for Saudi Arabia. Sometimes, the displays might seem upside down or even backwards. Because of these cultural differences, and because rates to convert currency from one to another float all the time, we see that the Dollar is very different from the Pound, and even alien to the new Euro. We see these currencies as different inventory items; they even have different SKUs or stock keeping units. It is called SWIFT (Society for World-wide Interbank Financial Telecommunications) for designating currency by a three letter designation. This code system is also standardized by ISO 4127 and a three-number code format. The point is that the world's currencies are segregated as different inventory items.

For example, compare \$1.00, DM 1.00., 1 FRF, ¥100, £1.00, or blue, yellow, white, or purple. However, just as colors fit any number of additive, subtractive, or other color models so that they can be compared, combined, or changed into each other, money can be compared, combined, or changed into each other too. Unfortunately for us, political, sovereign, and national pride have created false distinctions. This introduces perverse work flows, computer systems, and other steps reinforcing the differences in money rather than common similarities. Conversion rates are high, the process is awkward at best, and it is not mainstreamed in any way. Even now, banks, governments, and companies in Europe are trying to convert from a single native currency to a new still single native currency over a span of 8 years (5 years have already elapsed).

America and the rest of the world will see this European color change and try to create plaids, stripes, or paisleys too... just to be included. Nevertheless, Europe is only changing one color for another color. The Euro is a political change with functional benefits, but not a functional change. At least, 11 countries will all use the same one color to simplify intra-border business, but the change is barely relevant. The Euro is still another color from the Yen and some 190 other world currencies. This is a small step of legislating fewer colors, but not a substantive effort at creating a universal money wheel, which describes a simple metaphor for unifying how we see currency and other monetary assets, and actually interchange them.

The universal money wheel turns all currencies into a lowest common denominator. In other words, there is a way to reduce all the world's money into the same SKU. There is also a way, it is the same way, to reduce all types of monetarily denominated assets into the same one SKU. That means stocks, bonds, treasury notes, loans (from our point of view), debts, futures contracts, options, hedges, cash in every color of currency, bank accounts in every possible currency, mortgages, complex derivatives, stripped bonds, you name it, can be reduced into the same SKU. Money values from last year, from 1812, from next week, from 01.01.2001 all can be converted into the same SKU. One other convergence, spreadsheets which made What-If? look like the pass key to venture capital money, represents just another feature that is easy reduced into the same SKU. Currency rate conversions and interest or depreciation rates might seem more colorful and real than some hypothetical money conversion with 10% growth in sales volume, but all of these are just artificial displacement shifts from the basic money SKU.

When money is one SKU, change in basis, time, or hypothetical assumptions is a just a shift from that SKU. This means the Yen is another form of the U.S. dollar or the Euro. Blasphemy! We can hold onto prideful national sovereignty issues, but there is no profit in that. Which will it be, blasphemy in these dark ages, or profit from new opportunities?

Did we pick the one SKU? Of course, you are still reading! The table in Figure 1 shows how to restructure currency into a series of set of descriptive properties. Technically, these descriptive properties *objectify* the definition of money and *encapsulate* external meanings; this restructuring of the currency definition is a profound application for object-oriented programming (OOP) concepts. These four listed properties are the minimum for conversion to and from any world currency, handling time-value of money, and presenting the results in any internationalized or localized display presentation. Added optional properties expand the color wheel to support what-if and complexities of derivative monetary assets. There are probably other useful properties that are not obvious yet.

Field	Name	Purpose
1.	Value	Real "inventory" count of currency, just a raw number
2.	Basis	Description of foreign currency or other monetary basis
3.	Date	Transaction date (and sometimes a millisecond time)
4.	Display	Characteristics for localized/internationalized presentation

Figure 1. Simplified property table for normalized monetary data.

This new color wheel is a structure for money. We still need something to turn the wheel and make Yen into Euro or \$1.00 yesterday into Rands next week. That something is big stream of data and an engine that can handle an enormous number of constraints, rules, political declarations, transaction costs, ambiguities, and possibilities for arbitrage. The data requirements include ratios for the relative values of world currencies, interest rates for many periods of time and sizes of transactions, brokerage fees, brokerage arbitrage, and wire transfer fees.

So, we are wondering, how is this paradigm different from the existing foreign currency exchange markets and worldwide bond markets? It is the color wheel metaphor that lets us morph one color into others. The universal money wheel creates a *translatable linkage* and the paradigm infers the necessity for an automated translation engine and the underlying data delivery. Rather than viewing currencies as discrete and inimicable

entities with equity markets in New York City, Hong Kong, London, and Bremen, we are seeing an interrelated recipe linking all of them with a simple mechanism to convert among all of them. Although the simple flat concept of an *objectified* currency field now has at least four discrete properties, and while that seems more complex than the traditional currency variable, it is conceptually simpler. Instead of 206 world currencies and an infinity of monetarily-valued assets, we now have one unifying SKU with four known, useful properties. The paradigm makes it practical, simple, and unrestrained to implement a currency conversion and translation method for any and all "foreign" currencies and any and all bases for monetarized asset accounting, finance, and risk management. In financial and practical terms, the paradigm lowers the costs for multiple currency accounting, centralizes and simplifies the workflows, and automates a complex, error-prone, and time-intensive series of steps into a codified method. Although other solutions even current manual or automated methods exist, the paradigm yields, economies-of-scale, efficiencies, and accuracy not currently available. For example, while banks, brokerages, even web-based services provide currency conversion rate information, the factoring of monetary values is not automated or performed from a simple embedded rate table. Rates vary by timing, transaction size, negotiation skills of the involved parties, direction of conversion, and posted or hidden fees. This current situation threatens as much as 10% of the transaction in value dissipated through letters of credit (in countries with unstable banking systems) or more typically 1 to 4% in modernized and industrialized nations, still an enormous fee for the honor of converting the monetary basis for normal business transactions.

If there is a pall of gray (or grey, for some of you) over this color scheme, unfortunately we find it in the need for good data and the complexity of translation engine to filter, reduce, and make sense of that data to create useful currency conversion ratios and relevant interest, depreciation, depletion, or amortization rates. However, this part is just a process, method, or apparatus, in the lingo of Berne Convention patent law. No need to worry as there are solutions for that too, technical licensing agreements. What is important, nevertheless, is to see how a new paradigm for something as unassuming and rudimentary, like how we see money, can initiate a transformation in how we do internet-based business in better ways. We can create innovative new markets, and accelerate the ecommerce market into a global, hypercompetitive, and profitable channel. Indeed, the universal money wheel makes it straightforward to create multiple ("multiple" becomes "all" and "simultaneous") currency accounting systems for cash management, internet commerce, offshore bank account reconciliation, and increased integration in procurement or supply chains. The list of possibilities goes on. Here are some examples that are obvious to me, yet barely hint at the possibilities derived from a unified monetary system.

Examples

Any apparent complexity in this currency paradigm underestimates its potential to reform business expectations, integrate workflows, redefine the language of business, and initiate business evolution. The paradigm is practical, shown by these four real world examples.

For example, we can create multidivisional or multi-country corporate 10Q and 10K reports with full currency conversion and rollups in any currency display for printing or automatic Internet delivery. We can use language conversion software to convert the text of the report into other languages too. A French investor evaluating a German corporation might understand the annual report in French with franc evaluations better than in German with deutsche mark presentation. We might even consider an added column for euro presentations. Investments and currency fluctuations shown in local currency increases the worldwide desirability of our equities, bonds, and other financial instruments. Consider also all the forms required by government taxing and export agencies, or those provided by banks and brokerages with a mixed bag of currencies; how simple to consolidate to any single currency basis automatically.

For a second example, consider that land in Serbia, Croatia, Kosovo, and Albania is probably very inexpensive right now. These areas are not part of the European Union (EU), but will be rebuilt and modernized out of self-interested necessity by the EU. If land there is denominated in Euros, traded in Euros, building built with Euros, Dollars, or Yen and workers paid in the same bases for example, the liquidity for doing business in those areas is dramatically increased. The Lek, Denar, Dinar, or Kuna are complex to convert or relatively illiquid... if not purely unstable. Gold is complicated, and not conducive to ecommerce, if only from a weight and transport logistic. This war zone create a profitable investment zone if products and services can be exported from those regions within an interchangeable monetary form; certainly not when limited to local illiquid local denominations.

Suppose, as a third example, a divisional buyer at a large automobile manufacturer has the task of acquiring 10 metric tons per month of stainless screws for a new extended passenger SUV vehicle line: starting two years out for a duration of 5 years. This is, in fact, common market auto industry policy for planning, pricing, and manufacturing product. Because the inventory space, cash flow, and lot requirements demand monthly deliveries, the buyer prices acquisition over a period of time factoring the time value of money as well as comparing potential purchases from suppliers in Japan, Taiwan, United States, Sri Lanka, Brazil, and Argentina. Traditionally, bids are denominated in dollars or the country of manufacturer, and the automobile manufacturer will typically split upward or downward intercurrency movements 50/50% with the vendor. This is a primitive hedge tactic that in no way addresses competitive or economic market factors, or seeks to create a sustainable competitive advantage.

Consider a fourth example, a pension fund manager has inflows from government employees for the third quarter in the amount of \$38.76 million U.S. dollars to invest. Policy is such that the money must remain liquid for 35 days until the pension fund board of directors meets to vote as to how the funds should be invested long in equities. While short term U.S. Treasuries are providing rates of 3.47%, a capital shortage due to government and economic instability in Indonesia has created government-backed corporate bonds returning 8.95% for interest rate arbitrage. With spot market conversion rates and a 34-day forward option to buy U.S. dollars, the fund manager nearly triples the income during the mandatory holding period just on interest alone. Because the size of the currency trade was so large and value of U.S. dollars so high with respect to the rupiah, in addition, the fund manager has added net 2.7% in hedged currency trades. This yields an overall return of 3.0% for the 34 days, or 32.22% annualized with minimal financial risk (subject only to the political stability of the government of Indonesia).

Conclusion

The practical aspects of this universal color wheel paradigm are its innate support for multiple currency bases, the time value of money, complex financial accounting including equities. We can create new types of multinational derivatives (euro-based debentures for building chip plants in Kosovo, for example), risk management, new planning, process, and operational controls systems, what-if scenarios intrinsically because of the simplified structure. This allows for practical and immediate applications in electronic commerce, banking, brokerage, risk management, financial accounting, and the creation of global derivative products. Support for currency market quotations with bid and ask spreads, complex transactional fee structures, triangulation, rounding, conversion optimization, arbitrage opportunities, and other unexplored potentials are paradigmatically simplified (and made practical) when monetary assets and currencies are universalized. Specifically, conversions to Euro-based accounting can occur at the storage level rather than substituting new software code for every function throughout an application. A "Euro-Fix," therefore, is no longer just a politically necessitated transition but rather a strategic advancement given the intrinsic support for the all other world currencies and monetarized assets at the same time. This new paradigm can usher us past the dark ages with an ecommerce revolution where currency is a universal object in computer systems and information processing.

QueryDesigner: Simplifying Access to Remote Scientific Databases

Abstract: Many large-scale scientific data collections are stored in relational databases that use command-line SQL as the query interface. For years, scientists and other occasional users have had a difficult time accessing their data because SQL is terse and unforgiving of errors.

With the advent of the Web browser, forms-based interfaces have been layered on top of relational databases, shielding the end-user from the complexity of SQL. While these interfaces are easy to use, building them requires programming experience. The increasing demand for additional database interfaces is often not met due to declining personnel budgets and a shortage of programming staff.

Our solution was to build a user-oriented tool called QueryDesigner that enables non-computing experts to explore, construct, and personalize query interfaces from a Web browser. QueryDesigner is a Java applet that eliminates the requirement that the interface designer understand SQL, HTML, or any specialized language.

QueryDesigner was built in collaboration with scientists who actually work with large-scale biological databases. It was designed to allow the scientist to easily compose forms-based interfaces that support the way they search databases. QueryDesigner helps the user understand unfamiliar databases by acquiring information on database organization and presenting it as interactive diagram. The applet transparently composes SQL queries, issues requests to a remote database, receives and formats the results.

Scientists Have Special Requirements

Unfortunately, scientists — who are often not computer experts — do not have an easy time retrieving information stored in SQL databases. To formulate an SQL query, the user must first look up the names of tables and fields, which requires the use of a proprietary (non-standard) tool (e.g., Oracle's *sqlplus*). Moreover, SQL itself is terse, error prone, and unfriendly. It is easy to misspell a keyword or data name, omit a “join” clause, or construct a query that returns unintended results [Sme95]. There is also a lack of meaningful feedback during the query process, despite the fact that it is unlikely a casual user will be able to formulate a query correctly on the first attempt [JV85]. The user bears the burden of determining what went wrong, based on cryptic messages that reveal little about the source of the problem.

We were able to capitalize on what we learned about forms- and hypertext-based query interfaces for biological researchers during a previous interdisciplinary project [HNPM95] where we analyzed how users interact with biological databases [New96]. Scientists in the biological disciplines typically begin searches with only a partial idea of where they are going and what kind of results might be available. It is crucial for them to be able to explore the data and investigate the relationships between database entities, without having to formulate complex SQL queries.

With incomplete criteria, a search is likely to return a large result set; most database software simply returns all results in a rapidly scrolling display. Scientists need to be able to determine the size of the results before they are returned, in order to know whether the query needs refining. Support is needed for retrieving results in incremental blocks, paging through them, as well as saving the data in spreadsheet format. Moreover, keyword search is essential in scientific databases because they often contain unstructured data such as field notes or historical annotations.

Another common characteristic of biological data is the inclusion of a large number of attributes; no single organism is likely to contain values for every attribute, so database records contain a large number of empty (or null) data fields. This makes it difficult for users to find pertinent information, since current database management software provides no means of suppressing empty ("NULL") output.

We also found that a number of unsuccessful queries were caused by users' misspelling long scientific names, orthographic and typographic errors in the database itself, or the use of discipline-specific naming variants. When users must type values into empty blanks on a form, specifying search criteria becomes a guessing game. When no results are returned from a query, users are left wondering whether there really is no data available, or if their input was incorrectly specified.

How Query Designer is Used

The QueryDesigner applet (see <http://www.nacse.org/qd>) employs a graphical interface that permits the end-user to either personalize or create a forms-based query interface to a remote database. The tool eliminates the need for the end-user to learn SQL or proprietary scripting languages. Instead, the user formulates queries implicitly, by specifying on an interactive E-R diagram which data fields should serve as inputs and outputs. QueryDesigner checks to ensure that the joins are legitimate and that all database elements are joined, preventing several of the most common semantic errors. Once the interface elements have been specified, the tool generates an initial query interface, using default rules for placing elements; this can be edited by the user.

In designing a query form, the user can specify whether an input field is to appear blank, pre-initialized to a constant, or shown as a query-list. The query-list feature eliminates user guesswork and spelling mistakes on the query form, by pre-fetching a list of allowed values from the database. This is particularly useful for scientific databases, given that taxonomic and other scientific names tend to be long and easily misspelled. Although keyword searching is not supported directly by SQL, our software permits the scientist to search for keywords, even when it is not known in advance which fields should be searched.

When submitting a form, QueryDesigner automatically composes an SQL query, establishes a connection to the database, receives the results, and displays them. By default, QueryDesigner automatically suppresses the printing of empty (or NULL) fields to prevent screen clutter. A pull-down is used to limit the number of results returned at a time. A slider at the bottom of the screen permits the user to scroll through results one record at a time. Clicking the SAVE-AS-SPREADSHEET button permits the user to save results in a form accepted by most spreadsheet software.

Finally, QueryDesigner offers advantages in terms of its architecture. Accessible from a Web browser, QueryDesigner is platform independent as well as location-independent of the underlying database. Perhaps the most important advantage is that QueryDesigner is independent of any particular DBMS software. Through JDBC, QueryDesigner supports most relational databases that are addressable over the Internet.

Web-Support for Learning in Finland and Northern Europe

Rainer Nyberg, Abo Akademi University, Faculty of Education, Finland
E-mail: Rainer.Nyberg@abo.fi

Abstract: The project, "IT-pedagogy", described in this paper is pursued at the Faculty of Education at Abo Akademi University, Finland in cooperation with other researchers from Finland, Denmark, Greenland, Iceland, Norway and Sweden. The aims of the R&D project are (a) to explore how ICT (Information and Communication Technology, including smart phones and the World Wide Web) can be used to support learning and teaching and (b) to study which teaching methods are best suited for ICT supported learning. Three of its sub-projects -- in vocational, higher and primary /secondary education -- are described. Examples will be shown in the session. The paper also suggests several areas for possible international R&D cooperation.

Aims

The general aim of the R&D project "IT-pedagogy" (www.vasa.abo.fi/itped) is to explore how ICT can be utilized as support of learning in Finland and in Northern Europe, where the sparse population is spread out over vast areas.

Our more specific aims are to cooperate with researchers and teachers in other countries:

- 1) to find electronic information presented through new media (Internet, WWW, CD-ROM) which is educationally relevant and well structured for learning in primary, secondary and post secondary education,
- 2) to create some good examples of educational material and ways of examination that support learning (and learning-to-learn) and to publish it on the WWW, CD-ROM and in books,
- 3) to make this information (1 and 2) easy to find and accessible for students and teachers, and
- 4) to explore which kinds of learning material, learning strategies and didactic/teaching methods and forms of examination are most helpful when learning is supported by new technology.

Background and Partners

According to the new OECD report, Finland has the fastest growing economy in Europe. It also has the lowest population density in the European Union (EU, 17 persons per km²). Times Magazine claims that Finland rules when it comes to wireless technology [Murray Buechner, 1999]. Especially well known are the mobile phones produced by NOKIA, the world leader in cell phones. Finland has more cell phones per capita than any other country in the world, more than 60 per 100 inhabitants [Haven 1999, p. 9]. When smart phones (like the Nokia Communicator 9110, www.nokia.com/phones/9110/), are further developed many Finns will soon carry computers with wireless Internet access in their pockets.

Finland has been called "the most wired country in the world", not only because of the mobile phones. In Finland more computers (host) are connected to the Internet than in any other EU country: 88 per 1.000 inhabitants, and more than 18% of Finns aged 15-74 use the Internet daily [Haven 1999, p. 15]. In a new policy document the Ministry of Education [1999] declares the ambition that Finland in the year 2004 is among the top knowledge and interaction societies in the world. The Ministry has offered 300 million FIM per year to develop educational uses of ICT in 1996-2004. That is a lot in a country with 5 million inhabitants.

The five year R&D project (1996-2001) is supported by the Ministry of Education in Finland, the Council of Nordic Ministers and the Swedish Cultural Foundation. The majority of the teachers and researchers who take part in our project are from Denmark, Finland, Greenland, Iceland, Norway and Sweden. We invite partners from other European (and non-European) countries to get in touch to join our international R&D project.

Sub-Projects

1. *VocWeb - Vocational Education WWW for Northern Europe:*

This is a large web-presentation (www.abo.fi/vocweb) financially supported by the Council of Nordic Ministers during 1996-1999. The main purpose is to produce and organise educational material for students and teachers in vocational education and training. The web-site is created in cooperation with representatives from all Nordic Countries including Iceland and Greenland. The presentation now gives links to and information about vocational education and teacher

training in Finland as well as links to Centers of vocational education research in Europe, Australia and the USA. A plan for a course about how to use Internet and the web to support vocational education has been presented by a group of teacher trainers from Iceland, Finland and Denmark [Jeppesen, Mikkonen & Valentin 1999]. It is also important to explore how the Internet can support test administration, which has shown to be useful in vocational education [Knapes et al. 1998].

Suggestions for cooperation: Because of its English parts this presentation can easily be used also by other EU citizens and anybody interested in vocational education and training. We presume that the European Union can be interested to support this project (through the new program for "User Friendly IT") and make it a European matter to incorporate information relevant for vocational education and training in all Europe.

2. HiED - Higher Education Development International

Work on this web site in English (www.abo.fi/hied) begun in 1995 to serve the staff engaged in educational development of college and university teachers in the member states of ICED - International Consortium of Educational Development. The aim is to supply links to colleges, universities and centers for development of higher education. It also serves college teachers and students who want to find new material and strategies for teaching and learning. We now plan to produce a web-based, interactive course in information retrieval. The Ministry of Education in Finland has also decided to invest in an international Internet-university with web-based courses.

Suggestions for cooperation: Updating and further development of this site would be meaningful to pursue in international cooperation. Anybody interested in taking part in the development is invited to write to the author. We want to help future college teachers to learn how to produce web-based course material. However, teachers have to pass several stages of the ten stage process in working the web for education described by March [1999] before they can use the web to support learning and teaching

3. The IT-School - IT for elementary and secondary education

The Ministry of Education in Finland has during the last three years offered financial support to make computers and the Internet useful as tools for learning and to let Finland have the "most wired schools in the world". IT-school is a part of this work and probably the largest among the Swedish speaking minority in Finland, which is spread out over a long coastline and many islands. In Europe – as in the US – there are already web presentations to support teachers in elementary and secondary schools in Europe, as the European SchoolNet (www.en.eun.org) and the Nordic School Net (ODIN, www.odin.dk and www.odin.dk/english/). The aim of IT-school is to serve the schools for the Swedish speaking minority in Finland with multimedia material over the Internet and on CD-ROMs. We study how new technology can be used in support of learning and as tools in the construction of understanding [Lonka, 1997]. We want to help elementary and secondary school students profit from computers and Internet for learning, so they can grow up to live as active and interactive citizens in the "most wired country in the world".

Suggestions for cooperation: A new part of the IT-pedagogy project is to study how ICT can help small isolated rural schools to develop new teaching methods and cooperation. A doctoral student (Gunilla Karlberg, gkarlber@abo.fi) is searching for partners in this project. Most developed countries will soon see youngsters using cellular phones and Internet in schools. It should be a concern for researchers to find out how this modern technology can be used to support learning and motivation to learn, because, as Laurillard [1999, p. 183] puts it, "there is no point in using communications and information technology ... unless it clearly improves the quality of learning in some way".

The Impact of Instructional Design Methodology on Achievement in Alternative Course Delivery Formats: Two Field Evaluations

Drew Parker, Cher Hill, Vivian Rossner-Merrill
Simon Fraser University
Canada

Introduction

This paper discusses a work in progress that addresses the potential impact of using four models of learning to inform the instructional design of two university level online courses. We first present each course and the instructional design challenges they pose. We then show how selected learning theories are used to inform redesign of the courses, making them better suited to the online classroom environment. Finally, we discuss how application of these prescriptions enhance the ability to achieve desired learning outcomes and also demonstrate the flexible application of instructional design models in two distinct content areas.

Course I: The Analysis and Design of Business Information Systems

This course has been taught in a place-based format since 1989 and online since 1996. The course contains both conceptual material such as an explanation of roles in a project, steps in a process, and procedural challenges a systems analyst must overcome, and technique-oriented material, such as the drawing of particular types of charts, graphs, exhibits and models. Evaluation of differences between the two different mediums of instruction indicates that there are benefits and difficulties unique to each format. One noted difference is the tendency of the place-based students to express concern about the volume of conceptual information to be learned and discussed in tutorial and in examination settings. The virtual format, in turn, offers a different set of challenges. While students discuss conceptual issues in far more depth than afforded in the place-based setting (Parker & Rossner-Merrill, 1998), they expressed concern about their ability to deal with the required techniques and lacked confidence in their ability to apply them appropriately.

Redesign of the Business Course

A redesign experiment is underway where the virtual seminar takes place within three distinct modes of instruction using prescriptions drawn from cognitive flexibility, problem solving, and dual coding theories. Students will be randomly assigned to each mode. The control group follows the current cognitive flexibility design of the course (Rossner-Merrill, Parker, Mamchur & Chu, 1998). The other two groups will receive identical assignment sets, but these are redesigned in accordance with principles drawn from problem solving and dual coding theories respectively. In the first instance treatment involves a series of increasing challenges for students to solve, thus allowing them to acquire and apply problem solving skills and increased confidence in their ability to do so. In the second instance, text is combined with graphical and audio files to test the format's capability to instill technique-oriented knowledge. Results are recorded in identical assignments, but grades will be normalised within, not across, each mode. The course redesign process will be repeated for the place-based setting in the following term. Based on outcomes from preliminary work, these results are expected:

H1: Cognitive Flexibility (control) will yield highest conceptual scores

H2: Problem Solving will yield the highest confidence scores

H3: Dual Coding will yield the highest technique ability scores

H4: Overall, the virtual group scores on conceptual abilities will remain high as before, but technique abilities will significantly improve. The place-based group scores on technique abilities will remain high as before, but conceptual abilities will significantly improve.

Course II: Introduction to Educational Psychology

In this course students are expected to understand what makes “good thinkers” in terms of how knowledge is understood, used and applied. To this end they study models and theories in educational psychology, how to analyse educational practices and how to develop and defend positions on evaluating educational practices. The course is offered by correspondence and is currently undergoing redesign for adaptation to the online medium of instruction. It is a prerequisite for aspiring or pre-service student teachers who are required to work or volunteer in classroom settings as part of their preparation for formal entry into teacher training or into the classroom setting. Problems posed by the correspondence version of the course are twofold. First, contact with the instructor is limited to two hours per week for all students. Second, opportunities for students to benefit from exposure to expert teachers in ways that prolong and deepen their short experiences of the classroom setting are lacking. Thus advantages to be gained from the mentoring capacity and practical experiences provided by expert teachers are severely curtailed. The online version of the course offers an opportunity to redress these situations and to better prepare aspiring teachers for entry into the teaching training program or into regular classroom placements.

Redesign of the Education Course

Redesign decisions for this course are guided by prescriptions drawn from situated learning theory and related strategies associated with expert mentoring and collaborative learning. As applied, these include revising the Study Guide to reflect and incorporate the interactive nature of online learning, adding a conferencing component to the course, and designing a web site that allows students to access appropriate theoretical and practical knowledge available on the internet. Further, new activities and assignments are designed to maximise and extend students’ experiences in classroom settings and to enhance collaborative opportunities to acquire and apply conceptual understanding of educational psychology theories and models of learning. Compared to the correspondence version of the course, we expect that the addition of the virtual format described in the foregoing, will result in the following outcomes:

H1: The extension of expert mentoring to continue in the virtual format will significantly improve students’ abilities to analyse educational practices and to develop more effective means to assess their impact on classroom learning.

H2: The addition of web resources, collaborative learning and strategic learning practices will significantly improve students’ abilities to understand and apply knowledge gained from the more abstract study of theories and models of learning.

Fighting Fire with Fire: Using Web Based Training to Teach Faculty how to Develop Web Based Instruction

Dr. David Pedersen

Educational Technology, Embry Riddle Aeronautical University, U.S.A., pedersed@db.erau.edu

Abstract: Faculty development in the use of web-based instruction is always a challenge. That challenge is multiplied exponentially when those faculty are widely disbursed geographically. Embry Riddle Aeronautical University is unique not only in its aviation emphasis, but also in its world wide educational presence. This paper discusses the efforts being made to use the web to deliver faculty training on how to use the web for instruction.

University Profile

Founded only 22 years after the historic flight at Kitty Hawk, Embry-Riddle Aeronautical University has achieved recognition as a world leader in aviation. Each year thousands of graduates take their place in the aviation/aerospace industry as pilots, aviation managers, aerospace engineers, and other aviation professionals.

ERAU is unique not only as a pioneer in aviation, but also as a pioneer in distance education. The University has three campuses: two traditional residential campuses in Daytona Beach, FL and Prescott, AZ and an Extended Campus that is literally worldwide. The Extended Campus offers traditional courses in 125 education centers located around the world and independent study courses to students worldwide.

Instructional Technology Implementation

Because of its importance to aviation, ERAU has placed a high priority on technology implementation. For that reason, faculty members are highly motivated to make use of the web in their classes. Faculty at the residential campuses and Extended Campus education centers use the web to enhance their traditional classes. As such they need to learn how to use the web for everything from posting syllabi to electronic discussions and online testing. The independent studies courses also make use of the web to supplement and replace the traditional paper study guides and video tapes.

The Challenge

Providing faculty with the instructional technology training and support they need to utilize the web in their courses is always a challenge. At ERAU that challenge is multiplied a hundred times plus because of the 125 Extended Campus centers and the two residential campuses. The task of training 3500 faculty members is challenge enough, but when they are disbursed geographically over 127 sites the challenge becomes monumental.

The Traditional Approach

Until recently faculty development on the use of the web for instruction was delivered primarily in the form of a series of traditional face-to-face workshops. The workshops included topics such as browser basics, utilizing web resources, web page design, web authoring, and web publishing. Workshops were offered throughout the academic year, but the most successful implementations were during intensive week long Faculty Technology Camps in the summer months. Although the technology workshops have successfully helped a number of faculty make use of the web, the reality is that the face-to-face workshop approach will never reach even a small proportion of the entire faculty.

The Web Solution

A realization that if the web could be used to provide effective instruction for students, it could also be used to provide effective instruction for faculty was the genesis for beginning to deliver faculty training via the web. In reality, the primordial beginnings of web-based training started with posting some of the handouts used in the face-to-face workshops on the web. As the amount and sophistication of the web materials increased, there was a natural evolution toward web-based training.

The first faculty web-based training module was an overview of web-based instruction named Exploring Web Enhanced Education. The module includes a sampler of web components, a tutorial on incorporating web enhancements, an explorer of web enhancements, and a section on implementing web enhancements. The module is designed as self directed study and is used primarily to provide faculty with an awareness of how they might use the web to enrich their classes.

Additional modules are under development and others are scheduled for the future. A module on web authoring is well underway and a module on web design has been started. The next modules will include the use of templates to publish web pages and multimedia development.

New Challenges

Like most new initiatives, this project has encountered some difficulties. Development of web-based training requires a large commitment of resources. The Educational Technology Team at ERAU consists of three and a half instructional technologists and a graduate student. It has been difficult to reallocate those resources to web development and still maintain the expected service levels that had already been established. A reprioritization of services shifted some resource allocation, but the most productive solution has been a consistent focus on utilization of the web. In the past development of workshop materials was paper based. Today materials and instructional elements are primarily web based. Many of the workshops already have enough web-based components to make conversion to total online delivery a much less daunting task.

Another solution was to outsource some of the development, a solution with its own set of accompanying problems. The first challenge was to find competent developers. That task was accomplished by offering a free workshop on the use of WebCT to interested developers. The workshop provided an opportunity to assess the developers' skills and to establish development expectations for them. While the workshop helped identify good developers, outsourced projects do require significant oversight and management.

The Future

The first steps in using the web to teach how to use the web show great promise for meeting ERAU's unique faculty development issues. It is anticipated that further implementation will provide all faculty members with effective web instruction.

Summary

Web-based training holds great promise in addressing the unique faculty development challenges at ERAU. The evolution from face-to-face workshops to web modules is underway. That process is being accomplished by converting existing paper-based materials to web components and outsourcing development of other web components.

Using Multimedia in Distance Teaching

Gustavo Portela, Raimundo Viana, Eduardo Albuquerque
Instituto de Informática, Universidade Federal de Goiás, Goiânia, GO, Brazil
E-mail: {gjardim,raimundo,eduardo}@inf.ufg.br
Home Page : <http://www.inf.ufg.br/~eduardo/pfc99>

Abstract: This paper describes our initial experiences in Computer Based Distance Teaching development. We have studied the application of multimedia of hipermedia in a networked environment. We have also studied languages such as Java language for developing interfaces. As final product, we have developed a mathematics course for high-school teachers.

Keywords : Distance teaching, model of course, network, multimedia.

1. Introduction

Brazil, as many other underdeveloped countries, presents huge socio-economic discrepancies. The investments in education are usually scarce and often mishandled, contributing to increase both the poverty and the inequality of welth distribution. Besides that, Brazil is a country of continental dimensions, with vast cultural and social diversity among its regions. Distance learning may be a key aspect to reduce some of these deficiencies and to promote the education from the basic level to the superior level and also to increase the specialization and professional modernization of a country with these characteristics.

This work presents the fundamentals of a distance learning project. The project has been developed at Goiás Federal University, in Brazil, and its major objective is to create a model for implementing distance learning courses with an intuitive interface. These courses must also help the teachers on their practical activities, providing direct access to sophisticated multimedia resources, without forcing them to know the details of modern WWW based languages. Moreover, there should be means of assessing the students.

2. Objectives

a) Creation of a Model of Course

The main objective of this project is the creation of a model for distance courses, using computing resources. This model should specify the main characteristics of user interfaces, tools and techniques of multimedia creation and advanced resources of programming that should be used for the setting up each course.

We propose a generic model that should support the needs of the different contents and disciplines that can be taught at distance. It is important to validate this model with a practical case study, taking into account all aspects of the reality to be modeled.

b) Implementation of the Model

The validation of the model will be performed via the creation of a prototype for teaching a mathematics course at distance, using multimedia resources and the Internet. Once again it is important to make it clear that this practical setting up aims to validate the proposed model through a concrete example. In this case, we chose the context of recycling public high-school maths teachers.

Figure 1: Traditional explanation

3. Prototype

As an application of some of the multimedia resources, we have created a simple model to teach the Theorem of Tales. In this example, the user interface was designed to simulate the notion of a notebook, something very familiar to the students (Figure1).

In the first part, the contents of the subject were exposed in the traditional form, that is, a textual explanation and some related images. After this, we have created two alternative techniques for reviewing the subject: Cine Room (Figure 2) and 3D Room .

In Cine Room we have used Shockwave resources in order to create a kind of video class, where the subject is explained in the animation form. To facilitate a larger interaction between the student and the presented subject, we implemented a remote control device, allowing the student to control the animation.

Figure 2: Cine Room

In the 3D Room the student has the opportunity to navigate in a non-immersive virtual reality around the model that represents the presented subject. This allows the student to visualize and to understand the problem from different perspectives.

We also have a Chat Room, where students and teachers have the opportunity to propose questions and to clear up doubts. This model is geared towards the requirement of simplicity that the user interface of a learning system must provide.

4. Conclusion

Distance learning provides techniques and means that allows the students to understand the importance of their roles in the learning process. It places the student in the position of active subject of its own formation and leaves to the teacher the role of facilitator of this process.

Comparing to traditional systems of teaching, there is a considerable reduction of costs, involving the elimination of expenses from students and teachers deslocations, and the availability in places of difficult access, eliminating the need for deslocation from the work place to look for complementary formation. Considering these processes in scale, it overcomes the high costs of the initial investments to implement a distance learning system.

Although it presents many advantages, we are aware that the distance learning is not a panacea to correct all the educational problems. It cannot, in any way, substitute the traditional education, and neither it can complement all the defficiencies of this educational system. Distance Learning is an important piece of the educational process, and it should always be considered in this holistic context.

Our project is a cell that will compose an entire system of development of applications related to distance learning systems. With the implementation of more projects of this type, within governmental or private organizations, we intend to disseminate the search for solutions and for the improvement of the education in our country, guaranteeing, therefore, a better life condition to our people.

CONSIDERATIONS TO KEEP IN MIND FOR THE EVOLUTION OF A MULTI-AGENT SYSTEM

Angela Carrillo Ramos - acarrill@uniandes.edu.co
Universidad de los Andes - Systems and Computing Department
Santafé de Bogotá, Colombia

Abstract

Some aspects of an organization may be model with Multi-Agent systems (MAS) [Ucr96], specially those that require workgroups. Due to the dynamic nature of an organization, an MAS may evolve because of the changes that appear in the organization in which it is found, changes in the system itself (inclusion or exclusion of agents, new knowledge, renewal and/or update of system policies) , among others. This paper discusses some of the considerations that have to be kept in mind for the additions the system must have related to functionality, control, communication and knowledge to make the MAS flexible and capable to respond to the organizations dynamics. The coordination role becomes very important for the before mentioned aspects. For the modeling and specification of the MAS coordination, the YUBARTA model was used [Car98].

Key words

Coordination, Multi-Agent Systems, YUBARTA model, GroupWare, Evolution.

Introduction

The YUBARTA model is a system made of a set of modules or entities logically intelligent and independent called "agents". Each one has knowledge, about one or more areas, that makes them capable to deduce new knowledge and to answer questions or solve problems related to those areas. Also, working as a group, these entities have the ability to solve more complex problems. In other words, they are able to communicate at a high level: cooperation, coordination and negotiation to execute actions and solve conflicts; control to if they are getting closer or not to a solution of a problem, among others. Cooperative environments formed by a set of intelligent entities that interact with each other to find the solution for a problem, can be modeled and specified. The gathering of these agents make the multi-agent system (MAS); All their characteristics and those of the agents are better studied in [Ucr96].

Functionality, knowledge, control and communication are part of the agent's architecture (See figure 1). The homogeneity on ontology is very important, because with this there is no need for a translator or for an interpreter of knowledge and concepts between the model's agents, even if their knowledge representation differs [Ucr96].

Figure 1: An agent's architecture

In this paper each one of the changes that may occur in the system's evolution and its effects in the MAS is described. This evolution is proposed from the YUBARTA model [Ucr96], that more than a model is a tool for modeling and specifying cooperative systems; it offers, both, a mechanism for abstract workgroup representation (the model) and a formal language to specify the dynamics of the represented system.

Conclusions

When the conditions in which an MAS was design change, the need for it to evolve is imminent. For such a job, is necessary a coordination job, because there must be one in charge of making the evolution as effective and efficient as possible, and check other's labor (coordinator – coordinated scheme). Whatever the change may be, it will affect every agent's architecture, due to the constant communication between the system members. Changes and evolution spread, and it is in that point that lot of care must be taken to take advantage of communicating to learn from other's experience and to consult external sources when no agent knows what to do or how to carry out new tasks resulting from the evolution. Furthermore, all the agents must be ready to learn and know how to communicate new knowledge, along with knowing how to reuse the acquired knowledge of previous processes (experience).

It is worth to mention that this evolution may be easily implemented, because in [Car98] there is a complete and detailed specification. In general, it may be applied to any MAS, and specially those needing a strong coordinating labor. If there is no coordination because of lack of it or because there is no need for it, an agent may take these concepts and evolve with no need of a coordinating agent.

Web Applications as a Framework For Information Engineering Technology Education

Ashraf Saad, Sam Geonetta, and Vladimir Uskov
Information Engineering Technology
OMI-College of Applied Science
University of Cincinnati, USA
Ashraf.Saad@uc.edu, Sam.Geonetta@uc.edu, and Vladimir.Uskov@uc.edu

Abstract: Due to their integrative nature, we advocate that Web applications can provide a unifying framework to the course offerings of the Information Engineering Technology program at the University of Cincinnati's OMI-College of Applied Science. We believe that Web applications can provide a *solid foundation* for IET education since several IT technologies can be taught within such a framework, including: *Programming, Database, Multimedia, Networking, and Client-Server Systems concepts*. Web applications can also be used for the development of Senior Design Projects as well. That in turn will enable IET students in acquiring the advanced technical IT skills that are highly sought after by their future IT employers.

1. Introduction

A fundamental change is taking place in the economic structure of developed countries. Information technologies and the Internet have radically changed the way companies conduct business and the way organizations, governments and educational institutions strive to accomplish their respective missions. This has led to a rapid increase in the demand for skilled Information Technology (IT) professionals that are capable of integrating a variety of information and multimedia technologies in support of advanced software applications [ITAA 98]. Such demand, however, has not been met by a matching supply of workers [DOC 98].

2. Motivation

To help meet this demand, the University of Cincinnati's OMI-College of Applied Science (OCAS) has developed the Information Engineering Technology (IET) program to increase the pool of qualified IT workers for the State of Ohio and the nation [Uskov&Saad 98]. The program leads to the Bachelor of Science (BS) degree in IET and offers students the opportunity to master several information technologies prior to joining the workforce, in addition to a solid general education background and practical real-world experience via cooperative education (co-op) placements in industry. The program supports a "2+2+2" seamless transition for students from their junior year in high school, through an associate of applied science degree at the Community College level, or at the University of Cincinnati (UC), and onto the IET program to obtain their BS degree. A recent grant award by the National Science Foundation (May 1999) provides support for an Advanced Technological Education project that will enable us in transforming the IET program into a national model for IT education. The goals of this project titled "*An Evolving Program to Prepare Information Technologists in Southwest Ohio for the 21st Century*" include [Saad&Uskov 99]:

1. Evolutionary and progressive course and curriculum development that is competency-based, using the recently finalized (July 99) IT Competency Profile for the State of Ohio (available online at www.itWorks-Ohio.org).
2. Faculty development workshops to update the IT skills of instructors and faculty at all educational levels.
3. Industrial co-op opportunities at local and regional IT businesses for all IET students.

3. Why Web Applications?

In order to achieve the objectives of our ATE project, it has become imperative to provide a more comprehensive vision for the course offerings of the IET program for the three following reasons:

1. *Faculty perspective:* Our goal is for a better integration of all IET courses leading to a whole (the IET curriculum) that is much more valuable than the sum of its parts (individual IET courses).
2. *Student perspective:* IET students, therefore, would be the primary beneficiaries of this curricular integration.
3. *IT Employer Perspective:* IT businesses and companies are looking for highly skilled IT workers that not only possess valuable hands-on skills with a variety IT technologies, but that can also see *the big picture* of a given IT application being integrative in nature, comprising various software and hardware modules.

Thus a comprehensive vision for all IET course offerings would call upon using an *applied system-oriented approach* that can support the desired course integration. It therefore became obvious that Web applications can provide us with the framework we need to integrate IET course offerings for the following five reasons:

1. *Web applications are typically client-server applications:* Web applications can therefore be used as the vehicle to introduce students to the theory and practice behind the development of client-server systems.
2. *Web applications involve a significant amount of programming,* whether HTML, a scripting language, or a compiled language. A Web application can therefore be used to teach programming at all levels.
3. *Web applications can incorporate the use of a database:* Many web sites currently store information in databases that are dynamically accessible through active server pages.
4. *Web applications typically incorporate the use of multimedia:* Web sites have evolved dramatically over the last three years, moving away from pure textual information to a rich content format that incorporates audio, graphics, animation, as well as streamlined audio and video.
5. *Web applications are typically networked applications:* Connecting a web application to the Internet cannot occur without the connectivity provided by local and wide area networks. Therefore, teaching the theory and practice of networking can be taught in the context of supporting the deployment of client-server Web-based applications that not only integrate a database, but also multimedia features that may require special networking software and/or hardware.

These five aspects of Web applications provide *a solid foundation* for IET education since several IT technologies can be taught within such a framework, such as:

- *Programming:* Object-Oriented Programming, Event-Driven Programming and structured programming.
- *Database:* Databases and database management systems.
- *Multimedia:* tools to create graphics, animation, sounds/audio and video.
- *Networking:* Local Area Networking and Wide Area Networking.
- *Client-Server Systems:* Tools to create Web-based client-server systems.

4. Web Applications as the Basis for Senior Design Projects

In addition to providing a framework for all IET course offerings, Web applications are increasingly becoming the topic of Senior Design Projects of IET students. Senior Design projects that are currently under development fall in two distinct categories:

1. Projects in support of business applications: several student projects under this category are Web applications that are of relevance to a local IT company or organization.
2. Projects in support of educational applications: projects that fall under this category will enable the faculty of our department to offer Web courses in support of the College's Distance Education Objectives.

In summary, we believe that Web applications can not only provide a unifying framework to the course offerings of the IET program, but also for the vast majority of the Senior Design Projects as well. That in turn will enable IET students in acquiring the advanced technical IT skills that are highly sought after by their future IT employers.

Building a Web-based Organizational Learning and Information Support System (OLISS)

Mark Salisbury and Jan Plass
Organizational Learning & Instructional Technologies
University of New Mexico
Albuquerque, New Mexico, USA 87131-1231
salisbu@unm.edu
jan@unm.edu

Abstract: This is an in-progress short paper on the development of a Web-based Organizational Learning and Information Support System (OLISS). Designed for users with different levels of knowledge and with a variety of functions within a government agency, our OLISS application has six major capabilities: 1) online reference materials, 2) search, 3) communication, 4) instruction, 5) decision support, and 6) knowledge management. In this short paper, we discuss the features of these capabilities and the methodology we used to identify and evaluate the usefulness of the features.

In this in-progress short paper, we describe the development of a Web-based Organizational Learning and Information Support System (OLISS) that serves a diverse group of users for a wide variety of purposes. Designed for a government agency, the system is developed to support the application of "standard" business policies and practices across the organization. The system provides "just in time" capabilities for users of the system to apply these standard business policies and practices within the ongoing context of their everyday work. Users come to the system from different jobs, experience levels in their jobs, and knowledge of the standard business policies and practices. All the capabilities, in one form or another, provide not only a mechanism for individual learning but also a means for capturing and disseminating newly created knowledge in the organization.

In Figure 1, shown below, we list the major capabilities of the system and the categories of end-users. End-users of the system are *Members*, *Managers*, and *Customers*. Members are members of the organization and are directly responsible for correctly applying the business policies and practices on an everyday basis. Managers are supervisors of the members that apply the policies and practices but managers do not use them as part of their own daily work. Managers are, however, responsible for the correct application of the policies and practices by the members of the organization that they supervise. Customers take possession of the products that result from the application of the policies and practices by the members of the organization. Customers have a vested interest in the correct application of these policies and practices since it affects the quality of the product that they receive.

The capabilities of the OLISS system were designed with the diversity of end-user groups in terms of their function within the organization (Member, Manager, Customer) and their different knowledge levels in mind. A checkmark in the intersection between the row of a capability and the column of an end-user category indicates that it is a capability designed for that type of end-user. For example, in the second row of the reference materials capability, related materials, there is a checkmark in the category Members and no checkmarks for the categories of Managers or Customers. This means that Members of the organization will probably use related materials but Managers and Customers will probably not use that capability. Managers and Customers will probably get all the reference documentation that they require by accessing the procedure & policy documentation on the Web site.

In our case study, having online *reference materials* is an important capability. As Figure 1 shows, all users will benefit from easy access to online documentation describing the policies and practices. Organizational Members, however, will also benefit from easy access and cross-reference of related online materials. It will help them to ensure that the application of the policies and practices are consistent with the other regulations that they must follow. Managers and Customers do not benefit as much from access to these related materials.

Figure 1. Capabilities of a Web-based Organizational Learning and Information Support System (OLISS)

As shown in Figure 1, the *Search* capability provides an important service to the end-users of the Web site. It allows a free-form text search where end-users can type in keywords or phrases and return references to all the pages on the site that match the search criteria. It provides quick access to materials that relate to specific topics.

The *Communication* capability of our case study has four features. The first one is a "points of contact" e-mail feature -- allowing users to contact experts within a subject area. The second one is a "Q and A" feature that allows users to post questions on a listserv. The third feature provides a means to collect frequently asked questions into a FAQ list. The fourth feature is a threaded discussion list that allows users to follow the discussion of only those issues that concern them.

Instruction is an important capability in the design of our OLISS Web site. In Figure 1, we see that members of the organization will benefit from all the instruction that is available -- instructor led and stand-alone. The instructor led feature provides members an opportunity to ask questions concerning specific details relating to the application of the policies and practices. Managers and customers, however, can meet their needs with stand-alone instruction.

The *Decision Support* capability has two types of features. The first one provides for a guided search for the policies and practices. The second feature provides guidance in the completion of the steps for a policy or practice.

The *Knowledge Management* capability of the OLISS has two types of features. One is a means to capture and disseminate case studies. Case studies are general examples that illustrate the correct application of a policy or practice. Many times case studies are used for instruction. The other feature provides for the capture and dissemination of examples that show the correct application of policies and practices in the field. Using these two features, the knowledge management capability allows the capture and sharing of new knowledge -- concerning the application of the policies and practices -- as it is created in the organization.

We developed this list of capabilities through numerous interviews, meetings, and an analysis of the current training materials for the business policies and practices. We designed a prototype system with these capabilities that is currently undergoing an evaluation study. We plan to use the results of the study to finalize the requirements of the completed system by identifying the most useful features for the projected end-users.

Increasing the Adoption of Online Teaching by Modelling Good Practice

Graeme Salter, Department of Computing and Information Systems
University of Western Sydney Macarthur, Australia, g.salter@uws.edu.au

Steve Hansen, Department of Computing and Information Systems
University of Western Sydney Macarthur, Australia, s.hansen@uws.edu.au

Paul Davies, Department of Computing and Information Systems
University of Western Sydney Macarthur, Australia, p.davies@uws.edu.au

Abstract: An ever increasing number of academic staff are interested in online teaching. It has been found that staff are likely to benefit by actively experiencing online skills as a learner and that those who have positive experiences and have adequate support are more likely to integrate technology into their own teaching. Nevertheless, staff development activities, at least in Australian universities, still clearly favour 'traditional' methods. This paper examines the integration and modelling of effective online teaching strategies within a staff development program aimed at mainstreaming web-based teaching at the University of Western Sydney.

For a variety of reasons, large numbers of academic staff are taking an interest in adding web-based or online teaching to their repertoire. However, even with incentives and a willingness to change, teachers often retreat back to comfortable, more traditional teaching methods. There is often a discrepancy between 'espoused theory' made up of governing values and actual 'theory-in-use' [Zuber-Skerritt, 1992]. Even those who provide professional development exhibit this tendency - a recent study into staff development activities in Australian universities, related to online teaching, found that traditional modes of presentation were still clearly favoured over online methods [Ellis, O'Reilly, & Debreceeny, 1998].

One of the problems associated with traditional staff development activities is that they tend to attract the same people - usually the best teachers [Zuber-Skerritt, 1992]. Some staff may be reluctant to attend as they feel it may demonstrate a deficiency. Many more probably fail to attend simply due to time pressures. Providing staff development modules online not only models good practice, but also provides the advantages we so readily espouse for our own students. It allows staff to work at their own convenience, in private if they wish, set their own pace and target their 'just in time' needs.

While the simple process of moving content onto the Web provides increased availability of resources, many of the major benefits in online teaching are related to totally new teaching methods such as the moderation of discussion groups. Effective online teaching involves more than transferring successful face-to-face strategies. There is a significant need for staff development in web-based teaching and it is desirable that staff become comfortable with online strategies as learners themselves [Freeman, 1997; Wills et al., 1997].

Interest in this area arose from the initial success of PlatformWeb, a web-based teaching environment developed at USWM. A large number of staff, many who would not be considered 'innovators', are now trialling online teaching. Most software systems are developer-based and require the user to adapt to the system. The success of PlatformWeb is due, in large part, to using an adopter-based approach to design, which allows the system to adapt to the needs of the users. One of the key factors in this approach, modelled on Burkman's theory of user-oriented instructional development [Surry & Farquhar, 1997], is to provide significant post-adoption support.

As part of the user-centered approach a survey of academic staff at UWSM was conducted [Hansen et al., 1999]. It was found that concerns regarding traditional teaching delivery could be grouped into three main areas - general administration problems; general and specific communication to/from students; student attitudes and study habits. It is interesting to note that none of the respondents mentioned a possible fourth area of deficiency

– that of the teaching itself! With regard to moving to web-based teaching delivery concerns also fell into three categories – developing and learning web technology; use of existing material and resources; technology issues. By addressing these issues and continually developing the PlatformWeb environment based on user responses large numbers of staff are moving material onto the Web. Nevertheless, without sufficient post-adoption support it is likely that the bulk of users will drop the innovation as quickly as they moved on.

The staff development program associated with PlatformWeb does not adopt an ‘all-or-none’ approach with respect to delivery. It is made up of many traditional components, such as workshops and seminars, in addition to the online component which seeks to model best practice. The Web-based section contains benefits, problems, strategies, examples, issues and references for each online method currently available within PlatformWeb. The examples, where possible, make use of the technology (eg. online discussion groups).

Some common themes provided by experienced practitioners in online teaching are the need for structure, relevance, support and the importance of the teacher-student relationship. At the ‘classroom’ level, the literature provides a wide diversity of strategies. Sometimes the advice can be contradictory. For example, some encourage the use of lurking in discussion groups [Freeman, 1997; Shneiderman et al., 1998] while others discourage it [Klemm, 1998]. Nevertheless, a range of strategies and examples are provided to allow staff to select what might work best in their own teaching context.

Research is currently underway to see the extent that online methods can compliment more traditional methods of staff development and to identify any trends in the characteristics of staff who prefer such methods.

Abstract: This paper proposes a model relating student profiles and learning outcome in distance education courses offered on the Web. These profiles include: Age, GPA, ESL, learning strategy, attitude, motivation, and satisfaction. Data analysis so far has validated the influence of attitude and learning strategy variables on learning outcome. The conclusion is that students do best when their attitudes are matched to course format. Further, the Web is very conducive to students who use surface learning strategy that emphasizes memorization and reproducing ability.

Objective

Many Web-based courses subscribe to the paradigm that students learn equally if given the same materials. This ignores the fact that students bring with them a baggage of variables that influence their performance. During the evolution of instructional technologies in the last three decades, researchers have explored several issues regarding student learning performance in distance education. Earlier studies have compared performances between telecourses and lecture classes for groups of students but have largely bypassed the possible effects due to individual differences [Moore & Kearsley 96]. This research investigates what individual learner profile variables are likely to improve learning outcome in Web-based courses.

Figure 1: Proposed model showing variables influencing Performance in Web-based education

[Fig. 1] shows the complete proposed model that is currently being investigated. Preliminary results on effect of attitude and learning strategy as learner profiles on learning outcome are now available.

Methodology

The subjects of this study were students enrolled in an undergraduate business computer course (N=137). Fifty-six students chose the Web format and the remaining chose the lecture. The instructor covered the same course content

in both formats. Students were given a pre-test to measure their knowledge of content. As a measure of performance, all students were given the same final test in a lecture hall. A survey measured the students' attitude to Web and learning strategies.

Results

Student Attitude and Learning

The Attitude to Web Score (AWS) was measured on a range of 1-5. The AWS for the Web group was 3.3, and for the lecture group was 2.7. The difference was significant ($t=3.153$; $p=0.001$). There was no difference between the Web and the lecture group in the final test scores (43.7 for the Web group vs. 44.3 for the lecture group ($t=.732$, $p=.498$). Additionally, when we computed the amount of learning achieved by subtracting the pre-test score from the final score, there was no significant difference between the groups either. The authors wanted to know how the performance was affected if there was a mismatch between attitude to web score and course format. Students with AWS of greater than 3.7 were considered Web-oriented, between 2.3 and 3.7 format-neutral, and those below 2.3 lecture-oriented. Their mean incremental test scores are in [Tab. 1]. Most gains were made when the attitudes towards Web and lecture were matched to the course formats.

	Web Oriented	Lecture Oriented	Format Neutral
Student	Incremental Scores		
Took Web course	15.4	8.2	11.4
Took Lecture course	9.3	18.8	12.3

Table 1: Relationship between Attitude and Incremental Test Score

Student Learning Strategies and Performance

We studied the two types of learning strategies proposed in literature [Hoeksema 95] - deep (thorough understanding) and surface (memorizing). Our analysis showed that students who used either deep or surface learning strategies performed equally well ($t=.294$, $p=.755$). The reason can be that in practice, deep learning is often not required to satisfy many university examinations [Vermunt 96]. In this study, students who used deep learning strategy performed slightly better in the lecture group, whereas those who used surface strategy did slightly better in Web group. The explanation could be that the Web, with no direct verbal interaction, lends itself better to the presentation of course material in a structured manner. Important points in the material can easily be picked from the concise and organized web materials than in the detailed explanations of a lecture.

Implications

Students do show their preferences to formats in which they wish to take their course and perform better when they match the format. Thus, it would be beneficial to offer a course in multiple formats if at all possible. Our study also showed that students who use either deep or surface learning strategy perform well in both Web and lecture courses. Since the course content in both formats in our study was the same, it appears instructors who are planning to offer their lecture courses in Web format may be able to adapt their material with minimum redesign. This is encouraging to instructors who are contemplating the use of Web-based courses for the first time.

Grammar Based Navigation Flow Control For E-Commerce Applications

Ramesh Sarukkai
158 Concord Rd. K-19
Billerica, MA-01821

Abstract: A novel approach to web site navigation design is proposed in this paper. The design of a web site is viewed as a task decomposition that can be represented in the form of a context free grammar (CFG). The terminals of such grammars are URIs. The CFGs are written to clearly capture the task-structure of the web site. An algorithm is presented which will convert such grammars to a linked web site. The URIs are linked to each other using the FIRST/FOLLOW set information in order to produce the web site navigation design. An example application demonstrates the utility of the proposed CFG approach to web site navigation design.

1 Introduction

One of the important aspects of E-commerce application web page is the definition of transitions between pages within a domain. The design of the link structure in hypertext domains is crucial for building flexible and efficient navigation systems. The common approaches to design of navigation link structures are:

- a) Graphical Approach: Heuristics that designers use based on web site development experience. This is usually done with the help of graphical web site development tools.
- b) Database approach: The problem of navigation is viewed as a database access problem, and various database techniques applied towards the navigation link design. For instance, [Shwabe & Rossi 98] defines navigation class schema that's manually constructed, and various example scenarios used to actually develop navigation structures.

2 Web Sites and CFGs

It is important to structure these link transitions, rather than solely rely on the web page designers structural view, or depend on example scenarios that are difficult to generate/obtain. As an alternative, we present the "Context Free Grammar Based Flow Control Determination". The idea is to layout the web site structure in the form of a grammar. The algorithm for designing web sites using CFGs is as follows:

Algorithm CFGLinkage

- Step 1:** Write the web site as a CFG
- Step 2:** Identify Non-terminals that derive in a single step to terminals (URIs)
- Step 3:** Compute the FIRST and FOLLOW sets of all non-terminals
- Step 4:** Reduce the sets determined in step 3 using only non-terminals identified in step 2
- Step 5:** Extract the linkage structure using the output of step 4

3 Example Design

For example, a generic E-commerce application can be specified as follows: (Remaining non-terminals 1-step derive URIs).

```
<ECOMM_APP> --> <INTRODUCTION> <NEW_PURCHASE> <GOODBYE>  
<INTRODUCTION> --> <HELLO_KNOWN_USER> | <HELLO_NEW_USER>
```

```

<NEW_PURCHASE> --> <SELECT_ITEM> <BUY_TRANSACTION>
<BUY_TRANSACTION> --> <GET_CUSTOMER_INFO> <VERIFY_PURCHASE_LIST> <COMPLETE_PURCHASE>
<COMPLETE_PURCHASE> --> <AUTHORIZE_PAYMENT> <DO_TRANSACTION>

```

Individual web pages are classified into modules such as *<INTRODUCTION>* pages, *<GET_CUSTOMER_INFO>* pages and so on. These smaller modules can themselves be represented in terms of a context free grammar as non-terminals (hyperlinks). Next, we apply techniques from Grammar and compiler theory [Aho et al 99] in order exploit such CFG (Context free grammar) structures. Each term in the grammar within angled brackets (<.>) can be regarded as a non-terminal. The FOLLOW(<N>) can be computed using the algorithms specified in [Aho et al 99] (to build parsers). <N> is a non-terminal in the grammar. The FOLLOW set corresponds to all the nonterminals that can follow the nonterminal <N> as specified by the grammar. Now, certain documents belonging to the nonterminal set can be classified as "ENTRY" and "EXIT" pages. Each page P in the set <X> will have links to the FOLLOW(<X>)). Thus, the structure embedded in the context free grammar is incorporated in the web document link structure.

We have implemented a Java program that takes in a CFG as input and produces the set of follower links for each non-terminal. Thus, given a web site grammar, the Java program automatically generates the web site link structure. The proposed approach also allows the concept of "virtual hypertext documents". These correspond to non-terminals that are purely used in the structuring of the web site and do not have any URI addresses associated directly with them. The FOLLOW set of the example grammar shown above is computed, and the FOLLOW sets of all non-terminals that have a one step derivation to terminals are used to make the web site traversal graph.

Using the above method, the web site navigation can be constructed as shown in [Fig 1].

```

FOLLOW(<HELLO_KNOWN_USER>) = { <SELECT_ITEM> }
FOLLOW(<HELLO_NEW_USER>) = { <SELECT_ITEM> }
FOLLOW(<SELECT_ITEM>) = { <GET_CUSTOMER_INFORMATION> }
FOLLOW(<GET_CUSTOMER_INFORMATION>) = { <VERIFY_PURCHASE_LIST> }
FOLLOW(<VERIFY_PURCHASE_LIST>) = { <AUTHORIZE_PAYMENT> }
FOLLOW(<AUTHORIZE_PAYMENT>) = { <DO_TRANSACTION> }
FOLLOW(<DO_TRANSACTION>) = { <GOODBYE> }

```

iNK (interactive News for Kids) – a web-based collaboration and learning environment for children.

James Sawers, Institute for Interactive Multimedia, University of Technology, Sydney, PO Box 123 Broadway NSW 2007, Australia. Phone +61 2 9514 1627 Fax: +61 2 9514 1666 james.sawers@uts.edu.au

This paper introduces a system developed in 1997/98/99 by the Institute for Interactive Multimedia (IIM) at the University of Technology, Sydney (UTS) in collaboration with the Australian News Limited group. iNK (Interactive News for Kids) is an integrated web-based resource center and collaborative authoring, workflow and publishing environment for primary and secondary students that is specifically designed to allow students to concentrate on producing an online newspaper and not on the underlying technology. In this paper the author will introduce the features of the system and discuss some of the underpinning pedagogy that informed the conceptual, prototyping and design phases.

The iNK system is designed to 'help students learn the skills involved in how a newspaper works', including:

- news reporting
- feature writing
- opinion writing
- picture stories
- headline writing
- caption writing
- using cartoons for political or social comment
- producing a newlist (understanding newsworthiness)
- publishing an on-line school newspaper

It was initially thought that the site could be a resource of static HTML materials related to the processes of journalism and news production and it was suggested that production of the online newspaper could be facilitated by manually marking up stories submitted by email. However on closer inspection this seemed both labour intensive and potentially unscalable.

Drawing on the author's experience with TopClass (a Web-based Learning tool) at UTS it was proposed that the learning experience should be engaging and qualitatively different from anything achievable face to face [Sawers and Alexander 1998]. After significant research into other available online resources it became evident that for the site to be successful it would need to be interactive, dynamic and collaborative and provide something more than the equivalent of lecture notes and support materials online [Alexander et al., 1998].

The site was designed to help students learn the journalistic processes by actively participating in the production of an online newspaper, by providing them with a team based role-play/simulation of the processes that occur in a 'real' newsroom.

A group of students and teachers register to produce an online newspaper for their school which eventually becomes a live edition in the iNK system. They are each assigned a role which has a particular behaviour and capabilities. By logging into the iNK newsroom (via a standard web browser) with a username and password they assume that role and are given a virtual workspace and a set of tasks to complete. The roles of cartoonist, photographer, reporter, sub-editor, chief of staff, editor and publisher are defined in the system and inter-relate in the following ways.

- the **editor** registers their students online to produce an iNK edition <http://ink.news.com.au/ink/register>
- the **publisher** contacts the **editor** by phone and then creates the edition.
- an email message is sent to the **editor** with details of usernames and login passwords.

- the **editor** logs-in to the iNK newsroom and invites the **news team** to participate in a news conference using the in-built messaging system.
- the **news team** send ideas for stories to the **editor**.
- the **editor** creates story briefs in the **newlist**.
- the **chief-of-staff** assigns the story briefs to **reporters** and associated image briefs to the **photographers** or **cartoonists**.
- the **reporters** receive their briefs, research and write their stories and then submit these to their **sub-editor** for approval.
- the **photographers** receive their briefs, produce images for the stories and submit these to the **sub-editor**.
- the **cartoonists** receive their briefs, produce images for the stories and submit these to the **sub-editor**.
- the **sub-editor** checks the work and if it requires changes to be made it is passed back (with comments) to the **reporters** or **photographers** or **cartoonists** who make the suggested changes and resubmit. This review-change cycle repeats until the **sub-editor** feels that the work is of sufficient quality to submit to the **editor**.
- the **editor** (a Teacher) checks the work and accepts it or if necessary passes it back to the **sub-editor** and so on down the line until there is sufficient work of sufficient quality to make up the full publication.
- the **editor** then submits the publication content to the **publisher**.
- the **publisher** checks the work and if it is appropriate and has been submitted within the assigned timeframe it becomes one of ten current on-line editions on the iNK server.

The iNK system was officially launched on the 19th of march in Sydney Australia and currently has 700 students and teachers producing work in the virtual newsroom. iNK can be found online at <http://ink.news.com.au>.

Acknowledgements

No system of this scope and complexity is the work of a single individual but the product of a team effort. The author would like to acknowledge the significant input of the following individuals; Professor Shirley Alexander (educational design), Maralyn Parker (news and journalism process research), Cindi Drennan (visual design), Kate Sumner (writing), Lissanne Oliver (iNK name), Andrew Francois and Danielle Hickie (visual design), Justin Mclean (Cold Fusion and SQL programming), Justin Maynard (proof of concept programming) and all the team at the IIM.

Thankyou all.

Abstract: This paper explores a classification system for the level of interactivity and the amount of instruction delivered online. First, we introduce the underlying need for better initial design of online courses. A brief review of other classification systems and models is presented. Then a rationale for this classification system is presented, explaining the choice of the two measures of level of interactivity and amount of instruction delivered online, as well as defining both measures. Ways to use the classification system in designing online courses are proposed.

An Introduction to Online Course Design Need

Within the higher education community, there is a great debate about how to best provide online instruction, or even whether online instruction provides equivalent learning to traditionally delivered courses (Russell, 1998). However, for many, including recent graduates of the first degree-granting, Internet-only university to receive accreditation (Jones International University), that debate is moot [Bulkeley, 1999]. With this increasingly popular perception that online education is inevitable, many universities, colleges, corporations, and other providers of instruction and training are rushing to convert existing courses to an online environment. As of June, 1999, TeleCampus, an education clearinghouse reports over 12,000 classes offered by 700 colleges and other teaching organizations located throughout the world [Thornton, 1999]. Confronted by this reality of tremendous growth in the demand for online courses, higher education administrators are facing a daunting task in developing a usable taxonomy to guide them through this morass. To aid in this attempt, we propose a process for identifying common characteristics of existing courses as well as characteristics of online courses. The proposed process is implemented graphically with an interactivity/online matrix, facilitating rapid examination of existing courses within a context of degree of interactivity employed in the course as well as the context of amount of instruction delivered online. To better understand the proposed matrix, a brief review of other classification systems and models is presented.

A Brief Review of other Classification Models and Systems

The ACTIONS (Access Costs Teaching Interaction Organization Novelty Speed) Model [Bourdeau and Bates, 1996] provides a connection between the instructional design and distance learning world. Analysis of each of the ACTIONS criteria aids in selection and use of technology for Distance Learning and focuses primarily on cost/media usage tradeoffs. Another model focuses on building interactivity into web courses using two categories of interactivity, social and instructional [Gilbert and Moore, 1998]. This model characterizes the level of teacher, learner, and group influences in computer-mediated learning along a continuum of instruction types which range from directive, content interactive, directed collaboration, collaborative to social. Another model called Asynchronous Learning Networks (ALNs) using Computer-Mediated Communication (CMC) [Hiltz, 1997] illustrated the proposition that online learning is more effective utilizing a collaborative learning design such as the ALN than a pedagogical approach with an individual working alone and posting the results online.

These models provide insight into the necessity to clearly understand why interactivity is being used or considered for use in an online environment. The matrix aids in clarifying where current or prospective courses fall in their use of interactivity and amount of instruction delivered online.

Matrix Characteristics and Rationale

The proposed matrix can provide an initial framework for comparison and discussion with administrators and with faculty and instructional developers. The form that results from examining the two characteristics of interactivity and online delivery yields a matrix with two axes that can be graphically presented. The matrix is designed to be used as a tool that facilitates the classification of current teaching methods as well as providing options for alternative ways of designing a course. To see the matrix, access the Internet and go to this URL:
<http://dle.byu.edu/research/matrix/>

The horizontal axis of the matrix is characterized as representing the amount of instruction delivered online. It ranges from the left hand entry that represents courses with no current online content to the right hand entry representing courses that have high online content. The vertical axis of the matrix represents the amount of interaction occurring within the course. The bottom left of matrix portrays courses that have no teacher/student or student/student interaction (from a point of view that states that lectures, delivered without a question/answer mechanism present no teacher/student interaction). Additionally, the course always meets face-to-face with the instructor delivering instruction in an uninterrupted lecture format. As one moves up the matrix vertically, the amount of interaction of both teacher/student and student/student increases until the top of the matrix is reached. At this row of the matrix, participation in group activities is required and high teacher/student and student/student interaction is typical. As one moves across the matrix horizontally, the amount of instruction delivered online increases until the entire course is delivered online, including course reading materials.

The matrix can be used to clarify to faculty and instructional designers where their existing courses fall in an online orientation. Another usage of the matrix could be to facilitate moving existing courses from one part of the matrix to another. It is appropriate here to indicate that no value per se ought to be placed on location of courses on the matrix. In fact, we urge that administrators not make value judgments about a course based on location on the matrix. Some courses such as business management case studies lend themselves to high interactivity while others such as physical fitness courses emphasizing individual fitness do not. A course located at the top, right of the matrix (high interactivity and high degree of online content) is no better designed than a course located elsewhere and may be less well designed if the interactivity inserted into the course is artificial and detracts from student learning.

Instructional designers can make effective use of the matrix as they work with content experts in developing courses. The matrix offers visual prompts for discussing appropriate uses of technology in new or existing courses. Online technologies currently available contribute to instructional designers' abilities to add more meaningful interaction to courses through synchronous chat sessions and dedicated group discussion areas. As designers and content experts discuss how the course is currently taught or envisioned to be taught, the matrix provides guidance in clarifying understanding of why a course is placed as it is on the matrix—some courses are best taught via more traditional methods with a high degree of face to face interaction. Similarly, course content also can determine the amount of instruction that can effectively and efficiently be delivered online. For example, a current course which relies heavily on printed material may continue to employ printed material rather than place that material online when the course is converted to an online alternative.

Ways to Use the Classification System when Designing Online Courses

The matrix is a web-based, interactivity tool that can be used by educators to explore different design options for combining interactivity and the amount of instruction to be delivered online. This classification system is currently being used at the university level to assist instructional designers collaborating with faculty in designing online courses. The sample scenarios provided in the matrix help faculty realize that there are a variety of approaches to using online learning in the classroom and at a distance.

Future Research

Future versions of the matrix may consider course characteristics such as types of multimedia supported via the instructional environment, degree of mediation, types of learning styles supported, number of learning modalities supported, and degree of synchronous scheduling required. Other aspects of research to consider?

Note: this presentation and the matrix it highlights represent the current iteration of an ongoing research project. Some courses have been identified as examples for particular cells in the matrix. While every effort has been made to correctly classify each course example, given the information that was available, this matrix does not constitute a comprehensive analysis of all the courses offered by any of the institutions listed. (This would reveal who we are).

Collaborating Across Disciplines and Departments to Create a Virtual Foreign-Language Library: A Work in Progress

Department of Humanities, Michigan Technological University, USA, mmayer@mtu.edu

Abstract: A multicultural, cross-disciplinary team has initiated a three-phase project to create a virtual foreign-language library focusing on Spanish. In this paper, phase one—determining heuristics and analyzing a sampling of existing FL-web-sites and virtual FL-libraries—is discussed.

At Michigan Technological University (MTU), a team comprised of one foreign-language (FL) educator and two librarians, one of them specializing in web design and the other in visual representation, have come together to create a pilot virtual FL library. This library will be designed to support technology-intensive FL classes, to enhance student engagement in FL courses and in intercultural communication, and to integrate information literacy skills into the FL classroom. The pilot project focuses on resources in Spanish language and culture, and consists of three phases: 1) determining heuristics and analyzing a sampling of existing FL web-sites and virtual FL libraries; 2) determining and organizing the content to be included in a pilot virtual FL library; and 3) creating a model multimedia web site for delivering this library. Phase one is the focus of this paper. Major goals for this phase were the establishment of heuristics that would guide both the initial analysis and the development of our virtual FL library, and the comparative analysis of virtual FL resources.

The creation of a specialized virtual library requires diverse kinds of traditional and evolutionary expertise, as well as new patterns of cross-disciplinary and organizational collaboration, especially among faculty and librarians (Hansen, 1997). It also raises fundamental questions regarding the distinctions between virtual and conventional libraries in regard to mission, defined audience/community, scope, content selection and creation, organization, access, maintenance, archival/preservation functions, continuity, and application of standards (Waters, 1998).

Team collaborators began phase one by conducting an extensive search for Internet FL resources focused on Spanish language and culture. Search results included organizational, educational, personal, and commercial sites created by private individuals including learners and native speakers of Spanish, K-12 teachers, university professors, and librarians.

After reviewing existing heuristics for web-evaluation and design (e.g. de Jong & van der Geest, 1999; Kristof & Satran, 1995) and web style guides for general and instructional web sites (e.g. Lynch, 1999) team members adapted these heuristics to accommodate the specific nature of FL sites and FL pedagogy and created a linear arrangement of heuristic elements—design, rhetoric, pedagogy, content, technology and representation. They then applied the heuristics to a few test sites. The test application revealed that the linear statement of heuristic elements failed to acknowledge the synergistic relationships existing among these elements both in theory and in their functioning within sites. For example, one site evidenced the rhetorical strategy of inserting the logo of an organization supportive of illegal immigrants' rights into a resource page. To emphasize these synergies, we designed a dynamic heuristic model in the shape of a hexagon.

The goal of our site analysis was to identify general trends and patterns. Our analysis of sites created by professional librarians, many of whom were subject specialists or coordinators, indicated that these sites were not titled virtual libraries per se. Instead, they were referred to as guides, collections, pathfinders, and resources, e.g., *Subject Guide to Internet Resources*, *Guide to Spanish Language Sources on the Internet*, *Latin American Collections*, *Internet Resources for Latin American Studies*, and *Pathfinders to Spanish Resources*. Unlike many other sites, FL virtual libraries displayed their mission statements prominently. In addition, their organizational structures were readily transparent to users and they provided evaluative annotations to guide users' selection of resources. They often provided access to licensed electronic resources and links to local departmental pages. Print resources housed in physical collections were made available through such means as subject pathfinders and the

inclusion of call numbers. Some of the sites maintained mirror sites in Spanish and English. Overall these sites added value to their physical and virtual collections by tailoring their web sites to the information needs and use patterns of their campus and larger community.

Given the above, these web sites conform to many of the common definitions for digital and/or virtual libraries: 1) "libraries that offer access to digital information using a variety of networks including the Internet and World Wide Web" (Saunders, 1999); 2) "information housed electronically and deliverable without regard to its location or time" (Saunders); 3) a collection of, or an organization underlying the collection and provision of, digital works so that they are readily and economically available for use by a defined community (Waters, 1998).

Analyzed sites that did not conform to these definitions could be placed in broad categories such as teacher-created resources, layperson guides, and commercial language tutorials. These sites displayed a much wider variety of structure, organization, content, scope, level of abstraction, sophistication, and design. Among the most striking characteristics of the analyzed FI web-sites were their hybridity and their fusion of educational, commercial, and personal, even ideological elements. This hybridity reflects the very nature of the Internet, hypertext, and digital technologies and led us to review our understanding of the virtual library, in particular the challenge of balancing collection/resource integrity—as practiced in the conventional library—with a philosophy of content inclusiveness. Resolving this tension, which is founded on the making of value judgements and the creation of standards, will be critical to the creation of our own virtual library.

Major issues for phase two of our project will include determining guidelines for providing access to and/or integrating collections of digital materials with materials in other forms (Waters), defining the areas of responsibility, decision-making, and authority for the librarian, educator and designer; formulating criteria for site inclusion; and determining which hypermedia technologies to employ in support of specific dimensions of FI learning and pedagogy.

Streaming Technologies in Tele-Learning

Dahchiun Shen
ghost@alice.asahi-u.ac.jp
Marion R. Finley, Jr.
finley@alice.asahi-u.ac.jp
Multimedia Laboratory
Asahi University
Gifu, Japan

Abstract: Initial results of a study on the potential application of streaming and related technologies in tele-learning are reported in the following. The emphasis is on the streaming of interactive three-dimensional moving images.

Introduction

Of all the technologies that exploit the potential of the Internet and the World Wide Web, one of the most intriguing and, at the same time, the most challenging from the point of view of implementation, are those that are summarized under the heading of "streaming." The intuitive idea is easily enough grasped: continuous information is sent from a source to a subscriber through the Internet in much the same way that a television broadcast signal is sent through the television broadcasting system, either via spatial channels or cable television channels, in an unbroken, smooth, continuous way. The signal is thus "streamed" and, if everything works well, one can receive on one's workstation a television program, an FM music broadcast, and other such continuously streamed information.

This method of transmitting information is to be contrasted with the method whereby a file of continuous information, video or sound, is first downloaded then played. In the case of streaming the action is virtually real-time: the source broadcasts and the receiver displays the contents as it comes in, whereas in the conventional download case, the source transmits a file which is stored locally, then may be displayed ("played") later.

Three-Dimensional Graphics and Streaming

Streaming becomes all the more interesting when one attempts to transmit three-dimensional images, specially as in, say, such as Nintendo's "Zelda." In such games, one may maneuver oneself around in three-dimensional space: it is as if the user her/himself were embedded in the space being displayed. This type of streaming places special constraints on the streaming technology being used: it must permit upstream signals in real-time that will change the sequences of images being transmitted downstream to the images corresponding to the change in spatial orientation.

The applications of streaming in general boggle the mind: video-on-demand, news services, games, stereo music, and many others suggest themselves. In this work, we wish to explore the potential uses of streaming in tele-learning. This work is part of more general work on tele-learning that is being carried out at Asahi University [Finley et al 1999] and represents work in progress.

In this work, we are examining the whole gamut of streaming technologies, Both those that will accommodate three-dimensional streaming as described above as well as the more standard non-interactive types. We are testing both plug-in versus Java-based forms of streaming.

Streaming with interactive three-dimensional graphics is very promising in tele-learning, since the student

will be able to navigate a "course" or "learning" space. That, just as in an interactive three-dimensional game such as "Zelda," the student will be able to follow various "paths" through the space in which the objects to be studied may be presented in three-dimensional form.

Work in Progress

At this point, the emphasis is on the implementation of such as system and not on the courseware per se, although clearly the latter is of a non-trivial nature and must necessarily be dealt with at a later time. The implementation problems include such matters as Internet delays, workstation power, coding and compression techniques and so on.

In this part of the study, we are making a detailed inventory of the tools existing today that will permit us implement three-dimensional streaming as described above and are testing various products that are promising for the intended applications. In the full paper, we shall give an overview of these technologies and of the trials we are currently designing for this form of streaming. At the conference, we hope to be able to give a demonstration of the system developed so far.

Abstract

The purpose of this paper is to briefly describe our research with respect to the development of several recording and portfolio tools. These tool can record events after they have occurred, present extant text material in hypermedia format, and create portfolios for students and teachers that automatically incorporate video evidence of accomplishment.

Past Recording Software

PastRecorder transfers audio events to a random access memory buffer that is constantly being rewritten (Speitel et al. 1997). The user selects a duration for the buffer (e.g., 10 seconds). When the user presses the "record" button the "past" is locked in RAM while the "present" is recorded to hard drive. When the user indicates that the recording should stop, the "present" audio is preserved on the hard drive, with the buffered past (in this example, 10 seconds) inserted at the front of the audio file. The user is provided with the advantage of being able to decide to record something *after* they have heard it, rather than unselectively recording an entire event, such as a meeting or lecture. Hence, the software's name, PastRecorder.

One of the aspects of machine interviewing that we are examining is further uses or applications for pastrecording. In previous research (Speitel et al. 1997), we described uses that included students in lectures, people in meetings, persons with learning disabilities, visual or motor impairments that might affect rapid note-taking capabilities in lecture settings. We are in the process of investigating persons with slight hearing impairments who might miss a few things that would be helpful to record.

Professional uses that we are investigating include:

- linguists who are targeting certain types of utterances for further study. The targeted utterances could be recorded via PastRecorder as an adjunct to a full tape recording of the entire conversation, so that the whole context can be preserved, yet specific utterances can be examined in rapidly.
- ethnographers who might be interested in looking for specific kinds of verbal interactions for study.
- foreign language and ESL teachers who wish to preserve certain utterances for further study or as feedback to students.
- speech pathologists and related professionals who wish to collect data from clients repeatedly as indices of progress and as feedback to clients who need to replicate specific kinds of utterances.

In this presentation we will briefly share the status of our work with PastRecorder and its uses and provide a brief demonstration.

Computer-Aided Electronic Science Book/Instructional Guide

The second prototype tool is a computer-based multimedia science text, based on the Hawaii Marine Science Studies (HMSS) marine science texts, *The Living Ocean: Biological Science and Technology of the Marine Environment* and the *Fluid Earth.: Physical Science and Technology of the Marine Environment*. The multimedia instructional guides incorporate the original texts, along with several forms of assistance or enhancement for students, including video, sound, text, and pictures (Speitel et al. 1999). Additional types of assistance include definitions, examples, hints, rewordings of text, pronunciations, pop quizzes, and cross-referencing between figures and text.

One of the foci of our development of the electronic science text is the development of materials that most effectively facilitate comprehension, especially among low-level reading or low-level science students that might lack metacognitive skills and be less likely to effectively monitor their own understanding. This process becomes

even more central in working with multimedia presentations that afford numerous decisions on the part of readers about what they will examine further, etc. (Iding In Press). To facilitate metacognitive skills, especially effective comprehension monitoring skills, we are working with several major goals or questions that accompany our development of the science text. How can strategies be taught embedded within the book to facilitate effective comprehension monitoring and decision-making processes? What are optimal forms of note taking that can be built into the book so students may create "records" of their interactions in this type of environment?

Computer-Aided Electronic Portfolio Prototype Tools

Student electronic portfolios provide tools in which students can record and assess what they know or are capable of doing in ways that are useful for instructors and/or peers and others to view and respond to. Electronic portfolios can incorporate video, audio, and textual data. Questions that guide our current development of these prototypes include: What are factors that contribute to likelihood of teachers' use of these tools? Which aspects of electronic portfolios can most effectively be incorporated on-line with the electronic science book so teachers and students can incorporate the ongoing scientific investigation and inquiry so essential to the constructivist framework in which the science text was originally designed?

Electronic portfolio tools would be especially effective in conjunction with science texts because students can explain their own understandings of scientific phenomena. Students' levels of understanding of scientific phenomena as revealed via their own explanations would be of particular interest to teachers as students' potential misconceptions or preconceptions or incomplete understandings can be readily detected and challenged, if necessary. Additionally, students can challenge their own and each other's levels of understanding in a collegial and collaborative fashion, and, in viewing individual portfolios, see the development of appropriate levels of understanding or more complete understandings over time. This use of electronic portfolio tools as a performance assessment for students' and teachers' ongoing hypothesis building also provides a framework for epistemological development in science, and for attitudinal change.

Conclusion

In addition to facilitating science learning, several of these tools (e.g., PastRecorder and electronic portfolios) and related research among all of these technologies can be used to enhance learning in other content areas. Finally, as a conclusion to our presentation, work with teachers and their suggestions for optimal incorporation of such instructional tools into classes and existing curricula will be discussed.

In this paper, we present an innovative, web-delivered learning environment for teacher education, the Generative Virtual Classroom. This virtual classroom was designed to address a set of longstanding and seemingly intractable problems concerning the failure of teacher education to stem the tide of students' alienation from the study of technology and science (Seymour, 1995; Tobias, 1999). Typically, in Australia, as elsewhere, elementary school teachers lack confidence in technology and science and in their ability to teach these, often devoting little classroom time or effort to them (for example, Harlen, 1997). Furthermore, in the absence of accessible models of exemplary technology and science teaching, these teachers' views of learning (simply as instruction) appear to obstruct effective, investigative technology and science learning (Schmidt, McKnight and Raizen, 1997); and research-based attempts at innovation fail to permeate classrooms (White and Klapper, 1994). So as to address these problems, the Generative Virtual Classroom was envisaged as an information-age solution to the challenges of delivering the required, sophisticated professional development to large numbers of teacher education students, typically widely dispersed in time and space.

The prototype version of the Generative Virtual Classroom emerged from a sustained research and development program investigating early technology and science learning. Early studies (in the Learning in Science Project at Hamilton Teachers' College and Waikato University's Learning in Science Program and the Learning Research and Development Group at the University of Technology, Sydney) revealed the technological, scientific and philosophical ingenuity of young children (for example, Cosgrove, 1995; Cosgrove and Schaverien, 1994, 1996); and attention then turned to how to enhance often reluctant elementary school teachers in nurturing these children's ingenuity in their classrooms (Schaverien and Cosgrove, 1995, 1997a). A year-long, classroom-based mentor-supported approach was demonstrated to be of particular benefit in achieving the kinds of profound development in teachers' views of learning required to teach technology and science effectively. However, a way of scaling up these single-case interventions was needed for significant penetration of such sophisticated teaching approaches into classrooms. The Generative Virtual Classroom responded to this challenge.

As a product of a research program which conceived of learning as a generative act (after Wittrock, 1974, 1994; Minsky, 1985), the Generative Virtual Classroom was designed not only to develop Education students' understanding of this view of learning, but to do so in ways which are themselves in tune with such a view. In essence, therefore, the view of learning at the core of the Generative Virtual Classroom's design and operation is one in which learning is seen to be an adaptive behaviour of learners: that is, as iterative cycles of generating and testing ideas, on their value, keeping those which survive these tests (Plotkin, 1994, 1997; Edelman, 1992, 1993; Schaverien and Cosgrove, 1997b, in press a, in press b). Such a view is powerful in making sense of the learning at two nested levels of the Generative Virtual Classroom: as a behaviour of the children in the virtual elementary classroom, whose learning is at the core of the Classroom; and as a behaviour of the tertiary students in the virtual University classroom, who reflect on the children's learning, and their own, as they work in an electronically mediated learning community.

In the Generative Virtual Classroom, learners are able to view and review exemplary technology and science learning and teaching events, which they can select from a library of Quicktime movies. They can make personal notes about these events in a notepad for their private use and they can record ideas about particular, salient features of these events, in a searchable database. This database can also be used by learners to track the development of their ideas over time and to access other people's ideas about learning events. Learners can also participate in discussion of events with other members of the learning community by way of a threaded email discussion group; and they can access pre-recorded commentary about these events from the perspective of a particular (generative) view of learning. Learners are encouraged to treat this view as a plausible alternative way of making sense of the learning they observe and to think about whether they agree with it or not and why. The present version of the Generative Virtual Classroom (Version 3) is a hybrid system which uses a web browser to integrate the delivery of video from CD-ROM and data access via Cold Fusion (<http://www.allaire.com/>) from a back-end database over the Internet. The interface is created by the use of HTML frames.

So far, research has proceeded in parallel with development of the Generative Virtual Classroom. Two sustained, single-case autobiographical studies of learning in the Classroom have been undertaken (Allard, 1998; Sen, 1999). One (Sen, 1999) describes the learning of a postgraduate research student who became a member of the project team which developed the prototype version of the Classroom. The other (Allard, 1998) describes a nine-month study in which an Honours Bachelor of Education student investigated her own learning. Both studies affirm the worth of this computer-mediated learning environment in deepening students' views of learning, assisting them to be able to articulate their views of learning with confidence, to recognise learning when it occurred and to describe what they did not yet know but wanted to know about learning. Now that the Generative Virtual Classroom is robust and fully browser-based, we are poised to undertake a full-scale research investigation of learning in the Classroom with a large cohort of undergraduate Education students.

In this paper, the current version of the Generative Virtual Classroom will be demonstrated, its solution of design problems of the prototype version explained and opportunity for critical discussion of such research-based learning environments provided.

Assessment of Distributed Group Working and Learning Through Use of Computer Mediated Collaborative Systems

Rita M. Vick

Interdisciplinary Doctoral Program in Communications and Information Science
University of Hawaii
Honolulu, Hawaii USA
E-mail vick@hawaii.edu

Abstract: The use of computer mediated support for collaborative work and learning can be used to leverage human and technological resources to increase the effectiveness of organizational response to change. Because evaluation of how effectively a CMS system supports a particular task environment continues to escape quantification, it is important to identify how and when users develop "workarounds" to adapt to such systems. In an experiment conducted to determine some of the critical success or failure factors related to use of CMS systems, it was found that users often develop creative solutions that compensate for deficiencies in CMS systems as required.

How do teams of individuals learn to use technology that is new to them while concurrently performing accustomed as well as new tasks? This is an important question since this is exactly what workers and students are being required to do with increasing frequency and at a constantly increasing pace. The growing pervasiveness of the WWW, the Internet, intranets, and extranets as media for expediting collaboration and partnering has taken center stage in business. Developing collaborative ways of working, learning, and communicating is becoming increasingly critical in education. There are numerous ways of designing collaborative working and learning computer mediated support (CMS) environments. Designed properly, computer supported collaborative work (CSCW) and computer supported collaborative learning (CSCL) systems can leverage human and technological resources not only to extend the effective reach of business and educational institutions, but also to increase their flexibility and their capacity for responding to change. This allows scarce or expensive resources such as brick-and-mortar facilities, experts, texts, and equipment to be put to the highest and best use.

Effectiveness Assessment

An overriding flaw in the design, deployment, and use of CSCW and CSCL systems has, to date, been a lack of tools and methods for assessing the effectiveness of such systems. Numerous human-computer interaction (HCI) issues are involved in their design. Defining a collaborative work or learning environment means taking into account the task(s) to be accomplished, the context in which the productive activity is to take place, and the CMS system itself. This overall environment is what supports the work or learning process that is geared to production of a unique outcome through an efficient process.

There is no one, easy, universally applicable way to assess the effectiveness of CMS systems. Limited and often erratic access to in-use systems restricts how much can be determined about how users have ultimately worked out an accommodation with the system that supports their need for individualization of their work activities. The impact of this adaptation process needs to be assessed in terms of effect on work and learning style as well as degree of satisfaction the user requires in order to successfully adapt to a CMS way of working or learning. While resistance to change is characteristic of the worker or learner who has already identified and implemented a suitable and reliably effective set of procedures for accomplishing a goal, an important area of concern with regard to designing new or improving in-place CMS systems is identification of the hidden aspects of work and learning processes that are key success factors in realizing the related goals. These enabling factors must then be integrated into the functional structure of the CMS. In this way, the user's needs are reconciled with the demands of the technology. Rather than the user bending to the needs of a rigid technology, the user's needs are accommodated and supported by the computer-mediated system.

Rationale and Method

In an effort to identify some of the areas of work and learning situations that have contributed to lack of use and effectiveness of CSCW and CSCL systems, an experimental classroom scenario was designed to simulate a naturalistic distributed team work environment through use of the Internet, a local area network, scenarios and role taking. This design allowed analysis of qualitative and quantitative aspects of a number of dynamic teamwork variables (e.g., cohesiveness, conflict management, and various process gain and loss factors). More importantly, it allowed analysis of changes in learning and working styles of the members of each team as well as of the teams as a whole.

Teams worked in a computer laboratory setting where they simulated a distributed environment by using NetMeeting chat for all intra-team communication. The whiteboard function was used for logic diagramming and concept analysis. Team members shared a model-building application. Although this environment was set up to accommodate a reciprocal work style, one team regularly worked in a parallel style while another team used a mixed work style to solve decision-modeling problems as well as for collaboratively writing a final report.

The eighteen subjects in the study consisted of sixteen junior and senior undergraduate Information and Computer Science students and two master's level Engineering students enrolled in a course on CSCW in practice. The course contained elements of software analysis and design as well as practical experience with working in teams. Team membership was assigned based on a learning style inventory administered as a pre-test prior to beginning work on the first of two scenarios. This resulted in formation of two teams having four members and two teams having five members. Three of the teams were heterogeneous. One team was homogeneous.

The teams engaged in the design of decision models using software based on the analytical hierarchy process to help them structure their decision making. Two different kinds of scenario were used to test team reasoning and performance capabilities. The first scenario related to Y2K preparedness and the emergency response readiness of various municipal departments. The second scenario involved the design, implementation, and marketing of an ideal, user-tailorable CSCW system that could be used in a business or an educational environment.

For each of the two scenarios, each team was provided with experience working in each of four roles prior to a final "face-off" session. After these practice rotations, teams engaged in a "face-off" where they competed for budget or venture capital allocations based on the apparent efficacy of their decision model. Each team role was randomly assigned just prior to the "face-off." The design allows for analysis of within and between group differences in process, performance, learning, and outcome for each of the groups.

Initial Results

This Internet application-sharing interaction was the first distributed synchronous collaborative work in which any of the team members had engaged. Significant individual differences in working and learning styles emerged based on analysis of individual preferences as determined by administration of learning and work style surveys. While the learning style inventory was initially used to determine group composition, it was re-administered at the end of the course to determine the extent to which individuals had broadened the range of learning skills available to them as a result of the experiential knowledge-building treatment administered throughout the course. The treatment consisted of engaging students in interactive learning through simultaneous use of decision-making and collaboration software with which they were unfamiliar in a simulated distributed work setting. Comparison of pre-test and post-test results on the learning style survey indicated that all students had broadened their range of learning skills. Repeated measures of perceptions of software usability were also obtained via questionnaires. These revealed changes in perception of usability that were dependent more on performance reliability than on design features. Teams exhibited creativity in finding ways to work around software and equipment deficiencies in order to maintain productivity. Such "workarounds" indicate areas where adaptability of CMS systems to human needs can be improved. Repeated measures of teamwork variables were obtained via questionnaires focusing on individual team member perceptions of team performance, interaction, and results achieved. Although all teams achieved a high degree of cohesiveness, a higher degree of conflict would have benefited ultimate decision outcomes.

User-Centered Web Site Design: A Model for Development

Stephen P. Victor
BMC Software, Inc.
University of Houston
Houston, Texas, USA
Email: svictor@bayou.uh.edu

Introduction

This paper presents a model for creating user-centered educational and informational Web sites. Information design is the process of developing effective pieces of written or visual communication. While good information design stresses the importance of communication that clearly communicates an intended meaning, *user-centered* information design places primary emphasis on addressing the cognitive needs of the intended audience.

Distance education via the World Wide Web is becoming an increasingly popular form of instructional delivery. Because Web courses are often developed by teams of designers, a methodology for the collaborative development of educational Web sites can be a valuable tool for improving instructional effectiveness. This paper presents such a methodology and suggests areas of research to investigate the application of principles of user-centered information design to the development of effective instructional systems.

Theoretical Background

The field of information design embraces such diverse disciplines as business administration, computer science, cognitive psychology, graphic and typographic design, and technical communication. A user-centered approach to design is informed by principles of information theory and communication theory, information design theory, the findings of cognitive psychologists on perception and learning, and hypertext theory. Some of these theoretical considerations are briefly discussed below.

Information design theory draws on information and communication theory to suggest that designers structure information in ways that minimize "noise" and facilitate the transfer of meaning. Many factors, including personal characteristics, past experiences, and present feelings, can affect individual interpretation of sensory information (Stern & Robinson, 1994).

Jonassen (1993) states that hypertext resembles the associative network of human memory, and he suggests a technique of mapping the semantic network of an expert user. In such a map, concepts in the expert's mind become hypertext nodes, and the relationships among concepts become hypertext links. Vygotsky's (1978) sociocultural learning theory suggests that learning takes place as learners interact with more advanced peers and adults.

Using the notion of hypertext as a cognitive map, instructors can provide learners with a powerful tool for visually mapping their own representations of knowledge. Collaboratively-developed hypertext documents (cognitive maps) can also serve as sociocultural learning tools, providing learners the opportunity to "interact" with peers and expert users, even those who are geographically removed from the learner.

A User-Centered Model for Development

While *information design* is concerned with the development of effective pieces of communication, *information architecture* is the more far-reaching process of analysis, design, development, and implementation of a large-scale information product. The literature on information architecture suggests that Web site creation requires a systematic process of audience and content analysis; creation of detailed site diagrams and documentation; and production and implementation (Rosenfeld & Morville, 1998).

I propose that development of user-centered Web sites be guided by a four phase model: Design, Develop, Deploy, Document. This is a cyclical, iterative process, as illustrated in the following diagram:

Figure 1: A user-centered model of Web site development.

In the **Design** phase, the designer performs needs analysis, audience analysis, and task analysis. The activities associated with this phase are identical to those found in traditional models of instructional design. In collaboration with the intended audience or the client, the designer develops initial prototypes and blueprints. After client approval, the project moves to the **Develop** phase, in which the development team builds the product according to the specifications developed during design. In this phase, the designer works with graphic artists and technical experts to build the site. As the product is developed, the design/development team meets with the client for discussion and negotiation of modifications, if needed. Upon client approval of the final product, it is moved to the **Deploy** phase. In this phase, the Web site is installed and made available to the target audience. In the **Document** phase, the design/development team assembles project documents and blueprints and presents them to the client to guide future product revisions. This documentation feeds into future Design phases, and the cycle continues.

Conclusion

The four phase model I have described may be viewed as a framework for research into the processes of creating user-centered information: design of information (needs, audience, and task analyses), development of information (writing, graphical production, page/screen layout, programming), deployment (implementation and evaluation), and documentation of the product (to guide future expansion and revision). However, a presentation as limited as this often brings up more questions than it answers. What are the precise activities that occur in each phase of the model? As this model is refined, detailed procedures for each phase must be worked out. What is the correct balance of theoretical and applied knowledge to prepare students to be designers of effective instructional Web sites? What should we teach students to prepare them to be good information designers in instructional settings? What are the best approaches to teaching these skills? Ongoing research, including the development of a graduate-level course on instructional applications of information architecture (Victor, 1999), is investigating the appropriateness of applying user-centered information design principles to the development of instructional systems.

Templates for Generation of an E-Commerce Application

Joaquin Vila, Ph.D.
Applied Computer Science, Illinois State University, USA
e-mail: javila@ilstu.edu

Barbara Beccue, Ph.D.
Applied Computer Science, Illinois State University, USA
e-mail: bbeccue@ilstu.edu

Abstract: This paper presents an application that facilitates the implementation of electronic commerce sites. The application uses a series of templates or universal forms to accomplish this development. The forms are used to populate details needed for implementing an Electronic Commerce application. Businesses who are interested in having an online store can use this product to create or build an e-commerce application. The availability of such templates can enable small companies who do not have the IT support and expertise available to take advantage of this phenomena of e-commerce.

Introduction

E-commerce is becoming essential to today's business society. Essentially e-commerce is using electronic means to facilitate the buying and selling of goods and services between two parties. As the use of e-commerce becomes more prevalent in today's business market, it will be necessary for firms both large and small to utilize its services to attract and maintain their customer base and remain competitive. Dillon [1999] reports that worldwide E-commerce revenue will grow from \$98.4 billion in 1999 to \$1.2 trillion in the next four years and that the United States will continue to generate a majority of the dollars produced.

E-Commerce systems enable merchants to create electronic stores where they can sell their products and services globally over the Internet's World Wide Web (WWW). E-Commerce has allowed small companies to do business on the web and appear as competitive as any large organization. However, many small companies do not have the information technology (IT) support and expertise available to take advantage of this phenomenon. This paper presents an application of templates for generating an e-commerce site. The templates or universal forms incorporated in this application allow the population and customization of all the components needed for implementing e-commerce. Merchants who are interested in having an online store can use this product to create or build an e-commerce application.

Templates for Generation of an E-Commerce Application

The application provides two views of an e-commerce site, the merchant's view and the shopper's view.

The merchant's view facilitates the design and deployment of an e-commerce site. Components of the tool allow the merchant to customize the e-commerce interface for a specific business and to customize a database for catalog and client information. Functions within the merchant's view permit the specification of a business' logo, the specification of product categories, and the population of the catalog. This view is restricted to the merchant or store manager.

The shopper's view is the e-commerce public site which enables customers to buy products. The shopper can select items from the catalog for purchase. Customers can choose the activities that they want to perform from the shopper's menu shown in Figure 1.

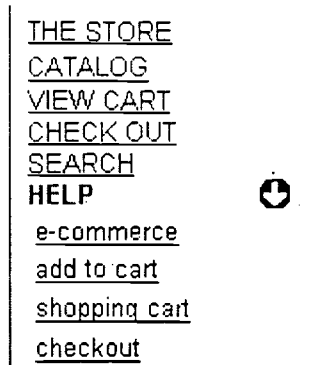

Figure 1: Shopper's Menu

The main page of the CATALOG presents the categories to the shopper. The shopper is able to select the category which is then expanded to reveal the details of each product within that category. This organization facilitates the customers' ability to locate and buy specific products. The customer can select any product and place it in the shopping cart.

The VIEW CART allows the shopper to view the contents of the cart as well as modify them. The shopping cart will hold any quantity of an item and will show both the unit and extended price of the item as well as the total cost of items in the cart.

The CHECKOUT requires each customer to provide billing and shipping information. The customer needs to confirm the contents of the order and accept the final total. The order is then recorded in the database for later fulfillment.

Technical Description

The templates for generation of an e-commerce application were developed using Active Server Pages (ASP). ASP is a scripting environment for the creation of dynamic Web-based applications. ASP with Internet Information Server (IIS) 4.0 provided a flexible method to interact with the ODBC compliant database used in implementing this application.

InterLearn – an Internet Learning Support Environment for Collaborative Learning

Leonard Webster, Ph.D
Centre for Higher Education Development
Monash University
Australia
Len.Webster@adm.monash.edu.au

David Murphy, Ph.D
Centre for Higher Education Development
Monash University
Australia
David.Murphy@adm.monash.edu.au

This paper outlines the design and development of an online learning and teaching environment named InterLearn. Designed by Monash University's Centre for Higher Education Development to deliver its Graduate Certificate in Higher Education and other Staff Development topics, it uses a database approach to provide learners with their own 'worksites' and online learning activities.

Based on notions of collaborative learning and constructivist approaches, InterLearn provides students the functionality to search and read each others responses to online activities and collaborate in forming a shared understanding of ideas and concepts (Fig. 1).

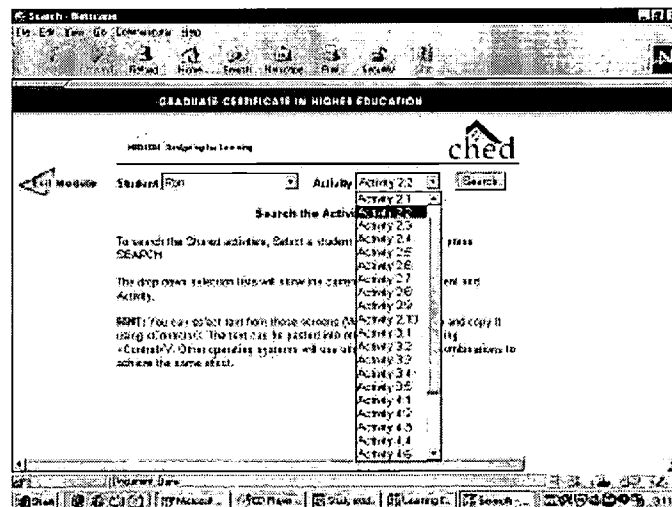

Figure 1: Activity search feature

Students may also edit or update their responses to activities whenever they enter their 'worksites', a secure and customised teaching and learning area for the student. Other functions include discussion group, news area and a maintenance module to enter student details and assign passwords and login identification (Fig. 2).

BEST COPY AVAILABLE

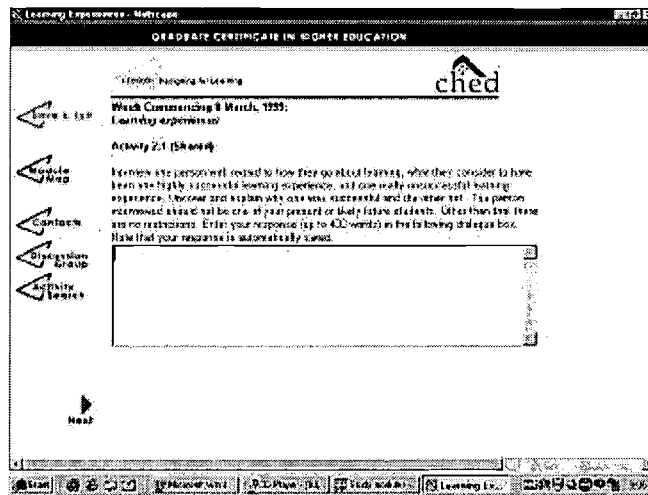

Figure 2: Features including activity editing

Tried this year in the Graduate Certificate in Higher Education, interim evaluations have indicated that the approach is welcomed by course participants. Further development is now planned to incorporate Staff Development topics and remaining subjects of the Graduate Certificate in Higher Education. Initial feedback by students (themselves University teachers) to the online learning environment is encouraging with remarks such as:

“I am particularly happy with the activity system adopted in the course under different modules. The activity system allows me to build my knowledge gradually in a very flexible way. It also allows me to share others experience and gain from their experience and knowledge. Another good reason is that I can practice what I learned from others in my own class and add that experience to activities.”

“Reading the various responses of other people is a great way of getting a better picture of what the class think as a whole.”

“The opportunity to reflect about my teaching practices. This is facilitated by a good choice of on-line and text resources which are readily available. The flexibility of the subject delivery. It would be very difficult to attend classes on a regular basis while having to undertake all my other academic activities. I can access the subject material from any of my offices (I operate on two campuses) and from home, and because I can choose the time to undertake the activities – away from telephones and interruptions of all sorts – the reflection time is more effective.”

“The course had stimulated reflection on my own teaching practice and I can see some changes in my teaching style in response to this. It has also encouraged a small group of us to share all experiences and fostered the creation of a small “teaching” community.”

InterLearn is seen as one teaching tool that can be used to develop online learning environments that are more interactive and independent. A further outcome of the work so far is that the interactivity between students in on-line courses can be stimulated without adding substantially to the overall teaching load. Although the functionality of InterLearn will not be significantly extended, some minor refinements are currently being undertaken including:

1. Multiple searching of responses
 2. To facilitate searching, only completed activities available if searching by name or vice versa
 3. Enhanced features for activities including formatted text, tables, images, video and sound.
 4. Maintenance module: Check links for validity and reporting function
 5. Maintenance module: View of students completed activities for teaching staff including assessed activities
- At this stage it is planned to have these refinements available in late 1999.

A Framework for Evaluating Web-based Instruction

David D. Williams
Department of Instructional Psychology and Technology
Brigham Young University- Provo, Utah, USA
David.Williams@byu.edu

Abstract: An evaluation framework based in work by Stufflebeam and Patton is proposed and illustrated for use in evaluating web-based instruction. Implications for building a similar framework into web-based instructional design are explored.

There is a flurry of effort to use the World Wide Web instructionally. A few educators discuss the value of these efforts and even fewer actually evaluate their web-based instruction to ascertain its merit and/or worth. See a summary of this literature at <http://mse.byu.edu/ipt/williams/literature.html>.

Do these evaluations help? Are we learning what we ought to know about the Web as an instructional medium? Will potential evaluation information users benefit from these inquiries? This presentation will propose and illustrate a framework for improving evaluations of instruction offered via the internet based on Stufflebeam's Context, Input, Process, Product (CIPP) model and Patton's Utilization-Focused Evaluation approach. Examples of evaluations of several instructional development projects at a major university will clarify the framework's utility.

The Framework

In planning, conducting, or reporting an evaluation, evaluators need to account for two important kinds of background information to make their evaluations useful: the context for the thing being evaluated (the evaluand) and the context for the evaluation process being used. Evaluand context information includes information about the request for the evaluation, if any, historical information surrounding the evaluand that might be relevant, and reviews of literature pertinent to the evaluand. For example, in most of the evaluations of web-based courses at Brigham Young University, the central administration has requested evaluations be done, each course has a unique history which has shaped the creation of the course for use on the web, and the evaluation literature cited earlier along with content-specific literature unique to each course is relevant to their evaluations. Examples from some of these evaluations are cited below.

Evaluation process context information includes the approach to evaluation that is being used and a rationale for that approach in each situation. Many approaches to evaluation have been proposed and employed since the 1960's when evaluation was mandated by the United States congress in conjunction with funds allocated for educational programs. The approach taken will determine to a great extent the kinds of information that can be gathered. So it is important for the evaluator to be explicit about the approach to be taken so the persons considering the evaluation proposal or reading the completed report can better interpret the results and their utility.

Presented in the links below are some fundamental elements of one approach to evaluation that we are currently promoting among units at Brigham Young University for use in the evaluations they are conducting. Our rationale for proposing use of this approach is that it combines a broad perspective to the life of most kinds of evaluands, ranging from organizations to instructional products as first proposed in the early 1970's by Stufflebeam and others [Stufflebeam et al 1971] (see <http://dle.byu.edu/williams/cipp.jpg>) with a user-focused approach that Patton has articulated (Patton 1997) for almost as many years.

The proposed evaluation framework (see <http://mse.byu.edu/ipt/williams/661Fall99/UFE-CIPP/index.htm>) combines these approaches into a comprehensive model which uses a basic logic (Scriven 1981) of comparing what is to what ought to be much as one would with a pan balance (see an elaboration at <http://mse.byu.edu/ipt/williams/661Fall99/panbalance.pdf>) and a further elaboration of these ideas at <http://mse.byu.edu/ipt/williams/661Fall99/framework.pdf> which outlines a process for carrying out evaluations of many kinds of evaluands for many different kinds of audiences. Material at <http://www.wmich.edu/evalctr/jc/PGMSTNDS-SUM.htm> describes published standards for judging evaluations or meta-evaluation as proposed by Michael Scriven and elaborated by Stufflebeam.

The framework organizes the interests, questions, values, and participation of potential evaluation users and stakeholders around four types of evaluation:

1. CONTEXT evaluations which investigate the socio-political, organizational, and other contextual variables associated with the need for instruction using the internet.
2. INPUT evaluations which compare alternative inputs or means for meeting the needs, including web-based instruction.
3. PROCESS evaluations which formatively assess the planning, design, development, and implementation of instruction to improve it.
4. PRODUCT evaluations which allow summative judgments to be made regarding the quality, utility, and value of existing instruction.

Ideally, evaluation of all four types will occur simultaneously and repeatedly throughout the life of an organization which has multiple instructional development projects, programs, initiatives, courses, and so on coming and going. As part of each evaluation, the following activities should be conducted by qualified participants (sometimes internal to the organization and sometimes by external consultants):

1. Clarify evaluation users (who cares?), such as administrators, faculty, students, designers, etc.
2. Invite users to clarify what the evaluand (thing being evaluated) is (what do they care about?). For example, various contextual variables, alternative inputs, elements of the process, or alternative products or dimensions of those products could be considered.
3. Work with users to clarify criteria or indicators of success to judge the evaluand against (what is success?). For example, the process should cost less than the status quo, the course should teach more people faster at a higher level of performance, etc.
4. Work with users to clarify questions they have and what they will do with results (what to ask?).
5. Use steps 1-4 to determine the inquiry methods, needed resources, timeline, costs, etc.
6. Meta-evaluate the plan, the process, and the actual evaluation formatively and summatively on a continual basis to improve it while improving the evaluands.

Examples

Example evaluation studies based on this framework at Brigham Young University may be found at <http://mse.byu.edu/ipt/williams/661Fall99/Studies.htm>. Depending on the time available, one or more of these examples will be reviewed during the presentation.

Implications

By building evaluation integrally into web-based instructional design, we at Brigham Young University believe we will not only improve the instruction but will also involve all the potential stakeholders in clarifying their interests in the instruction and its evaluation so they want to use the results to improve their performance as it relates to the instruction.

Participant buy-in is crucial to the success of educational evaluation and thus to the success of the courses and other evaluands evaluated. The framework described in this presentation promotes buy-in by everyone concerned with web-based instruction.

Pedagogical Possibilities of EMail Communication

Julie W. Yen, English Department, California State University, Sacramento, USA
E-mail julie.yen@csus.edu

Abstract: Assumptions about email often fan faculty fears about the changes that technological advancements are bringing to the field of education. However, when we recognize that email can be adapted for use within various pedagogies, and that students' expectations will inevitably make it an integral part of our teaching practices, we will realize that it is time to seriously explore the pedagogical possibilities of electronic communication.

Some time after I began writing this talk, I saw an announcement for a seminar on teaching email as a writing genre on the AAHE-affiliated TLT Group listserv. Posting a message in response, I said that I have always thought of email as a form of expression closer to freewriting than anything else that we teach in the composition classroom, but I agreed with the seminar leader, Trent Batson, that some rules were necessary to maximize the potential benefits of this new form of communication. Batson used a wonderful metaphor to convey his sense about these rules: he suggested that they would be "patterns of usage that people develop over time," or "footpath rules, letting people walk on a campus for a while and then laying concrete where paths develop." After my post, someone very quickly responded with another message, cautioning against this kind of dialogue about ground rules. Assuming that a discussion about using email to communicate with students necessarily implies distance education, the writer argued that rules would make it harder for "distance learners" to create a sense of community in an online environment.¹

Initially, I was struck by the writer's immediate assumption about the connection between email and distance education. I have not yet taught an online course, and indeed, I have not yet even used email in a class in any systematic way. I do, however, put my email address on course syllabi and tell students that I check email more frequently than voice mail. I also encourage students to participate in a listserv or a mailing list that I sometimes set up for smaller classes. And already, I have discovered that this informal use of email has added to my teaching in ways that I had not expected before.

Email, I have found, offers students various learning opportunities, which they are quick to discover and take advantage of on their own, sometimes in rather creative ways. Students have sent me email to clear paper topics, bounce off ideas, and receive feedback on early drafts. After a Shakespeare course ended, one student continued to reflect on her responses in the final exam, not that there was any expectation her grade would be affected, and sent me something along of the lines of "This is what I wish I had said. . . ." In a survey of English literature class, a student who was about to transfer to a different school not only asked about her grade, but also asked about her performance in the final exam, whether she had improved in the specific areas that I had commented on in a mid-term. Other students in an Asian American lit. class have continued to send me email, as they continued to reflect on class discussions that occurred at different points in the semester. And finally, some students have also used email to tell me about difficulties they were experiencing in other classes. From my perspective, receiving students' email gives me a chance to reflect on what they say, both before and after I see them in person. It enables me to prepare more carefully considered responses than I otherwise would be able to come up with in class. It also allows me to go back and reread their messages if I find myself wondering whether a response or advice that I'd given was appropriate.

I am often surprised and/or delighted by the email messages that I receive from my students. One of the more memorable ones begins something like this: "Hi, I was painting and I started to think about what we were saying about Shakespeare in class the other day. . . ." But at a faculty meeting this semester, I heard a startling story about using class listservs from a colleague who teaches business law and ethics. He said that he keeps a file of student papers for a course he regularly teaches, and one year he found a paper that was so obvious and flagrant in its plagiarism that he wondered how the student could have expected to escape detection. He wondered how he should respond and finally resolved his dilemma by posting a harsh reprimand to the offender on the class listserv, without naming the student. The next morning when he arrived at his office, he saw one of the best students in the class waiting for him. The student sat down in his office, and with tears in his eyes, confessed his crime. But of course, this student was not the culprit that my colleague had in mind; this student's plagiarism had been so subtle that it had escaped detection. Stunned by the unexpected development and his discovery of this potential use of an electronic bulletin board, my colleague briefly debated the ethical implications of posting a similar message every semester, before any cheating had occurred in a class.

Whenever we venture into uncharted seas, we are bound to discover the unexpected, and sometimes we even have to weather some storms. To many faculty, any talk of using technology in the classroom still means an attack on and attempt to replace sound, traditional pedagogical practices, which returns me to the anecdote with which I began my talk. Some people assume that email communication necessarily implies distance education. Some people are reluctant to impose any rules which might restrict the liberties of expression made possible by email. And sometimes, some people would even consider any effort to critique student email styles, such as gratuitous use of profanity, as akin to censorship and a desire to ban the teaching of Darwin's theory of evolution. These kinds of assumptions and concerns, of course, only underscore the need for faculty to hold more conversations about our pedagogies and what it is that we hope to teach our students.

In reviewing the email messages that I have collected, it occurred to me that mostly they have come from students who I see regularly. The value of email communication, then, is that it deepens and strengthens the relationships that I develop with my students: it does not replace classroom interaction. And this point, I think, cannot be over-emphasized, that rather than supplant in-class discussions, electronic conversations actually supplement and enhance face-to-face teaching.

In the rest of my talk, I'd like to focus on how email worked in the Asian American lit. class that I taught last semester. A few days ago, a student remarked to me that that course was one of the best classes she'd ever taken, because she had found great friends there. I suspect the small class size was a significant factor, but I would also like to believe that the students' practice of posting regularly to a class mailing list contributed to their sense of community. Some more thoughtful students developed the habit of writing long, reflective essays as they continued to think about class material after they left the classroom. Other students posted their in-class writing exercises, which I encouraged as a way for quieter or more passive students to share their thoughts with the whole class. I told the students that their contributions were voluntary, but the effort would count as a kind of class participation. Many students took me up on this offer, and consequently the entire class was able to enjoy reading the class work that is usually only submitted to the instructor.

This method of continuing class discussions enabled us to transcend the time and space limitations of a physical classroom. It also gave us new ways of discussing sensitive and controversial topics such as religion, race, and cultural differences. The electronic forum allowed us to diffuse the tension and sense of discomfort that often accompany such conversations; and paradoxically, the distance in time and space also enabled us to cultivate a sense of intimacy as students freely shared their thoughts without the fear of face-to-face confrontations. In many of our virtual conversations, the students impressed me with their willingness to reveal deeply held convictions, courage in challenging a peer's apparent stereotypical thinking, and ability to communicate in an articulate and compelling fashion. The electronic forum also gave me a way to respond to students privately and quickly if necessary, and I have no doubt that it facilitated many difficult discussions that otherwise would not have occurred.

Since this medium of communication is ubiquitous in contemporary culture, most students instinctively know how to appropriate its capabilities and adapt them for their own use. For example, many naturally know how to take advantage of email's "Q and C" feature,² which gives them the option to respond very precisely to another writer's remarks by quoting exact words and commenting on them. Even those who initially think themselves computer illiterate pick up requisite skills very quickly and wonder how they ever got along without email. Students like using email because it is informal and easy; it can accommodate different learning styles; and its immediate transmission improves their chances of getting fast feedback from instructors. So it would be logical to think that if faculty integrate email communication into our teaching, students would be inclined to write more thoughtfully and reflectively, because they would be writing with a purpose.

Many faculty still regard with anxiety the sea changes occurring in education brought about by the advent of technological advancements. But we must acknowledge the fact electronic communication will inevitably become a part of our pedagogies, as more and more students enter our classrooms with the expectation that we will be accessible through email. Today, if students don't see it on the syllabus, they will ask, "What's your e-mail address?" Soon enough, they will also be asking, "And what's your URL?"

Learning the Internet through the Internet: A Case Study

Yasemin Yigit, Computer Education and Instructional Technologies Department,
Middle East Technical University, Turkey, gulbahar@metu.edu.tr

M. Yasar Ozden, Computer Education and Instructional Technologies Department,
Middle East Technical University, Turkey, myozden@bote.fedu.metu.edu.tr

Abstract: The Internet can be a delivery tool, a search tool or a development tool for any WWW-based Instruction. But without knowing the basic services of the Internet, it is difficult to use it effectively. Thus, the main purpose of this study is to develop a WWW-based Internet Tutorial including visual examples in order to teach the Internet Tools and analyze this tutorials' effectiveness. At the end of the study, the findings led to a profile of the participants' (a) attitudes toward computers; (b) achievement about the Internet; (c) perceptions' about the Internet Tutorial.

Introduction

Integrating Internet and World-Wide Web into education has come up with some problems. It was really a huge world to explore. Since every student who tries to meet this technology was getting lost in this world, the basic question was "how to teach the basic Internet tools to students".

Putting information together and creating WWW-based instruction is very simple by using WWW tools. But, there are some points which a designer or teacher must be careful while developing the instruction. Most important ones are: (a) Defining the domain and provide content; (b) Designing instruction and (c) Evaluation (McManus, 1996). In the future, with increasing experience and research studies we will be guided more effectively. But for the time being, the development of technology is so rapid that there is neither enough research studies nor experiences for us to reference (Kearsley, 1997).

The purpose of this study was to develop a WWW-based Internet Tutorial, which can adapt to students with different backgrounds, prior knowledge of the subject and learning goals. So that, any student apart from his age can learn the Internet via using the WWW-based Internet Tutorial.

Design of the Study

The main purpose of this research is to investigate the effectiveness of the tutorial, which is developed to teach the basic Internet Concepts via World Wide Web. At the end of the research, the subjects' achievement will be investigated. The second purpose is to investigate the effectiveness of applied materials in terms of student demographics (gender difference and school factor) both quantitative and qualitative, in order to see if any difference occurs in terms of attitude towards computers and the achievement of the Internet concepts.

The Computer Attitude Scale Test was administered online as a pre-test at the beginning of the treatment to control students' attitudes toward computers. Tests during the treatment after each topic and a general test after the treatment was administered online as a post-test to measure the students' achievement in learning the services of the Internet. And finally, an open-ended questionnaire was administered to randomly selected students from each three school, in order to see qualitative results. The subjects of this study for quantitative analysis were totally 80 students. 45 students from two high school college students and 35 students from freshman. The open-ended questionnaire was administered to randomly chosen 11 students from high school college students and 5 students from freshman. Namely 16 students were the scope of qualitative analysis.

Instruments and Treatment

Before the treatment, the Computer Attitude Scale (CAS) was administered to the students. This scale was originally developed by Loyd and Gressard (see Loyd, B. H. and Gressard C. 1984) and then, translated into Turkish and analyzed by Berberođlu and alıkođlu (see Berberođlu, G. and alıkođlu, G. 1992). In the treatment part, developed WWW-based Internet Tutorial was administered. Since it is thought that basic services of the Internet can be learned online without a teacher by every student herself, the WWW-based Internet Tutorial used in this study was prepared using some WWW Tools by the researcher. The tutorial is prepared in Turkish, because of the lack of Turkish Documentation in this area. Then during and after the treatment Internet Tools' Achievement Test (including 8 short and 1 final test) was administered to students. This test was developed by the researcher. To have qualitative results an open-ended questionnaire was developed by the researcher. The questionnaire was distributed to 16 (6 females, 10 males) students who was randomly selected by the researcher and agreed to participate in it.

At the beginning of treatment, the answers to the Computer Attitude Scale were taken from the students online. Then the instruction i.e. WWW-based Internet Tutorial was administered to the students. The only explanation made by the researcher to the students was the goals and objectives of the tutorial. During the treatment, students answered 8 topic tests and when they finished the tutorial they answered a general test, that were all online. After the treatment, open-ended questionnaire was given to randomly selected students.

Data Analysis and Results

In this study, both quantitative and qualitative research techniques were used. For *Quantitative Analysis* the results of Computer Attitude Scale and Internet Tools' Concepts Achievement Test were used. For *Qualitative Analysis* the results of open-ended questionnaire were used.

Based on the statistical analysis and results which was presented in the previous sections, the following results have been reached:

- Freshman got higher scores in terms of general achievement than high school college students.
- There was no relationship between attitudes toward computers and general achievement.
- Boys were found out to be more successful than girls in terms of general achievement. And also boys were found to have more positive attitudes toward computers than girls.
- The WWW-based Internet Tutorial was overall successful and adding more pictures, animations and video films can increase the effectiveness of the tutorial.

Using Virtual Teams in an On-line Software Engineering Class

Timothy Youngman
University of Houston-Clear Lake
Houston, Texas, USA
Email: youngman@cl.uh.edu

Introduction

This paper addresses the issues involved in creating and facilitating virtual teams in an on-line software engineering class. It includes an epistemological foundation for creating virtual teams, a detailed description of the process, an overview of the key issues and challenges that were encountered, and an overview of the technology.

In recent years, the availability of technology has increased significantly, making on-line distance education classes a viable option for many students. Through tools and strategies such as videoconferencing, file exchange, electronic libraries, virtual cafes, whiteboards, debates and opinion polls, role-taking activities, and student dialogues, there is ample opportunity for learners to apprentice each other on-line (Bonk & Cunningham, 1998). As such, it is necessary to develop classes based on a foundation that recognizes the potential for collaborative technology.

Theoretical Background

Vygotsky (1978) stressed the specific social nature presupposed by human learning in his description of the zone of proximal development. From this perspective a learner is capable of solving more difficult problems in collaboration with a peer than what can be done independently, which outlines the importance of interaction in facilitating internal developmental processes (Vygotsky, 1978). A major tenet of Vygotskian psychology is that social interactional, cultural, institutional, and historical contexts all play a role in the development of an individual's mental functioning (Bonk & Cunningham, 1998).

A sociocultural epistemology builds on Vygotskian psychology by defining effective teaching as that which falls within the zone of proximal development, thus stressing the importance of providing opportunities for collaboration and mentoring of students (Gredler, 1992; Hedegaard, 1990; Moll & Greenberg, 1990; as cited in Althausen & Matuga, 1998). Accordingly, students are encouraged to explore new ideas and apply their knowledge and skills while sharing their mental processes (Althausen & Matuga, 1998). Through this collaboration, the individual learners and the team are able to generate solutions, solve problems, and gain insights that are beyond their individual capabilities (Bonk & Cunningham, 1998).

Description of Current Research

The Software Engineering Department at the University of Houston-Clear Lake responded to a call to develop on-line distance education classes. In the initial meetings, it was established that collaboration must be a major component, since software engineering is a team-oriented profession. With this idea in mind, the department opted to move toward a sociocultural epistemology because of its emphasis on building a collaborative network of learners, recognizing the value of different ideas in understanding reality. For the initial pilot of the program, the department selected a course in software project management to go on-line. The development team was established, consisting of an instructor and instructional designer, with a Web developer and graphic designer assisting.

A modified Dick and Carey (1976) model was followed to cultivate a unified, methodical approach for development of the curriculum. At the initial level, a list of outcomes was developed, reflecting the abilities that students must possess at the end of the course. Since the material is procedural in nature, the instructional analysis resulted in a clear list of learning objectives. At this point, the development team analyzed the progress, and made some decisions about how these objectives could be attained in a team environment. Rather than developing a series of small tasks, the team choose to use two parallel semester long assignments, comprised of an individual project and group project. All of the tasks on the group side were contributory in that they were designed to specifically prepare the student to work on the individual components after resolving issues collaboratively. In this way, the assignments were designed to scaffold the learning within the zone of proximal development (Matuga, 1998). A flow chart was

designed showing how the assignments coordinate throughout the semester, and assessment rubrics were created. At this point, the group determined what content was necessary to support the activities in the flowchart, and short tutorials were designed to introduce students to the more classical ideas of software engineering.

Since the class will be offered in an on-line format, the issue of facilitating the virtual team has been an important part of the process since much of the success of the class depends of the groups working through the project collaboratively. Palloff and Pratt (1999) describe seven steps that help build a virtual community including clearly defining the purpose of the group, creating a distinctive gathering place, promoting effective leadership from within, defining the norms and a clear code of conduct, allowing for a range of member roles, facilitating subgroups, and allowing members to resolve their own disputes.

With these ideas as a guiding principle, a basic structure for the groups was defined with clear roles and responsibilities for each person. All teams have a project manager who is responsible for reporting the progress to the instructor, coordinating the work of the other team members, and helping to develop the end product. Each of the other team members has responsibility for a specific area within the field of software engineering: development, testing, build and integration, and system engineering. All of these areas overlap, and require a great deal of interplay. The teams have a unique software problem to solve written in the form of an RFP (Request for Proposal), which basically outlines the needs that the software must fulfil. The specific purpose given to the group helps the members to naturally establish a sense of community (Berg, 1999).

The department elected to use WebCT; a Web-based program designed to facilitate on-line classes. As a part of the structure of this program, each team has its own discussion board, chat room, and area to post presentations. In this way, students have the ability to meet their own needs for communication and, the technology is available to them at all times, empowering the team to make their own decisions about meetings, responsibilities, and timelines.

Data Gathering and Analysis

The pilot of the class will be taught on-line in the Spring, 2000. Primarily the students are working at the Master's level, and many of them are employed in an engineering-related field. It is anticipated that students will span a large geographic area surrounding the university and will come from a variety of backgrounds. An instrument for formative evaluation is under development to assess the achievements of the program. This instrument will measure the attitudes of the students in regard to their virtual teams. A measurement will be taken at the beginning of the group project and again at the end. This will help to determine what changes may be necessary to improve the course before it becomes a more permanent fixture in the distance-education curriculum.

DSM-CC Extension for MHEG-5 Applications on the Web

Abstract: In this paper, we extend DSM-CC for distribution of applications and providing additional services based on MHEG-5 via web. Proposed extension defines mapping between MHEG-5 to CORBA. It can support user and resource controls, real distribution of application servers and providing additional multimedia service facilities.

1. Introduction

Network technologies and multimedia are being popular. There are new requirements for mechanism to interchange and present multimedia and hypermedia information on the network. Also we have required mechanism to process real-time user interactions. But, the web has poor ability about those. The MHEG (Multimedia Hypermedia Encoding Expert Group) standard defines the representation and encoding of multimedia and hypermedia information for interchange between various applications [ISO97].

The MHEG-5 standard is the fifth subset of the MHEG standard. It defines some classes in detail. Those classes are appropriate to some applications such as video on demand, audio on demand, interactive TV and hypermedia navigation [ISO97].

As defining only final form for transmission and representation, MHEG-5 is currently used as simple interactive multimedia presentation. Regard of its various application areas, an MHEG-5 application will require formal distribution of contents and additional security services such as billing, authentication, authorization, etc.

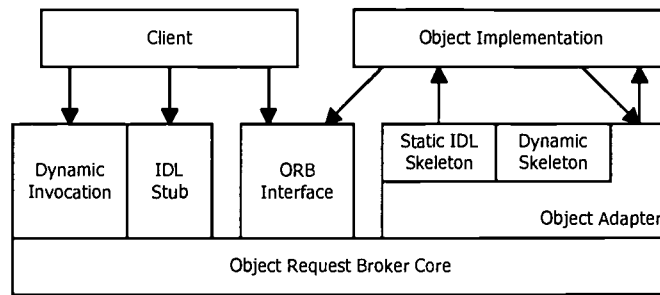

OMG (Object Management Group)'s CORBA (Common Object Request Broker Architecture) [OMG98] can provides those facilities for MHEG-5 applications. In this paper, we define mapping between MHEG-5 to CORBA. We extend DSM-CC (Digital Storage Media Command & Control) [ISO98] for distribution of applications and providing additional services based on MHEG-5.

2. Consideration of International Standards

In this chapter, we consider the international standards, CORBA, MHEG and DSM-CC, for distribution of interactive multimedia applications.

2.1 *OMG's CORBA*

The CORBA (Common Object Request Broker Architecture) is structured to allow integration of a wide variety of object systems [OMG98]. Figure 1 shows the structure of an individual Object Request Broker.

[Figure 1] The CORBA architecture

The Client is the entity that wishes to perform an operation on the object and the Object Implementation is the code and data that actually implements the object. The ORB is responsible for all of the mechanisms required to find the object implementation for the request, to prepare the object implementation to receive the request, and to communicate the data making up the request.

The interface the client sees is completely independent of where the object is located, what programming language it is implemented in, or any other aspect which is not reflected in the object's interface. To make a request, the Client can use the Dynamic Invocation interface or an OMG IDL stub. The Client can also directly interact with the ORB for some functions. The Object Implementation receives a request as an up-call either through the OMG IDL generated skeleton or through a dynamic skeleton. The Object Implementation may call the Object Adapter and the ORB while processing a request or at other times.

2.2 The MHEG standard

MHEG-5 provides a framework for the distribution of interactive multimedia applications across minimal resource platforms of different types. An MHEG-5 application resides on a server, and as portions of the application are needed, they will be downloaded to the client. In a broadcast environment, this download mechanism could rely, for instance, on cyclic re-broadcasting of all the application [ISO95].

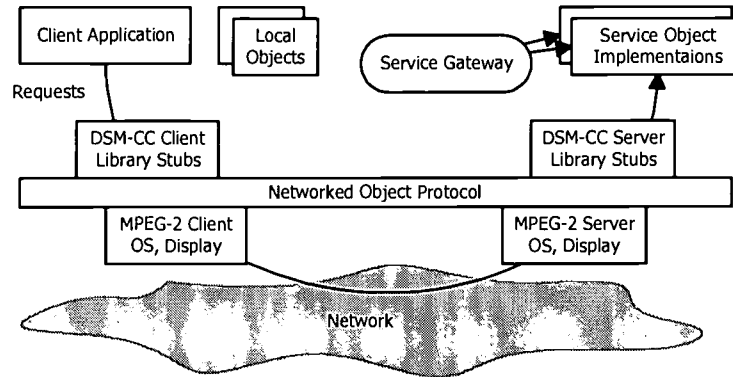

A minimal MHEG-5 runtime environment has to provide an entity for decoding of the MHEG data structures and an entity called MHEG engine, which parses and interprets the MHEG-5 objects. The engine also communicates with the local presentation environment and the MHEG-5 objects. It responds to the events initiated by the application or the user in the application specific way. A MHEG application is always event driven.

An MHEG-5 application consists of Scene objects and objects that are common to all Scene within an Application object. At most one Scene is active at any one time. This is the part of the application that has to be loaded on the clients' system. Navigation in an application is done by transitioning between Scenes. A Scene contains a group of objects, called Ingredients, which represent information. The content data is typically not part of the encoded Scene object. Instead, content data can be referenced and stored externally.

2.3 Digital Storage Media Command & Control, DSM-CC

DSM-CC systems are composed of client using service, SRM (Session and Resource Manager) managing needed session and resource when it is provided with service, and server providing service [ISO98]. The

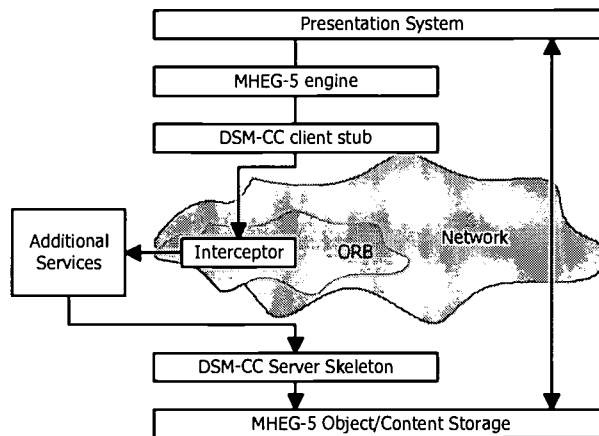

composing entities have U-N (User–Network) signal that connect client and SRM, server and SRM and U-U (User–User) signal. DSM-CC describes a command for control of digital storing medium and concrete procedure. Primitive defined by DSM-CC is able to divide U-N (User–Network) and U-U (User–User) primitive. Figure 2 displays DSM-CC client/server system architecture.

[Figure 2] DSM-CC client/server architecture

3. System Design

Figure 3 displays composition of multimedia service system including extended DSM-CC protocol. Extended DSM-CC protocol is able to use event, security, transaction, life cycle, and naming service.

[Figure 3] Proposed architecture

3.1 Interface Design

DSM-CC U-U primitives can operate on the CORBA system environment and support RPC and defines OMG IDL to operate language and protocol independently. Client applications provide server environment with independent interface using DSM-CC library and connect service gateway of server. Table 1 defines interface and primitives of DSM-CC U-U.

[Table 1] DSM-CC U-U primitives

Interface	primitive	Interface	primitive	
dsm.Service	open	dsm.Stream	open	
	close		close	
dsm.Directory	open		play	
	close		pause	
	read		scanForward	
	clean		scanBackward	
dsm.File	open		jump	
	close		status	
	read		dsm.DBClass	list
	write			getSchema
	getData	dsm.DBField	getValue	
	getSize	dsm.DBSQL	exec	

User-User interface separate the essential functions, which are a minimum, demand item and the optional extended function. On the proposed architecture, extend function of life cycle, security, and event use CORBA service. As DSM-CC U-U primitive has service connection, directory service, stream, file, and database access, directory service among these uses Naming Service of CORBA.

3.2 DSM-CC mapping to MHEG-5 operation

First MHEG-5 application is began, service gateway of DSM-CC is activated, and is made name space inside of application object. This name space can be mapped DSM-CC directory, and a directory can be included other directory, file, and stream. If these objects are included in a application, DSM-CC directory service become to get the only object reference. Using these methods, MHEG-5 engine can access a various objects of server's application.

MHEG-5 object is identified by ObjectReference composed of GroupIdentifier and ObjectNumber. GroupIdentifier is mapped DSM-CC, and ObjectNumber gives unique value in their object. The ContentReference which reference actual content of Ingredient object is mapped the same method in ObjectReference.

As StreamEvent interface of DSM-CC can transfer private data using PrivateDataByte field, this field is mapped StreamEventData of StreamEvent to each other. Also, CounterPosition which is inner attribute of MHEG-5 Stream class is mapped NormalPlayTime of their stream to each other.

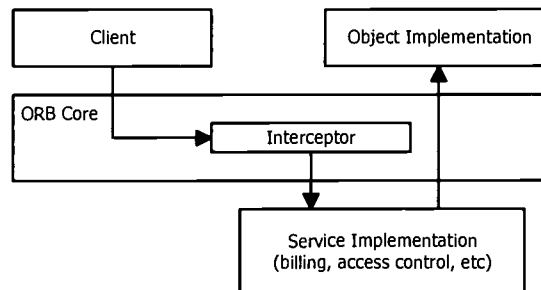

Table 2 defines the mapping between MHEG-5 actions and DSM-CC U-U primitives.

[Table 2] Mapping MHEG-5 actions to DSM-CC U-U primitives

Object type	MHEG-5 action	DSM-CC U-U primitive
Application	Launch	dsm.Directory.open() dsm.File.read()
Scene, etc.	Prepare	dsm.Directory.open() dsm.File.read()
Video, Audio	Run	dsm.Directory.open() dsm.Stream.play()
Stream	SetSpeed(0)	dsm.Stream.pause()
	SetSpeed(1)	dsm.Stream.resume()
	Stop	dsm.Stream.close()
	StreamTimer	dsm.Stream.getNormalPlayTime()

3.3 Additional Services

In this section, we'll discuss about extension of DSM-CC for additional multimedia service offering. If DSM-CC implements the general RPC, the extension of service or the distribution of different mechanism cannot be considered. On the CORBA based implementation, it is able to use the existing defined CORBA service as previously stated. Service extension using an interceptor who defines the CORBA standard is easy. Figure 4 displays the service extension example using an interceptor.

[Figure 4] Interceptor & service extension

Extensible services using this mode are billing services that are adaptable in services of video on demand, audio on demand, home shopping, and digital interactive TV, the user competence control function for the distributed multimedia framework, and can complete distribution of service using CORBA.

4. Implementation strategy

In this chapter, we suggest an implementation example for the proposed architecture. For various media resources, we use the web as infrastructure. We implement MHEG-5 clients as Java applets, portable format of Internet applications, and use CORBA as middleware for the DSM-CC C/S environment. Figure 5 shows our implementation example architecture.

[Figure 5] Implementation example

In client side, using the web, end users easily access multimedia services. In addition, in server side, service providers can provide additional services via web, worldwide hypermedia environment, and huge amount of resources. We are currently implementing billing service, additional service component for video on demand.

5. Conclusion

In this paper, we proposed new architecture for MHEG based distributed multimedia system. It appears as an extension of DSM-CC, the digital media control protocol. It is based on OMG's CORBA, mapped into CORBA interfaces and MHEG-5 objects' behavior.

Proposed design has several advancements that are impossible in pure MHEG standard and current web. User and resource controls, real distribution of application servers and providing additional multimedia service facilities.

Abstract

Many factors have led to the wide spread use of content databases on the web. The provider feeds information to and from their content database(s) through a system which tailors the required content into formats suitable for display on the clients' machines.

This paper looks at designing information feeds for a different set of client needs. It is often the case that the basic information base held by a provider is of interest to disparate client populations. The technology which provides the format for content feeds also introduces graphic and interactive design into the display. The impact of the site depends on these elements, and makes a fundamental difference to how (and if) the information is received.

Two sites, one set of content

I am currently working on a site which 'speaks' to two separate audiences. Content held in one central location outputs two separate sites which have different purposes. One site delivers information to students on the courses within Staffordshire University. The University would like to tell people in the community about opportunities for returning to education and lifelong learning. Both these need course information, but will approach their selection of information in separate ways, and need a different level of description. The process of creating separate design structures for separate users is as crucial as getting the same designs to appear on different technological formats

Never Mind the Browser - Feel the Width

Darius Khadjenouri

Live Information Systems and School of Art and Design; Staffordshire University; UK. darius@liveInfo.co.uk

Abstract

In print design, desktop software has allowed designers to control the form of final publication. Type, content, imaging and pre-press are all part of one design process. By taking ownership of the entire medium of networked multimedia; from content to delivery, a designer can look developing in three broad areas. 1/ the backend server process; 2/ content organisation and interface design 3/ delivery in a browser. This panel presentation uses an example project - just completed - to highlight the need of a specific browser to deliver controlled content within an educational environment.

Designing to the medium

Our brief was to create a content generator (for staff) and delivery system (for students) that tracked student progress through a work experience module at Wolverhampton University, England. The content had to be editable (by staff); it had work from a central server to remote clients (within the University's student facilities); and it had to be able to be installed on student local drives (at home and at their place of work). The software's design and functionality had to provide students with a consistent interface to the University and its corporate identity.

We based the system around a locally held database, as we could not guarantee access to the internet while on work placements, but we still built the students' interface using HTML protocol. So we created our own browser based on Microsoft's internet explorer. We then created a rich text to html converter to allow easy document creation for the editing of content (for staff) and entry of information (for students). Because of the browser integration, the completed project is now able to sit easily off-line or on-line, integrating activities into a unified environment on and off campus.

Abstract: The purpose of this panel is to look critically at distance/distributed learning courses that panel participants have/will taught/teach with an eye to making recommendations for correcting any "negative" fall-out. Web based courses are a dramatic change in the teaching/learning process and many educators and administrators jump in with only an eye to the "positive" and are dismayed when confronted with the "negatives."

All of the panel participants are enthusiastic proponents of Distance Education, with experience in televised distance learning as well as both synchronous and asynchronous Web based instruction. Every delivery system has its pluses as well as minuses, and it is imperative that the appropriate system be used as well as an analysis of the target audience.

Statements from Panel Members:

Melissa Lee Price, Ph.D.

Research on the personality characteristics of successful distance learners has been conducted for over thirty years. Successful distance learners are generally more internally motivated and are usually non traditional in age. This research is exemplified by the success of programs such as Phoenix University, which focuses on working professionals eager to complete a Master's degree in business. As more and more universities offer courses at a distance, the number of traditional aged undergraduates taking them has increased. One of the issues that faces anyone teaching in higher education is motivating 18-22 year olds. This is difficult enough in a traditional classroom but what are the implications of a class of students needing external motivation taking a course that is appropriate to students who are internally motivated?

During the past five years, I've taught several courses in a Web based chat room. The first experience was with fifteen doctoral students enrolled on a Ed.D. course at a university in Louisiana. The students, however, resided in many different areas of the state, Texas, and even Canada. Twice a week in groups of six or seven the students logged into a synchronous chatroom to discuss weekly readings. As the summer progressed several academics at other universities 'dropped' into the chat room to participate in the discussion. These 'guests' had not been planned prior to the course beginning, but were a spontaneous result of my discussion of the teaching process with friends.

I quickly noticed that when there were 'guests' in the chatroom the conversation was much more vibrant. I utilised guest speakers in a more formal way the next time that I taught in a synchronous chatroom. This occasion was with an undergraduate class at a private college in New York state. The students were for the most part traditional aged and were all resident at the college. The course was designed to showcase the potential for distance learning for the administration. Again, it was very successful, with students giving high marks for the process of teaching/learning in a chatroom.

The next time this course was offered it was decided to split the delivery method to using both the synchronous Web based chatroom and an asynchronous environment, Lotus Learning Space (LLS). Several months were spent in locating material and building the LLS Courseroom. Again, students were assigned weekly readings to be discussed in the synchronous chatroom. I expected the experience to echo the previous years. Alas for high expectations. The semester got off to a rocky start with several of the students using the chat time to discuss where they would go to party that weekend. The harder I tried to pull them back on task the more they moved off topic. After a face to face meeting with the students to discuss appropriate behaviour we again met in the chatroom with somewhat better results. As the semester progressed, however, it was obvious that there were some disruptive students.

On several occasions a student entered the chatroom under a fake name and proceeded to post pornography and to make off colour remarks. One student made a habit of asking the guests personal questions about their love lives. I ended up spending half the chat time trying to chase down the disruptive elements. At the end of the semester the student evaluations, which in the previous semesters had been very high, were much lower, with many of the students complaining about the disruptions.

So, how does an instructor handle students who aren't prepared for the distance learning experience? In a face to face class room one can always make a disruptive student leave the room. In Cyberspace, it's very easy for a student to hide behind an alias and bring the entire class to chaos. Unless the you have the software to boot them from the room, you're stuck with them.

Michael R. Ogden, Ph.D.

I will be discussing the "tentative" results of a comparison between last year's synchronous, web-supported, interactive TV graduate class and this Fall's totally web-delivered, asynchronous (with a few sync "tutorials" in WebCT Chat Room) "Distributed Learning" model of the same course.

If I might "pontificate" for a moment, I believe that the future of higher education is bifurcating into the more "elitist" residential programs that have prestige as a "pull" to fill the traditional classroom, and those institutions that are seeing their traditional revenue stream(s) drying up (for various political and/or economic reasons) and are needing to diversify their revenue streams (without incurring much additional cost) beyond traditional classroom delivery... Distance education used to be the big THING, but this required all involved to be "present" at the same time to participate (synchronous); interactive teleconferencing classrooms were built, networks developed, methods of keeping geographically removed students involved were employed... Well, as the world becomes increasingly more "networked" to the desktop and as "students" become less and less "traditional" in their educational needs/expectations, and as work/social pressures put more and more demands on our time, we are seeing the development of DISTRIBUTED EDUCATION, based on an asynchronous model; student driven, outcomes based, multi-modal in delivery (web, broadcast, email, correspondence, fax, phone, etc.)... All well and good, but "so what?"

The "so what" question is almost as hard for those of us who are distance/distributed ed. enamoured as the "what can go wrong" question... I received (via the Red Rock Eater Distribution List, 04/7/1999) the following question from Phil Agre which I think pertinent to what I'm trying to get us to examine.

So my question is, what *can* go wrong with technology-based teaching, especially in large college classes? I'd love to hear any anecdotes, checklists, rants, speculations, concepts, references to the research literature, and so on, and especially the sorts of things that the [teachers] who are embracing this technology might not have thought about. What can go wrong educationally? politically? financially? administratively? technically? sociologically? psychologically? All of that. My own stance, as you know, is not that technology in teaching is inherently good or bad, but simply that one should take the entire context into account, articulate all of the values that are at stake, and make conscious decisions from the whole range of social and technical options.

I have been to many conferences where panellists talk at length about "their" system of distance/distributed delivery of education. Pretty "gee whiz" and positive in their presentation -- nobody talks of the down side... I agree with Phil (above) that we need to "contextualize" the discussion; to look realistically at the possible socio/cultural and politico/economic impact of such a significant, technology-induced, change to education and educational delivery (both positive & negative).

Brian L Griffiths, BA, MA, ATD

Many educators still perceive Synchronous-Asynchronous Digital Learning Environments (DLEs) to be 'easier', more efficient and more appropriate delivery vehicles for courses in the HE context. In fact many HE managers and administrators see this technology as 'THE' solution to the enormous pressures on institutions to do more and better with less.

As a DLE project leader and developer one of the most important issues is that of appropriateness and context of the 'course' or material that are delivered via DLEs. The School of Art & Design at Staffordshire University where I am based delivers a wide range of practice and theory based courses covering Fine Art, History of Art & Design in its many forms, Graphics, Glass, and 9 other design disciplines as well as Ceramics. These are delivered with varying levels of support from DLE elements - but are predominantly delivered in conventional, traditional mode in common modular framework. In this practice based curriculum, both learning and teaching say the practice of Glass (blowing or slumping) or Ceramics (throwing or casting) via a DLE is, I believe, less than realistic or possible with current and affordable technology resources - webcams are not appropriate! Such teaching and learning requires direct, real time support with dangerous and expensive capital equipment; total sensory feedback for the practitioner and for the supervisor; and must cope with texture, scale and colour fidelity.

In fact, beyond the utility of email communications and web-based information centres/bulletin boards/intranets this type of experiential learning probably should rarely be considered for DLE support.

However, Staffordshire University is located in the 'Potteries' where the original industrial revolution was nurtured, where there are world class and important collections of ceramics, where the HQs of many key industrial players (Wedgwood, Royal Doulton, Spode etc) are located and where there are internationally recognised HE courses such as the MA in Design for Ceramic Production and the MA in the History of Art and Design.

From this background the 'MA in the History of Ceramics'; a predominantly visual and textual study is an 'ideal' and appropriate programme for bringing together existing experiments in DLEs for a genuinely international market/audience who wish to study at a distance asynchronously. The ceramics collections based in the region (private, public, commercial and at Staffordshire University) will be made available together with access to the University's growing resources in staff webpages (handbooks, information packs, study guides etc), Lotus LearningSpace resources (collaborative learning tools (the course room) and the computer aided management of learning) and COSE (a Staffordshire University developed DLE).

In addition, this flagship project, as for all DLE courses/programmes/awards, must have a very well defined structure and educational context - beyond a modular framework. This should encompass clear definitions of terms for all participants of such as independent learning, resource based learning, collaborative learning, a learning community, non-traditional assessment methods and assessment criteria etc. It must also include an extensive induction programme; a supervisor-student learning contract (to support independent learning and maximise the supervisor-learner contact [the tutorial clock]); differentiate learning between 'high-flyers' and those with (some) learning difficulties (say dyslexia); online help for those experiencing technology difficulties and with some social and physical interactions e.g. summer schools or study trips.

This context ensures the success of the course. As a DLE evangelist it is my belief that without this such projects/environments will be prone to both random failure and success; making evaluation of the REAL opportunities difficult if not meaningless.

Marie Lewis, BA (Hon)

Over the last two years I have been involved in the development and teaching of web based modules via a Digital Learning Environment (DLE). The evaluation of this new mode of delivery is currently under review, however, the perceived benefits and persistent trend towards DLE's promises an unlikely return to the traditional mode of delivery for these modules.

There is a growing pressure at Staffordshire University, as with many other institutions of higher learning, to deliver and assess students using a DLE. While it is pertinent to say that some modules would seem particularly suited to this mode of delivery, the effectiveness in terms of teaching and learning is by no means assured. Do the benefits outweigh the extensive efforts required to develop effective DLE's? In order to answer this question we require feedback from students, developers, tutors and technicians alike.

To assist in assessing the effectiveness of using a DLE to deliver the said modules, students were required to complete a questionnaire. I am currently reviewing the resulting feedback and comments, and additionally, numbers enrolling onto follow-up modules in order to assess student satisfaction. It has, however, been noted that although a student may appear to enjoy a module, a good pass grade is not guaranteed. It is important therefore to correlate assessment grades with the student questionnaire feedback in order to gain a genuine overall picture.

Ideally we need to look at the outcomes of the same module being delivered using both traditional and DLE modes. We cannot, however, rely on such information being 100% accurate, as some successes/failures would be attributed directly to the students preferred mode of learning. I hope, however, that the data collected will provide a fair indication of how effective, from a student perspective this new mode of delivery has been.

Another major attribute to the success of courses delivered using DLE would be the structural quality and usability of the system as a teaching, learning and assessment package. Educational consistency is a major benefit of CBT, but the danger is that we may be consistently using poorly designed and implemented systems. Student resistance is most often attributed to the prior level of computer literacy but it is also extensively connected to the quality of the learning package.

Included in this evaluation will be responses from staff involved in the development and tutoring of such DLE modules.

Abstract: This panel examines the current and future Internet as a world-wide marketplace of ideas and of commercial goods and services. It investigates the motivations for regulating the maintenance of free electronic communications and trade, identifies current and future technologies and other (primarily legal) mechanisms for maintaining control over them, analyzes current national and international attempts to regulate them, and proposes an international solution for minimizing interference with the operations while addressing the major objections against a minimally-restrictive oversight. This topic is important to all who need and deserve a minimally-regulated Internet, because the Internet is a marketplace of ideas and information as well as a marketplace of goods and services. Furthermore, the Internet is a medium for self-expression and self-fulfillment. While some regulation of this medium is essential, proposals to minimize this regulation are in the best interests of all who access the Internet.

1. Position of Brian C. Snow

The Internet is a superior technical medium for popular communication, because it transcends national borders. Wired communication does not respect borders, except where communication is artificially constrained by government regulation. Anticipated developments in wireless Internet delivery further minimize the mechanisms available to control content. The Internet provides for two-way and multi-way communication as well as synchronous and asynchronous communication modes. It provides for the creation of true multimedia documents through the use of audio, video, text, and interactivity providing for a richer communication experience among users. The Internet also provides for anonymity, breaking down barriers and the fear of reprisal against unpopular or controversial beliefs, opinions and ideas.

Governments around the world seek to regulate the Internet because they fear the maximization of public access to ideas and information. Ideas are the foundation of self-governance; information provides the means of self-governance and many countries fear self-governance. Countries such as China are afraid of the possible social consequences associated with the unrestricted free flow of ideas and information. Many governments including the United States fear that the free flow of information across the Internet may compromise national security. Commerce on the Internet is also a concern of many governments because of the access to goods and services that were once available only on the black market in some countries. As with information, the influx of new goods and services may result in new and unforeseen social consequences. Another concern is that taxes, quotas, tariffs and other restraints may be evaded.

Countries have to face the reality that the Internet is not a passing phase, but a new medium that is growing at a pace never before seen in a medium. To deal with this, governments have reacted with knee jerk responses to silence or at least lessen the potential and often overblown impact of the Internet on society. Consumers are restricted access to information through a variety of devices and controls such as filtering and screening devices, tracing devices, interception technologies, exorbitant charges for Internet service, confinement of Internet access to select populations, and in some countries requiring Internet users to register with the state. There are moves to place more controls on Internet service providers (ISP's) requiring the use of screening devices, providing site ratings, required disclosure of users of selected sites, direct licensing or registration of ISP's, cryptography controls, holding ISP's responsible for conveying outlawed information, and direct penalties that include search and seizure of computers. Some governments have gone so far as to restrict access to the Internet to a state controlled gateways, and are placing restriction on access to government information.

Governments are also creating Web sites (e.g. Indonesia) that actually promote the idea of free speech, creating Web sites that refute or confirm information or ideology available on other Web sites. Hotlines are also being created that provide avenues for complaints against Internet sites and for investigating such complaints.

Future technological developments threaten to circumvent most of the currently-effective controls on the Internet. These developments include the introduction of wireless internet delivery services, including personal communication services (PCS) and two way satellite communication services. Most of the current restrictions focus on land based not ether based connections. With the computer becoming even more portable it will become more difficult to track people getting on and off the Internet, especially when connecting through ether based systems. As more corporations, schools, libraries, governmental agencies become wired it will become increasingly difficult if not impossible to track people and what they are doing and saying on the Internet. In those countries that require a permit to access the Internet a black market is sure to emerge with unrestricted access permits going to the highest bidder.

2. Position of Dr. Warren Sandmann and Dr. Daniel Cronn-Mills

The Internet has opened a new realm of communication practices, allowing instantaneous communication regardless of geographic location, so long as one has access to the medium. People are able to both produce and criticize communication--again, as long as they have access to the medium. This new freedom of communication has been perceived as a threat, both by countries and nationalities wishing to control access to information, and by corporate entities fearing a loss of control (profits) over content which can easily be digitized. Music, books, images--all are forms of information which can easily be transmitted through cyberspace.

Given this state of affairs, national and international governmental bodies, at the prompting of both local political leaders and corporate executives, have begun discussion concerning the regulation of computer-mediated communication. In this paper, we will focus on three issues concerning international regulation of the Internet. First, how does the concept of national sovereignty play in the attempt to create international regulations? Second, what role would (or should) multinational and national "owners" of information play in the possible creation of international regulations? Finally, what effect would national legislation play in the possible creation of international regulations? Here we will discuss two U.S. attempts at regulation of the Internet, the CDA and the COPA.

Position of Dr. Richard Parker

The international solution for a minimally-regulated Internet relies upon the creation of international covenants of cooperation among nations desiring to regulate the Internet for specific purposes: (1) regulating child pornography and pedophilia; (2) regulating hate speech; (3) preventing the disclosure of identities of intelligence agents, law enforcement officers, etc.; (4) regulating threatening speech; (5) preventing the disclosure of the content of ongoing legal proceedings; (6) regulating the publication of libels; (7) preventing the disclosure of national-security information; (8) enforcing a ban on sales of prohibited products, such as prescription medicines, weapons, illegal substances, etc.; (9) enforcing bans upon specific services, such as prostitution, gambling, slavery, or prohibited medical practices.

The proposed covenants would require participating nations to cooperate in several ways. First, the nations would need to agree upon a definition of the prohibited idea, content, product or service. Second, the nations would

need to maintain free hotlines for telephone and e-mail reports of sites in violation of the covenant. Third, the governments of participating nations would agree to report the existence of sites that violate the covenant to the nation of origin. Fourth, these governments would agree to initiate investigation and prosecution of website and home page creators under existing laws, and to institute operational shutdowns as necessary, where reports of violations warrant action within their borders or jurisdictions. However, national rules of criminal and civil procedure would remain in force, the civil rights of individuals charged under the laws would be protected to the extent such protections are currently provided, and the national sovereignty of participating nations would be insured. Fifth, the governments of participating nations would agree to report the outcomes of investigations and prosecutions to the originating nation.

The proposed covenants would contain two additional provisions designed to minimize regulatory interference with expression on the Internet. First, participating nations would remain free to create or subsidize government or government-promoted websites that provide "correct" information and/or rebut "incorrect" information provided on non-governmental websites. Second (and most controversially), participating nations would agree to place no additional restrictions on Internet content, such as those identified in Dr. Snow's position paper, for the purpose of regulating the prohibited idea, content, product or service. This would mean that participating countries would agree to eschew national regulations, such as those discussed by Dr. Sandmann and Dr. Cronn-Mills, in favor of the more tolerant Dutch approach emphasizing minimal regulation.

The proposed system of international covenants is likely to work, for several reasons. First, it sanctions existing controls upon materials that nations mutually agree to regulate, rather than asking participating countries to reduce existing regulations. Second, it guarantees a cost-efficient mechanism for reporting violations by using toll-free telephone numbers or government-maintained websites. Third, it provides for international pressures upon a nation to comply with the terms of the covenant. For example, the United States would cooperate with the Netherlands in taking legal action against an offending website originating in the U.S. not only because both nations signed the covenant, but also because the U.S. action would provide a bargaining chip to convince the Netherlands to take legal action against Dutch offenders. Fourth, the covenants obviate the need for additional controls upon Internet content, ISPs, consumers, etc. Enforcement of the covenant would strike directly at the origin of the problem—the offending website. Fifth, the system of covenants ensures a minimally-restrictive regulatory system for the Internet because it constitutes an agreement among signatory countries to use the hotline system rather than more restrictive means. This frees ISPs, consumers, libraries, schools, cyber-cafes, etc., from imposing cumbersome and oppressive regulatory measures in order to comply with government regulations.

The Earth is a Book: Using Hypermedia to Teach Archeology

Eduardo Simões de Albuquerque

Eduardo@inf.ufg.br

Instituto de Informática-UFG-Brazil

The motivation for this work was the construction of the hydroelectric plant “Serra da Mesa” in the state of Goiás (middle west of Brazil). To minimize ecological impact, the Brazilian government requires that an “Archeological Salvage” program to be executed in the area to be salvaged.

In the beginning, the purpose of this work was to help the museum by building a data base and processing information about the pieces collected in the field.

The development of the project, however created a rich environment involving researchers from several areas such as cartography, geography, biology, anthropology, chemistry, sociology, physics, journalism, etc. That environment was the trigger to expand the project from a simple database development to the proposal of a project to develop hypermedia based teaching material (or a system) using the multidisciplinary knowledge available.

The project was incorporated into the Metropolitan High Speed Network program sponsored by the federal government. The project was decided to target teachers and students of public high schools which are being equipped with high speed network and multimedia computers.

The main guidelines of the project can be summarized as follows:

1. *Communication with specialists*: asynchronous communication using e-mail.
2. *Discussions groups*: moderated by museum’s staff, discussions on specific subjects are encouraged among students and specialists.
3. *Chats*: the environment should allow users to take parts in chats with specialists and also with students;
4. *Videoconference*: although a high speed network is available, the costs of the stations should be kept low. It was decided to use the video conference software CuSeeMe;
5. *Assessment*: instructors should be capable to assess students development;
6. *Fun*: the environment should be fun to be used;
7. *Multimedia*: actual films, photos and location of objects of archeological sites should be available,
8. *Access to museum’s database*: although this feature is not directly related to learning, it was decided to allow users to query the museum database;
9. *Virtual reality*: although it was decided that immersive virtual reality (based on the use of helmets) should not be used.

Acknowledgements

This work was partially funded by CNPq/RNP/PROTEM/REMAV Brazil.

Knowledge Net: A Web-enabled Information Service For Continuing Education

Jay Alden (alden@ndu.edu)
The Information Resources Management College of National Defense University
Washington DC

The National Defense University *Knowledge-Net* is a web-enabled service of the Information Resources Management (IRM) College. It is seen as an alternative Information Age strategy for the university to deliver just-in-time continuing education to its graduates and provide a vehicle for life-long learning. The first channel under development is intended for Chief Information Officer staff. It provides the following frequently updated services for each of ten CIO competencies:

FAQ: Questions and Answers concerning fundamental concepts

NEWS: Summary of recent developments related to the competency

ISSUES: Current and emerging issues, options being considered, and their implications

CASES: Best practices in real-world applications of the competency

EVENTS: A listing and links to conferences, training, and educational programs grouped by the competencies

RESOURCES: Annotated links to other web reference sources grouped by the competencies

DISCUSS: An asynchronous threaded conferencing service for discussion of topical issues

CHAT: Scheduled real-time chats on particular topical issues

Thyroid and WWW

Urii Alexandrov, Mikhail Mogoutov, Eugeny Akkuratov
Yaroslavl State Medical Academy, RUSSIA

The eradication of thyroid disease was declared a priority by the World Health Organization. One of the obstacles of this fight is the lack of a unified approach to the problem. Local territorial conditions influence the prophylaxis and treatment of patients in a particular region. This situation can only be dealt with if a wide access to modern scientific data, exchange of information, and education of specialists of all levels is provided worldwide. Formation of an international network dedicated to thyroid disease may be the first step in this direction.

At the present time under the guidance of the Informatics Department of the Yaroslavl State Medical Academy, efforts of specialists from many fields including physicians, programmers, and scientists have lead to creation of a new website about thyroid disease (<http://gw.yma.ac.ru/~thyrpath/index.html>). This website covers most of the aspects of thyroid disease in the Yaroslavl region of Russia, where this condition is endemic.

Main topics of this website are:

1. Ecologic aspects of thyroid disease,
2. Prophylaxis of thyroid disease,
3. Newest developments in the diagnosis and treatment of thyroid disease,
4. Electronic library on thyroid disease available to students,
5. Information for patients.

Dialogue Programming for WWW-based Systems

Bollin Andreas, bollin@ist.tu-graz.ac.at
IICM Software Technology
Technical University Graz, Austria

Abstract: This work describes the approach of classification, specification, description, and automatic generation of dialogues in WWW-based systems. Using Design/CPN and Coloured Petri Nets, common applications and their dialogues are formally analysed and several basic dialogue elements and their structures are deduced. The basic idea is the separation of the structure of a dialogue from its style. This separation enables the description of dialogue systems without spending too much effort on the presentation. It is possible to change the presentation of a dialogue by using different style files. Furthermore the system can change the style of a dialogue, depending on the user who is working with it. Our set of dialogue elements, called S-Dialogues, is forming this fundament of general dialogue systems. The system itself can be described by using an extension to Latex, called Latex-ES, where additional tags and style files are provided to the application designer.

**The Savvy Cyber Teacher™:
A Professional Development Series Integrating Internet into the Curriculum**

Geoff Andrews
Technology Director
Polaris Career Center
Cleveland, OH, USA
gandrews@polaris.edu

Lani Ritter
Educational Technology Office
Cleveland Municipal Schools
Cleveland, OH, USA
Ritterla@cleveland.k12.oh.us

Promoting four unique and compelling applications of the Internet in the classroom — real-time data, unique resources, global collaboration, and web publishing — in a hands-on course with ongoing on-line support not only reinforces national content standards for K-12 teachers, but also nurtures enlivened classroom instruction and student engagement in authentic tasks.

A Technology Innovation Challenge Grant from the U.S. Department of Education supports this turnkey training program for professional development, in which trained master teachers become instructors within their schools and districts. Miami, Phoenix, and Cleveland schools collaborate with career centers, higher education and research groups in this unique partnership. Workshop materials include comprehensive, detailed trainer and participant guides, web projects and data to improve and deepen student understanding of concepts, lesson activities, and online support tools. In ten 3-hour sessions, teachers not only master technical and pedagogical skills necessary for effective Internet integration, but more importantly, concepts and resources for engaging students in authentic tasks, critical thinking and problem-solving.

A Simple Organizational Social Structure Which Enables Technology to Infiltrate the Faculty and the Curriculum.

John L. Bailey,
School of Education,
Brigham Young University – Hawaii Campus,
baileyj@byuh.edu

Ensuring that technology infiltrates the learning experiences of students at all levels is often the task of the politically naïve on-site CIO techno-guru. While there is no doubt in most peoples minds that technology is relevant, even crucial to the finished product – the educated student, the actual embedding of the technology in the curriculum and more especially in the lives of the faculty is a social, not a technical process. The CIO would be well served by the formation of a “technology council” which meets regularly, presided over by the CEO and staffed by representatives of all of the big budget departments on site. The CIO takes the position as the secretary to the council, regularly demonstrating potential applications and generally provoking the departments to compete for credibility in the meeting with their own implementations. Outside the meeting, creative ideas are presented to departments individually by the CIO who assists in making them happen.

Theoretical Foundations of Computer Supported Sustainable Learning Processes (CSSLP)

Ulric Björck, The Viktoria Institute, Göteborg, Sweden

Abstract: This paper introduces the concept of computer supported sustainable learning processes (CSSLP) and presents a theoretical framework of the research area. Key aspects are discussed in relation to relevant terms and issues such as, learning processes, collaborative learning, distance education, distance learning, situated cognition, and situated learning. The main focus of the paper is to clarify the terminology introduced and used in our research about CSSLP. Constructivism and Papert's constructionism is discussed as well as Resnick's Distributed constructionism.

Normally the learning process, in educational settings is based on activities such as lectures, seminars, tutorials and practical work. From our point of departure the learning process differ a lot, and it is essential that within the research area of CSSLP different learning-processes and attached activities are elaborated and evaluated. The paper describes some fruitful approaches in this process.

Use of Video analysis to Enhance Faculty Teaching Performance

Sally Blake UTEP sblake@utep.edu. Sandra Hurley, UTEP shurley@utep.edu, Gregory B. Lush, UTEP, lush@ece.utep.edu, Josifina Tinajero, UTEP tinajero@utep.edu, Steve Rollins, ASU

Abstract: Although it has been possible to videotape teachers in their classrooms for a number of years, methods for analyzing the contents of the tapes are not fully developed. The use of formative, reflective evaluation of teaching is not commonplace among university faculty. The thoughtful development of video analyses and its corresponding reflective tools is important for faculty as teaching becomes a more important focus for faculty advancement. The instruments used here are being piloted at the University of Texas at El Paso (UTEP) and used for faculty self reflection.

Students and Computers; Ability, Availability and Attitudes

Carol S Bond,
Institute of Health and Community Studies, Bournemouth University, England.
cbond@bournemouth.ac.uk

Before introducing computer based distributed learning into its nursing curriculum the Institute of Health and Community Studies conducted some research into students' computer ownership, use and attitudes (n108)

Computer ownership amongst students prior to starting the course was 64%, however nearly a fifth (18%) used computers less than monthly, and over a quarter had never searched the WWW. Less than half (43%) responded positively to the statement 'I like working with computers' and around one quarter (24%) only use a computer if they have no choice.

The attitude of students to being asked to use IT was encouraging, with almost half looking forward to using it, but there was a significant minority who did not relish this requirement. The results suggested that students would need quite a lot of support if they were going to successfully cope with the IT requirements of the course, and a support programme has been implemented ahead of the introduction of online materials.

Holistic Approach for the Use of Multi Media and Multi Modality: Digital Storytelling

Norbert Braun, Manfred Gaida, Ulrike Spierling
Dept. Digital Storytelling, ZGDV Computer Graphics Center, 64283 Darmstadt, Germany
{Norbert.Braun, Manfred.Gaida, Ulrike.Spierling}@zgdv.de

The components of humanlike conversation are ought to be connected by a dramaturgical context. This dramaturgy approach used in multi media, multi modality and programming logic is a main aspect of Digital Storytelling. Digital Storytelling principles are to be transferred to the following tools and methods:

- Programming language for designing holistic applications.
- Methods to evolve the way of thinking of authors.
- Methods to encourage an intuitive designing.
- Designing methods to evolve the power of expression of multi media applications.

First results are a avatar system for conversational interaction in virtual worlds as well as a audio and video systems, including dynamic hyperlinks in combination with speech recognition.

At-Risk in Cyberspace: Enhancing Engagement of High Risk Students in Internet-Based Courses

Roger Bruning, PhD

Christy Horn, PhD

Steve Lehman, MA

Douglas Kauffman, MA

Center for Instructional Innovation, University of Nebraska-Lincoln, 212 Bancroft Hall, Lincoln, NE 68588-0384
Tel: (402)472-5213, Fax: (402) 472-6126, E-mail: rbruning@unlserve.unl.edu

Abstract: Concern has grown about the utility of technology based education for at-risk learners. This study explored effects of enhanced motivational and relationship building communications on at-risk students' engagement in an internet-based multimedia course. Patterns of engagement and moderate to strong effect sizes point to the need to systematically incorporate motivating dimensions into teacher-student communication.

Making the WWW Accessible - Just DO-IT

Sheryl Burgstahler,
Adjunct Associate Professor
College of Education, University of Washington, USA
sherylb@cac.washington.edu

Richard Radtke
Professor
School of Ocean and Earth Science and Technology, University of Hawaii, USA
radtke@hawaii.edu

Abstract: Technology has served to level the playing field for some individuals in under-served populations, opening doors to success that were not there in the recent past. For example, a few years ago electronic mail and gopher information servers provided individuals who were blind, using computers equipped with voice output, access to people and printed resources. For the first time printed publications became available to this group at the same time it was offered to others. Similarly, individuals who were deaf could communicate with others "privately" and efficiently, without the need for lip reading or sign language. As graphical images and audio clips become more widespread, will individuals with certain types of disabilities be the information have-nots once again? Stop by this poster session to obtain information about legal requirements, resources, and guidelines for making your Internet resources accessible to individuals with disabilities.

User Interface Guidelines for I*net Applications

Fabrizio Calì, Paolo Morandotti, David Frontini
Intrasoft S.p.A.
v. Donatello, 30 - 20131 Milano, Italy
{fcali, pmo, david.frontini}@intrasoft.it

Abstract: During the last years the user interface has played a growing role in the applications' development, and often, especially in small enterprises, the analysis is restricted to the GUI drawing. This practice, which is basically wrong, may cause serious problems when it is used for the development of Intranet applications. The GUI's impact on these kind of applications is deep, involving the system architecture [Frontini & Morandotti, 1999]. A well written GUI should give high functions to heterogeneous users, using a subset of HTML and JavaScript to be cross-browser. The most relevant aspect of HTML-based interface is his ability to reproduce the same operations known by the user, requiring no technical knowledge about the GUI itself, therefore the user can keep his experience on the work to do and forgot any technical problem. We define such an interface "transparent". In this poster we explicate some guidelines to create transparent interfaces.

Web-Based Support for Educator Staff Development

Dr. Catherine Cavanaugh
Florida Center for Instructional Technology
University of South Florida, USA
Cavanaugh@tempest.coedu.usf.edu

Dr. Terence Cavanaugh
Secondary Education
University of South Florida, USA
Cavanaugh@tempest.coedu.usf.edu

Teacher training enhanced with Web pages can give teachers continual just-in-time support. While most teachers are experienced Web consumers, some lack experience using the Web. The opportunity to grow in Web experience adds value to training workshops. Workshop Web pages fill a continuum from full Web-based distance learning delivery to companion materials for a traditional class. The Web pages serve a multitude of purposes before, during and after the workshop. Before the workshop group meets formally, participants can read the Web page to become oriented to the topic of the workshop. During the workshop, the Web pages become a multimedia, interactive agenda where participants can return after the workshop concludes. After the conclusion of the workshop, participants have access to all materials and their additions and updates. For added functionality, and for teachers in schools still lacking Internet connectivity, the contents of the Web pages can be distributed on CD-ROM.

Remote Measurement System Using Internet

M. Cervera, F. Gómez, J. Martínez

Lab. de Microelectrónica. E.T.S. de Informática y Dpto. de Física Aplicada. Universidad Autónoma de Madrid. Campus de Cantoblanco, 28049 Madrid. E-mail: Javier.Martinez@ii.uam.es

Abstract: A vehicle for a complete engineering and scientists practical formation is presented. It is made possible by the use of virtual instrumentation, not in the sense of a simulation tool, but as the remote access to facilities located in related research laboratories. Internet World Wide Web provides a best way to materialize this remote access, reducing the requirements in the educational laboratory to workstations (WS) or personal computers (PC). The different parts that integrate the whole remote access measurement system are: the measurement instrument, a controller equipment that will be called instrumentation server, a web server and the client computer (PC or WS) from which the user accedes to the system. The user application has been developed in Java, in order to provide it a multiplatform characteristic. It contains the graphic interface, reproducing the front panel of the measurement instrument, by mean of which the user performs the set of remote measures.

The Role of Hypervideo in Learning Environments

Teresa Chambel

DI-FCUL, Portugal, E-mail: tc@di.fc.ul.pt

Nuno Guimarães

DI-FCUL, Portugal, E-mail: nmg@di.fc.ul.pt

Abstract: The educational potential of the motion picture was early recognized by many, but technological and use constraints have limited, or perhaps just postponed, the fulfilment of this vision. Significant technological advances and the new tendencies for media convergence and integration are transforming video into a dominant medium, suggesting new ways to support learning activities. The purpose of this presentation is to contribute to the understanding of the effective use of video in education, in particular by discussing the role of hypervideo in learning environments.

Our approach is based on human cognition concepts, the way media relates to learning, and hypervideo characteristics. Video and television are usually watched in an experiential mode. Effective reflection requires some structure and organisation. Hypervideo provides the mechanisms to structure and navigate video, and to integrate it with other media. Its ability to integrate video as an active resource has immense possibilities. However, there are still some technical and methodological challenges. Technology will provide the tools; methodologies will guide the design for its effective use.

A System for Detailed Student Profiling

Colin R Chambers

School of Art and Design; Staffordshire University; UK. c.r.chambers@staffs.ac.uk

Abstract

This poster demonstrates a system to track an individual student's performance in core criteria across a wide range of Art and Design modules. The BA(hons) Design Degree at Staffordshire University envelopes glass design to media production; but the underlying ethos of the Degree is that all courses share common skills and knowledge.

In 1998 the School of Art and Design set up common intellectual criteria for all student learning; to be used to assess students at all levels on all modules. The shared criteria give the School an important tool. They can be used by faculty and students to understand an individual's progress and tailor the way that individual studies.

To make use of this opportunity, the School needs a system for capturing and collating individual grade for each criteria in each module. This poster show work results and work in progress towards this seemingly simple aim.

Interface Repository Viewer for CORBA

Chang-Jen Chen, Ruey-Shyang Wu, Shyan-Ming Yuan, Kai-Chih Liang

Department of Computer and Information Science, National Chiao Tung University, Taiwan, R.O.C.

Tel: +886-3-5712121-56631, Fax: +886-3-5721490,

E-mail: {gis87524, gis87539, smyuan, Kcliang}@cis.nctu.edu.tw

Abstract: The Common Object Request Broker Architecture (CORBA) is structured to allow integration of a wide variety of object systems. It is convenient to serve a request through an Object Request Broker (ORB). All request objects, which are correlative, are encapsulated. Interface is a description of a set of these request objects. A service provider can provide a service and register his Interface to Interface Repository. In other words, a client can query the Interface Repository and get the information of an interface which is provided in the environment.

We present a CORBA client application for programmers to query interface definitions. It is named Interface Repository Viewer (IRV). A programmer can get information from the Interface Repository by the graphical user interface of the IRV easily, like the file manager in Microsoft Windows. Besides, the contents of any object nodes can be directly retrieved and the detail information is shown in HTML form.

Reading Chinese Together: Uses of the Web Forum for Individualized and Group-based Language Learning

C. Candace Chou, National Foreign Language Resource Center, Univ. of Hawaii, USA
Jung Ying Lu-Chen, National Foreign Language Resource Center, Univ. of Hawaii, USA
Stephen Fleming, National Foreign Language Resource Center, Univ. of Hawaii, USA

Abstract: This session tackles issues in teaching foreign languages on the Web. The poster presentation on course design for a Web-based third-year level Chinese reading class will address the following challenges:

- creating a model for Web-based course design that will be useful to educators without advanced programming resources
- designing strategies for use of the forum, or bulletin board, as a locus for several kinds of language-learning tasks
- coordinating hardware and software so that students working with various system configurations can all communicate in written Chinese
- selecting a combination of Web-based tools that suits our needs
- making use of students' background knowledge of the real world and of the target language as a jumping-off point for each lesson
- structuring lessons to conform to natural reading behaviors
- providing a combination of group-based activities and individual, off-line activities with opportunities for reflection and reaction

iPROXY: A Programmable Proxy Server

Herman Chung-Hwa Rao and Yih-Farn Chen
Network Services Research Center
AT&T Labs - Research
Florham Park, New Jersey, USA
herman@research.att.com, chen@research.att.com

Ming-Feng Chen and Josic Chang
Department of Computer Science and Information Engineering
National Chiao-Tung University
Hsin-Chu, Taiwan
mfchen@ieee.org, cwchen@csie.nctu.edu.tw

Abstract: The main functions provided by traditional proxy servers are storing and forwarding web pages. In upstream, a proxy accepts browsers' HTTP calls and forwards them to Web Servers. In downstream, it caches data from Web servers and forwards it to original callers. iPROXY is an active, intelligent and programmable proxy server that performs additional computations for new services on HTTP calls and/or Web data during the storing and forwarding process. Computations are in fact performed by individual agents, implemented as CGI-bin on iPROXY and executed based on requested URL's. Furthermore, iPROXY provides a common platform for programming agents and a generic mechanism for hosting, integrating and executing agents. To demo its functionality, we have introduced new services in iPROXY, including TCP Tunneling, Chinese URL, Home Page Walking, Pre-Fetching, Archiving Services, and Personal Portal, without changing standard protocols like HTTP, DNS, or HTML, nor modifying existing components such as servers and browsers.

Using Student Experts as Technology Assistants in Schools: An Untapped Resource

Robert J. Clinkert, Ph.D., Assistant Superintendent for Instruction
Woodridge School District 68, 7925 Janes Avenue, Woodridge, IL 60517, U.S.
Clinkertr@wdgdst68.dupage.k12.il.us

Abstract: One of the best resources for helping teachers implement their technology curriculum is a student tech assistant. In Woodridge School District a select cadre of students from each school is given formal training in advanced topics such as creating web pages, hypermedia, and network trouble shooting in order to assist the classroom teachers.

**Teacher Training and Support of the Technology Curriculum:
What to Do After the Network is Unpacked and Connected**

Robert J. Clinkert, Ph.D., Assistant Superintendent for Instruction
Woodridge School District 68, 7925 Janes Avenue, Woodridge, IL 60517, U.S.
Clinkertr@wdgdst68.dupage.k12.il.us

As school districts grapple with the related problems involved in implementing their technology curriculum, the biggest problem (after the funding battle is won) is training. The familiar refrain is: Now that we have the necessary funding for our technology hardware and software, how do we jump-start the new curriculum? Getting the network infrastructure in place and connected to the internet is only half the battle. Hiring a technology coordinator may keep the network "up and running" but it will not guarantee curriculum integration of technology into classrooms, which are understandably often under the leadership of a techno-phobic teacher who needs immediate, intensive training and support. There is a clear-cut need to discuss this aspect of technology education among people who have successfully implemented creative strategies, and people who would like to benefit from the experiences of others. A special interest group should be available for sharing training and support solutions. Our school district would like to share two of these solutions which have helped our teaching staff immensely. Two critical approaches should be used in training and support. First, use teachers as trainers who already exhibit an interest and aptitude in technology. Such teachers are perfect mentors because of their enthusiasm for technology. Concentrate further training on these teachers first. Then utilize them as trainers of the remaining staff. Role models are just as important as skill training during the crucial birth period of your technology curriculum. The second urgent strategy is providing teachers with expert support service "at their elbow" as they launch their technology curriculum. Accomplishing this may be simpler and less expensive than imagined. One of the best ways to help teachers implement their technology curriculum may surprise many educators who overlook a nearby, untapped, inexpensive resource - their own students! The reason for this blindspot is that educators naturally view students as the consumers of the educational process rather than as part of the team of producers. In Woodridge School District located in suburban Chicago, a select few students from each school who demonstrate "high tech" aptitude are given formal, advanced technology training in special summer school classes. The advanced topics they learn are not those found in the normal technology curriculum. They include how to create web pages, hypermedia and trouble shooting.

The "Virtual Classroom": Perspectives From Educators And Students On Computer-Supported Instruction In Higher Education

Jo Ann Coe, Nancy Brown, Miriam Johnson, University of South Carolina, USA

This poster/demonstration system will present a project that utilized a course management software system (Intrakal) for developing on-line materials for graduate social work courses. The authors discuss their experience in relation to teaching and learning as well as present the evaluation results of students' experiences with the course management software system.

Multi-Dimensional Web-Based Learning in Freshman Chemistry

Leon L. Combs, Ph.D.
Department of Chemistry
Kennesaw State University
Kennesaw, GA 30144
lcombs@kennesaw.edu

Abstract: The dimensionality referred to in the title is the many different learning styles of students. The presentation gives information related to a study of how to incorporate the many different learning styles of students into a web-based course in chemistry. We tried to develop a site that accommodates visual, verbal, sensory or intuitive, inductive and deductive, reflective, linear or non-linear, and many other types of learners. Some degree of socialization was developed with components of WebCT and the use of office hours with NetMeeting. The site is still being developed as other topics such as continual assessment and multiple feedback are being incorporated. The site is at <http://stern.kennesaw.edu/~lcombs/GenChemI>, but some components of it are password protected. An on-line text also incorporates video (Real streaming) in short segments (<10 minutes) presented on various topics encountered in the first semester of general chemistry.

New Realities, New Rhythms, other Structures

Laura Herrera Corona
Comunicación y Filología
Instituto Tecnológico y de Estudios Superiores de Monterrey, Campus Ciudad
de México
México
laherrer@campus.ccm.itesm.mx

Abstract

It is important to analyze the role of screens – computers specially – in the image era we are living, the development of computers as new characters in our every day lives and the intimate relationship established between the user and the multimedia background in front of him.

E-mail, internet, animation programs, image processing and other social-artistic advantages of the computer bring other alternative means of self and world perception. New concepts of time, space, thinking, feeling and sensing permit the user a self identification with a medium that doesn't judge, that will let him express freely and will permit "reality" manipulation according to the new interactive person's interests.

We like to DO by ourselves, to modify, to propose; we enjoy expressing ourselves in writing, we love contacting the outside world in a matter of seconds, we like having varied information available via images... All this is offered by new communication technology systems represented and presented on the computer screen (our matte).

Web-based Learning for Practicing Health Professionals- Does it Work?

Janet Curran-Smith, BN, MEd
Professional Development Consultant,
IWK Grace Health Centre
Nova Scotia, Canada

Meg McCallum, BSc, MA
Director, Learning & Organizational Development,
IWK Grace Health Centre
Nova Scotia, Canada

Maureen White, BScN, MN
Collaborative Associate ,
IWK Grace Health Centre
Nova Scotia, Canada

During the Fall of 1998 an information management strategic planning group in the IWK Grace Health Centre identified five key directions for information management in the organization. One of these directions outlined the use of innovative learning technology to support learning for health centre staff, patients and families and partners. In response to this direction a working group conducted a pilot study in which a learning opportunity was offered to multidisciplinary health professionals using a web-based learning environment. The learning opportunity was a certification program which had been traditionally offered using a paper-based self-learning package. Two groups participated in the study, one group had previously completed the paper-based version, the second group was experiencing the content for the first time. This presentation will include a description of the pilot study and demonstrate the key features of the web-based learning environment. Results of the pilot study will also be presented with suggestions for future web-based learning applications in a health care environment

Participative Evaluation of Collaboration Projects of Computers in Education

Ph.D. Valdemarina Bidone de Azevedo e Souza

valde@pucrs.br

Msc. Helena Sporleder Côrtes

helencor@pucrs.br

MBA student Andréia Petry Sarmiento

deiapetry@pucrs.br

Centro de Informática na Educação

Pontifícia Universidade Católica do Rio Grande do Sul
Brasil

The integration of computer as an educational innovation implies to become completely submerged in researching as a way of appropriation of knowledge, narrow the distance between theory and practice, acquisition of solid theory basis as a reference point to analyze practices and also for the construction of autonomy using the scientific education.

We live the time of creation, of restauration of singular elements, of the appearance of new potentials.

Through this perspective, the CIEPUCRS - Brasil” proposes the accomplishment of participative evaluation of collaboration projects which may qualify teachers for the re-invention of pedagogical techniques and for critical utilization of technological resources, that alone demands improvement and personal appropriation of the role as a professional, enabling a collective re-invention in an interdisciplinary way.

The Functional Web: User Testing Your Site

Judith Dean
Web Project Leader, Information Technology Division
University of Michigan
jude@umich.edu

Abstract: We recently put our content-rich information technology site to the test by sending members of our campus community on a "scavenger hunt" for some of our most frequently requested Web-based information. By observing their actions, we discovered first-hand dozens of usability problems concerning content organization, navigation, naming conventions and more. The good news was that our two testing cycles led to many improvements that were both easy to make and resulted in faster and more intuitive information retrieval for our users. This poster session will highlight our testing process and results. I can also answer questions about how we planned for and evaluated low-cost observation-based testing and how we're continuing to build this important activity into ongoing Web projects.

How and Why Faculty Are Incorporating WebBased Technologies into Teaching Practices

Jean A. Derco, Ed.D., University of Tennessee, USA, jderco@utk.edu

This study's purpose was to identify how selected university faculty members are integrating instructional technology into their teaching practices and to determine the primary intrinsic and extrinsic rewards and incentives that influenced them to do so. Data were gathered using a survey instrument and interviews. Email was reported as being used more than any other computer-driven instructional technology followed by using web-based materials that support course content; showing computer-projected visuals while lecturing; and, providing a web-based syllabus. Faculty members were overwhelmingly influenced to start using instructional technologies by intrinsic rewards and incentives, primarily because they wanted to increase their teaching effectiveness and improve their instruction. The most influential extrinsic rewards and incentives were related to receiving work-related support and recognition. It can be concluded from this study's findings that instructional technology will be adopted by faculty who want to improve their instruction and perceive technology use as beneficial to students.

Web Resource Collaboration Center: Providing an Integrated Tool to Support Lifelong Learning

Joanna C. Dunlap
School of Education
University of Colorado at Denver
U.S.A.
Joni_Dunlap@ceo.cudenver.edu

Influenced by generative and intentional learning methodologies, the Web Resource Collaboration Center (WRCC) was developed to provide a structure and forum for lifelong learning activities by empowering learners to build their own Web-based knowledge bases and support systems. The WRCC – written entirely in Perl – enables learners to collaboratively build comprehensive knowledge base systems that use the Web to provide on-demand access to integrated information, guidance, training, and tools that support learning and performance.

To provide a structure for these activities, the WRCC is broken into three functional areas: Discussion Forum, Link Manager, and Resource Construction System. Using the Discussion Forum, learners can communicate and work together on ideas and challenges. Learners use the Link Manager to categorize and critique resources found on the Web. The Resource Construction System is a learner-centered collaboration tool for developing unique resources for inclusion in the WRCC's Link Manager. For an example, please see <http://www.cudenver.edu/~jdunlap/wrcc/example>

ON-LINE LEARNING WORLDS FOR COMPUTER APPLICATIONS INSTRUCTION

Gloria Edwards, Ph.D.
Educational Technology
Purdue University
West Lafayette, IN
Email: gloria@purdue.edu

Kathy Weedon
Business and Industry Training
Ivy Tech State College
Lafayette, IN
Email: kweedon@ivy.tec.in.us

Abstract: The pace at which high speed, high powered computers are being produced mandates a new mindset from those empowered to produce the manpower for the next millennium. The past decade has quickly produced the majority of job opportunities that specify "computer experience required" for both business and industry, and educational environments. Purdue University and Ivy Tech State College - Lafayette recognize that on-going computer instruction is a viable solution to some of the instructional goals defined as a result of manpower needs in our society. As such, this poster/demonstration presents the preliminary works of this collaborative effort to develop on-line learning worlds for teaching computer application skills that have the potential to increase learning, recall, retention, and ultimately transfer into both workplaces. Included in the demonstration will be preliminary data and analysis of student performance, overall learning, and comments/feedback from students participating in the learning worlds project.

Nicole English

Fancy Interfaces: What Are They, and Why Do We Need Them?

~180 Words

Email: nenglish@cctr.umkc.edu

Abstract: Historically, there has always been resistance to new media. Even as far back as the invention of the printing press, there has been distrust of new channels of communication. Later, early film, radio, telephone, television, and more recently, digital technology, have all suffered the same distrust by government and society. All have been subject to legal constraints, licensure, controls, prior restraint issues, and social concerns. This fear and distrust of new media is historic, natural, and not unexpected. We should indeed be alert to the power and influence media has over our lives. This should not, however, deter us from pursuing or developing new channels of communication. Rather than be fearful of new technology and fighting or avoiding it, we should, rather, examine it in the light of what we have learned about dealing with new media in the past. Unfortunately, interfaces with this new digital medium, are still clumsy. The interface with technology itself is still a bit of an obstacle, and often, so is the expense of using or owning it. As these interfaces become better designed, more efficient, cheaper, more playful, simpler to use and understand, the more people will be better able to actually use the technology, creating more opportunity for interactivity.

BURKS 4: An Educational CD-ROM

John English
School of Computing and Mathematical Sciences
University of Brighton, Brighton BN2 4GJ, UK
Email: je@brighton.ac.uk

Abstract: This poster presents a practical demonstration of the 4th edition of the Brighton University Resource Kit for Students (BURKS), a non-profit product for students of Computer Science. BURKS is a self-contained website on two CD-ROMs for use on any IBM PC running Windows 3.1 or later.

BURKS includes tutorials, reference manuals, compilers for over 20 different programming languages, published papers, complete textbooks, a dictionary of Computing with over 12,000 hyperlinked entries, a copy of Linux (the popular free Unix clone for IBM PCs) and a large selection of other software. The entire collection (about 1.3 gigabytes of material) is also available online at <http://burks.brighton.ac.uk/>.

Since the CD-ROM is designed for use by novices, it includes a pre-installed copy of Netscape Navigator which runs directly from the CD with no need for a separate installation step, and which is configured with a set of helper applications to automate the process of installing software packages from the CD.

Tribal Computational Science Program

<http://www.ahpcc.unm.edu/Alliance/Tribal/>

Evans Craig, Education Outreach and Training Manager
Albuquerque High Performance Computing Center, University of New Mexico, United States of America
Voice: 505-277-9544 Fax: 505-277-8235 E-mail: ecraig@ahpcc.unm.edu

Abstract: The Native American Distance Education Community Website (<http://www.ahpcc.unm.edu/Alliance/Community/>) is gathering, cataloging, and distributing high performance computing programs, tools, and resources for utilization by Native American serving schools, colleges, and universities. Institutional technology infrastructures are being assessed, and a feasibility study is being created to support infrastructure-funding proposals for high-speed connections to the Internet2 (vBNS) Research Network. A computational science curriculum is being accumulated for use by both faculty & students. The teacher programs being designed will be used to "train faculty" to use the HPC programs, tools, and resources. The student programs are being designed to run "High School Student Programs in Computational Science" by utilizing these HPC programs, tools, and resources. The Albuquerque High Performance Computing Center is developing programs to reach Native American students in supercomputing and computational science, with emphasis on Internet technologies and other related distance learning technologies, in approximately 50 Native American serving schools.

Problem Solving With a Internet Database ‘The Hit-List’

Farrukh Farid

University Continuing Education, San Jose State University, California, USA.

Tel: (408) 924-2675, Fax: (408) 924-2666, E-mail: ffarid@cemail.sjsu.edu

Abstract: University Continuing Education, San Jose State University, has built a database using MSQL software. The database is used by the non-technical staff to enter their day to day computer related problems. This database, named “The Hit-List”, resides on the department’s Intranet and is checked regularly by the technical staff. Tasks to troubleshoot and resolve problems are assigned to different technicians according to their skill level. The database was designed using W3Msql interface, and is not dependent on any particular browser. The strength of the database is that it can be worked on from anywhere over the internet...

The database also helps the Director of Technology to manage and supervise the technical support staff. It can be determined that if a technician closes more tasks on the “hit-list,” he/ she is consequently providing better service to the users. This helps to quantify staff evaluations, and can result in better biannual reviews and promotions. It also helps the Director to find out which technician is weak in resolving problems, and who needs to improve his/ her skills in order to help the customers more efficiently.

In conclusion, the database is very cost effective, and can meet the demands of the modern day web technology era. It is a fast, reliable and a very effective way of keeping in contact with our daily technical issues.

Acknowledgements

The author wishes to thank Marc Graham whose good will, enthusiasm and dedication helped design the database.

Eliminating Traditional Library Instruction: Requirements for the Successful Online Replacement

David A. Flynn
Central Information Services
Business, Humanities, and Social Sciences Department
University of Hawaii at Manoa Libraries, USA
dflynn@hawaii.edu

Randy Burke Hensley
Library Administration
University of Hawaii at Manoa Libraries, USA
rhensley@hawaii.edu

Abstract: Interactive web applications offer academic libraries an effective platform for teaching basic library skills and can replace the traditional, and often unproductive, “one-shot” freshman visit to the university library. A new online headquarters for information literacy and library instruction under development at the University of Hawaii at Manoa Libraries will move beyond the earlier static web versions of bibliographic instruction and begin to engage the user in an active learning process through animation, feedback, and flexibility.

Successful web-based delivery of basic library skills instruction begins with careful planning, an organizational commitment to the technology, and attention to sound pedagogical practice. More specifically, the design should: 1) provide the user with the opportunity to interact with the lessons and receive immediate feedback; 2) allow for easy integration by faculty to course-related assignments; 3) be flexible and accommodate alternate learning styles; 4) move beyond simple mechanics of navigating a database or catalog; 5) bridge familiar experiences to new applications; and 6) provide clear and easy access to a librarian for further assistance.

Companies & Teleconferencing Tools: An Impact Study

Paola Forcheri, Maria Teresa Molfino, Alfonso Quarati
Istituto per la Matematica Applicata – Consiglio Nazionale delle Ricerche
Via De Marini, 6 16149 Genova, Italy – e-mail: (forcheri,molfino,quarati)@ima.ge.cnr.it

Abstract: The project *Teleconferencing*, part of the EC's ADAPT2 initiative, aims to study the potential of network technology, especially teleconferencing tools, in response to the need for intra-company and cross-company collaboration. The project was run by IMA-CNR, who drew up the project guidelines in partnership with eight companies representing a cross-section of the local economy in Liguria, a region in north-west Italy.

Liguria has been seriously hit by the general decline in industry; the reduction in heavy industry in particular has brought serious consequences, including high unemployment, demographic decline and ageing of the population. The socio-economic transformation underway calls for considerable flexibility, the capacity to exploit innovation and the fostering of exchanges and co-operation in order to open up new opportunities.

Within this framework, we carried out a survey to gauge companies' attitudes towards teleconferencing tools so that methodologies could be devised to exploit the potential for growth SMEs.

NAU Web Course Evaluations; Online Learning from the Students' Perspective

Timothy Foster – Northern Arizona University, Office for Teaching & Learning Effectiveness
Tim.Foster@nau.edu

Marilyn Fritz – Northern Arizona University
<mailto:Marilyn.Fritz@nau.edu>

Abstract: Northern Arizona University (NAU) is the only university located outside major Arizona metropolitan areas. The university's mission is to serve rural Arizona through distance education initiatives. Recently NAU has added web courses to further serve a growing number of statewide students. It is recognized that to offer meaningful courses on the Internet changes to the organization of class materials and method of instruction have to occur. Student evaluation of web courses is key to understanding the impact of this method of delivery on the students and the institution. It is crucial for effective planning and to improve the web courses. More research must be done to continually improve the web courses and the methods for delivering class materials for the students to work on. This process has just begun at NAU and will continue. Results of the Fall '98 and Spring '99 semesters can be viewed at <http://jan.ucc.nau.edu/~tdf/eval>.

Interactions Examined from Multiple Perspectives

Shirley Ann Freed, PhD
School of Education
Andrews University, MI, USA
freed@andrews.edu

Marilyn Eggers, PhD
Advancing Technology in Education, USA
meggers@atie.org

The first study sought to clarify ways in which active learning strategies were incorporated into the winner and honorable mentions of the Paul Allen Virtual Education Foundation's contest to identify outstanding online courses. Interactions emerged as critical in web-based learning. The diverse ways this was accomplished makes this study intriguing and valuable. Findings are organized in a theoretical framework based on the American Psychological Association's Learner-Centered Psychological Principles.

A second study analyzed the conversations in a bulletin board during a WebCT delivered course. By mapping the various interactions it became obvious that certain individuals and topics elicit multiple responses and very rich interactions. An interaction analysis model emerged that is different from others that focus primarily on the types of individual interactions without a holistic view of the total conversation event. The patchwork quilt metaphor of Gunawardena, Lowe and Anderson (1997) is extended to a crazy quilt metaphor where patterns are less predictable and chaos seems to reign supreme!

Software for Supporting Virtual Classrooms

Kathy Gates

This SIG will focus on the evaluation, use and performance of integrated software applications for supporting virtual classrooms. Participants will share their experiences with these packages so that they and others can make informed decisions. This forum will provide an opportunity for faculty, administrators, and technical support staff to compare features, discuss support issues, and propose future enhancements. An important related issue is that of standards for on-line courseware, e.g., the Instructional Management Systems (IMS) project. Integrated software applications for supporting virtual classrooms are maturing and gaining in popularity and are facilitating the shift toward Web-centered classes. The investment in faculty time and effort to develop on-line course materials requires that institutions carefully consider the available options and choose wisely. This SIG will serve to guide participants as they make important decisions for their institutions.

Developing Multimedia-based Courseware: A Student Team Member's Perspective

Carol A. Gilley, M. Ed.
Department of Adult Education
University of Arkansas
United States of America
cgilley@comp.uark.edu

Abstract

Developing multimedia-based courseware can be a very positive experience for students as members of a student development team. The roles of the student development team would be many. They would develop a contract with the content expert. They would develop a time line of activities and a production finish date. Development activities include organizing, flowcharting, story boarding, and authoring. They would arrange for and produce video, audio, and other forms of media. A learner verification review with potential users of the product is an extremely important and useful step. Multimedia development can be a totally self-directed and problem solving experience for those involved. The role of the facilitator and content expert is to be responsible for determining goals and objectives for the content, and also to oversee the team's progress. The facilitator's responsibility is also to provide equipment and advice for development.

Business German and the WWW

**Dr. Lawrence F. Glatz
Department of Modern Languages
The Metropolitan State College of Denver
Denver, Colorado, USA
glatz@mscd.edu**

Abstract: With the Worldwide Web of the Internet, businesses and governmental organizations present their products, services or information to a large audience. The material found on the WWW is rich in possible pedagogical uses and current. Students enjoy applying concepts to tasks involving the WWW, reading and understanding the target foreign language vocabulary in the context of the real world, and continuing the learning process by finding their own WWW materials for assignments. This demonstration provides an introduction to the pedagogical assumptions and methodology involved in undergraduate instruction of business-oriented foreign language courses involving the WWW, with assignments for Business German and German websites used as examples. The Metropolitan State College of Denver offers a two-semester course sequence in Business German. Business students pursuing German language skills, students minoring in German and native German speakers interested in the topic of Business regularly select these business-oriented advanced foreign language seminars.

Catch the Stars in the Net!

Project for Astronomy Education and Outreach via the Internet

Federica Guadagnini, Astronomical Observatory of Padua, Italy
guadagnini@pd.astro.it

The Web site "Catch the Stars in the Net!" (www.pd.astro.it/stars) represents the "visible" part of a more complex project of didactic and popularisation of Astronomy via the WWW, managed by the Astronomical Observatory of Padua (Italy). It is presented here in its English version.

Our aim is to meet the needs of all the users whether they are looking for information regarding concepts of Astronomy.

The site is composed of "module" of didactic or popular behaviour, organised in different levels of complexity and depth. The exposition of its contents and themes (i.e. didactics, outreach, history, curiosity/news, information) has been carefully developed. Each module is tested "on the field" on a sample group of students, teachers and selected users before publication.

The site is completely created and managed by professionals in Astronomy, with whom is possible to interact via Net, so guaranteeing valid educational methods and scientifically correct contents.

Developing New Therapeutic Recreation Web Sites

Thomas T. Gushiken, Ph.D., C.T.R.S.
Department of Recreation Management & Therapeutic Recreation
University of Wisconsin-La Crosse
U.S.A.
gushiken@mail.uwlax.edu

Abstract:

How are the over 30,000 people employed in therapeutic recreation staying current in their field? A number of therapeutic recreation professionals have designed web sites with information specific to the therapeutic recreation field. The two national organizations (ATRA and NTRS) and the national certification council (NCTRC) also maintain web sites. In addition, a few therapeutic recreation professionals maintain up-to-date web sites with agencies now developing their own web sites. Although these sites exist, it is sometimes difficult to locate them. This poster session will introduce five existing therapeutic recreation websites at the University of Wisconsin-La Crosse that are related to accessing therapeutic recreation information over the World Wide Web. These sites include project TRAIN (Therapeutic Recreation Access to the Internet) TRIPS (Therapeutic Recreation In Public Schools), WINTR (WISconsin Network of Therapeutic Recreators), TRIC (Therapeutic Recreation Internet Connections) and TREAT (Therapeutic Recreation Educational Access to Technology Sources). All of these sites can be accessed at: <http://perth.uwlax.edu/hper/RM-TR/threc.html>

Weaving a New Web: Identifying Resources for Virginia Educators and Education Leaders

Lisa A. Heaton
Curry School of Education
University of Virginia

Introduction

“Very few web resources are indexed to curricula, state frameworks, or national standards” (Roschelle & Pea, 1999, p. 23). In reviewing a series of issues related to the potential of the World Wide Web in education, Roschelle and Pea discussed the need to “tune” resources more closely to specific situations. They added, “The cost of identifying relevant resources on the web is much too high for overburdened [educators] to undertake” (p. 23). While there are a growing number of web-sites that provide links to education resources on the World Wide Web, the sponsors of the majority of these initiatives have not specifically connected their content with the needs and interests prevalent within a state. With this problem in mind...

VITaL, the **V**irginia **I**nitiative for **T**eaching **a**nd **L**earning, is being developed as a web-based clearinghouse of up-to-date information pertinent to the needs of educators and education leaders in Virginia. The project, which is in the early stages of development, will focus on identifying World Wide Web resources and organizing them according to state education interests and initiatives. Providing teachers and education leaders with resources pertinent to state's education agenda will enhance their ability to "locate, communicate, and process information" that may allow them to "become more proactive in approaching [education] challenges" (Donatucci, 1995, p. 14).

Web-based Object Oriented Multimedia Assessment System

TAN Hock-Guan(thg@np.edu.sg) & LUA Seu-Kea(lsk1@np.edu.sg),
Computer Based Learning Centre, Ngee Ann Polytechnic, Singapore

The need to separate the content and programming logic during the question development stage in the implementation of computerized assessment is inevitably necessary in view of the technology proficiency of the end-users, cost, development time and pedagogy issues.

This paper presents the use of object oriented technology in the implementation of a Multimedia Assessment System. It will report on our applied research project currently being carried out at the polytechnic to create re-usable question templates for easy creation of multimedia question items. It will also discuss how contents and testing strategies could be separated and form re-usable resources. The session will present a complete architecture of the system, inclusive of the component of administering mastery learning tests and generating test papers of similar difficulty level and reliability indexes. The full benefits of the system and difficulties encountered during the implementation will be discussed.

Selection: Individual Diagnostics in Personnel Selection and Consultancy

Misja Hoebe (M.N.Hoebe@ppsw.rug.nl)

Karen van Oudenhoven-van der Zee (K.I.van.Oudenhoven-van.der.Zee@ppsw.rug.nl)

Rob van Ouwerkerk (R.J.van.Ouwerkerk@ppsw.rug.nl)

Selection is part of a large scale project that aims to enhance the skills education in the study of Psychology. Training takes place in advanced courses for professional conversation skills in, among others, personnel selection and consultancy. The program Selection shows the student the proces of selection and the tools available (techniques, methods, tests, etc.). It focusses on teaching diagnostic and conversation skills in an interactive manner. The student has the role of a junior consultant and with the guidance of a virtual senior advisor he has to select the most eligible person applying for a job. When students are finished, the skills are practiced in threesomes under supervision of a teacher. The program is distributed via an Intranet and multi-media elements are used extensively. A preliminary evaluation has shown that students are satisfied with the contents of the program and enjoyed doing it, and think it represents the professional practice very well.

The Ecology of Education: Creating the Natural Environment for Inductive Learning

David M. Holmes-Smith, MEd, MSIS
Instructor, Computer Electronics, Heald College, Honolulu, Hawaii
Founder, Hawaii Institute of Technology, Honolulu, Hawaii
david@mahalonet.com

Abstract

Since time began, humanity has sought to manipulate their environment to minimize the impact of the unpleasant forces of nature upon the frailty of the human body. It began with primordial man learning inductively through discovery rather than applying known laws or theorems. Today the inductive process is largely lost in the field of electronics where complete circuits are provided in school labs and industry.

In remedy, this author provides an inductive learning 'game' by modularizing electrical circuits into cards that are placed from left (input) through the microcontroller to right (output). By simply modifying (amping or dividing) voltage (V) and current (I) between each card, students design and can build sophisticated circuits that control the forces of nature in real time [Tab. 1]. It is the microcontroller programmed in 'C' that defies nature. Today, the final frontier is global Internet control of these local 'micro' masters of nature.

Table 1: Forces of Nature Under Control.

Forces of Nature	Input Devices	Output Devices	Application
1. Magnetism	Hall Effect Sensors Digital Compass	Motors Servos Inductor Coils Relays	Compass for magnetic north
2. Light	Phototransistors, Photoresistors Solar cells, Photodiodes	LED Incandescent Flourescent Laser	Identify moving objects by motion sensor device
3. Rotational Motion	Generator Alternator Dynamo	Actuator	Determine speed (RPM) of engine
4. Pressure	Piezo Conductive material (foam)	Servo Muscle wire	Measuring the force of water, air, or wind.
5. Temperature	Thermister, Thermo couple	Heater coil Refrigerator Thermo Pile	Thermometer
6. Sound	Microphone Piezo	Speaker Piezo	Sonar distance sensing
7. Gravity	Accelerometer Tilt sensor Digital scale device Pendulum motion	Bent gravitational fields	Bringing back in the Shuttle
8. Conductivity	Proximity sensor Conductivity meter	Electrolysis	Presence of human in door way
9. Radio Frequency	Radio antenna and receiver coil	Radio transmitter coil	Remote control using RF
10. Friction	Digital scale device	Resistant motion	Tire traction

Lone Star 2000: Creating a Web-based Collaborative University and K-12 Learning Environment

Dennis M. Holt, Ph.D., Division of Curriculum & Instruction, College of Education and Human Services,
University of North Florida, USA
E-mail: dholt@unf.edu

Abstract: This educational technology project enabled teacher educators at the University of North Florida to establish a successful collaborative educational partnership with several accomplished elementary and secondary science teachers in the Duval County Public School District in Jacksonville, Florida. The project received funding from the Corporation for Public Broadcasting, IBM, Logical Business Systems of Jacksonville, and MediaOne. The main goal of the project was to improve science teaching and learning for K-12 students and preservice teachers using educational technology. The participants received training in multimedia production and advanced educational technologies, including videoconferencing and the world wide web. This conference presentation will feature work products produced by the participants, including web site work, electronic portfolios of preservice teachers, and web-based portfolios of K-12 students.

Classroom Access Through Technology: Accommodation Solutions Online

Christy Horn, Accommodation Resource Center, University of Nebraska-Lincoln, USA, chorn@unl.edu

William Udell, Accommodation Resource Center, University of Nebraska-Lincoln, USA, wudell@unl.edu

Karen Ketelhut, Accommodation Resource Center, University of Nebraska-Lincoln, USA,
kketelhut@unl.edu

Roger Bruning, Center for Instructional Innovation, University of Nebraska-Lincoln, USA,
rbruning@unl.edu

The Americans with Disabilities Act has made it necessary for universities to provide increased services to students with disabilities. The Accommodation Solutions Online website provides easily accessible information concerning accommodation solutions for various classroom environments, assistance to the faculty in providing Braille, raised line drawings, etc., provides expert advice on accommodations questions, and includes a searchable database on hardware/software solutions to accommodation challenges. In addition, the website provides campus maps that highlight accessible routes, restrooms and entrances and a resource guide to accessible restaurants, churches and other community resources.

CONGA: Information and Consulting System for an International Degree Course

Axel Hunger, Frank Schwarz, Stefan Werner
Gerhard Mercator University of Duisburg, Department of Data Processing, Germany
swerner@uni-duisburg.de

Abstract: In 1997 the internationally master degree course „Computer Science and Communications Engineering“ started at Gerhard-Mercator University of Duisburg. This degree course aims at students of all nationalities and offers several innovations to the German university education system: lectures are equally offered in German and in English language, the possibility to enter the degree course in a higher semester due to an international bachelor degree and the obligation for German students to stay abroad. Also, the students have the choice to receive either the German „Diplom Ingenieur“ degree or the international degree „Master of Science“. The degree course itself has a reform character and already turns to be an object of research during its five year pilot-phase. Additionally, new methods for transferring knowledge are to be created and applied (Hunger & Werner, 1998a). Further information about the degree course can be found in (Hunger 1998). The set-up of international degree courses is a first step towards the globalization of university education which requires other steps to be followed. This article presents the thought of and partly already realized steps taken in Duisburg.

1. Introduction

The setup and introduction of new degree courses requires efficient tools to support different target groups. Students on the one hand and academic staff on the other hand represent these target groups. For the preparation of the studies, students have to be supported in finding information, in decision-making, in dealing with all the formalities when entering the country or filling in the application forms. The academic staff has to be supported in administrative problems, e.g. project administration and documentation, as well as subject-based questions, e.g. questions about the acknowledgement and classification of students, who have already earned a degree. A further aspect lies within the worldwide advertisement for this degree course. Therefore special tools are needed. The conception and implementation of these tools is done within the Conga Project (Course Online/Offline information and Guidance System). In doing so, we make use of different media as CD-ROM for advertisement and student information purposes, several Data Bases for planning, administration and documentation purposes and Internet for our self-projection and student advisor and – information purposes. The separate systems are realized in different parts of the project. The CD-ROM was originally created to be shown at educational fairs. In the meanwhile it proved itself being an integral part of the information package. The CD titled „Living and Studying in Duisburg“ contains in the current version: videoclips showing foreign students who study in Duisburg saying words of welcome in their native language, general information about the degree course, the curriculum of the degree course, a description of the contents of the offered subjects, information about Gerhard-Mercator University (articles, pictures, video) and information about the city of Duisburg (articles, pictures) A detailed description of the CD is given in (Hunger & Werner, 1998b). The set-up of different database applications and the internet connection takes place within the scope of the CONGA project. This parts will be described in the next two sections.

2. Conga-DB

Planning of new degree courses and study rules is marked by producing and updating tables and documents. The number depends on several parameters, for example the number of courses to deepen the studies in, the complexity of the electives catalogue. Furthermore, different point of views concerning the data holding

demands distinct tables which contain the same information though. The database contains personal data of lecturers, student data, characteristic data about the degree course, as well as data and description of the subject contents.

The effort necessary for updating the data is closely linked to the number of views at the data holding. apart from the application for updating the database further applications are needed for planning and administering new study courses, for generating study plans, for generating personal study plans and schedules, for time- and room-planning, for realizing experimental games and to help the study advisor with questions about acknowledgement and classification.

3. CONGA-Web

Informing and advising students has an outstanding importance in the globalization of higher education. In the case of our degree course most of the students received their first information via the internet. Applicants from foreign countries get into first contact almost exclusively by e-mail. An information- and advise center should be build up within the scope of CONGA-Web, which not only supplies the student with organizational and subject-based information. The system also deals with standard consultations and therefore helps out students with their choice of degree course and place. Thus, the set-up of an intelligent WEB-information-system is planned. The system consists of a WEB-site, an internet database and a knowledge base, including rules. The Web Site contains all relevant information concerning the degree course as well as an agent-based consultation system.

The internet database is a connection to the Conga-DB database and thus has access to the above mentioned data. To adjust curricula of other universities, it is planned that the database contains their curricula and the matching offers. The rule base contains conversion tables for credit point systems and rules for acknowledgement procedures. This system enables students to inform themselves extensively ahead of time. During the next step, students can be advised interactively, after entering their personal background. Students, who have already reached a degree, can be classified according to the database and the general basis, and a plan can be made about the course of study. All the other forms, e. g. application forms, help with applying for the visa etc. can also be done system-based.

This system is especially interesting for students who have already started or finished their studies. For these students the system offers as result of the consulting a study plan for the degree course in Duisburg. The student has to give details about his studies so far. He needs to assign his achievement in the different subjects to the curriculum of Duisburg. This information is collected in a cookie in the students' system and transferred to Duisburg for the final evaluation. The student is supported by an intelligent agent throughout the entire session. The comparison of foreign curricula with the curriculum in Duisburg is one of the most difficult parts to be implemented in the consulting system.

4. Summary

This article presented tools to support the planning and the set-up of international degree courses. Tools for the LAN environment have been used successfully since the winter semester 1998/99. The tools for self-projection and advertisement are being used since the beginning of the course and are constantly updated. Current work deals with the implementation of the student consulting system. This module represents an essential innovation of the system in comparison to the usual practice.

Integrating VRML and Java to Build Practice Environments

Janet Faye Johns
The MITRE Corporation
USA
jjohns@mitre.org

Abstract: This presentation will describe how to create meaningful 3-D web-based practice environments using JAVA and the Virtual Reality Modeling Language (VRML). VRML provides an interactive 3-dimensional (3-D) world where the user can learn by discovery and by doing. JAVA adds the ability for a practice environment to coach and guide the learning process. Integrating JAVA with VRML adds the power of dynamic assessment, coaching, and feedback so the user can understand and analyze his actions in the 3-D VRML world. A mechanical skills training example is used to illustrate the 3-D practice environment.

Academic Library Instruction Using the WWW

**Carolyn R. Johnson, Associate Librarian
Arizona State University West Library
Phoenix, Arizona, USA
carolyn.johnson@asu.edu**

Web-based library instruction holds great promise. Students can access the details they need, and take “side trips” to related tasks or information at their own pace, as they follow a research strategy mapped out by a librarian. Instruction can be delivered remotely (at any hour), information can be easily updated, and there is no competition for classroom instruction time—all shortcomings of other library instruction methods. Faculty and librarians traditionally have collaborated on the type of library instruction that students need in conjunction with their courses. With web-based instruction, there can be more encompassing instruction in “information literacy” skills. The web page format enables the seamless integration of skills related to library research. Internet research skills, computer skills (i.e., downloading, reformatting, using graphics), and writing instruction can all be incorporated into the “library instruction” web page by collaborative effort from the faculty, library, computer lab, and writing center.

Low-Tech Classroom Management Through the Web

Luther Killebrew
The Center for Language Research
The University of Aizu
Aizu-Wakamatsu, Fukushima, Japan
luther@u-aizu.ac.jp

As an ESL teacher with a limited amount of classroom contact, I found myself spending too much time “managing”, taking large chunks of limited class time for non-instructional tasks, which were done in-class due to a lack of opportunities for them outside of class. However, once in a situation that made computer applications a possibility for all students, I was able to explore ways of maximizing limited classroom time through Internet applications. The three main applications are posting lecture notes/explanations, posting answers to exercises and moving in-class exercises to the Web for outside work.

Low-tech is emphasized for two reasons. First, many educators are relative newcomers to computing and are often frightened off by excessive high-tech. Second, many schools lack the budgets to purchase state-of-the-art computers and thus many high-tech applications are not possible. The Internet is a valuable educational tool, but often the most valuable tool, and certainly the most utilized, is the simplest one.

For more detail, please follow links at <http://www.u-aizu.ac.jp/~luther>

Two Different Approaches to the Distance Learning

Marjan KRASNA, D.Sc.,
Center for computer science and multimedia in education,
University of Maribor,
Faculty of Education,
Slovenia - si
marjan.krasna@uni-mb.si

Danilo KORZE, D.Sc.,
System Software Laboratory
University of Maribor,
Faculty of Electrical Engineering and Computer Science,
Slovenia - si
danilo.korze@uni-mb.si

Abstract: In today's world new knowledge is produced very fast and if we are trying to be at the top we have to update learning material every year. Traditional book printing is too time consuming and too costly for frequently updating. For this reason we put one of the most important thing in the distant education - learning material to the Internet. There is no prescription how to do this nor which technology to use for producing Internet learning material. We are presenting two different approaches. One is the oldest known to the Internet (pure HTML) and the other one is one of the newest (Java applets). The first approach is used in the environment where students have almost no programming experience and the other is for computer science students. We highly recommend using the technology that allows students to actively participate in updating learning material – “live” learning material.

An Inquiry of the Social Functions and Social Interaction in the Internet

Lackner Elisabeth (Student), Department of Sociology, Karl Franzens Universität
Graz, Austria, lackner@Tweety.geol.qc.edu

The internet is a product as well as a shaping part of modern societies. As such it changes social structures and interactions. The Cyberspace provides new opportunities for participating in seeking, organizing, presenting, talking about and creating information in many ways. I identify six social functions of the Internet: the function of communication, the function of a mass media, the function of a workplace, the function of a marketplace, the function of social interaction, and the function of socialization and education. The nature of global communication and information exchange in the Internet can be considered as immediate, overwhelming, and to a large degree uncensored. Although the participants in the WWW have already internalized social norms and values of the society, new customs and norms of social interaction are created through the communication in the Internet. The Internet promises to be a source of infinite global information. Therefore it may shape the perspectives of the participants.

An Interactive Learning Environment Based On Cases

Dominique Lecllet

University of Picardy - New Educational Technology Research Group – Pôle cathédrale - IUP Miage

BP 2716 - 80027 Amiens Cedex 1

Dominique.Lecllet@u-picardie.fr

ABSTRACT: This presentation is related to the design of multimedia systems for vocational training in domains involving problem solving in contextual situations. Medical diagnosis, catering duty and companies' management have first been studied for several years. These activities involve several kind of theoretical knowledge but overall the heuristic aspect seems more and more prominent. In fact, a major difference between novices and experts will be the ability of these latter to exploit the *context* and link together *similar* situations. In order to tell about contextual situations, we have defined within a particular apprenticeship environment: an interactive learning based on cases. The aim is to enable the learner to experiment "real" situations in an adapted pedagogical environment. The WWW version is under progress to constitute teaching platform. The students would be able to get the complementary and enriched pieces of information through the access to data banks, and they would be able to dialogue with a distant teacher, tanks to the e-mail.

The ADDIE for ACTIONS Model Matrix: A Tool for Decision-Makers in Distance Education

Jack Lee, Workforce Education, The Pennsylvania State University, U.S.A., jtl106@psu.edu

Kelly Ann Yamashiro, Instructional Systems, The Pennsylvania State University, U.S.A., kxy125@psu.edu

Distance education, which may once have been thought of as insignificant to the survival of an academic institution, can no longer be ignored as vital to an institution's success and reputation, and possibly even its existence in the new millennium. The student market which was once reserved for traditional institutions is now being preyed upon by competition from both public and private non-traditional, educational providers [Olcott 97]. Therefore, key decision-makers at both small and large traditional institutions are being forced to implement distance education programs to be more competitive in the marketplace. The authors will present The ADDIE for ACTIONS Model, which combines The ACTIONS Model [Bates 95] and The ADDIE Model [Rossett 87], that decision-makers can use when implementing a distance education program.

Patient Support using the World Wide Web

John Lester, Information Systems Director, Department of Neurology, Massachusetts General Hospital,
USA, john_lester@hms.harvard.edu

Deirdre Norris, RN, Clinical Coordinator, MGH/PHS Epilepsy Program, Massachusetts General Hospital,
USA, Norris.Diedre@mgh.harvard.edu

Daniel B. Hoch, MD, PhD, Neurologist, MGH Epilepsy Service, Massachusetts General Hospital, USA,
Hoch.Dan@mgh.harvard.edu

Abstract: Traditional medical care relies on face-to-face encounters in which patient and physician work collaboratively. However, many patients have limited mobility, want additional medical information and wish to share experiences with others in similar medical circumstances. This poster illustrates how the Web can be used as a computer-based tool to augment the physician-patient encounter at the Epilepsy referral center at Massachusetts General Hospital using our "PatientWeb" system. Patients are given access to a library, discussion groups, chatrooms, and the opportunity to communicate privately with healthcare providers. Patients were included in the design process and are involved in the evolution of the site. Monitoring of the project is performed by Epilepsy care providers. We are in the process of examining the impact of this technology on patient satisfaction, quality of life and comparing/contrasting its use to traditional face-to-face encounters. For more information please see www.patientweb.net.

« Graphs à la carte »
Scientific graphs dynamicly generated on the Web.

Thierry Levoir

CNES - French Space Agency
DTS/MPI/PS/VD

18, avenue Edouard Belin
31401 Toulouse Cedex 4
France

Phone: +33 (0)5-61-27-42-50

Fax: +33 (0)5-61-27-30-84

E-mail : Thierry.Levoir@cnes.fr

Abstract : The space experiments generate a huge amount of data that are only easily exploitable using graphic representations. So, the CNES (French Space Agency), that provides space scientific data access through the Internet, has developed a tool which can interactively generate graphs on a Web page, using Java and PV-WAVE.

"Graph à la Carte" provides to the user a JAVA applet. This applet first calls a CGI script that returns the names of the graphic modules which are available for the chosen data (the available types of plottings).

The user then, just has to compose the Final Plotting by adding different graphic modules and parameters. The image is calculated by PV-WAVE and then returned to the applet to be displayed.

The Construction of a Supportive WWW Web Site for Australian Primary Science Teaching

Min-Jin Lin
Graduate Institute of Science Education
National Hualien Teachers College
Taiwan, R.O.C.
E-mail minjinlin@hotmail.com

Abstract: Previous studies indicated that Australian primary science teaching had been in a state of crisis. Teachers need more support to strengthen their background scientific knowledge and skills, to design programs, to access teaching resources, and to find answers for their questions quickly. A web site has been set up on the Internet in which seven science-units were constructed in the homepage formats. The characteristic of each science unit is its theme-based contents that link to other Key Learning Areas in Australian primary curriculum. Each unit also contains template program overviews, links to teaching resources, links to other Internet lesson plans, links to frequently asked questions, links to experts and news discussion groups, and links to fun sites for kids. This research demonstrates the educational potential of the WWW in primary science education to overcome some of the Australian primary school teachers' difficulties and to meet their needs.

Online Activities for Research: Science with OAR

Brenda C. Litchfield
John V. Dempsey
Department of Behavioral Studies and Educational Technology
University of South Alabama
UCOM 3700
Mobile, AL 36688
bcl@jaguar1.usouthal.edu
jdempsey@jaguar1.usouthal.edu

Science with OAR is a collaborative effort between the University of South Alabama and the Office of Oceanic and Atmospheric Research (OAR). The purpose of this project was to work with middle school science teachers to design and develop 12 interactive lessons for students in grades 5-8. These activities focus on several of the major topics consistent with ongoing OAR and National Oceanic and Atmospheric Administration (NOAA) research efforts. Students are involved in gathering information and data from actual NOAA sites on a variety of topics. They use this information to complete activities and conduct science investigations related to topics they are covering in their science courses.

Creating a Personalized Web-Based Library Tour

Michelle Mach, University Libraries, Colorado State University, U.S.A., mmach@manta.library.colostate.edu

Ben Fernandez, University Libraries, Colorado State University, U.S.A., bfernand@manta.library.colostate.edu

Abstract: Unlike other Web-based library tours, the Colorado State University Libraries Virtual Tour [<http://manta.library.colostate.edu/tour/>] permits customization options allowing different users to access information that suits their needs and experiences. Users may select various access points, including a pre-arranged order, an alphabetical list of stops, an arrangement by floor, or may assemble a customized list of tour stops. Each tour stop features a photo, a map, bulleted information, and links to in-depth information. While designed for maximum accessibility, the tour also offers optional high-bandwidth features like 360 degree panoramic views, audio segments, and JavaScript enhancements. A brief interactive quiz at the end of the tour checks for retention of basic information. This customization has numerous benefits including an interactive, more personalized tour experience for users and more classroom time devoted to library instruction, rather than physically navigating the building.

Web-Based Instruction in Geographic Information Systems

John Mackenzie
Spatial Analysis Lab, Dept. of Food & Resource Economics
College of Agriculture & Natural Resources
University of Delaware
Newark, DE 19717 USA
johnmack@udel.edu

A Geographic Information System (GIS) creates and analyzes digital maps and other geographic data, and the Web provides a natural medium for teaching GIS. My GIS classes use the Web as a medium for participation in problem-based learning (PBL) labs.

I deliver all course materials via the Web, and for the past four years I have also required students to submit all of their class projects via the Web. I encourage students to write raw HTML to de-mystify it, and to learn digital image basics by experimenting with Xview (UNIX graphics editor). Web-authoring skills empower students. Each class session begins with a brief lecture followed by a PBL lab session. Students demo their work on the Web, critique each others' work and develop on-line portfolios. My GIS classes now require more instructor and teaching assistant time than previously (and more student time!), but they earn very high student evaluations.

A SOFTWARE TOOL FOR EVALUATING NAVIGATION

Rod McCall, David Benyon
School of Computing Napier University, Edinburgh, UK, EH14 1DJ
Tel: +44 131 455 4675 Fax: +44 131 455 4552
EMAIL: {rmccall,dbenyon}@dcs.napier.ac.uk

ABSTRACT: Traditional methods of usability evaluation ignore some aspects related to navigation. In contrast the navigation in information space paradigm sees the user as situated within the space. The ENiSpace (Evaluating Navigation in Information Space) system builds on a paper based checklist to support designers in addressing navigational issues. The software version also includes reporting features, supporting documentation and references the aim being to inform design as well as to provide a method of evaluation. The current version consists primarily of the checklist, however the completed version will include collaborative evaluation features via an internet server.

Intranets in the K-12 Arena: Establishing a Process for Developing a Distributed Learning Environment

Tammy McGraw and Betty Blair
Appalachia Educational Laboratory, Inc., USA, Email: mcgrawt@ael.org

Alan Hall, Dirk Rodenburg, and Hugh Ranalli
Inform Interactive, Inc., Canada, Email: dirk@informinteractive.com

Abstract: Corporate America has rapidly embraced the concept of an intranet; however few developers have considered the potential uses of an internet-based communication and distributed publishing system in the elementary and secondary school settings. We will focus on the process of implementing an *instructional* intranet in a public school system from the evolving conceptual framework to the deployment of a state-of-the-art communication and publishing system.

In this session we will share how we have responded to the challenges of adopting a distributed learning environment, most of which can be broadly categorized as balancing competing demands. Issues related to understanding and committing to the level of support required to maintain the environment, accounting for access issues, and the protection of learner privacy will be explored. In a greater context, we will examine how this powerful technology might be used to revolutionize learning environments and support learning communities.

Acknowledgements

The development and implementation of the Franklin County Public Schools intranet is supported by the United States Department of Education and the Technology Innovation Challenge Grant Program. All statements made, and the views expressed are solely the responsibility of the authors.

tr1A Web-based Relational Database-backed Exercise and Quiz Delivery System

Damien McKeever, Sean McKeever & Andrew Sweeney
Department of Computer Science
The Queens University of Belfast
N.Ireland
e-mail: d.mckeever@qub.ac.uk

Abstract: An interactive web-based system is described which allows the construction and editing of quizzes, delivery of quizzes, provision of user feedback and recording of user performances. Questions and responses, exercises, client details and performance statistics are held in a server-side database. An input system is provided to facilitate the construction and editing of quizzes via the WWW. The system described here has been implemented as a Microsoft Active Server Pages (ASP) web application. This work contributes to the second phase of on-going research into higher level authoring tools. The web pages produced in this version concentrate on functionality with little attention being paid to presentation issues; versions built in related projects enable presentation characteristics of pages to be defined and edited and the corresponding HTML source to be generated automatically.

An XML-based Generic Architecture for the Construction of Interactive Web Components.

Sean McKeever, Damien McKeever
The Queens University of Belfast, N.Ireland
s.mckeever@qub.ac.uk, d.mckeever@qub.ac.uk

John Elder
UlsterWeb, Bangor, N.Ireland
jelder@ulsterweb.com

Abstract: A generic architecture for constructing interactive web-based components or subsystems is described. Examples of component types are custom content navigation and presentation components, interactive exercise and testing components, and an electronic catalogue and ordering system component. The instances of a component type are collections of structured data which share a common syntactic and semantic model. The data model for a component type is described using an XML Document Type Declaration (DTD). The data of a component instance is stored and described by an XML document conforming to the component DTD. An interactive component combines the content data with behaviour and presentation characteristics. A generic architecture has been developed using an XML and CSS-based modelling language for describing and mapping data objects to layouts, styles and behaviours. A generic runtime engine reads, parses, loads, instantiates and renders the described model into DHTML/HTML at runtime, or statically during authoring. The runtime engine itself can be implemented on either the client-side or server-side. Simple authoring tools can be developed on top of the architecture to automate the construction process.

Application of WEB based Interactive and Multimedia Technology in an Introductory Engineering Course

Bhavin V. Mehta, Ph.D.

mehta@ohio.edu

Ming Wang, Ph.D. Candidate

Liang Zhang, Ph.D. Candidate

Department of Mechanical Engineering

Eric P. Steinberg, Ph.D.

Department of Civil Engineering

Ohio University

Athens, Ohio 45701

Abstract: Statics, an introductory core engineering course was developed as a web based course. The course contains animated GIF, Java based animations, 3-D models using Virtual Reality Modeling Language (VRML), and interactive tutorials and examples to demonstrate the principles of mechanics in a more dynamic and interactive form. The primary emphasis was on using the site as a supplement to the regular class lectures. The web-based course is geared towards interactive problem solver (IPS) and analysis models where the student can actually solve myriad of problems on a specific topic till he/she has a better understanding of the concept. The interactive problem solver keeps a track of the number of attempts made by the student and the content of the trials. This facilitates the instructor in grading the student and structuring the course review as the course progresses. The web site also includes the lecture notes for review. (<http://www.ent.ohiou.edu/~statics>)

The Virtual Psychology Laboratory: A Web-Based Resource For Researchers and Educational Users

Gareth E. Miles & Andrew Howes
School of Psychology, Cardiff University, P.O. Box 901, Cardiff, UK. CF1 3YG.

Nicholas Hammond & Richard Plant
CTI Psychology Centre, York University, UK.

Ruediger Ohlemann
Data Archive, Essex University, UK.
Contact: HowesA@cardiff.ac.uk

Abstract: The Virtual Psychology Laboratory (VP-Lab) is a collaboration between the School of Psychology at Cardiff University, the Computing in Teaching Initiative (CTI) Psychology Centre at York University and the Data Archive at Essex University, funded by the UK's Economic and Social Research Council. The intention of VP-Lab is to archive experimental psychology data and materials so that they may be located and downloaded by interested researchers and students. VP-Lab is accessed via the World Wide Web using a standard HTML browser. There are several different target audiences for VP-Lab. Firstly there are research psychologists who wish to, or are required to, make their data available. Researchers may also wish to access other's data or materials, perhaps to do a meta-analysis or when trying to gain a more comprehensive understanding of materials described in a published paper. A second audience consists of those who are teaching or studying psychology. The poster presented at WebNet 99 describes VP-Lab and focuses on how educational users might benefit from using it.

Web-Based CAI for a Distance Education Neurology Course

Anita Miller, M.S.
Department of Medicine
University of Illinois College of Medicine at Rockford, USA
Email: anitam@uic.edu

Shannon Lizer, M.S.N.
Department of Medicine
University of Illinois College of Medicine at Rockford, USA
Email: slizer@uic.edu

James Lockard, Ph.D.
Department of Educational Technology, Research, and Assessment
Northern Illinois University, USA
Email: jlockard@niu.edu

Abstract: At the University of Illinois College of Medicine at Rockford, the Rural Medical Education Program prepares students with the special knowledge, skills, and attitudes to be successful as Family Physicians in rural Illinois. Students in this special medical education track spend four months off-campus on a rural preceptorship under the supervision of a practicing rural family physician. This poster session presented an instructional unit that was developed to provide these students an opportunity to complete their required senior neurology clerkship off-campus. This unique distance-education neurology course provides a focused tutorial on the neurological physical exam plus sixteen WWW-accessible case studies whose medical content is identical to the paper cases used in the traditional clerkship. The unit proved to be an effective vehicle to support mastery of a defined set of learning objectives in neurology. Most participants expressed interest in further web-based courses after this initial experience.

Identification of Swallowing Patterns Associated with Dysphagia

Mark Mizuko, Rachel Komarek, John Hatten
University of Minnesota, Duluth
Communication Sciences & Disorders

Joe Piette, Peggy Stone
St. Mary's/Duluth Clinic Health Systems

E-mail: mmizuko@d.umn.edu

Abstract: The present project was designed to allow graduate students to observe swallowing patterns (both normal and disordered) through the World Wide Web. This web site utilized QuickTime technology to present these video segments as actual video segments. This web site deals with the diagnosis of disordered swallowing patterns commonly produced by dysphagic individuals. Students in communication disorders must evaluate swallowing disorders and determine their relationship to the anatomy and physiology of the swallowing mechanism. In order to perform this role successfully, the student must be skilled in evaluating the interpreting radiographic studies of patients with swallowing disorders. The student must learn to be a reliable observer and to recognize, describe, and interpret evidence of anatomical and physiological conditions that are provided by the swallowing patterns. As the student learns about the different swallowing patterns, it is helpful to have visual tutorials that supplement classroom presentations in order train students to become proficient observers in determining the presence of specific swallowing problems.

A Visit to Purdue University Via the Web

James L. Mohler
Department of Computer Graphics,
Purdue University, West Lafayette, IN 47907 USA
Tel: 765.494.9089, Fax: 765.494.9267, Email: jlmohler@tech.purdue.edu

In the summer of 1998, the Department of Computer Graphics began developing a web-based informational and marketing resource for individuals interested in attending and visiting Purdue University's West Lafayette campus. The result is an interactive campus map that provides information about the various campus buildings using text, photographs and VR movie clips. It also provides the ability to search for specific buildings and locations and an online-guided tour. The site allows the user to navigate the campus using a unique, vector-based graphical user interface. The completed interactive map, titled *The Purdue University Virtual Visit*, became available in August of 1998. Since that time the university has supported the project through various grants, which has allowed many features to be added. This contribution displays the project and its associated features.

Empowering Educators with Intelligent Web-based Productivity Tools

Robert Molek, Carlton Solutions for Education, USA
Rmolek@carltonse.com

Abstract : With the advent of the Internet, educators now have access over the web to the first artificial intelligence productivity toolsites. This presentation will demonstrate a unique online lesson planning toolsite and a research toolsite where educators actually create documents in the website. Following a process guide, the user applies a natural language retrieval algorithm to locate educational resources and to align lesson plans to district, state, and national standards. The research toolsite educators retrieve educational literature using this same natural language query system. The benefits of this approach include: 24-hour access to user documents from any Internet computer; intelligent search and expert system features; no software installation requirement; and instant access to new features and data, such as instructional resources, new lesson plans, revised standards, and current research documents. Future application include assessment systems, direct instructional systems, and comprehensive school management systems delivered totally over the Internet with web toolsites.

Development and Operation of a Website for Enhanced Artificial Intelligence Applications in Medical Diagnosis, Treatment and Prognosis

Bela Molnar, Semmelweis University of Medicine, 2. Dept. of Medicine, Szentkiralyi-str 46, 1088-Budapest/Hungary, mb@bel2.sote.hu

Rainer Schaefer, Roche Diagnostics GmbH, Werk Tutzing, Dept. Biometry & Labor.-IT, Bahnhofstrasse 9-15, D-82327-Tutzing/Germany, rainer.schaefer@roche.com

Abstract: Medical diagnosis and decision making is rather an empirical than a statistical process. Improvements in artificial intelligence methods (Neural networks, fuzzy systems, genetic algorithms) have opened a new way for developing *Medical-Decision-Support-Systems*. As there is no established communication platform in this specialized research field, the authors designed a "virtual-text-book" for interested specialists from both the medical and the mathematical discipline. The site contains the following chapters:

Neurons/networks:	introduction/backgrounds
Networks/models:	mathematical treatment
Neural networks @work:	<i>PENN</i> -application for Hook-Effect-Detection
Literature:	search in literature- and patent-databanks
Medicine/AI:	medical information, data collection, alternative AI-methods
Neural networks:	training program, links to other Neural network information sources

The present development intends to establish a "*Community*" working on the application of artificial intelligence techniques in medical diagnosis and decision making. Topics are the communication platform, medical databases, training and evaluation, announcement of new methods, mathematical aspects, standardized application interfaces. Representatives from industry are invited to test the Neural network algorithms/tools for implementation into automated diagnostic systems.

Object Oriented Analysis and I*net Applications: an Experience-based Approach

Paolo Morandotti, David Frontini, Fabrizio Cali,
Intrasoft S.p.A.
v. Donatello, 30 - 20131 Milano, Italy
{pmo, david.frontini, fcali}@intrasoft.it

Abstract: One of greatest problems in building I*net applications is the lack of a model that matches the Object-Oriented Analysis and the particular characteristics of I*net applications. Traditional analysis' methods often fail in predicting performances, in creating screen layouts, and in some other important operations: there is a traceability gap between analysts' requirements and technological constraints. We present here our Work product structure to integrate an I*net analysis [Zeffiri et al., 1998] to the OOTC's approach to software development [IBM Object-Oriented Technology Center, 1997], in order to manage correctly every impact of I*net technologies in the software production.

ScienceSite: Building the Perfect IT Learning Tool

Soren Bjergoe, Stig Brostroem, Frede Morch
DTV/DTU
Denmark

Abstract: ScienceSite[®] is a small program, which adds "advanced" features to normal html pages. It is not an html editor - you are still free to use which one you like - but it provides you with a simple, user-friendly interface that automatically generates a menu structure with onmouseover facilities, offers a dictionary feature that makes a link out of every word which have been put into the dictionary, and offers the possibility of different views. Furthermore the program generates smartlinks[®] - links pointing to pages with related content, and you can easily shift between different languages. Everything is built on metatags. By changing the metatags, you change the way the content is presented.

ScienceSite is made by Learning Resource Center, The Technical University of Denmark.

The Web-based Integrated Science Environment (WISE): Connecting to the World

Jeff Morrow

Lead Designer, Web-based Integrated Science Environment Project
Graduate School of Education, University of California at Berkeley, USA
jmorrow@alum.mit.edu

James D. Slotta

Director, Web-based Integrated Science Environment Project
Graduate School of Education, University of California at Berkeley, USA
slotta@socrates.berkeley.edu

We will present an ambitious extension of the WISE Project in which we adapt the WISE technology and curriculum for use in school systems around the world. Educators from several nations have expressed an interest in having their students, teachers, and schools be a part of our new and exciting ideas for science instruction. Visiting scholars from Norway and Israel have already begun the process of translating curriculum, and scientists from other countries have approached our project to inquire about similar collaborations.

The WISE Project has responded to this interest by developing a powerful model of internationalization. This program involves the translation of WISE curriculum activities and professional development materials, the training of foreign staff correspondents, and the set-up of devoted server technologies. We will describe how this model was developed in the course of a single collaboration with Norway, then generalized for use in other countries.

Friscawai'i: A Trans-Pacific Classroom Web Collaboration

Mike Mosher
Community Art Machines
Mountain View, California U.S.A.
mikemosh@well.com

"Friscawai'i" Opening Screen, February 1998

Artists Violet Murakami and Mike Mosher planned to see their classes collaborate on an internet-based art project in Spring, 1998, when Violet taught at Kapi'olani Community College in Hawai'i and Mike taught at San Francisco State University in California

The concept behind "Friscawai'i" was to create a site for the "Culture" and "Nature" of a fictitious nation created by seismic cataclysm that moved San Francisco to rest beside the Hawai'ian islands.

Each student was paired with a partner to send and receive three statements via email about "the other side", and then to construct an image and text from that information.

The instructors intended students to take a critical stance in this artwork, and even to question the trustworthiness of online communications. Yet "Friscawai'i" was hobbled by students' differing senses of time, priority and classroom curricula.

Business English on the Web for M. Sc. Students

Teija Multisilta
Pori School of Technology and Economics
Pori
Finland
Email Teija.Multisilta@pori.tut.fi

Abstract: For teaching English the Web is an endless resource of study material and a useful tool for communicating. This goes especially for Business English, as most of the business letters are sent by e-mail and it is common to have international business meetings using videoconferencing programs on the Web. The purpose of this poster is to present an action research on the use of the Web in language teaching, and also to demonstrate the Web design of Business English course in Pori School of Technology and Economics, Finland. The experiences from the pilot project in August-October 1999 are described comparing two study groups. The first group consists of part-time M. Sc. students that participate in the Web course, and the second group of full-time students that participate in normal classroom tuition. The results are shown, aiming at giving some advice for the design of future language courses on the Web.

The Bulletin Board as a Tool for Curriculum Development

James Munton
National Science Resources Center
Washington, DC
jmunton@nas.edu

The National Science Resources Center developed a Web-based bulletin board for teachers who were field testing four new curriculum units in the Science and Technology Concepts for Middle Schools (STC/MS) series. The bulletin board was set up as a method of quickly disseminating information to the field-test teachers and also as a communication tool to facilitate discussion among the teachers and curriculum developers.

This poster-presentation examines whether the bulletin board was successful as a tool for curriculum development. It focuses on two main areas. It examines the efforts by the facilitator to accommodate the variation in technological backgrounds and abilities of the group and to maintain the bulletin board's effectiveness throughout the lifetime of the project. Secondly, this paper will explore patterns of use of the bulletin board and the content of messages posted in a curriculum development environment.

Developing a Digital National Library for Science, Mathematics, Engineering and Technology Education: Building upon NEEDS—The National Engineering Education Delivery System

Brandon Muramatsu, University of California at Berkeley, USA, mura@needs.org

Alice Agogino, University of California at Berkeley, USA, agogino@needs.org

Flora McMartin, University of California at Berkeley, USA, mcmartin@needs.org

Abstract: A Digital National Library for Science, Mathematics, Engineering and Technology Education is envisioned as a one-stop shop for digital learning resources to support a wide range learners from K-12 through higher education and beyond. With funding from the National Science Foundation, we are developing an Information Portal into Science, Mathematics, Engineering and Technology Education (SMETE) based upon our past five years of experience developing NEEDS, a digital library for the engineering education community. This digital learning space supports cataloging, searching, displaying and reviewing digital learning materials from target SMETE disciplines. We will demonstrate the Information Portal, see www.smete.org, and present our findings about the SMETE community's views regarding the potential value of a digital library for SMET education; level of probable use, as well as how community members envision using it; and type(s) of editorial oversight needed.

PAMA Courseware:
Learning the Psychological Analysis of Human Task Performance

F.L. Oldersma, R.J. van Ouwerkerk, M.N. Hoebe, A.G. de Vries-Griever, & T.F. Meijman
Institute of Experimental and Occupational Psychology, University of Groningen, Grote Kruisstraat 2/I, 9712 TS
Groningen, Netherlands, E-Mail:F.Oldersma@ppsw.rug.nl

The PAMA courseware provides an introduction to the theory and practice of work and organizational psychology. The courseware will be made available in a digital learning environment that can be approached via the Internet and Intranet. First, PAMA provides an introduction to models of work and physical and psychological health. It also provides methods of psychological analysis of human task performance, as well as practices of professional skills. The introduction to theory and research is included in electronic books that contains additionally educational matter. In addition, PAMA is designed to support the development of professional skills that are required as a work psychologist. Using a case-based learning application (via Intranet), the course provides the opportunity for students to act as a work analyst and to learn that job analysis.

Collaborative Online Instruction for the Teaching of Internet, Language and Culture Skills from a Distance

Leslie Opp-Beckman
University of Oregon, American English Institute, U.S.A.
Email: leslieob@oregon.uoregon.edu

Abstract:

When you can't bring students to your campus for a high quality face-to-face cultural and language learning experience, can you effectively take the experience to them, thousands of miles and many time zones away? This is a question TESOL (Teachers of English to Speakers of Other Languages) educators around the world are asking themselves, both because of and in spite of the current state of computer-based technology. At the University of Oregon's American English Institute (AEI), our Intensive English Program has developed a successful model where our instructional services have become an integral component of distance education courses with non-U.S. institutions. Course objectives are established each term, and appropriate computer-based technologies are selected and used to help reach those goals. Faculty from the two institutions work in tandem through the planning, implementation and evaluation phases. This session will describe the pedagogical, logistical and administrative underpinnings of these courses. Examples available through the <http://darkwing.uoregon.edu/~aei/senshu.html> web site.

Value Chain Of Functional Interactive Product Models In E-Business

Jorma Palo & Pekka Parnanen, CYBELIUS Software, Inc., USA; Mikko Kerttula, VTT Electronics & Infotech
Oulu, Finland

Enabling technologies, like Internet and advanced prototyping techniques have opened new possibilities for companies and their business activities.

Web-enabled *virtual interactive virtual product models* can be benefited in different business activities to implement E-Business solutions that includes strategic new ways to handle activities like distributed product development, web based marketing, e-commerce, training and service as well as support to distribution channels and partners.

Virtual prototypes can be benefited both in company's activities from concept design to customer service, and in customer's side starting from initial need for some goods and ending in receiving help from the supplier. Very small size interactive virtual product models with real behavior offer undisputed benefits compared to current static or animated 2-dimensional presentations on the web.

For more information please contact jorma.palo@cybelius.com and visit our Virtual Gallery at www.cybelius.com. Real business. Virtually. Interact to understand.

The Shuffler:
Software for a World-Wide-Web Based Form Routing System
DEMONSTRATION

Matthew A. Pfeiffer
Michigan State University

Michigan State University
1138 Engineering
East Lansing, MI 48824
517.353.6488
cbowen@pilot.msu.edu

Abstract: The Shuffler is a software application created to help remove the conventional shuffling of paper from the routing of forms in the workplace. It is designed to run entirely via the WWW, either on Intranets or using encryption on the public Internet. The software allows a set of administrative offices to create, edit, route, verify, and archive paper forms. It includes a security system to authenticate the identity of the users as well as to authorize them. The system software is designed to be as generic as possible in order to allow it to be used by any office as well as on almost any computer and operating system. The purpose of this poster/demonstration is to present an applied view of the various functions of The Shuffler.

Creating Computer Based Learning Artefacts For Implementation In The United Kingdom's National Grid For Learning As A Third Year Interactive Multimedia (BA Hons) Degree Project.

Melissa Lee Price, Ph.D. , School of Art and Design, Staffordshire University, United Kingdom,
mlprice@ibm.net

Abstract:

This poster session is designed to showcase how students enrolled on a BA(Hons) course in Interactive Multimedia can participate in a government educational initiative (the UK's National Grid for Learning) while fulfilling degree requirements. The Web based work that the students developed demonstrates how the concept of a national educational resource can be used in teaching and learning for all levels of education.

From an instructional point of view the project was an excellent one that allowed students to control a 'real world project' and at the same time be involved in teaching the use of interactive multimedia to a teaching professional. Technology students tend to forget that the rest of the world isn't as technically 'savvy' as they are. This brief forced them to step back and take a look at the user population.

The Web and Meeting Documents

Gitesh K. Raikundalia
School of Multimedia and Information Technology
Southern Cross University
Coffs Harbour, New South Wales, 2457
Australia
graikund@scu.edu.au

Abstract: Formal meetings are a universal form of group interaction required in all types of organisations. Such meetings typically have the following features: meetings are driven by an agenda, involve a chairperson and secretary and require minutes to be generated to summarise the meeting and yield actions to be carried out by participants. The agenda and minutes are the formal documents that are the important foundation of these meetings. Methods for creating, archiving, accessing, retrieving, manipulating and distributing these and other types of documents for a meeting provide great scope for study on the highly relevant Web platform. Very little work has been done with regard to formal meeting documents and the Web, one of the few examples being that of Raikundalia (1997, 1998).

Value Based Computing

Peter Reilly & Mark Samis
BOCES- Lower Hudson Regional Information Center

Value Based Computing is the next phase in the evolution of technology. Once your technology is in place, how do you maximize its effectiveness? How do you get the most value for your investment? School need to understand how to fully utilize applications that exist today; to integrate disparate systems, and to make modifications in their work environment that allow them to fully benefit from the potential of technology.

Most schools use only a fraction of the computing power available to them. They employ multiple applications and databases that are not integrated, hold duplicative information, and are not customized to user needs. These “islands of information” become sources of frustration to end users who can not easily get at the information they need. Finally, many school organizations have processes that are inefficient and ineffective so that the application of technology only automates the inefficiencies. Nothing really gets better.

Value Based Computing is a response to these and many other common problems. Solutions promise to make schools run more efficiently and more effectively with existing resources. The methodology for **Value Based Computing** is simple and straightforward:

- **Utilization** – focuses on maximizing the features of programs already in place to help users work more efficiently.
- **Integration** – targets “islands of information” and converts them to easy to use analytical and reporting tools.
- **Modification** – centers on modifying the workplace, work habits, and workplace culture to insure efficient and effective processes.

Student attitudes towards Web-based learning: an action research project

Jonathon Reinhardt
Miyazaki International College
Miyazaki, Japan
jreinhar@miyazaki-mic.ac.jp

Katharine Isbell
Miyazaki International College
Miyazaki, Japan
kisbell@miyazaki-mic.ac.jp

Abstract: Applied Information Science and Environmental Issues, a project-based, web-integrated course, is a class for first-year Japanese college students with three main objectives: build environmental awareness, develop computer skills, and expand English language skills. In planning the class, the authors incorporated an on-line action research project to help formatively evaluate the students' perceptions of the web-integrated course design as well as the web-based delivery of the course materials. Students responded to weekly online feedback logs that focused on student attitudes and reactions to the course. Interpretations of the feedback logs influenced not only the implementation of the course as it was taught, but also the redesign of the course for the following semester. A description of the project and poster presentation is available at <<http://www.miyazaki-mic.ac.jp/classes/fall99/sci151/webnet.html>>.

Cooperative Web of Knowledge Construction

Luiziana Rezende
Federal University of Rio de Janeiro
Brasil – Rio de Janeiro
luiziana@lci.ufrj.br
luiziana@castelobranco.br

Abstract

The purpose of this work comes from the necessity of teachers at several levels and areas with an open environment where it is possible to get a dynamic and cooperative structure. The main goal develops an special environment in the Web that should helps a fast courses's creation, based on a lot of small modules previously wrote by different authors. Trough this purpose we used the map concept strategy and some ideas based on software reuse. A formal and an informal description, using the object oriented language UML and the OOSE (Jacobson) are been applied, in the specification of the environment. At this moment, a specific tool helps the integration of the modules and semi-automatic courses generation, that is being developed.

Developing Digital Media Materials - A Team Approach

Duane C. Roberts, Broadcast Services, Brigham Young University, USA duaner@byu.edu
David W. Monson, Center for Instructional Design, BYU, USA david_monson@byu.edu

Abstract During 1998-99, BYU Broadcast Services Division developed a digital media teaching resource for faculty and students of Civilization 201/202 courses at BYU. A project team was organized with 1 full time project manager, a part time associate project manager, graduate student instructional designer, and 6-8 student graphic artists, researchers, production managers, and technical assistants. During the production of more than 6000 digital media objects, the team also created a multimedia project development process that has become a model for future courseware development efforts at BYU. Project conclusions highlighted the following recommendations: Capture what is currently being done in the class. Then establish course instructional objectives with the faculty member. As the team works to assess digital media needs, identify areas or concepts that difficult to teach using traditional methods. Digital images used to replace slides in the classroom were no more effective than the slide itself. But they were often easier to use and thereby were of value. But digital media proved to be particularly effective when trying to teach difficult concepts. Poster will include demonstration of process.

Ricardo M. Barcia, , Graduation Program in Production Engineering – PPGEP/Federal Univ. of Santa Catarina – UFSC, Brazil.
rbarcia@inf.ufsc.br

Abstract

The application of Internet as a media for distance education has been showing an exponential growth, generating the necessity for new configurations of the existent media, as well as a new parameter of analysis. This work presents the planning process and construction of a WWW site for academic orientation at a distance, to be used in the M.A. Program in Logistics offered to students of PETROBRAS – the Brazilian Oil Company – following ergonomic criteria. The intersection between the areas of CMC, Software Ergonomics, and Academic Orientation was the selected approach to build a site that can answer the assessed needs and expectations of the potential users. The result of this work was a project specification presented to the Distance Education Laboratory of the Federal University of Santa Catarina – UFSC, to be used in the program above quoted. This paper describes the experience of the generation of the *Distance Orientation Support System* (SAAD) specification.

The Development of a Curriculum Template for Applied Problem-Solving in Distance Education Learning Communities

Cyndi Rowland, Ph.D.
Center for Persons with Disabilities
Utah State University
U.S.A.
Cyndi@cpd2.usu.edu

Abstract: The purpose of this project is to create and evaluate a low cost multimedia curriculum tool (hybrid CD-ROM with Internet capabilities) that will assist students, particularly distance education students, to (a) apply and reflect upon what they have learned with instructor support and feedback, and (b) participate in a community of learners who engage in constructive problem-solving. The project will support nine field-tests across five disciplines found in postsecondary education. Given formative data at the conclusion of each field-test, the curriculum will be refined and readied for the next field test. Dissemination of the findings and use of the curricular tool and process is an important aspect of the project. Staff working on this innovative project hope to provide postsecondary educators with a low-cost, practical, and replicable solution to the problem of getting students to apply what they have learned in their coursework and to participate with communities of learners.

Regional Identity Preservation Using The Internet

Nicoletta Sala
Academy of Architecture of Mendrisio
University of Italian Switzerland
Largo Bernasconi
CH 6850 Mendrisio - Switzerland
nsala @ arch.unisi.ch

This work presents two different educational projects that have involved two secondary schools in Italy (students aged 17-19). The aim of these projects is the preservation of the regional identity. The Internet plays an decisive role in the globalization of information, but it is important to defend our traditions (i.e. the regional cooking, the play and the poetry in dialect, and so forth). In the first project, scholastic year 1996/97, 30 students of a fifth class at Vocational Institute in Verbania (Northern Italy) have created a collaborative hypertext (using HTML language) to introduce some particular aspects of the new province of Verbano Cusio Ossola (e.g., its geographical characteristics, the gastronomic local specialities with the tasty recipes). The final work has been available for two years for the Internet "surfers".

The second project, scholastic year 1997/98, has been developed by 29 students of a Technical Institute in Verbania. This collaborative hypermedia (developed in HTML), that also contains the tape recording of the play and poetry in dialect, can be read at the Internet address:

<http://www.verbania.alpcom.it/verbania/Alpen/inie.htm>

It can be browsed from our emigrants that can not come back in Italy, and in this way they can preserve the memory of their origin. These educational projects are two examples of "learning by doing" environment, because the students have learnt some their unknown traditions while they were developing the hypertexts.

Utilizing Desktop Video-Conferencing and Web Delivery for Faculty Technology Training

Perry Schoon, Florida Atlantic University, USA
Roberta Weber, Florida Atlantic University, USA
Jeffrey Hecht, Illinois State University, USA
Jennifer Singler, Florida Atlantic University, USA

The ability of higher education faculty members to engage in professional technological development is still limited by time constraints and fear of appearing incompetent. The purpose of this project is to overcome these problems by utilizing and subsequently evaluating desktop video-conferencing and web-based delivery as arbiters of collaboration and agents for change in an academic world where change does not come easy. The training and evaluation project takes the approach of utilizing low-cost desktop video-conferencing, data collaboration, and web-based delivery systems to deliver technology instruction to our fellow colleagues. Several technology workshops have been designed, delivered via desktop video-conferencing and the World Wide Web, and subsequently evaluated. These workshops were delivered via web-based software using synchronous and asynchronous instruction using: (a) multipoint video; (b) multipoint audio; (c) instructor-led and narrated web touring; (d) web-based pre-, post-, and in-class materials; (e) shared whiteboard; (f) text chat; and (g) interactive instructor questioning.

Return on Internet Investment (ROI²)™

John Seasholtz, Director of Business Consulting
Free Range Media
USA
johnse@freerange.com

Abstract: Organizations building online solutions are beginning to recognize the value of measuring Return on Internet Investment (ROI²)™ early. Determining methods to measure ROI² needs to be one of the first major steps in the up-front planning process, and continually evaluated and applied throughout the entire project lifecycle. ROI² provides a foundation for organizations to determine the success of their online business solution and develop future plans to bring the project to the next level. It should be stressed that ROI² is the end result of an effective Web strategy. A Web strategy should support corporate objectives and should have a clear plan for measuring its effectiveness. Identifying planned benefits and a means to measure them is a critical first step to measuring ROI².

Course Management: A Complete Asynchronous Environment Architecture in Education

Abstract: Technological improvements have enhanced our range of educational experiences with such things as distance-learning. The education systems of today are needed to be supported by new architectures for managing the courses, instructors, students, performance records, for grading homeworks and exams, for supporting assessment, legacy systems, and security. We have developed a multi-tier architecture which integrates back-end tools and systems with commodity interfaces. Data at the back-end databases transformed into knowledge at the front-end browser through a hierarchical middle-ware using various object web technologies. We implemented an asynchronous open information access environment. This asynchronous resource is used to support traditional classroom and interactive synchronous lessons offered using TangoInteractive. It evolved with the needs, reached a large audience, 450 users, including on-campus and on-line distance courses. This paper presents a technical architecture overview and discusses its functionalities gained from our experiences.

Breaking the shackles of the physical page: Site level authoring for XML using ASML.

Nick Shapiro

Charles B. Owen

Media and Entertainment Technologies Laboratory
Michigan State University
East Lansing, MI
{shapiron,cbowen}@cse.msu.edu

A major problem with web authoring today is the page-at-a-time HTML approach. As web sites grow larger and more complex, it is essential that tools treat the site as a single, large, hypermedia document. Even newer technologies such as XML are still shackled by this dependence on the physical page relationship. This poster describes the use of ASML site-level processing in conjunction with XML content to author web sites as a single hypertext document. ASML treats a web site as a single large hypermedia document. Within the structure of a site, content can be several modules, corresponding to a logical hierarchy of the data. This approach to authoring simplifies the production of sites that present content in different forms and allows for simpler management of link and final presentation format consistency.

Connect-2-Tomorrow: Internet Access and Email in a Children's Hospital

Linda G. Shivers, Ed.S., Department of Pediatrics, University of Mississippi Medical Center, USA,
lshivers@ped.umsmed.edu

Michelle D. Revord, M.Ed., Department of Pediatrics, University of Mississippi Medical Center, USA,
mrevord@ped.umsmed.edu

Abstract: The Connect-2-Tomorrow project is a federally funded grant which utilizes Internet connectivity to provide children receiving care at University of Mississippi Medical Center (UMMC) the opportunity to continue their education and maintain contact with peers, teachers, family members and newly assigned keypals. The Blair E. Batson Hospital for Children in conjunction with the Mississippi Department of Education (MDE) is working to ensure that along with the medicine that heals the physical body we not forget about the healing of the mind and heart. Patients within the hospital have the opportunity to email classmates, "meet" new friends through a keypal program and participate in their classrooms using video conferencing equipment. In addition, problems and solutions regarding confidentiality and firewall protection to provide access for a multi-platform system will be presented in this poster demonstration.

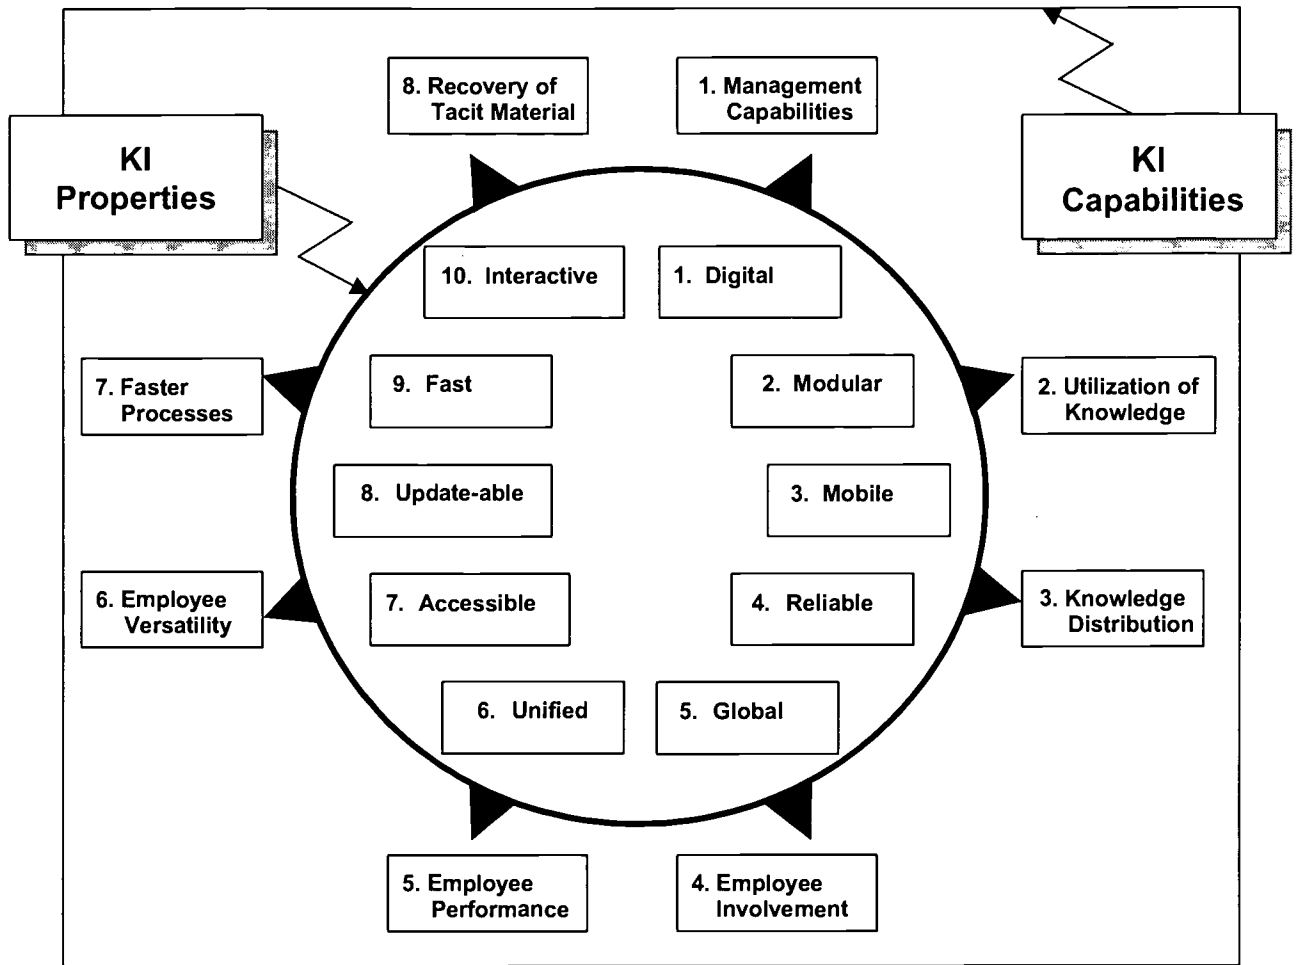

A Modern Knowledge Infrastructure: Properties and Capabilities

Yesha Y. Sivan
Klab.com
and
Tel Aviv University
School of Education
Tel Aviv, Israel
yesha@klab.com

A modern knowledge infrastructure has specific technological properties that enable organizations to function with far greater efficacy. It is digital, modular, mobile, reliable, global, unified, accessible, update-able, fast, and interactive. These ten properties of a modern knowledge infrastructure in turn enhance the capabilities of the knowledge management system. The strengthened capabilities of the infrastructure lie in: (1) management potential; (2) utilization of knowledge; (3) knowledge distribution; (4) employee involvement; (5) employee performance; (6) employee versatility; (7) organizational processes; and (8) recovery of tacit material.

These capabilities yield benefits to the organization as a whole and to individual organizational members. Capabilities 1, 2, 7, and 8 enhance primarily the organization; in contrast, capabilities 3, 4, 5, and 6 enhance the organization, but through the individual. A knowledge infrastructure thus works to promote individual organizational members, understanding that the organization as a whole is most likely to benefit through the advancement of the individual.

Knowledge Infrastructure (KI) Properties and Capabilities

Standards for Educational Technology – IMS

Phil Siviter, University of Brighton UK. Phil.Siviter@brighton.ac.uk

1. Introduction and Background

The last decade of the millennium has seen rapid progress in the development of learning technologies, giving hope to many that we may be approaching the realisation of a vision of an educational landscape in which education providers form virtual partnerships to deliver distributed provision. A landscape in which learners sharing the same learning programme can do so across fading boundaries of time and space.

Throughout that same decade however, some of us have been pointing out that this vision requires more than just good learning technologies - it requires *interoperable* learning technologies. This is because the vision is predicated on education providers (and learners) being able to piece together resources from diverse sources, and present them as coherent integrated packages in which the components interact to provide rich educational experiences. Without interoperable courseware components this kind of "pick and mix" facility is just too difficult for most people to bother with. But, to achieve interoperability amongst courseware components requires technical standards. Until now, there have been none.

The word is now out however. The world is waking up to the problem of incompatible learning technologies and the need for technical standards to enable them to interact. There are now three major initiatives attempting to address the problem of technical standards for learning technologies:

- IMS is a consortium with scores of academic, government and commercial partners including all the leading computing industry companies.
- The IEEE working group P1484 (now renamed the Learning Technologies Standards Committee - LTSC) is another prominent initiative with widespread support.
- The European Union standardisation mandate in the domain of "Learning and Training Technologies & Educational Multimedia Software".

Even better, the three initiatives appear to be talking to one another and attempting to harmonise, and even build upon, each other's efforts. In addition, they are making great efforts to build on top of well known software standards, such as CORBA, DCOM, HTTP, and XML.

This Special Interest Group discussion focuses on either (or both) of two issues which I believe are vital to the success of these standards-forming initiatives:

1. The generation of a wide range of innovative, futuristic scenarios involving learning technologies - i.e., "fleshing out the vision". This is important because scenarios are what drive the requirements gathering process. They form reference points which can be used to verify the outputs from standards projects.
2. A discussion of how the outputs from the projects can best be implemented in the delegates' host institutions/organisations.

Building a Web-based Research Center: Ideas for the UNM-CLARIS Web

Tracy John Skipp, M.A. (c)
University of New Mexico, University College, UNM-CLARIS Group,
Building 73, room 11 Albuquerque, New Mexico, 87131 USA
Tel: 505.277.7996, Fax: 505.277.8283, Email: tjskipp@unm.edu

Abstract: The UNM-CLARIS Web is a new research center, designed to exist solely on the World Wide Web, dedicated to collecting and conducting research on the new and expanding field of individualized studies in higher education. Many specialized and innovative degree programs exist throughout the United States that allow undergraduate/graduate students to design their own degree curriculums. However, those programs are not efficiently connected in a pro-active way sharing ideas or resources for the students benefit. Our research center is building a digital *interactive* encyclopedia and listserv that will help students, faculty, and staff in interdisciplinary and individualized degrees to make the most of their opportunities creatively. Creativity is the key to student development and post graduation marketability. We intend to create a forum for exchange (ideas, strategies, and research) that will continue to develop and strengthen the various programs that exist, as well as provide guidance for new/changing programs.

The Virtual High School

Alice Smith, Virtual High School, Concord Consortium, USA, alice@concord.org
Raymond M. Rose, Concord Consortium, USA, ray@concord.org

Abstract: The VHS (Virtual High School) project is a collaborative of high schools from across the United States. In exchange for contributing a small amount of teaching time, a school in the collaborative can offer its students over one hundred NetCourses ranging from advanced academic courses to technical and specialized courses. Each school provides a VHS site coordinator who is responsible for project management and support of teachers and students at their local school. The VHS grant provides training, software, and technical and administrative support. Each school can enroll up to 20 students for each course a teacher contributes. Quality of teaching is maintained by requiring each teacher to successfully complete The Teachers Learning Conference, a graduate-level NetCourse designed to give participants exposure to the best educational strategies and technologies for NetCourse teaching. The VHS will become a membership organization after the funding ends.

Directed Web Searching

Randall E. Smith
Associate Professor Curriculum & Instruction
Southern Illinois University Edwardsville
Box 1122
Edwardsville, Illinois 62026
resmith@siue.edu

Steven Crooks
Assistant Professor, Instructional Technology
Texas Tech University
Lubbock, Texas
scrooks@TTACS.TTU.EDU

A few years ago we were asked to make a staff development presentation at a rural school district in Central Illinois. We were asked to focus our presentation on helping teachers to use the Internet as an information-gathering tool for both themselves and their students. As the presentation got underway, we decided to pick a safe topic like "Bears" as a search term for demonstrating how a search engine operates. To our surprise, the search results returned several links to web pages that were highly inappropriate for our audience. This incident led to a discussion with the teachers about the dangers of allowing students to indiscriminately browse the Internet for information. At the time, our advice to the teachers was to combine the use of Internet blocking/filtering software with some careful monitoring of student Internet activities. This advice led to some further discussions about the inadequacy of this approach for protecting students from the "dark side" of the Internet. Some of the teachers with classroom Internet experience related their futile attempts at trying to monitor an entire class, while others told "war stories" of students by passing the blocking/filtering software.

Architectural Detailing at Random.
An Interactive Artist-Made Book On-Line

Starla Stensaas
School of Art and Design
Southern Illinois University
United States of America
stensaas@siu.edu

Abstract: *Architectural Detailing at Random* is an interactive artist-made book that was first conceived of in 1986 after shooting Polaroids of "details" encountered doing house renovations in a small Wisconsin town, Random Lake. Because local people talk about what goes on in this village as being "at Random," I imagined a book focused on architectural details of a house renovated "at Random." I loved moving the Polaroids into different visual combinations and wanted to design a book that invited viewers to devise their own variations. This sense of a book without finite limits is another play on the title "at Random."

It wasn't until I started working with web page design in 1995, however, that I found a form that would allow for the interactivity I imagined. It had taken nearly a decade for the Internet to develop to a place where I could realize my earlier concept in physical media.

DIALANG - An Internet-Based System For Diagnostic Language Assessment

Peppi Taalas, University of Jyvaskyla, Finland

DIALANG is a European project which develops diagnostic language assessment tools in 14 European languages. These languages include all the official EU languages as well as Irish, Icelandic and Norwegian. The assessment materials will cover all levels from beginners to advanced, the skills being reading, writing, listening, and speaking, structures and vocabulary. The project will complement traditional approaches to language assessment by exploiting the use of new technologies in assessing the use of language.

Characteristics of the system:

- An assessment system, based on a shared foundation (assessment framework and test specifications) and constructed by assessment experts from all EU countries.
- A diagnostically oriented system, and one of its purposes is to promote diversified language learning in Europe.
- Self-assessment as an integral part.
- Internet delivery. (Existing computer-based assessment systems usually run on single machines or on local networks.)
- Adaptiveness over the Internet. (Adaptive language assessment systems are being, but the Internet is a new context for adaptive engines.)

Data Integrity and Web-based Experiments in Cognitive Psychology

Mark Tew, Department of Electrical Engineering
Ken McGraw and John Williams, Department of Psychology
University of Mississippi, USA
psychexps@olemiss.edu

Java and Macromedia's Shockwave technology allow interactive cognitive psychology experiments to be delivered via the worldwide web. The existence of sites established for educational support has raised interest in the prospects for "research-grade" web-based experiments. In order to provide research-quality data, web-based experiments must answer questions that include the accuracy with which tachistoscopic displays can be presented, the accuracy with which reaction times can be measured, the control of the experimental environment, and falsification of subject variables. This SIG discussion will address issues regarding the integrity of data collected from web-based cognitive psychology experiments such as: Control over the selection of research participants, Control over the commitment of research participants, Control over the truthfulness of research participants, Control over ambient conditions, Effect of bandwidth on stimulus timing and accuracy of determination of reaction times, and Effect of machine differences on stimulus timing and accuracy of determination of reaction times.

Applying the Methodology and Art of Making Films to Producing WWW Videos

Ray Thompson, University of South Dakota, USA

The presenter was recently assigned the course 'Production of Digital Audio and Video Resources'. Because he didn't have formal training in the production of film and video projects the presenter developed a professional development plan with the following learning goals: (1) operate a variety of cameras and lighting equipment; (2) set-up shots; (3) direct a scene; (4) record sound; and (5) use digital editing equipment. The presenter attended a four-week experience at the International Film and Television Workshops in Rockport, Maine where the skills listed above were a taught. This poster session will be used to share what the presenter learned about applying the methodology and the art of filmmaking to producing WWW videos. The presenter has established a web site to make contact with others who are producing web-based videos. The web site includes discussion board and video segments demonstrating specific film making techniques as applied to web videos.

DeltaM - a Decision Support System for the Public Participation in Decision Making in Spatial Planning

Ir. Alexandra Tisma
Department of Urban Design
Faculty of Architecture
2628 CR Delft, Netherlands
Phone ..31-15-2781689,
Email: a.tisma@bk.tudelft.nl

In the highly urbanized and densely populated western part of the Netherlands the space is scarce and therefore under the constant pressure of multiple claims. Changes in the use of space are often the result of interaction between designers and decision-makers. Currently used procedures in plan evaluation and approval in The Netherlands do not properly support this interaction. The process of a plan development and approval is long lasting and inefficient, based on the old-fashioned unicentric model of decision-making. The changes in modern society reflect in growing need for other models than those of hierarchical type.

The aim of this research is to develop a tool, a Decision Support System (DSS) for the *competent citizen* in the *pluricentric* society. The system named DeltaM is meant to help individual users to choose appropriate plan among many and to estimate the consequences of the choices before they take part in collective negotiations with other decision-makers.

Using Technology to Reach Students, On Campus and Beyond

Ann Tolzman
International Business Information Centre
Thunderbird, The American Graduate School of International Management
United States
Tolzmana@t-bird.edu

Abstract: At Thunderbird, our library patrons include many different types of key constituents. We constantly strive to reevaluate how, when, and where this diverse group of patrons acquire knowledge so that we can provide them with the instruction and skills that they need to be lifelong learners and users of technology. Students must learn both the value and the skills of locating information in an electronic environment. In the International Business Information Centre (aka, the Library) at Thunderbird, we use various methods to provide students and alumni with the knowledge and the skills they need to locate international business information from print resources, electronic databases, and the Internet. In my presentation, I will discuss and demonstrate the methods that we use to ensure that students have access to the most current, comprehensive, and valuable business information, both from on campus and beyond.

Similar Syntax Search Function on Web Based Japanese Educational System

Yutaka Tsutsumi
Kyushu Teikyo Junior College, Japan
yutaka@kyu-teikyo.ac.jp

Ryoji Matsuno
Prefectural University of Kumamoto, Japan
matsuno@pu-kumamoto.ac.jp

There are growing number of foreign people who are interested in learning the Japanese language. However, there are not enough teachers and courseware of Japanese education. One of the problems is a wide range of interests: daily conversations, business correspondences, technical documents, etc., which cannot be covered in a single courseware or a class. Making a textbook with a comprehensive set of sample sentences is also time-consuming. Another problem is the number, shapes, and pronunciation of the characters used in the Japanese language, which would be an immediate barrier to start reading/writing Japanese text.

We have been developing a Web Based Japanese Educational System which aims at providing an environment for both courseware builder and courseware users. Fig. 1 shows the overview of the system. In this figure, Japanese-English Text Database is used for providing students example sentences including focused words in a courseware, and for providing teachers example sentences searched by Similar Syntax Search Function.

RAIN Network distance learning and telemedicine projects Internet content development at the Community Level -

Timothy Tyndall, RAIN Network, USA

Working with the USDA Rural Utilities Service distance learning and telemedicine program, California Department of Education, University of California Extensions and Department of Commerce/NOAA RAIN takes education resources directly into the Community at the Neighborhood level.

Our "Neighborhood Technology Master Family", "Youth Technology Corps" and "Community Technology Advisory Councils" are the tools by which we create effective, actively used Community level Internet resources. Three essential "Change Agents" within our programs.

RAIN begins use of two "Internet Bus" vehicles in September 1999. Each bus equipped with 4 computers, lending library, large screen for group teaching and satellite Internet connection. This new generation of "book mobile" takes our distance learning and telemedicine programs to rural communities and inner city projects in an essential new way, giving access to many who would otherwise not have Internet access.

Designing Web-based Image Databases To Enhance Medical Education

Sebastian Uijtdehaage, Ph.D., Anju Relan, Ph.D.

Instructional Design & Technology Unit, UCLA School of Medicine, Los Angeles, CA, USA.

Email: bas@ucla.edu

Abstract: The WWW is not merely an electronic equivalent of a textbook. It can provide a dynamic interface with databases in which knowledge can be stored and retrieved in complex ways to promote educational outcomes. The objectives of this project were (1) to design an online database of pathophysiological images that would allow second-year medical students to retrieve and search for images; (2) to create an "intelligent" database that direct students to similar cases of the same disease or alternative representations of the same case; (3) to create an easy, online interface for faculty to manage the content of the multimedia database. The web browser interface was programmed with ColdFusion[®]. A Microsoft Access[®] database contained fields with information related to the location of the image, descriptors of the image, clinical and patient information, and proprietary information. Feedback from students and faculty has been very positive.

BioPsy : An intranet application for biopsychological experiments

R.J. van Ouwkerk, T.F. Meijman & L.J.M. Mulder,
Institute of Experimental and Occupational Psychology, University of Groningen, Grote Kruisstraat 2/I, 9712 TS
Groningen, Netherlands, E-Mail:R.J.van.Ouwkerk@ppsw.rug.nl

Students who specialize in experimental psychology are confronted with a substantial amount of technical information on the instrumentation and the design of biopsychological experiments. Although mathematics at high school level is a precondition to enter psychological education, several students have difficulties understanding these technological aspects. BioPsy is developed to support those students who are confronted with deficiencies in knowledge of physics, electronics and instrumentation techniques. It is also developed as a remedial teaching tool to update the necessary knowledge and skills. The application is additional to face-to-face teaching and can be completed at any convenient time. Multi-media elements are used to enliven the course material. The application consists of three different modules. Students can search on specific terms to look up knowledge elements. They can also complete an introductory course on instrumentation techniques. In the last module, participants can apply their knowledge in several exercises based on actual experimenting.

Information Architecture and Web-Based Instruction

Stephen P. Victor
BMC Software, Inc.
2101 CityWest Blvd.
Houston, TX 77042 USA
Email: svictor@bmc.com

This poster session presents the application of principles of information architecture to Web-based instruction. Information architecture is the structuring of data to meet the informational and management requirements of an organization or group of people. The discipline of information architecture is informed by principles of information theory and communication theory, information design, and the findings of cognitive psychologists on perception and learning.

In this presentation, I examine relevant literature on information architecture and web site creation, consider the application of the principles of information architecture to Web-based instruction, and discuss ongoing research to evaluate the efficacy of such an application. The following topics are addressed:

- Theoretical background: communication theory, information design, cognitive psychology, hypertext theory, distance learning theory, and the social construction of knowledge
- Using information architecture to construct effective web sites
- Using web-based information architecture to assist students in their own construction of knowledge.

Students' Response to Web Based Language Learning

Kelly Wainwright
Information Technology
Lewis & Clark College
USA
kelly@lclark.edu

Wendy Woodrich
Foreign Languages
Lewis & Clark College
USA
woodrich@lclark.edu

Abstract

Foreign language instruction is central to the College's mission, and in order to strengthen the program, we explored how using the WWW can provide access to authentic material, offer more efficient ways to practice and test grammar, and give instructors flexibility in determining the curriculum of language and content courses.

After a semester of using the WWW in a Spanish class to supplement materials, we gave students a questionnaire to evaluate its use. They were asked to give written responses on questions ranging from their computer expertise to their understanding of the goals of the web exercises, and whether the use of the WWW should continue in language classes.

The majority of the students felt that web-based exercises accomplished stated goals which included acquiring increased confidence in reading and listening to Spanish through real life examples and exploring topics not available in their textbook.

Positive student reception of web-based curriculum indicates that, with modifications a, the use of the WWW in Spanish courses at the college should continue.

Maximizing Resources, Expanding Access and Maintaining Quality in Web-Based Courses in the Community College

Mary Wall, Associate Dean
Atlantic Cape Community College
Mays Landing, NJ, USA
Wall@atlantic.edu

Joyce Grohman, Associate Dean
Atlantic Cape Community College
Mays Landing, NJ, USA
Grohman@atlantic.edu

Abstract:

Atlantic Community College is a small community college, located in southern New Jersey, which offers four complete degrees via online Web-based distance learning. Developing online courses and working with others is now assuming a major role at our college. This demonstration will emphasize:

- The strategies necessary to *maximize resources*, particularly faculty expertise.
- The logistics of *increasing access* by encouraging faculty development and by sharing courses among several colleges.
- The mechanics of *maintaining quality* by following the ABC's of distance learning:
 1. Assessment
 2. Built-in support
 3. Collaboration

The strength of this demonstration will be the dissemination of practical, replicable strategies to assist schools in planning for and enhancing the online delivery of Web-Based courses. Attendees will receive workable plans, ideas and methods to maximize resources, increase access and maintain quality in online course delivery

Using Email and the World Wide Web to Teach and Improve a New Technology-Based College Course

Lih-Ching Chen Wang
Department of Curriculum and Foundations
College of Education
Cleveland State University
U.S.A.
Email: wang@cis.csuohio.edu

William Beasley
Department of Curriculum and Foundations
College of Education
Cleveland State University
U.S.A.
Email: w.beasley@popmail.csuohio.edu

Abstract: National standards have arisen in recent years to address the process of preparing teachers to incorporate technology into education in effective and appropriate ways; both pre-service and inservice teacher education now commonly include technology components. This presentation will describe the ways in which one particular College of Education in an urban setting has chosen to include technology within its required coursework, with particular attention to the ways in which Email and the World Wide Web have been used both as a teaching methodology and a means of gathering evaluative data. Details will also be provided regarding the difficulties encountered in the early stages of implementation, the ways in which the coursework has been modified, and the current results of these efforts at improvement. Our purpose is to provide an example for other teacher preparation programs considering the various options available to them in addressing technology within the context of pedagogy.

How Computer Tools/Systems Support Cognition: An Examination of Theoretical Foundations and Design Strategies

Minjuan Wang
Center for Technology Innovation in Education
University of Missouri, Columbia
wang@coe.missouri.edu

This poster reviews how computer tools/systems support cognition by examining the cognitive benefits of selected computer tools/systems. Earlier research has investigated this area, and the common focus has been on the interactive process between student and cognitive tools. My poster builds on this conceptual underpinning, but I go on to analyze tools/systems from cognitive perspectives. I classify tools/systems by the cognitive theories embedded in them, e.g., distributed cognition, situated cognition, activity theory and constructivism. This poster displays theories, exemplary tools, research perspectives and design strategies associated with distributed cognition and situated cognition.

Using the WWW to Guide Science Inquiry Lessons: Barriers and Solutions to Creating WebQuests in Elementary/Middle School

Herman Weller, Jim Chiavacci
College of Education and Human Development
University of Maine
U.S.A.
E-mail herman.weller@umit.maine.edu

Abstract: There is questionable educational benefit in elementary/middle school in having learners surfing the Web without a clear task in mind. This is a report on the barriers and solutions encountered by three elementary/middle level teachers during their creation of two science WebQuests during the WebQuest/PDN Project, a joint university/school network venture in Maine. In the development phase, the barriers to creation of the WebQuests included the following examples: a) Scarcity of Reflective Time (absence of time in a teacher's busy schedule for unhurried, thoughtful computer access); b) Web-Surfing Tendencies of the "Read and Click Generation" (rapid and often unfocused web-surfing practices of students); and c) Students' Tendencies to Merely "Copy and Paste from the Web" (frequent lack of student reflectiveness and analytic ability while on the web). The teachers' WebQuests will be demonstrated, and their solutions for surmounting the above, and other, barriers will be examined.

PsychExps: A Resource for Instruction in Psychology

John Williams and Ken McGraw, Department of Psychology
Mark Tew, Department of Electrical Engineering
University of Mississippi, USA
psychexps@olemiss.edu

Abstract: PsychExps (<http://www.olemiss.edu/PsychExps>) is a web-based cognitive psychology laboratory supported by the Department of Education FIPSE program and the University of Mississippi. Cognitive psychology experiments written in Macromedia's Authorware language are delivered via the worldwide web to participants, where they are executed in "non-trusting" mode using the free Authorware Web Player. After completing an experiment, the participant may choose to submit data to the publicly accessible archive on the UM server. For analysis, the data may be sorted by affiliation and date, and Excel macros are provided that separate data by participant and create a summary page. As of Spring '99, more than sixty university, community college, and high school classes had registered to use this resource. On-campus workshops are available to psychology instructors who wish to learn to write experiments in Authorware. The Principal Investigators of PsychExps will demonstrate the site and the construction of experiments at this demonstration/poster display.

**The Department of Education's Distance Demonstration
Project:
Research and Data Collection**

Gail Wisan, Ph.D.
Office of Institutional Planning and Research
University of Maryland University College
College Park, Maryland 20742-1699
USA
gwisan@umuc.edu

Abstract: The Department of Education has selected fifteen participants—colleges, universities, and consortiums—for a pilot project which will assure financial aid for institutions that have a large number of students participating in distance education, including web based instruction. As part of this pilot project, the Department of Education has required a substantial research and data collection component. The University of Maryland University College has been selected to participate as a distance demonstration university. The methodological design involves comparing distance and classroom based programs. The Department of Education has provided a data collection spreadsheet to collect data on Distance and classroom based students. Conceptual and methodological issues such as how to categorize students that are not purely distance or classroom based as well as how to track a cohort that changes categories will be presented. Initial data that touch on issues of diversity, access, and quality will be exhibited.

The Fruits of ADDIE: Instructional Products of a Web-Based Distance Education Seminar Using Virtual Reality

Kelly Ann Yamashiro, Instructional Systems, The Pennsylvania State University, U.S.A., kxy125@psu.edu

Jack Lee, Workforce Education, The Pennsylvania State University, U.S.A., jtl106@psu.edu

Xun Ge, Instructional Systems, The Pennsylvania State University, U.S.A., xxg4@psu.edu

Virtual reality (VR) is the ability to immerse the computer user, as an active participant as opposed to a passive viewer, in a computer-generated experience [Grimsdale 95]. The use of VR applications in web-based distance education is still in its infancy. Instructors and instructional designers do not have specific models, let alone many case studies, upon which to design and implement web-based distance instruction using VR applications. Therefore, the problem arose when instructional designers were called upon to design and develop distance instruction for a one-hour web-based seminar using a VR application. Designers followed the ADDIE model of instructional design [Rossett 87] to address the problem. The purpose of this demonstration/poster session, therefore, is to showcase the instructional products that were designed and developed for the virtual seminar as well as inform the audience of how the ADDIE model was used by the instructional designers.

Internet Technology Links Three Generations: A Case Study

Shirley F. Yamashita, PhD
Department of Educational Technology
University of Hawaii at Manoa
United States of America
E-mail sfyamash@hawaii.edu

Lianne Morita
Department of Educational Technology
University of Hawaii at Manoa
United States of America
E-mail liannem@hawaii.edu

Abstract: The Internet is taking root with a wide cross-section of Americans. In just a few years, the Internet has emerged from near obscurity to being a common household word, largely due to the replacement of difficult computer language with user-friendly graphical user interfaces with point-and-click interactions (Ryder & Hughes, 1998). This case study in progress will take an in-depth look at three generations of a family and their experiences with learning and using Internet technology. A sample of the research questions that are being investigated include: (1) Is there a difference in the learning styles, attitudes, and achievements of the three generations? (2) What challenges are faced by the participants? (3) What kinds of instruction are most helpful to the participants? Reference: Ryder, R.J., & Hughes, T. (1998). *Internet for Educators*. Designing and Implementing a Web-Based Course

Steve Chi-Yin Yuen, Ph.D.
Department of Technology Education
University of Southern Mississippi
E-mail: steve.yuen@usm.edu

Abstract: The Web has attracted teachers with promises of access, interactivity, ease of use, dissemination, and a potential universal presence in the lives of students and teachers. This presentation will describe experience learned in developing and delivering a Web-based course currently offered via the Internet with emphasis on what worked, worked well, caused problems, and failed miserably. The presenter will provide an overview and hands-on demonstration on his Web-based course at the University of Southern Mississippi [<http://dragon.ep.usm.edu/~yuen/teaching/toe648/toe648.htm>].

CGI Application for Automated Creating and Updating of Subject-Oriented Internet Resources Databases

Xiwen Zhang, Pfau Library, California State University, San Bernardino, U.S.A.
xiwen@csusb.edu

Mark Hoskins, Computer Science Department, California State University, San Bernardino, U.S.A.
mhoskins@mrhm.com

Abstract: A directory of Internet resources by subject is an important section of any academic library's Web pages. A common problem faced by many libraries is the difficulty of updating such a page. At CSUSB library, we have developed a large "Internet Resources by Subject" database. Fourteen quick-launching Perl CGI scripts have been written to create a user-friendly interface to update the database, allowing all subject specialists to participate easily. Without HTML experience, a librarian can create or delete directories or sub-directories, add or delete Internet links, and add or change descriptions. The librarian just copies and pastes the URL and the description, then clicks the "Submit" button. The CGI script executes and generates new HTML pages dynamically. Files can be edited far more quickly than by traditional methods of HTML editing and FTP publishing.

TITLE: *WebNet* 98 World Conference of the WWW, Internet & Intranet Proceedings, (3rd, Orlando, Florida, November 7-12, 1998).

AUTHOR: Maurer, Hermann, Ed.; Olson, Richard G., Ed.

PUBLICATION_DATE: 1998

ABSTRACT: This proceeding of the third *WebNet* conference--*WebNet* 98--addresses research, new developments, and experiences related to the Internet, intranets, and extranets. The 265 contributions of *WebNet* 98 presented in this volume consist of the full and short papers accepted for presentation at the conference from a collection of more than 600 submitted from 40 countries. Included are position papers by leading experts in the field; descriptions of ideas and products; reports on concrete applications of the Web; discussions of the impact of the Web on various aspects of life; plus considerations as to how society might adjust to the resultant changes. Major areas covered at the conference include: (1) commercial, business, professional, and community applications; (2) educational applications; (3) electronic publishing and digital libraries; (4) ergonomic, interface, and cognitive issues; (5) general Web tools and facilities; (6) personal applications and environments; (7) societal issues, including legal, standards, and international issues; and (8) Web technical facilities. (AEF)

DESCRIPTORS: Computer Assisted Instruction; Computer Interfaces; *Computer Networks; Computer System Design; Computer Uses in Education; Conferences; Electronic Libraries; Electronic Publishing; Optical Data Disks; Standards; *World Wide Web

IDENTIFIERS: *Intranets; Technology Implementation; Technology Plans
