The implementation of a local navigation assistant must fulfill several requirements. On the one hand there are technical requirements. On the other hand there are features that are required to optimally support the user. Since one aspect of the great importance of web browsers is their ability to provide the same functionality to access documents on different platforms, it is very important to implement the navigation assistant the most platform-independent as possible. But not only the different platforms have to be taken into consideration. Each browser is slightly different in its implementation. An aim of the navigation assistant must be to run at least on the most important current browsers. Of course, the assistant has to stay in the background if the user does not need its support. It must be implemented as an additional value that can be used if required but that does not hinder the user while working. Furthermore, it should provide a long history functionality that facilitates the finding of documents accessed some longer time ago.

The main feature that the assistant must provide is the visualization of the navigation path. It must display the structure of the visited web sites, but also show the location of the actually accessed document in that structure.

The access to any URL displayed in the assistant should be easy and fast. Finally, it would be nice if the user could attach comments to URLs. A classification scheme would be an optional feature of the category 'nice-to-have'.

3. The Navigation Assistant

Out of these assumptions consequences for the implementation arise. Since the navigation assistant should be implemented mainly as a platform and browser independent tool, it seems impossible to use a browser feature such as the history function for the implementation. Although the use of the browser history in combination with a Java-script is principally possible [Bekavac 1998], this solution is hindered too much by security restrictions in its functionality. The access to the browser's history-log-file by some other tool is hindered by the lack of a common browser history log file format. In spite of web servers, that use a more or less common log file format, each browser uses its own conventions for logging. Since browser history files differ depending on the used browser type, the creation of an own history list is desirable. This solution is browser independent and provides a maximum of freedom for the implementation of additional functions that support the user in navigation. One possibility to access the user's browse history, is the use of a proxy server for browsing. Since a proxy can be configured as gateway, it can easily be used to log the browsers requests. Furthermore this solution allows the user to switch the logging function on or off just by configuration of his browsers preferences. A comfortable method for logging is the use of a database. The data stored in the database is almost instantly available for other applications. Especially the navigation assistant is such an application. Therefore, the assistant has to be a database aware application. Based on the browse history stored in the database, the assistant provides the capability to display the hierarchical dependencies of the browsed URLs. In order to present that structure to the user, a appropriate designed tree-view can be used [Mukherja 1995]. The tree-view has the advantage

[Czerwinsky 1997] that many people are used to working with similar programs as the windows file-manager. They also display documents in tree-views and allow the users to explore with them the structure of the file system. In spite of a tree-view of the file system that is based on the complete set of directories and files available on the computer, the navigation assistant can of course only present those directories and documents that the user already requested during the browsing sessions. For those elements already visited, the navigation assistant enables the user to explore the underlying directory structure. Next to the aspect of exploration, this facilitates and quickens the navigation to previously accessed documents that are located in different branches. URLs can be accessed quite fast without a confusing search in the history list. It becomes easy to determine neuralgic locations in the web sites that should be preferred for further exploration.

Nevertheless, a tree-view alone can hardly display the navigation path the user took. Therefore, an additional feature is required. A time series is that feature. The combination of both tree-view and time series does not only display the documents the user visited but also shows the sequence of requests. This enables the user to determine in which order he visited a URL and how it fits in the web site structures.

In spite of the time-series that supports the user most effectively in the recent history, a URL classification and documentation functionality provides a more long term support. URLs can be classified by many different classification schemes. For example classification schemes can be the document type or importance of a document located at the URL, the affiliation to a subject and the availability (short or long term). Combined with prediction facilities as they are mentioned in [Tauscher 1997] the tool will support the user very well in browsing.

3.1 Prototype Implementation

Since the browser independence requires a gateway to create the browse history, the prototype implementation of the navigation assistant consists of three components. Those components are the gateway, the database and the client, which is the front-end for the user. A brief overview of the system architecture is shown in [Fig. 1].

Because of the aim of platform independence the prototype assistant is implemented in JAVA. While the gateway is implemented as a JAVA application, in the context of browsing a JAVA applet is a good choice for the client. While browsing with one or more windows the user can open an additional window that contains the applet. Now the user can easily switch between the assistant applet window and the browser windows. Since gateway and client can connect to the database at the same time without any conflict, the client has immediate access to the requests logged by the gateway. So the users is always given the most recent URLs he/she has visited.

Figure 1: The system architecture with the gateway that logs each browser request into the database (DB) and the Navigation Assistant that uses the database for the provision of the navigation structure.

3.1.1 The Gateway

The gateway is a JAVA application that runs as a multithreaded server [Sridharan 1997] program. On the startup the server reads a configuration file that specifies the system parameters. Such parameters are e.g. the hostname, the gateway port, a probable proxy and the database connection parameters. The server process listens on the configured port. It requires HTTP 1.0 as protocol for the browser requests. Although the server is accessed as an HTTP proxy by the browser, at the moment it provides no proxy functionality at all. It is configured as a gateway that transfers the requests of the browser to the web servers specified in the requests. An additional proxy to be used by the gateway can be configured. For privacy reasons the gateway by default accepts only requests that are sent by a browser on the same computer. Also, as this mechanism does not work in a multi user environment, it provides sufficient security on a single user system at its recent prototype state.

When the gateway is initialized, each request transferred by it is logged to the database. Furthermore, the responses of the web-servers concerning the mime types of the delivered documents is also stored in the database.

3.1.2 The Database

The navigation assistant uses a conventional relational database as history file. This database is accessed via JDBC [Reese 1997] by the gateway and the client. Therefore it is easily possible to switch between different databases that are available on the desired platforms.

The data model, needed to fulfill the requirements of the navigation assistant, is quite simple. It consists of three entities. The main entity is the URL. Attributes of the URL are the connection address, the mime type and the comment. The mime type is handled as an entity itself. The last entity is the Visit. The Visit just has a time-stamp as attribute. The relation between URL and Visit can be describes like each URL was visited at least once. Of course a URL can be visited numerous times. Further entities will be added to the data model with the implementation of further classification schemes and the provision of further functionality.

3.1.3 The Client

Since the navigation assistant is to be used during browsing the implementation as a JAVA applet was the obvious choice. While browsing the user easily can open an additional window to start the navigation assistant. After the initialization the applet opens a frame that contains the tree-view component. A menu in the top allows the configuration of display parameters. Three different views are available. The frame will either display the tree-view alone or with the time-series or comments on the right hand of the tree-view. For each view the time-window to be displayed can be chosen. By default, the client displays the URLs requested at the current day. The bigger the time window becomes the more the number of URLs to be displayed increases. Since the program is coded in JAVA, the performance is poor if the list becomes to big.

When the client queries the database a list of URLs matching the criteria is created. The URLs are parsed and the server addresses are extracted. This list of visited web servers is used to generate the nodes on the first level

of the tree-view. In a recursive way, visited documents, directories and subdirectories are attached as leaves or folders to each node as it is shown in [Fig. 2].

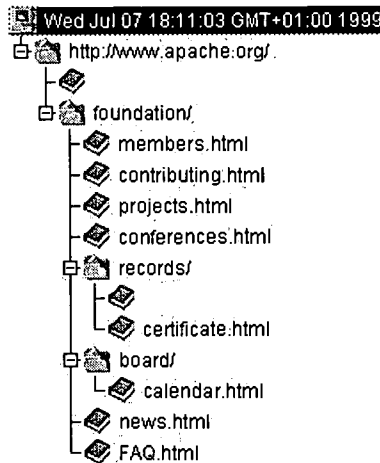

Figure 2: A sample part of the tree showing the web-server with its browsed documents and subdirectories. One can easily determine the directory structure of the visited web-site. Naturally only documents with their location in the directories requested by the browser in the time period can be displayed

A click with the left mouse button will open or close the folder in the tree-view. If a folder or document is clicked on with the right mouse button the browser will open the document located behind this folder or leaf in a new window. Thus it becomes easy to access any previously visited document. Since the assistant is to be used only periodically at certain occasions, the update of the tree-view and its additional views has to be done manually.

With the time series representation [Fig. 3] a third dimension is added to the two dimensional view that is given by the tree-view component itself. It consists of a time axis that is displayed on the right hand of the tree-view. The axis of ordinates is given by the entries of the tree-view itself. Since the tree-view requires a lot of space to display the nodes in a readable size, the space available for the time-series representation is limited. The used tree-view component provides the capability to display any user data in columns next to each folder or leaf icon. For the ease of the prototype implementation this capability is used to display the time series on the right hand of the tree-view. For each entry in the tree-view an adequate set of user data is generated that results in a flag at the right position on the time axis. A URL that was called n times in the recent history is represented with n flags in the time-series.

Figure 3: The time-series representation showing the way the user took while browsing on the web-site. The session started at *www.apache.org*, the next document requested was */foundation/members.html*. The flags on the right hand display the temporal sequence.

As it is known from the bookmark function of browsers, it is nice to attach a small comment on certain URLs. The navigation assistant provides a similar functionality. If the user selects this representation form, the tree-view's user data as it is mentioned above will be set to the comment for a URL instead of the time-series. Comments may be entered or removed by the use of the menu.

3.1.4 Limitations of the prototype

The navigation assistant cannot keep track of any movement the user undertakes in the browser's cache. Since this will not produce a request that is sent via the proxy, it will not be logged to the database. Therefore the navigation assistant will only work in the expected way, if the browser cache is disabled. A solution for this problem is a complete proxy functionality of the proxy program as it is discussed in the outlook. Another limitation arises from dynamic documents. URLs that consist of content generated dynamically by a server side script depend usually from the parameters sent with the request. The same URL can represent different contents changing from visit to visit. The tree-view will not distinguish between such documents if the parameters are transferred with the HTTP POST method.

4. Outlook

Since the system at the moment only works in the expected manner if the browser cache is disabled, the implementation of a complete proxy functionality is aspired. The documents can be stored in the database next to the URL. Based on the documents stored in the database a local search engine for historic documents can be implemented. Furthermore, the sphere of documents and directories known to the system can be enhanced by the extraction of links from the browsed documents. Those links can be displayed as child leaves of the document leaf in the tree-view. It would allow the user to follow in an easy way the links originating from any document. In combination with an intelligent prefetching mechanism, a satisfying overview of the visited web sites would be available.

5. Conclusion

By combination of two dimensions in space and one dimension in time the described system allows a navigation in the browse history that is a lot more accurate than the default history function given by the browsers. Particularly, the described system provides two main advantages for the user: On the one hand, it supports the user in exploring the web-site(s) he/she visits with a file manager like tree-view. The tool gives him/her a good overview about the internal structure of the web sites, which eases the finding of previously visited contents. Furthermore, it becomes very easy to reload already visited pages.

On the other hand, the time series representation allows the user to track the navigation path he/she went on in the near history. This makes it easy for him/her to determine certain critical navigation points in order to follow other links from there or to add them to the bookmark file.

A prototype implementation allowed to test the usability of the navigation assistant concept. Although the prototype only demonstrates the aspired functionality it can offer very helpful support for browsing in the world wide Web.

Abstract: Combining resource-intensive learning objects with rapid, template-driven course design provides a cost-effective method for developing pedagogically sound online courses. This paper describes the implementation of such a system at San Diego State University, with a detailed example of a learning object and an in-depth description of course design. Learning objects are self-contained, multi-purpose instructional modules separate from a course. Learning objects are integrated into a course by adding a “docking object” which may connect the object to other course content, or give special instructions. Learning objects can be time-consuming and expensive to develop, so we integrate them into a pedagogically sound instructional environment that is easy and inexpensive to develop (I CARE). I CARE is an acronym for Introduction, Connect, Apply, Reflect, and Extend. By carefully combining these two types of systems, organizations can maximize the effectiveness of online training and education through object learning on the World Wide Web.

What is a learning object?

Broadly speaking, a learning object is a piece of instruction or a learning environment that may be used in a variety of ways, for a variety of purposes. Beyond that, definitions vary widely, from “any specific type of content that has been bundled together as a single unit” [Connolly, 1998] to David Merrill’s description as every piece of text, every picture, every video scene, and every component of an instructional product. For Ms. Connolly, objects contain objectives, content and assessment, providing the optimal structure for affording reuse of knowledge.

Here at San Diego State University’s Department of Educational Technology we adopted a learning object approach for a five-course online certificate program in Multimedia Development. The SDSU Defense Conversion program sponsored the development of the course objects and the course management and tracking system.

For our purposes we like to think of a learning object as a more-or-less self-contained, multi-purpose, scalable, and re-usable instructional module. Our objects are intended for use in the context of instructor-facilitated university graduate courses. The objects are mainly web-based and are integrated into a pedagogically sound online course delivery system known as I CARE.

We set the following benchmarks as we set out to design our objects.

- Objects should be self-contained, and independent of other learning material— that is, a learner should be able to complete an object successfully without access to additional materials.
- Objects should feature well-defined prerequisites. For instance, before being able to use the *Visualization* object described below, learners must already know how to categorize types of learning objectives.
- Objects should require only “docking objects” to integrate them into a course. Docking objects might specify objectives, assign a particular task or approach to using the object, and evaluate or otherwise integrate the learner’s experience with the object back into the context of the course.

In this paper we will explore one example of a learning object in depth, and then examine the course structure in which that object is integrated.

EPSS for Visualizing Information

An example of a learning object in this context is *Visualization*. We developed the *Visualization* object for the Multimedia Development & Management Program Distance Learning Project at the SDSU Defense Conversion Center.

Visualization is an Electronic Performance Support System (EPSS) for helping designers specify appropriate visuals for instructional products such as presentations, computer-based training, job aids, informational web pages and kiosks, and so forth.

According to the dual-coding theory of working memory [Paivio, 1991], most ideas are easier to understand with a picture than with words alone. Words and pictures are stored in the brain separately, but are linked with one another. If your brain can't immediately retrieve the words, it might be able to retrieve the image that illustrated the words, and thereby eventually retrieve the words as well. Brain hemisphere research shows that verbal and visual learning are different, but when combined they strengthen one another [Sousa, 1995, p. 96].

Visualizing information is an important theme in training new instructional designers and educational multimedia developers. Recent developments in imaging and image processing have made visuals less expensive to produce and distribute than ever before. Yet much of what educational technologists have done in the past is write instructional or informational text. Visuals are often an afterthought or developed unsystematically as the need becomes obvious or as ideas occur to graphic artists or video producers, usually untrained in visualizing information.

The *Visualization* object takes the form of an electronic performance support system, or EPSS. An EPSS is a combination of an expert system and a tutorial. As an expert system, it prompts users to enter information and make decisions, and delivers a recommendation—in this case, a specification for an instructional or informational visual. As a tutorial, it helps learners understand the rationale that lies behind choosing one approach or system over another. The *Visualization* EPSS is designed to be used by novice instructional designers until they internalize the principles and examples they need to specify visuals without the aid of the EPSS.

Let's walk through a typical visualization problem with the help of the *Visualization* object. The EPSS involves a six-step process, with the seventh step displaying the recommendation or specification.

At the beginning of the object, there are three optional pages of introductory information (<http://defcon.sdsu.edu/1/objects/visual/intro/>). For newcomers, these pages explain the purpose of the object and how to use it, and introduce some basic concepts such as a taxonomy of both concrete and abstract visuals, including still and motion pictures (photos and drawings); conceptual, temporal, and spatial diagrams; and pie, line, and bar graphs.

1.1 Step 1: Objective/Topic

Repeat users may skip the introductory screens and go directly to the first decision screen (<http://defcon.sdsu.edu/1/objects/visual/index.htm>) which prompts them to identify the type of information—the type of objective or topic—they wish to visualize. We used the popular Facts, Concepts, Principles, Processes, and Procedures taxonomy described by Clark [1989] and others.

While classifying information types is not the central theme of this EPSS, learners can access definitions and examples by rolling their mouse over the name of each type. When they've identified the type of information they wish to visualize, they select it by clicking on a button, and type in a brief description of the topic or objective in a text box.

Suppose we classify the topic we're visualizing as a "concept," type in a few words about the concept, and then click on "Next" to go to the next decision point.

1.2 Step 2: Questions

This screen suggests a number of questions about concepts (or whatever you classified your topic as in Step 1) that visuals can help answer. For instance, when people are trying to understand a new concept they might want to see an example of a concrete concept or an analogy of an abstract concept. They might benefit from seeing the parts or characteristics of the concept or understanding its subordinate or superordinate categories.

Again, rollovers present users with descriptions and examples of the questions. There is no need for the user to type in specific questions—it's enough to identify the type of question you wish to address with the visual. In this case, we'll select "Parts" and click on "Next."

1.3 Step 3: Representation type

The next screen offers a list of appropriate representation types, based on the type of information and the question specified in the two previous screens. Notice that these decisions, as well as the description of the objective we typed in Step 1 are displayed for the user's reference at the top of each screen. These accumulate at each step until the complete specification is shown.

In this case, we want some suggestions as to how to represent the parts of a concept. The EPSS suggests using a still or motion drawing, a spatial diagram, a still or motion photo, or a concept diagram, in order of likely usefulness. We can weigh the choices ourselves by reading brief text descriptions available as rollovers and viewing example visuals by clicking on their titles.

We'll choose "Still and motion photographs" and click on "Next."

1.4 Step 4: Production methods

Once we know what type of representation to use, we can determine an appropriate production method. For instance, for a photograph, we might consider archival sources such as clip art or libraries, or we might have the resources to send out our own photographer to capture the image. Rollovers help users assess the pros and cons of each method.

There's no need to click on a choice here, but if the user wishes they can type some notes to flag a particular clip art file or give specific directions to a photographer or illustrator. In the case of a diagram or graph, the user can suggest the sources, methods or software tools for producing what she wants.

We'll type in some specifications and click on "Next."

1.5 Step 5: Visuals and text

As we noted earlier, visuals used appropriately in conjunction with text are usually more effective than either media used alone. This screen prompts the user to consider that fact and specify appropriate labels, captions, or other accompanying text. As before, rollovers remind users of the utility of each option and a few rules of thumb for writing each one.

We'll specify some labels for the parts in our photograph and click on "Next."

1.6 Step 6: Visuals and sound

Similarly, speech, music, and sound effects can complement visuals (and text) to help people understand. This screen prompts the user to specify audio to accompany the visual, if appropriate.

We'll pass on this option and click on "Next."

1.7 Step 7: Summary

This page displays the finished specification for the visual. There are many, many variations in the specification, based on the type of objective or topic we identified, the question we wish to address, the type of representation we choose, the production method, and any text and sound we specify—the choices available in the steps outlined above. Given other knowledge types or questions, users might be prompted to specify a timeline, a map, a table, an exploded diagram, or a pie graph.

If the user is working through the EPSS in order to specify a visual for a school or workplace project, they may wish to copy the specification to a text file or print it, available from the page following the Summary. Alternatively, they can return to Step 1 and begin specifying another visual.

This EPSS is but one example of a variety of objects we're creating for the Multimedia Development distance learning project. It exemplifies the object approach as we understand and are using it.

The *Visualization* object is re-usable—it can be used repeatedly by learners at a variety of levels, and by instructors in a variety of educational settings. It is designed to serve a variety of purposes, from introducing basic ideas about types of visual representations and production methods to internalizing more sophisticated heuristics for specifying appropriate visuals. It can be used in the context of instruction or in on-the-job environments. It is scalable, to accommodate short course-related assignments, whole instructional units, or extended production work. It is self-contained in that it provides enough internal explanation and direction to enable almost any learner to succeed in accomplishing their objective.

Like other objects, instructors can integrate the *Visualization* object into their courses by developing a simple “docking” objects. For example, in our Advanced Multimedia Development course here at SDSU Educational Technology, students receive specific assignments for which they must use the *Visualization* EPSS. They launch out to the EPSS from the assignment web page, and when they return they receive feedback on their own specifications for a visual in the form of one or more model specifications provided by the instructor. Later in the course they use it to prepare specifications for their own course projects.

The I CARE system

For objects to be used effectively, they must be integrated into a larger system. Because the objects we built required careful design and, in many cases, more extensive (and expensive) development to achieve the production values we desired, we decided to integrate them into a course system that provides a pedagogically sound instructional environment but is easy and inexpensive to develop. We settled on the I CARE system, which we developed several years ago with a grant from the California State University Office of the Chancellor to train university professors to develop online courses.

I CARE is an acronym for Introduction, Connect, Apply, Reflect, and Extend. Using the I CARE system helps content experts, instructors, and other course developers remember and apply principles of good teaching to their online course modules.

At the same time, it provides a framework that helps learners focus their learning efforts effectively. Indeed, we found it helpful to make the system apparent to the students. We discovered that when learners are aware of a clear lesson structure they will spend more time focusing on the content and less time guessing about what is expected of them.

The elements of I CARE are based on widely accepted lesson planning and instructional design systems common to the fields of educational psychology, teacher education, and curriculum development. These lesson planning or instructional sequencing systems are based, in turn, on brain and cognitive scientific research.

The I CARE system may be adapted to fit any content area. Indeed, in our original CSU faculty development project, professors in content areas from physics to foreign languages, and from engineering to the humanities, successfully used I CARE to create online course modules.

Instructors who teach face-to-face go into their classrooms early to arrange chairs, adjust the temperature and lights, lay out materials, and so forth. They prepare the environment for learning to take place. The I CARE system affords online instructors a similar way to prepare the virtual learning environment for their students.

A typical I CARE course might look like our own Advanced Multimedia Development course (<http://coe.sdsu.edu/courses/et561/> and click on modules 1, 2, or 3). Each of the elements of I CARE serves a distinct purpose.

1.8 Introduction

The introduction of an online module should include two key elements, the context and the objectives:

Context. The introduction initiates the module by explaining how this particular section fits within the context of the online course as a whole. It reminds learners about what they have already learned, how this new information will build on previous knowledge, and how it is relevant to them.

Objectives. An example of an objective is:

"At the end of this lesson you will be able to identify and describe the function of the major organs of the respiratory system."

Including clearly stated objectives is important to good instruction. First, objectives provide instructors or course developers with a sound basis for the selection or design of instructional content and activities.

Second, objectives are useful for evaluating or assessing the success of instruction. Third, objectives can be an advanced organizer which sets learner expectations. This allows learners to form a meaningful scaffolding to which to attach the content which is about to be presented [Mager, 1984].

1.9 Connect

This area is where learners acquire new information and concepts. Important guidelines for structuring the Connect section include:

Chunk Information. Short-term memory holds about seven chunks or bits of information at a time. If material is organized into chunks there is a better chance that learners will encode this information into their long-term memory. Moreover, small chunks of text are easier to read on screen.

Provide Context. Learning can be made more meaningful to students by setting the new information within the context of real-world tasks. For example, if a course objective is for students to learn how to collect and identify flowering plants, it might be useful to point out how this knowledge or skill will be useful to them in their future career as a botanist.

Consider Prior Knowledge. Take into account learners' prior knowledge of the topic. Provide ways for them to preview the content so that they can focus on what is relevant to their needs. Features for activating prior knowledge include tables of contents, headings, marginal notes, questions, visuals, and other cues.

Accommodate Learners. Provide students with multiple forms of representation to help them visualize concepts. There are several ways to do this: illustrations, visual analogies, demonstrations, graphs, diagrams, and tables, to name but a few. For instance, course developers might use a diagram to illustrate how bacteria reproduce, or a visual analogy to relate an abstract idea to a concrete one.

The connect section often serves as a docking object to a learning object. By providing some background information and context, it prepares learners to engage in particular ways with the object. For instance, a Connect section that docks with the *Visualization* object described above might prompt learners to pay particular attention to the classification of types of information, or it might prepare them to question the taxonomy of types of representation.

1.10 Apply

This is where learners practice using the new information in an "authentic" context. The practice should relate closely to the stated objectives for the module. Practice activities may be online or off. Online activities might include learning objects or parts of them. Offline activities might involve field visits, interviews, hands-on projects, and so forth.

An Apply section might dock with the *Visualization* object, for example, by posing a particular visualization problem for learners to solve using the EPSS. When they return from using the EPSS, the Apply section could provide feedback in the form of model specifications.

1.11 Reflect

The purpose of this section is to encourage learners to articulate their newly acquired knowledge both to themselves and to others. This provides learners opportunity to mentally process and organize their thoughts and construct or amplify their mental schema or conceptual structure. For example, learners might construct a concept map of the new content. A concept map is a visual representation of the relationship among concepts and can be an effective learning tool for many students:

Another way to promote reflection is to have learners communicate their thoughts and ideas to the instructor or, perhaps better, to their peers. Much has been written about building online communities using strategies such as online chat, email exchanges with peers or instructors, posting to a threaded forum, or participating in a listserv.

1.12 Extend

Extending the module includes enrichment, remediation, and/or evaluation activities.

Enrichment and remediation. Course developers can provide enrichment activities or resources for "further information" for learners who have mastered the content and are excited about learning more. For

those learners who are less successful, include remediation exercises. This is also a good area to provide "if time permits" activities for learners who may want additional practice with the same content.

Evaluation. There are two things to evaluate—the learners accomplishments and the course module or program itself.

Instructors may want to know whether or not students have learned what was intended. Be sure to base this evaluation on the original instructional objectives stated in the Introduction section of the module. Students may evaluate their own learning or you can build in electronic or other assessment systems to measure skills and knowledge. This will help determine grades and provide students with useful feedback. Evaluation may be quantitative or qualitative.

Evaluation is also an opportunity to determine the success of the course of module design. Course developers may want to know whether learners have difficulty navigating through the pages, or whether some section requires elaboration, or how they might modify learning activities so that students are more apt to complete assignments and learn more deeply and easily. The answers to these and other questions can help them make necessary revisions to courses, modules, and objects for the next iteration of the course.

In addition, course designers may be held accountable to sponsors and need to provide information about how well students are receiving the online instruction.

Conclusion

The I CARE system provides a pedagogically sound, easy and inexpensive framework for delivering online instruction. It provides a variety of opportunities to dock with selected learning objects, carefully designed and (usually) developed at greater expense.

By carefully apportioning resources between these two types of systems, organizations can maximize the effectiveness of online training and education through object learning on the world wide web.

Abstract: Educational institutions have long been involved in planning and implementing new initiatives, but with the profusion of technology innovations, the race to stay ahead of the game has intensified. Planet Innovation is a grant-funded organization offering online solutions for technology planning and implementation, especially in K-12 schools. This paper will discuss two online tools that support an essential element of technology planning - the staff responsible for integrating technology in their curricula. A web-based instrument for measuring concerns about adopting innovations and the development of a user-centered web site designed for communicating technology stories and networking among teachers will be described.

Introduction

Educational institutions have long been involved in planning and implementing new initiatives, but with the profusion of technology innovations, the race to stay ahead of the game has intensified. In today's climate of rapid change, Wall says it is "difficult for anyone outside the industry to stay current" [Wall 1994]. Technology planners face a number of issues in making decisions about technology acquisition, implementation, and evaluation. Among them are nuts and bolts decisions concerning types of networking and equipment, software, and access [Fries & Monahan 1998; Rennie 1996]. Ongoing cost considerations for upgrades and maintenance are essential, yet often overlooked [Davis 1995]. However, providing technology equipment is only the beginning. Sustaining the human infrastructure that shapes the equipment into tools of learning is vital. Too frequently, we find schools equipped with adequate hardware and software that is virtually unused. Equally disheartening is finding the school where technology is being misused. Instances abound:

- Computer labs where technology is seen as separate from everyday learning activities and classes are scheduled for routine lab time.
- Teachers who use computers as little more than a time-filler for students who have completed their work or who offer computer game time as a reward for desired behavior.
- Instructional methods that waste technology's potential by offering the equivalent of electronic worksheets.

This paper will discuss online solutions that support an essential element of technology planning - the staff responsible for integrating technology in their curricula [Strudler 1993; Weiss 1996]. For optimum use of technology to occur, many components must be in place. Shared vision, adequate training and support, sufficient infrastructure - all are vital for full utilization of technology's capacity [Wedman, Laffey, Andrews, Musser, Diggs, & Diel, 1998]. And, "at the center of it all, 'headware,' not hardware, is the central element in the successful development of an effective, coherent, and cohesive long-range plan for technology in K-12 schools" [Jukes 1996]. Ultimately, student success is the goal of both administrators and teachers. Yet success does not happen accidentally.

We will describe the development and application of web-based tools that support reflective decision-making, change and ultimately, success. Two solutions using two different strategies to

address the critical area of support for technology implementers will be examined. The online Stages of Concern About the Innovation Questionnaire (SoCQ) tool assesses staff concerns about innovation use as a first step in identifying and developing appropriate assistance. TechConnect, a web site for sharing stories about technology use in educational environments, illustrates a mechanism for supporting change and technology use through creating a networked community of users.

Planet Innovation

To understand the development of these two change tools, it is helpful to situate their origins. Since 1995, Planet Innovation has been part of the Center for Technology Innovations in Education (CTIE), which operates on the University of Missouri-Columbia's College of Education campus. The purpose of the Center is to engage in research and development dedicated to the innovation of new technologies for the support of teaching and learning. Planet Innovation grew from the U.S. Department of Education's establishment of the Regional Technology in Education Consortia (R*TEC) program, whose goal is improving student achievement through technology. The R*TEC emphasis is on improving teaching and learning, professional development, and infrastructure development. A unique feature of the R*TECs, in contrast with similar organizations, is their exclusive focus on effective technology use to support school reform [U.S. Department of Education 1998]. During early regional planning, the South Central R*TEC (SCR*TEC) identified online delivery as an emerging vehicle allowing asynchronous, wide distribution of information and learning resources. Initially, SCR*TEC's Planet Innovation specifically targeted administrators, technology coordinators, and other leaders involved in technology planning. The charge to use technology for driving school reform led to this decision. For real change to occur on a systemic level, in this case on the district or building level, it is critical that individuals in leadership roles make informed decisions. Change can and does occur in one classroom at a time, but is more likely to occur in a community that shares common goals and vision. To support decision-makers, Planet Innovation designed a web site offering tools that assist in technology planning, implementation, and evaluation. Scheduling conflicts, time constraints, and distance barriers are limitations that may prevent groups of decision-makers from communicating effectively. To facilitate this process, Planet Innovation envisioned an on-demand web environment based on a model of "Right-Time, Right-Place, Right-Form" [Wedman et al. 1998]. This meant that technology planners could choose appropriate web solutions based on their individual needs and, if desired, form groups to work in a distributed environment. Participation in an online group is not contingent on physical location or precise time frames, with group members free to choose the most convenient time and place for collaborating with others. Among the online tools developed to assist the planning and decision-making process were a Group Calendar, Group Survey Creator, Delphi Planning System for group consensus building, and Stages of Concern About the Innovation Questionnaire (SoCQ).

Measuring Concerns About Adopting Innovations

One of the primary issues facing individuals responsible for facilitating innovations involves human nature more than the innovation itself. Individuals are often resistant to change, and many innovations fail because those in charge have neglected to adequately consider the people affected. Teachers are frequently expected to integrate new technologies and adapt their instruction, often with inadequate time, training, or information about the innovation's effect on their teaching or students. Network connectivity has ushered in new possibilities for learning, with the potential of forever changing the way we think about the traditional school environment. While some individuals embrace these changes, others are less enthusiastic about adopting innovations. Hassinger, as

described in [Rogers 1995], contends that people are open to an innovation only when they have a need that the innovation will fill. Even then, unless the innovation is relevant to that need, as well as consistent with the person's belief system, there will be little effect. Change is a complex process involving not only the innovation, but also the growth of individuals *over time* as they implement the change [Hord, Rutherford, Huling-Austin, & Hall 1987]. Hord et al., describe common mistakes leading to innovation failure. Among them is the tendency to provide initial training without follow-up monitoring and additional help. A second mistake is viewing as identical all the individuals involved with the change instead of realizing that each individual will react uniquely to the innovation. The Concerns-Based Adoption Model (CBAM) was designed with the belief that the individuals affected by change are the most important factor in the change process [Hord et al. 1987]. The model provides tools that enable a change facilitator to offer support and interventions in a flexible, yet systematic, process. A central part of the CBAM is the 35-item Stages of Concern About the Innovation Questionnaire that measures the current concerns of a person encountering change. Concerns are defined as "the feelings, attitudes, thoughts, or reactions an individual has related to a specified program or practice" [Rutherford, Hord, & Thurber 1984]. Statements are rated using a Likert scale with dimensions ranging from "irrelevant," or "not true of me now" to "very true of me now." The responses fall into one of seven stages. These stages consist of concerns about the innovation itself, concerns about effects it may have on the person responsible for implementing it, concerns about consequences it may have for students, and concerns about ways users can collaborate or extend the innovation. The CBAM was developed through extensive research at the University of Texas in Austin to "conceptualize and facilitate educational change" [Hall, George, & Rutherford 1979]. Planet Innovation was granted permission to develop an online version of the Stages of Concern About the Innovation Questionnaire that could be administered either to a single user or to a group of educators. The tool was designed to calculate scores for each stage and display a graph representing each individual's position in each of the stages. Anyone who registers on the Planet Innovation web site has free access to creating groups and administering this survey instrument. To begin a group survey, the innovation for which the statements are to be answered is entered into a text field. The group creator then builds the group by entering individuals' e-mail addresses in the Group Population Tool. This utility is used for all Planet Innovation tools that involve group collaboration or action. Next, an automatic e-mail is generated, prompting each group member to log-in to the Planet Innovation web site where they will find a notification linking them to the SoCQ. Upon completion of the survey questions, the data is automatically analyzed and available to the group creator. The results include individuals' scores in each of the seven stages of concern and a group graph representing each individual's results displayed in a different color. Thus, individual profiles may be examined as well as compared with others who are involved with the innovation.

The Stages of Concern Tool: Two Applications of Use

Pre-Service Administrators Using an Online Problem-Based Learning Environment

Because change facilitators are often educators in leadership positions, the following use of the SoCQ tool is of particular significance. To familiarize pre-service administrators with support tools for innovation adoption, the Information Environment for School Leader Preparation (IESLP) project is utilizing Planet Innovation's online SoCQ tool. IESLP is a web-delivered, problem-based learning environment preparing students for leadership roles in education. Problem exercises and information environments are available to IESLP users, who access actual school data that has been entered with name changes to protect anonymity. Complicators for a situation may be introduced that keep the conditions fluid and changing, as would be expected in actual situations. Computers are used as information and communication tools for IESLP work groups, which are modeled after teams of education administrators as found in real-life settings.

Students have the opportunity to engage in practical problem solving, make proactive leadership decisions, and gain valuable insight into the responsibilities and competencies necessary for education administrators. The rationale behind IESLP is the endeavor to bring about fundamental change in school leader preparation. Rather than train leaders in a reactive or “in-basket” model, IESLP strives to change the underlying thinking of these individuals and to reform the way administrators approach their profession. Active “problem-finding” is emphasized, encouraging leaders to reflect and engage in identification of problems and opportunities [Mayer, Crawford, & Forsyth 1998]. IESLP learning modules may position students as administrators who seek to implement technology innovations or other changes in their schools. To underscore the importance of understanding the attitudes and readiness of staff members to adopt an innovation, IESLP turned to Planet Innovation's SoCQ tool. As the tool was originally developed, only the group creator could view results for the entire group. Individual group members were allowed access only to their own results. Because IESLP students needed to understand how the tool works, adaptations were requested that would allow all members of a SoCQ group to view the entire group's results instead of giving that capacity only to the group's creator. Planet Innovation programmers modified the tool to allow a group creator the option for this level of permission when setting up a group SoCQ. Next, programmers set up a simulated group based on real-life data that IESLP provided. IESLP's cohort groups are now able to use the SoCQ results to analyze staff needs and concerns about adopting innovations and to develop mediating support strategies. Knowledge of a tool that measures innovation adoption concerns and is easily accessed for online administration and scoring increases the likelihood that these pre-service administrators will remain aware of individual staff concerns as they implement changes as in-service administrators.

Teachers Implementing Online Curriculum

To illustrate a second application of the SoCQ tool, we next examine a small rural school district that acquired unlimited access to a commercial online curriculum program as a result of its membership in an educational consortium. Although the online curriculum had great potential and might have been highly successful in some schools, it was underutilized in this particular setting. Why? Several factors may have contributed to the situation. First, the majority of the teachers had not identified the need for a resource such as the online curriculum. Second, the teachers were not integral to the planning process. Instead, the online program was presented with an initial training session and teachers were left to implement the program or not as they saw fit. Little follow-up or support was forthcoming. Clearly, a well-thought out process for initiating and sustaining this innovation was lacking. Third, it is possible that teacher beliefs about the efficacy or value of the program affected their level of adoption. If this innovation did not mesh with their attitudes about using packaged lesson plans, if they perceived the materials as lower quality than their current instructional materials, or if they found the mechanics of accessing the material online prohibitive, then non-adoption would be expected [Rogers 1995]. A group of seven teachers agreed to fill out the web-based Stages of Concern About the Innovation Questionnaire. Analysis of the results from this survey indicated that several individuals were not yet in the implementation stages, but had concerns regarding how to use the online curriculum and how it would personally affect them in regard to time and logistics. Until these concerns were recognized and appropriate support given, the teachers were unlikely to change their present teaching methods and adopt the online curriculum. Issues of individual concerns are essential for change agents, who are often school administrators, to keep in mind as they plan for policy and implementation. In each of the stages of concern, there are identifiable strategies and assistance that a change facilitator can offer. Identifying concerns and offering support mechanisms increases the likelihood of the innovation's success [Hord et al. 1987]. Taking advantage of tools such as the online SoCQ gives change facilitators crucial information that is instrumental in successful adoption of innovations.

TechConnect

In studying professional development, a distinction is made between change driven by administrators and change agents and “bottom-up” movements that focus on the teachers involved in the change [Pennell & Firestone 1996]. Historically, teachers have been isolated in closed classrooms with little time or opportunity to collaborate or share their experiences. Recently, however, teacher networks have become powerful vehicles that encourage and value exchange among participants [Lieberman & McLaughlin 1992]. Face-to-face networks, while effective, encounter the constraints of time and physical proximity. This type of network is no longer the only model, as online social networks are developing that support collaboration and connection among teachers [Wellman, Salaff, Dimitrova, Garton, Gulia, & Haythornthwaite 1996; Reilly 1999]. Online networks can foster the “bottom-up” diffusion of ideas about using technology among teachers. The traditional barriers encouraging isolation are removed and change can occur in a grassroots method. A key concept in successful online communities is empowerment [Palloff & Pratt 1999]. Planet Innovation’s goal in creating its companion web site, TechConnect, is to provide a networked community for sharing technology stories whose design is driven by the educators it serves. To achieve this, we initially surveyed 83 teachers to determine their preferences in content, delivery, and submission mechanisms. Although as developers, our initial plan was heavy reliance on audio as the delivery medium, 85% of those surveyed preferred a mixture that included text. Likewise, the preliminary plan for an automated recording system for teachers to submit technology stories was postponed because only 10% of those surveyed indicated the preference to submit information using this technique. Over one-half of the teachers preferred entering their stories in an online form. Of the teachers who responded to the question regarding their type of Internet access, one-third had 56K modems and one-third had Ethernet access. Since less than 20% of the respondents accessed the Internet using a 28.8K modem or less, streaming audio and video are options provided on many stories to enhance the user’s experience. At this time, teachers are beginning to offer their stories and we remain attuned to their needs in further developing the web site. Usability testing has occurred on a small scale and will continue. Future plans include additional online workshops with subjects determined by the users, a chat function to supplement the bulletin boards, and featured guests. Research goals focus on assessing the effectiveness of this approach in increasing technology integration in learning situations.

Conclusion

A key to successful change and innovation adoption lies within the individuals affected by that change. Support for those involved is a vital component of successful change and may include strategies that are initiated at the change facilitator level or that are generated by the individuals themselves. The online Stages of Concern About the Innovation Questionnaire is a proven tool that makes appropriate support strategies possible by identifying the current concerns of an individual regarding change in which he/she is involved. A second model of support is exemplified by TechConnect, which uses an online environment to create support through communication and collaboration. Web-based tools such as these offer increased possibilities for change by overcoming barriers and fostering connections.

Abstract

The Postsecondary Education Programs Network (PEPNet) offers interactive multimedia web-based training on the PEPNet web site at www.pepnet.org. The training, entitled *Orientation to Serving College Students Who are Deaf or Hard of Hearing*, is designed for postsecondary education professionals who are serving students who are deaf or hard of hearing. The instructional goal of the project is to provide postsecondary administrators, faculty, and staff with a basic understanding of hearing loss and its implications for communication and learning in a postsecondary setting. PEPNet, is the national collaboration of the four Regional Postsecondary Education Centers for Individuals who are Deaf and Hard of Hearing. The Centers are supported by contracts with the U.S. Department of Education, Office of Special Education and Rehabilitative Services. The goal of PEPNet is to assist postsecondary institutions across the nation to attract and effectively serve individuals who are Deaf and Hard of Hearing.

Introduction

The Postsecondary Education Programs Network (PEPNet) now offers one hour of multimedia web-based training on the PEPNet web site at www.pepnet.org. The training, entitled *Orientation to Serving College Students Who are Deaf or Hard of Hearing*, is designed for postsecondary education professionals who are serving students who are deaf or hard of hearing. Others who may benefit from completion of the training include prospective employers of deaf and hard of hearing students and beginning students preparing for careers in deaf education, audiology, communication disorders, rehabilitation, or sign language interpreting. The training is offered at no charge, and individuals who complete the training may download and print an official certificate of completion issued by PEPNet.

Instructional Goal

The instructional goal of the project is to provide postsecondary administrators, faculty, and staff with a basic understanding of hearing loss and its implications for communication and learning in a postsecondary setting. Upon completion of the course individuals will be able to: 1) define basic terms and concepts related to deafness and hearing loss, 2) Explain how deafness and hearing loss influence people's life experiences, 3) identify languages and communication strategies used by people who are deaf and hard of hearing 4) apply skills for communicating with students who are deaf or hard of hearing, 5) describe the services available for students who are deaf and hard of hearing and 6) adapt instruction to accommodate the needs of students who are deaf and hard of hearing.

PEPNet

PEPNet, is the national collaboration of the four Regional Postsecondary Education Centers for Individuals who are Deaf and Hard of Hearing. The Centers are supported by contracts with the U.S. Department of Education, Office of Special Education and Rehabilitative Services. The goal of PEPNet is to assist postsecondary institutions across the nation to attract and effectively serve individuals who are Deaf and Hard of Hearing. The training was developed with collaborative participation of a team of content experts from each of the four Centers:

- Debra Wilcox Hsu, Dissemination Coordinator (team leader) and David Buchkoski, Training Coordinator, Midwest Center for Postsecondary Outreach (MCPO) at St. Paul Technical College, St. Paul, Minnesota
- Charley Tiggs, Project Field Specialist, Northeast Region is served by the Northeast Technical Assistance Center (NETAC), located at the Rochester Institute of Technology in Rochester, New York.
- Marcia Kolvitz, Associate Director, Postsecondary Education Consortium (PEC) located at the University of Tennessee at Knoxville
- Allisun Kale, In-Service Training Specialist and Gary Sanderson, Outreach Program Coordinator, Western Region Outreach Center and Consortia (WROCC) located at the National Center on Deafness at California State University, Northridge.

The PEPNet content expert team contracted with Seward Learning Systems, Inc in Minneapolis, Minnesota, for the design, development and programming of the web-based training. The training module was available on-line within six months of the inception of the project. Team members worked together during those months through one face-to-face meeting and many telephone conference calls and chat meetings.

Role of Web-based Distance Learning

The four Regional Postsecondary Education Centers for Individuals who are Deaf and Hard of Hearing were created to ensure that every postsecondary institution in the United States could easily access the technical assistance and outreach services that the Centers provide. The Centers serve over 10,000 colleges, universities, proprietary schools, and community based rehabilitation centers throughout the United States. Multimedia web-

based distance learning is an ideal training and dissemination tool for organizations like PEPNet which provide outreach and training under the following conditions:

- Large populations - PEPNet serves over 10,000 postsecondary institutions.
- Geographically dispersed - PEPNet serves postsecondary institutions in rural and urban areas in every state and territory of the United States
- Continuous stream of trainees - PEPNet serves a continuous stream of professionals in postsecondary institutions.
- Learners at various levels - PEPNet serves professionals with varying levels of experience and knowledge about working with students who are deaf or hard of hearing.
- Stable content style and scope - *Orientation to Serving College Students who are Deaf or Hard of Hearing* content is stable and universally needed to effectively serve students.
- Accountability is required - PEPNet is accountable to the US Department of Education to provide training to professionals in postsecondary education and to document the training. Interactive web-based delivery of PEPNet training will allow for electronic tracking of completed training and automated credentialing of training for professionals in postsecondary education.

In addition to the collaborative web site and multimedia web-based training, PEPNet offers an on-line Resource Center on the PEPNet web site with thousands of listings of resources related to deafness and hearing loss. For more information about the PEPNet services or to participate in the on-line training visit the PEPNet web site at www.pepnet.org or contact Debra Wilcox Hsu at 651.221.1432 or dwilcox@stp.tec.mn.us.

Academic Information Management: an Open Linking Approach

Gareth Hughes, Wendy Hall, Tony Hey and Les Carr
Department of Electronics and Computer Science, Southampton University
Highfield, Southampton, United Kingdom. SO17 1BJ.
{gvh, wh, ajgh, lac}@ecs.soton.ac.uk.

Abstract: This paper describes a Web based document management system developed as a Lotus Domino application and the continuing research work of providing users with a variety of link services and agents that enhance the basic content of the system. The system is designed for use by administration personnel in an academic environment taking into account the wide variety of systems and methods already in use. Users do not need to know how to author Web pages as the source material for the system are files produced by common word processors. The system features a number of management tools to complement this concept written into the Domino application. The document management system is complemented by the use of an open linking service to dynamically cross-reference the documents.

Introduction

It is becoming commonplace for academic departments to maintain a Web site of official information for staff and students. The creation and maintenance of such a site is far from trivial. The AIMS (Academic Information Management System) project sets out to make it a very simple matter for the people who create paper documents within a department or organisation to contribute them directly to an automatically generated Web site. Advanced linking technology is used to enhance these online documents with as much relevant information as possible. The AIMS server becomes a fully featured Web-based repository and archive for the information. The user is simply required to provide a minimal amount of information when submitting a word-processed file from a Web form. AIMS has been designed around the concept of making use of the content of files rather than just being a Web-based file store. Users are expected to continue to work as normal on their own machines and submit finished versions of documents to AIMS.

An external link service enhances AIMS Web pages by embedding links on words or phrases found in AIMS pages. The links are not embedded in the documents on the server but are added to the Web pages on the fly by the link service. For example, a set of links can be automatically created that link staff names and user id's to user's home pages. The link service and other agents attempt to reflect the structure of the department complementing the information contained in the documents.

The AIMS Document Management System

This section contains a summary of the key features of the document management aspects of the system as implemented using a Lotus Domino server. Documents are submitted as actual files using a simple Web form. A small amount of information is required about the document but every effort has been made to make it a quick and easy process to upload a file. A complex LotusScript program manages the creation of a document in the Notes database and conversion of the actual content of the file into the internal Notes format whilst also storing the original file. Numerous formats are supported including Microsoft Word and WordPerfect. This ability to work with the content of a variety of file formats is the main reason why Lotus Domino was chosen as the application development environment for the project. From this database of rich text information the Domino server can generate Web pages on the fly. The overall design is targeted towards making a simple and fast process for putting normal word-processed documents online with the minimum of effort.

Features of the document management system include :

- Documents are accessed from various generated listings designed for the application.

- Version control is supported. Users can update documents in the system as required. The system maintains the relationships between versions of documents.
- A custom designed search interface allows searching of the document content.
- AIMS stores all original files as well as storing the Notes version of the content.
- Automatic generation of Adobe Acrobat PDF files for all word-processed documents. This allows users to obtain print accurate copies of documents.
- Online editing of document details, future versions of AIMS may allow direct editing of the document content using a Java applet.
- Special facilities for large documents. These are stored in sections with a special table of contents document defining the relationship between them. This concept has been extended to allow users to define collections of documents such as 'All the minutes for 1997'. This is implemented using dynamic database lookups so the collections are continuously updated. The code library for this could be used in other Lotus Notes applications.

AIMS are now in use within the author's department and being evaluated by a number of others at Southampton and other UK Universities. Currently there are three Domino servers running 5 separate AIMS databases.

The Application of Open Linking

The consequence of the AIMS design is that documents do not contain embedded links in the way that a normal Web site would. The initial research goal of the project was to provide useful links on this content in a way that is easy to maintain. This is achieved by making use of an open hypermedia link service developed within the group. Over time the service has been implemented in two flavours though both work along similar principles. The first is the Distributed Links Service (DLS) [Carr et al 1995] [Carr et al 1998] [Carr et al 1998a] [Hill et al 1995] developed within the group mainly funded by the Open Journals Project [Hitchcock et al 1997] [Hitchcock et al 1998]. The commercial version, Webcosm, is developed by Multicosm Ltd, a company originally founded to exploit the Microcosm [Fountain et al 1990] system. Each brings differing advantages for the AIMS project. Webcosm has a larger feature count and will be used when the linking service is made available to users of AIMS whereas the DLS source is controlled by the group and the system can be altered at a low level for experimental purposes.

The link service is implemented as a Web proxy. The user configures their browser to use the link service as their Web proxy. When the browser requests a page it will ask the link service for the page. The link service will retrieve the page from the server (AIMS) and annotate the HTML with extra links before passing the enhanced Web page back to the user's browser. Links are stored on the link server in link databases or linkbases. An entry in a linkbase consists of the word or phrase to make an anchor, the destination URL and a description of the link. When the link service is in use any occurrence of the word or phrase in pages the user views will become a link to the destination document even though this link is not in the original Web page. This is a generic or glossary link as first implemented in the Microcosm hypermedia system. An example of an entry in a linkbase would be to link the acronym of a research group in the department to the home page of the research group. A link of type local restricts the anchor to only occur in a single document.

The main linkbases in use with AIMS are a set of links for all undergraduate courses to the relevant course page, a large linkbase linking user id's and user names to home pages and a linkbase with a variety of acronyms and other useful words or phrases. The key advantage of using the system is ease of maintenance. If the home page of our research group changes then the link can be updated in one simple action by altering the entry in the appropriate linkbase. The first goal of using the link service with AIMS is to author linkbases of official terms and definitions for the department with effort going towards automating link creation at every opportunity.

Linking Items in Minutes

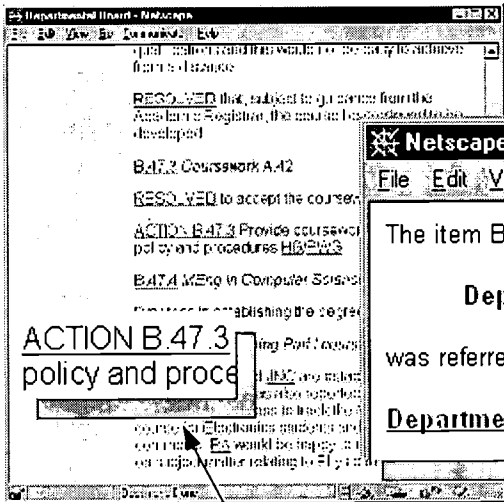

A more advanced application of the linking service is to try and make more use of the structure of the minutes stored in AIMS. In the diagram below [Fig. 1] the Distributed Links Service has been modified in an experiment to link the items and actions in minutes together. The minutes of the Department Board of Electronics and Computer Science contain item numbers of the form B.n where n is a number. Frequently items in minutes will be following on from Actions and Items in previous editions of the minutes. The Distributed Links Service has been used to link together these item numbers enabling readers to follow the trails of issues back through time.

Item B.2 contains a reference to an ACTION B.47 in the previous set of minutes. The user follows the link B.47. This link triggers a program on the AIMS server.

B.2 Actions
ACTION B.47 Draft Chair of Academic

A program on the AIMS server searches the database to find the most likely document containing the item B.47 by using the date of the document the user is viewing. The result is below.

Netscape
 File Edit View Go Communicator Help
 The item B.47 in
Departmental Board 1995 - 1996 Minute 1 (04/10/1995)
 was referred to in the following document.
Departmental Board 1995 - 1996 Minute 44 (03/07/1995)

The server returns a link to the referred document. In the body of this document is the Action B.47.3

Figure 1: Using the Distributed Links Service to link items in minutes allowing the user to follow trails of issues back through time.

This example needs further investigation to ensure that the techniques apply to more generic document types and are not relevant to just a few documents that match a certain pattern. For pattern matching algorithms to be more successful users must be trained to be accurate in their use of the numbering schema. Users submitting documents could be constrained in what they can enter in the fields or more fields could be added to describe the document in more detail. This will quickly discourage users especially if they lack confidence and are concerned that their categorisation would be considered 'incorrect'.

Link Authoring From A Browser

Webcosm ships with a Java link editor form. A more preferable solution would be to create links whilst viewing the documents. Microsoft Internet Explorer 4 allows users to add items to the context menu allowing the creation of a simple authoring tool. The user opens the destination and selects the appropriate word in the text to use as

the anchor. An additional entry on the context (or right click) menu 'Create Generic Link' uses Javascript to create a filled in form for submission directly to the Webcosm server.

This experimental application has enough functionality to allow users to directly author links between documents. The links will also have a high probability of still being relevant as new versions of documents are added. If the destination document is updated then the link will point to the new version of the document. If a document containing an anchor is updated then the link will survive if the same word or word-pair still occurs in the content of the new version. Whether these links are still relevant to the content is a more complicated issue. If the experiment is pursued further then this will need to be addressed.

Alternative Ways of Using the Link Service

Experience of the use of Webcosm and the DLS in a number of projects have shown that the implementation of the service as a Web proxy has a number of disadvantages. Users may not know how to set up a proxy or may not be allowed to make use of a proxy. The use of firewalls may restrict its operation. When in use the service will alter all documents the user reads no matter whether the links are in context or not. This particular issue has been addressed by the DLS which allows a linkbase to be used for a limited URL domain.

Alternative implementations do exist. Webcosm has also been developed as a plug-in library using the NSAPI interface for Apache Web servers. The link service is a library resident on the Web server and alters Web pages before the Web server delivers them to the browser. The consequence is that only documents on the server are enhanced. This is not a problem for AIMS and could be seen as a definite advantage. A similar low level interface to the Domino Web server does not currently exist though there are other methods for achieving a similar effect. Webcosm is implemented as a Web proxy component and a link server engine. It is possible to write programs that communicate directly with the link server. Within the AIMS application programs have been written that run every time a document is requested from the server. Java code asks the link server for the links for that particular document when required. The link service returns just the list of links it would have placed into the document and these links are processed and placed into a field in the document just before the Domino server renders and delivers the document. The links appear in the margin as a list of recommended sites for the user to view. Though the links are not being embedded in position in the main flow of the document the links are being generated on demand and in context depending on the users chosen linkbases.

The next step has been to try a process of pre-compilation of links. A system has been devised that can 'pull' the body of AIMS documents through the link service which adds the appropriate links. This HTML representation is stored in the database and served to users who are unaware that the main portion of the document is not actually being generated on demand. Though this has the obvious disadvantage that links are not being created on the fly the system now looks and feels like a normal Web site to users. This will make it easy to develop a system for creating point to point links between documents. The envisaged procedure would be for the link author to update documents overnight as required. This is still in development and no conclusions have yet to be drawn from its use.

Beyond Generic Links

The limitations of generic links soon become apparent. Too many links will overwhelm the user and be a distraction. This problem has been addressed by work done for the Open Journals project by modifying the DLS. The DLS has a concept of link priority schemes, different links can be given a priority by their author and the system can colour the links accordingly or even not display certain priority levels of links. Using pattern matching to create links in text is shown by the example of linking Board Minutes to be a promising way to find more link anchors with less explicit link authoring. Another application of such techniques would be to help with recognising names of people within documents though such techniques are much harder to implement. Pattern matching algorithms to solve this problem would need to be complicated compromising the performance of the service and slowing the access times of documents. There needs to be an alternative approach to the proxy synchronously processing each page. See [Carr et al 1998a]. The proxy could farm out the processing of documents to agents that would each examine the document and try to provide the user with useful information and links. These results would need to be delivered to the browser separately from the document causing a number of implementation problems..

An important implementation issue is how to create useful links for the documents. Some linkbases are automatically generated by extracting data from other online systems such as the staff database. This is useful but is limited to specific topics. Another method could be to require users to supply potential keywords and metadata for a document. This places unwanted demands on users and would be very difficult to implement. A more interesting method is to use some system that can understand the content of the documents and generate keywords automatically. Such a system, Refindment, has been developed by Multicosm and is being tested with AIMS.

Related Work

Other open hypermedia systems have evolved to encompass the Web in some respect and offer enhanced Web pages. Chimera [Anderson et al 1994] has been integrated with the Web in a number of ways [Anderson et al 1995]. One was to use a Java applet inserted into all Web pages that gave independent access to the information in the Chimera store. Another method was to write a CGI gateway from Web server to Chimera server allowing a browser access to the Chimera structured information. Hyperwave [Hyperwave 1999], now marketed as an advanced Web server, started life as an open hypermedia system Hyper-G [Andrews et al 1995], [Maurer 1996]. In it links are first class objects stored separately from documents and are also bi-directional. Links are merged into the documents when delivered to the browser. Webwise [Grønbaeck et al 1999] has evolved from the DHM/WWW integration project into an enhanced Web service offering contexts, links, annotations and guided tours stored in external databases. Users can collaboratively create links and other hypermedia content using the Microsoft Internet Explorer 4 Browser utilising COM technology. The same group is now drawing on the lessons of many of the systems listed here and working on the ARAKNE framework [Bouvin 1999], [Bouvin 1999a]. This is an object-oriented component-based, three layer model aimed at providing Web augmentation tools a unified access to structure servers, proxies and Web browsers.

The Memoir [DeRoure 1998] project used an open architecture including proxies and link services to support researchers working with vast quantities of distributed information. The system not only used the DLS link services but also supported the trail as a first class object. Users could record their trails through documents whilst pursuing a particular task and the system could match trails thus connecting users with similar interests.

A number of systems have used Web server or proxy based methods to provide annotation services for applications such as discussion groups. Critsuite [Critsuite 1999] includes the CritLink link service component that will annotate existing documents with links. The author's first mediator was Shodouka [Shodouka 1999], this proxy could render Japanese Web pages as images on Web browsers that did not support the Japanese language.

The Wide Area Information Browsing Assistance (WAIBA) [Brooks et al 1995] project was set up to investigate the use of the Web for collaborative work. One of the underlying technologies developed was transducers [Meeks et al 1996]. Transducers were defined as proxies that alter the message streams between server and browser. A toolkit, STRAND (Stream TRANSDucer) was produced that allowed developers to rapidly build transducers. It was available until recently for free use as part of WebWare. Another architecture for building transducers or intermediaries is WBI [Barrett 1997]. This is a toolkit of Java classes that are currently in use for building a variety of applications. These include a personalisation proxy for a user to run on their own machine that will annotate pages the user reads. A more powerful system is to use a pair of transducers that can convert HTML or XML into other formats to transmit using wireless technology and then convert back at the client. A third use is as a filter for allowing children to use the Web.

Conclusion

We have created a Web based document management system using Lotus Domino with facilities designed for academic as opposed to a large-scale industrial environment. The use of such a flexible development platform now allows us to bring these documents alive for users in ways that are not possible on paper or on a traditional Web site.

All of this research is trying to find as many ways of adding value to the basic content submitted to AIMS. At its most basic AIMS simply stores files originally written on a word processor that were destined to be printed. These electronically frozen documents need to be kept alive by as many means possible to ensure their

continuing relevance to the users of the system and to make it easier for people to find the information they need on a daily basis. By making use of the content of these documents and many other live sources of information forms a considerable advantage over the paper versions outweighing the small amount of effort required to submit documents into AIMS.

PASSENGER: A CSCL Tool for Spatially Distributed Software-Engineering

Axel Hunger, Frank Schwarz, Stefan Werner
Gerhard Mercator University of Duisburg
Department of Data Processing
Germany
swerner@uni-duisburg.de

Abstract: In this paper we will describe the Passenger-Concept and our motivation for applying new media to support a Software-Engineering Course. For this approach the international degree course „Computer Science & Communication Engineering“, which was first offered at Gerhard Mercator University Duisburg during the winter semester 1997 plays an important role. The development and setup of the new international degree course are described in (Hunger, 1998). With the usage of new media and communication technologies it should be easier for foreign students to follow the studies in Germany. Further, it can give students the ability to take part in the Software-Engineering Course during their abroad year of the studying. Thus students not only have the ability of shortening their study-time, but also have the chance of obtaining knowledge in systems known as Computer Supported Collaborative Working (CSCW) Environments (Kremer, 1991).

1. Introduction

Nowadays, industrial Software-Engineering has the meaning of developing high-quality complex Software-Systems with a given budget and a decreasing time-to-market span. One of the main problems result from the fact that used methods for modern Software-Engineering are often not setup for those complex Software-Systems. One must realize that software belongs to our everyday life and that one could be confronted with problems resulting from defective software. Examples for these incidents can be found in (Nuseibeh, 1997) and (Leveson & Turner, 1993). The worldwide extension of the data networks and the continuing globalization added another component to industrial Software-Engineering: the development in worldwide distributed teams. Based on this scenario, new concepts and tools for the Software-Engineering-Education are developed.

The presentation of the course Software-Engineering is a combination of two hours of lecture and six hours of practical training per week. The Software-Engineering syllabus is orientated on the basics of classical Software-Engineering and the methods and models used in this area. The practical training aims at applying subject matters which were imparted in the lecture in a realistic scenario. Thus, at the beginning of the semester project-teams are formed, which will consist of four students. During the semester the teams will experience the entire life cycle of Software-Engineering. In order to divide up the life cycle into phases the Waterfall-Model (Boehm, 1978) is applied. The project-teams meet once a week at a certain time for two hours in a computerroom of the university. During this time tutors are available. One tutor is responsible for several groups. His job is to support the project-teams if necessary and to check the progress of the teamwork. Furthermore, the tutors offer consulting hours during the week. This offer is optional. The students can arrange the remaining four hours of the practical training on their own. The task has to be completed within a period of 11 weeks, during which time regular interim reports have to be submitted within set deadlines to the designated tutor. So far, no Case-Tools have been put into usage. Problems given in the past were amongst others simulating an elevator control for a high-rise or the simulation of a car-production-plant.

2. The Passenger Concept

The above described organization of the Software Engineering lab is supposed to be extended by aspects of distributed teams in the future. This scenario has long become reality in the Software-Engineering industry and is well-known in the literature (Nakatani, Nishida and Takeda, 1991). Following this scenario, the Passenger-Concept defines four modules for the conduction of the Software-Engineering course: the Passenger-

CD to support the lecture, the Passenger Case & Video Tool to conduct the practical training in a distributed manner, the Passenger Web Site to solve organizational tasks and Passenger –Doc to versionize the documents automatically

In the following sections we will focus on the development of the Passenger Case & Video Tools. A description of the other part projects can be found in (Hunger & Werner, 1998a). The implementation of the concept requires efficient tools to transfer the knowledge of the lecture and conduct the practical training in a distributed manner. A condition for conducting the practical training is the availability of tools for a synchronous communication and for common document processing. For this purpose, a Software-Engineering-Case-Tool is needed. Altogether the following modules have to be realized: 1st. Synchronous communication tools for text, audio and video, 2nd a session handling to control the synchronous sessions, 3rd Protocol stacks to meet the required network services, 4th a Software-Engineering-Case-Tool for common document processing, 5th a control system to handle different kinds of permissions, 6th a version control system for the common documents.

Commercial available videoconference tools e.g. Microsoft-Netmeeting, CUSeeMe or others do not offer the above mentioned functions. Some systems support the functions mentioned in point 1, 2 and 3 and especially the Whiteboard included in Microsoft Netmeeting meets some requirements of the functions mentioned in point 4. But none of these systems support the absolutely essential support of the students during a session. Neither a support for the processing of the common documents is offered by these systems. Therefore commercial available videoconference tools can not be considered for the conduction of the practical training.

3. Passenger Case & Video Tool

The scenario of distributed Software-Engineering places additional demands on the students. Apart from learning the actual contents and how to work in a team, the following three aspects will lead to a steeper learning curve.

a) The students are not used to applying Software-Engineering Case-Tools.

The application of Software-Engineering-Case-Tools requires additional time of the students because they have to learn how to use the Case Tools. The Case-Tool learnability depends essentially on its complexity (Boloix & Robillard 1998). Beyond that, modern Case-Tools perform a consistency check according to the rules of the design method they are based on. But this work however should be conducted by the students. For the reasons specified above we have decided to develop our own Software-Engineering-Case-Tool. This Case-Tool will contain the modelling levels and symbols defined in the Ward & Mellor approach but no rules for a consistency check will be included. Thereby the Case-Tool is reduced to a custom-made graphic design tool. The design of the Case-Tool interfaces takes place in a way that other Software-Engineering-Case-Tools based on different design methods can also be integrated. later. If beyond that, these Case-Tools can also perform a consistency check then the CSCL-Tool becomes a CSCW-Tool. This is important to not limit the application of the Passenger case&Video Tool to the practical training.

b) For the students, discussing by the means of video conferencing represents a new form of communication.

A preliminary study was conducted to assess the possibilities and limitations of telecooperation capable software for the usage in a practical training in Software-Engineering. One of the most important results of this study is the demand for a mechanism which should portray a face to face discussion through the computer as far as possible. Methods for the set up and intensification of relationship aspects are also part of this. More results of this study are published in (Hunger & Werner, 1998b).

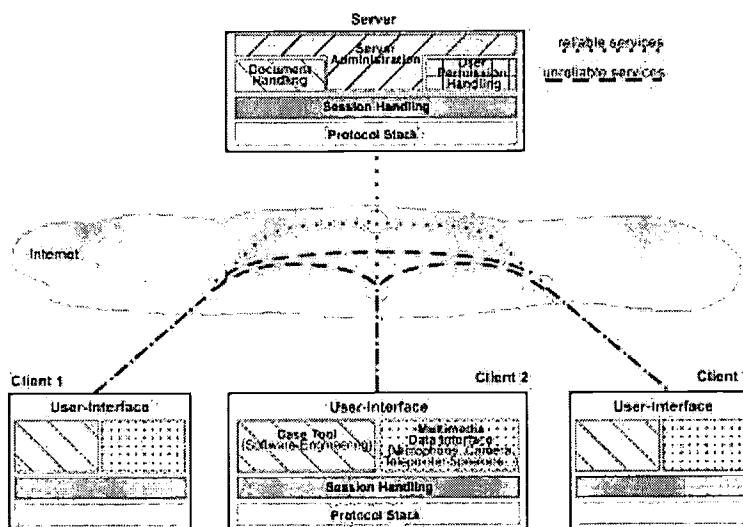

c) Common document processing over a network is new to the students.

During the practical training two basic working methods are conceivable. On the one hand common synchronous processing of a document and asynchronous processing of the documents by individual students on the other. This results in a necessity to administrate the documents at a central place. During synchronous sessions in particular access to the documents has to be regulated. Furthermore the students have to be relieved from the process of Document-Versionizing. This is true for both synchronous and asynchronous forms of document processing.

4. System Architecture

The development of the Passenger Case & Video Tools requires not only the development of a user interface from a didactical and a psychological point of view and the integration of a Case-Tool, but also mechanisms for multimedia data exchange in order to make working on a network and the transport of data possible. In this section we start presenting the general system architecture and then go on to discussing the resulting communication requirements. The user interface is presented in the next section.

The Passenger Case & Video concept sees windows based systems as its target platform and the global internet as its transport medium. Communication takes place over both reliable and unreliable services. Fig. 1 shows the system architecture of the Passenger Case & Video Tools for the technical implementation of its communication.

For the clients the multimedia data interface represents the interface to the input and output peripherals like keyboard, mouse, video camera, speaker and monitor. The Case-Tool is used for common software development. The current session is controlled by the session handling module. The protocol stack handles incoming and outgoing data and resource reservations. During the conceptional considerations of the Passenger-System-Architecture, different possibilities for the data transfer were discussed. As a result of the discussion several methods of data transfer have been implemented: several unicast-connections for client/server-communications and several multicast-connections for interclient-communications.

Furthermore, Fig 1 shows the requirements which individual connections place upon a service. Client/Server connections require reliable services, inter-client connections on the other hand only require unreliable services, but a guaranteed band width and delay. In order to achieve these guaranteed quality-of-service we make use of resource reservation. Both protocol stack and session handling modules also exist with corresponding tasks for the server. The session handling module administrates the global session variables. The document handling and user permission handling modules are there to guarantee the conflict free access to the distributed system resources. The server administration module administrates not only the server but also the groups. Corresponding modules on the server and clients are represented by using the same hatching in Fig.1. A session starts with the participants logging themselves into the server. After that, a video conference is coordinated by the session handling. During the video conference, real-time data (audio and video) is not routed through the session server in order to reduce long signal and processing delays. The interchange of this data results directly. Parallel to the interclient communication, several client/server connections exist for exchanging document data and all over session relevant information. In the sense of the system architecture even the tutor is a "normal" client.

BEST COPY AVAILABLE

For the realisation of the above described architecture, a suitable protocol stack has to be developed. In a first step only implementations of standardized protocols which are currently available, or which will become available in the near future are used. The protocol stack is based on the Internet Protocol Version 6 (Deering & Hinden, 1998) for the realisation of multicast connections in the Internet, associated with the Resource ReSerVation Protocol (RSVP) (Braden, Zhang, Berson, Herzog, Jamin, 1997) for quality-of-service support. The Real-Time Transport Protocol (RTP) (Schulzrinne, Casner, Frederick, Jacobson, 1996) is used to meet the multicast and real-time requirements of the Audio/ Video Conference. The actual data transport is carried out, using the connectionless User Datagram Protocol (UDP). Parallel to this the classic connection orientated and reliable Transmission Control Protocol (TCP) above IPv6 is used to transmit signalling-, chat- and document data. Measures to increase performance arise in the first step by strictly splitting the connection types in reliable and unreliable services and implement them in several parallel protocol stacks. Measures like adapting certain protocols should be considered later.

5. The Client User Interface

Working in a team, dividing up the given task into subtasks, discussing provisional results and integrating first results afterwards, already require discipline of the students without using Video-Conference-Tools and the implicit usage of a process model. The usage of Video-Conference-Tools also requires that students work in a completely new scenario. Thus interface design obtains an outstanding meaning. The client-user-interface contains video screens of each member and a case-tool in a public window for the common process on the outline documents. Fig.2 shows the user interface of the Client-Software.

Each member has the same view of the window according to the WYSIWIS-principle, but only one of them can alter the document at a certain time. A telepointer serves to elucidate and to present facts. Each member is also equipped with a private working window for trying out ideas. A chat window was implemented so the conference could be ended simultaneously in case of bad transfer circumstances.

Other specific features of the user interface result from the above mentioned demands to support a natural face-to-face discussion and to setup and intensify relationship aspects. These demands take following implementation-measures into account neither size nor position of the video screens can be changed, none of the video screens can be covered by another video screen, the members always appear in the same video-screens and a specific permission-control supports the students during the synchronous sessions.

6. Permission Control

The permission-control is part of the user-permission-handling which is implemented on the server and handles the access to the public window and the documents. Furthermore it coordinates the course of communication through an administration of different kinds of permissions, e.g. permissions to speak, permissions to alter the documents. Therefore, the permission list (PL) is an essential part of the permission-control. The PL to handle the permissions to speak can have three possible entries. The actual spokesperson is followed by the next two clients who request to speak. Each demand of the permissions and each passing of the permissions result in updating this list. Important is that the list never shows two equal entries. Thus two members can not exclude the third person from the discussion. According to the fact that the list is automatically updated after every pass-right the system can never reach the state of a deadlock, even if the third person did not request the permission to speak. Fig. 3 shows the state-transition-diagram of this part of the user-permission-handling.

In state 1 (Discuss by PL) all parallel processes for accepting client inputs are enabled. A user can always ask for all permissions (ask for rights in Fig. 3) or pass all permissions to the next user in the permission list (pass rights in Fig. 3). Both cases lead to an update of the permission list but not to a new state. A new state can only be reached by ending the communication, requesting an intermediate call or by calling the tutor.

An intermediate call represents a specific feature during the communication. A user can request an intermediate call at any time, while being in a discussion (state 1). Then the spokesperson is notified on a statusbar, that client x wants to make an intermediate remark. At the same time the system goes over into state 2 (wait on answer) without making changes in the PL. The spokesperson can reject the request using -NACK-, which would make the system return to state 1. The discussion would then be continued by the spokesperson. If the spokesperson accepts the intermediate call though, he has to use -ACK-. In this case the system changes to state 3 (Discuss by Intermediate Call). This does not change the permission list either. Since the intermediate caller has not the right to accept other intermediate calls, the process wait for intermediate call is disabled. That way it is ensured that the course of discussion will not get out of control. The intermediate caller receives all rights for working with the documents, but his time is limited. After two minutes a reminder appears on the statusbar, requesting to give the rights back to the previous spokesperson. If he does so, the discussion will be continued according to the PL.

BEST COPY AVAILABLE

Every user can call the tutor anytime using the call tutor function. This does not cause changes of the states, it only enables the process wait for tutor. This protects the system from a deadlock in case the tutor is not in his office. The system goes on to state 4 (wait on next pass) as soon as the tutor logs in. After the tutor logged in, the members are notified on the statusbar and the PL is updated. The tutor is set on the top of the PL and the discussion member who called the tutor is set to be the next. The third place stays unoccupied, one of the other members can apply for it though. With the next pass of the rights the system goes on to state 5 (discuss by Tutor), whereas the tutor is the spokesperson with all permissions.

Should the tutor login without any explicit request of the members, the system goes over into state 4. In this case the tutor is also set on the top of the PL and he will receive all permissions after the next passing of rights. In this case the other entries in the PL stay empty.

7. Summary and Outlook

This paper presented a new concept concerning the University-Education on the subject Software-Engineering. Based on this concept new tools were developed and implemented. The essential innovations of the presented idea in comparison with known concepts are in this case

- integrating different tools under a common user interface,
- the way in which face-to-face discussions are taken into account
- the development and integration of case tools especially for the usage in a practical training,
- the assembly of parallel protocol stacks with usage of given protocol structures.

The implementation of the CD for the lectures and the implementation of the client-user-interface took place in 1998. Current work deals with the implementation of the protokol stacks and the server and an outline of the software-engineering case tools. The first version of the communication tools is expected during the summer of 1999. Concerning the practical training of Software-Engineering, the tools are supposed to be put into practice during the summer-semester 2000

Abstract: The enormous amount of information available through the World Wide Web, that are of possible interest for an organization or a workgroup, requires the development of effective tools for extracting and summarizing relevant data from Web sources. In this paper we present a Web data model and a query language that allows for simple implementation of wrappers extracting specified data from a set of Web pages.

1. Introduction

The amount of data available through the World Wide Web that are of possible interest for an organization or a workgroup is constantly growing. The World Wide Web can be considered as a huge collection of possible interesting information sources and, in fact, it is a fundamental resource for information discovery.

However it is often the case that such information are not easy to be automatically accessed and cataloged. The main reasons are: (i) information in the World Wide Web are usually presented in a human-oriented way (i.e. they are produced to be understandable by "human eyes"), rather than in a machine-readable format; (ii) information sources are heterogeneous and hence similar data are often presented in different ways by different sources. Therefore, a user has the need of extracting and summarizing relevant information from different sources and of presenting these data in an appropriate format. With this respect, many tools for accessing relevant information have been developed in the last years (see [Iocchi & Nardi 1997, Florescu et al. 1998] for a survey).

Information Extraction from the Web is the process of extracting data from a set of Web pages in order to fill a given data base schema. With respect to other extraction tasks (such as the ones performed within the MUC conferences [MUC]), Web Information Extraction presents two particular features: (i) the input documents are semi-structured: they are neither raw data (full text) nor strictly typed (relational tables), but a structure is provided by HTML or XML tags; (ii) the information sources are heterogenous, i.e. the same kind of information is often presented in different formats.

A Web Information Extraction system receives two kinds of input: (i) a data base schema that represents the information the user wants to retrieve; (ii) a set of information sources (Web sites) containing the data to be extracted. Such a system aims at populating the data base with data extracted from the sources and must provide mechanisms for dealing with semi-structured documents and for accessing heterogeneous information sources. The presence of heterogeneous information sources, whose models are not known a priori, makes scalability to be one of the main features for these systems. In other words, the system must be "easily" programmed for dealing with a large number of different information sources.

An important design element for these systems is the representation techniques used for modelling the data base schema and the information sources. Indeed, this issue permits a classification of approaches to Web Information Extraction.

1. *Customized extraction* is based on writing *customized wrappers* for accessing required data from a given set of information sources (e.g. softbots traversing and parsing the Web pages of a site) [Hammer et al. 1997, Kistler & Marais 1997]. In these systems the models of the data base schema and of the sources are implicitly recorded in the wrapper code.

2. *Automatic wrapper generation* is based on defining a high-level description for generating a customized wrapper [Papakonstantinou et al. 1995b]. In this case the models of the data base schema and of the information sources are explicitly represented.
3. *Automatic extraction* consists in developing a general purpose wrapper generator that is able to build a customized wrapper from (a "simple" translation of) the data base schema given as input (see [De Rosa et al. 1998, Lacroix et al. 1998] for instances). The models of the information sources are not given and thus they must be automatically generated from the actual documents in the sources. Observe that this is a complete automatic process, since the user is not involved in the extraction process.

The classification above highlights a deep relation between the representation technique for modelling information sources and the scalability of the information extraction process. Indeed customized extraction presents a very limited scalability with respect to new information sources, since accessing a new source requires including its description within the wrapper code. On the other hand, automatic wrapper generation allows for describing at a higher level the models of information sources and thus provides a more flexible and powerful tool for effective integration of information. Finally, automatic extraction systems should (ideally) be able to deal with every information sources, thus allowing for the maximum scalability.

In this paper we present a simple Web data model and a query language suitable for automatic generation of customized wrappers based on an explicit representation of the data base schema and the information sources.

2. A data model for the Web

In order to develop effective Web extraction systems, a data model is needed for an explicit representation of the Web information sources and of the data to be retrieved. Classical data models, such as Entity-Relationship and Object Oriented, are not adequate for representing semi-structured data from heterogeneous information sources. Indeed a data model for the Web must consider not only the semantics of data, but also their presentation (formatted layout) in the Web pages. Furthermore, it must provide a framework for modelling at least the following structures: (i) recursive structures; (ii) ordered collection types (tables, lists); (iii) unordered collection types (sets).

In fact, a number of flexible data models for semi-structured data have been proposed [Papakonstantinou et al. 1995, Mendelzon et al. 1997]. We exploit this work for defining a data model that is specific to the representation of Web pages.

2.1 Web-OEM data model

Web-OEM is a simple data model for representing Web pages (specifically HTML pages), that can be considered as a specialization of the Object Exchange Model (OEM) for Web pages [Papakonstantinou et al. 1995].

A Web-OEM object is defined as a tuple $\langle Label, Values, ObjID \rangle$, where: *Label* is an element of a set specifying the object type (for example some HTML structures can be represented by the set { Page, TableRow, List, Link, Image, Header, Text }); *Values* is a set of pairs $\langle attribute = value \rangle$, with *attribute* denoting an attribute name and *value* being either an integer, a string, an object, or a listofobjects; *ObjID* is the object identifier. A Web-OEM object can also be written as $id.Label \langle a1=v1, \dots, an=vn \rangle$.

Web-OEM can be graphically represented as a labeled direct graph, in which each node represents either an object (labeled by its id and its label) or a basic data (a string or an integer value), and each arc, labeled by an *attribute*, represents a pointer to the corresponding object *value*.

Example 1. A Web-OEM data instance for a personal home page is shown below.

```
p1.Page<url="http://w.a.b/c/",title="My home page",structures={i1,t1,l1}>
i1.Image<url="mypicture.gif",alt="My photo">
t1.Table<nrows=2,rows={r1,r2}>
l1.List<nelem=2,elements={k1,k2}>
r1.TableRow<ncols=2,elements{x11,x12}>
r2.TableRow<ncols=2,elements{x21,x22}>
x11.Text<text="Telephone Number">
x12.Text<text="000 0001",format="B">
x21.Text<text="Fax Number">
x22.Text<text="000 0002",format="B">
k1.Link<anc="Publications",ref="pub.html",page=p2>
k2.Link<anc="Preferred Search Engine",ref="http://w.x.y/">
```

Observe that this representation can be generated through a simple parsing process on the Web page. The parser definition does not depend on the page contents and therefore a user can easily implement HTML or XML parsers for associating a Web-OEM representation to a set of Web pages, by considering only the structures of the pages (and not their contents).

2.2 Web-OEM Query Language

In order to extract data from Web pages represented in the Web-OEM model, we define an SQL-like query language, called Web-OEM-QL, that is similar to the OEM query language [Abiteboul et al. 1997].

A query is described by a sentence

```
SELECT Fields
FROM Objects
WHERE Expression
```

The clause SELECT specifies a projection over the attributes of retrieved objects. Therefore *Fields* is a list of expression of the form $X.<attribute>$, where X is an object variable. The clause FROM consists of a list of expression of the form $\langle WebElem \rangle : X$ where $\langle WebElem \rangle$ is one of the predefined label in the Web-OEM and X is an object variable. Finally, the clause WHERE is a boolean expression that determines conditions that must be verified by the retrieved objects.

In order to access nested structures, we define regular expression on the attributes (as in [Abiteboul et al. 1997, Christophides et al. 1996]) by means of two operators ? and * that are interpreted respectively as "any attribute" and "a sequence of zero or more attributes". In this way the expression $p.?$ denotes the value of any attribute of object p , while $p.*$ denotes the values of all the possible sequence of attributes of p . Finally the notation $[i]$ is used for accessing the i -th element within an ordered structure.

Query execution allows for actually extracting data from a Web-OEM description of Web pages. For example, the following query retrieves the boldface texts in the second column of all the tables included in the page with title "My home page".

```
SELECT x.text
FROM Page:p, TableRow:r, Text:x
WHERE p.title="My home page" AND r IN p.structures.* AND
      x = r.elements[1] AND x.format = "B"
```

According to the Web-OEM representation given in the Example 1, the query retrieves the strings:

```
000 0001
000 0002
```

3. Automatic wrapper generation

The Web-OEM query language provides for a tool for automatic generation of customized wrappers. Indeed, a Web-OEM query represents a high-level specification of the wrapper and a Web-OEM query executor can be seen as an actual wrapper generator.

In order to generate customized wrappers, the user must provide the system with an explicit representation of the data base schema and the information sources. It is worth noticing that the models of the data base schema and of the information sources are included in the Web-OEM-QL query. Indeed the FROM and the WHERE clauses define a model of the information source, while the SELECT clause denotes (a portion of) the data base schema.

Specifically, the information extraction process with Web-OEM is performed by the following steps:

Denominazione	Ultimo	Ora	Var.%	Quantità	Apertura	Minimo	Massimo	Ul. Od.	Rit. Od.	Note
B. Acq. Martini	24009.75	13.44	-0.83	500	24009.75	24009.75	24300.1894	-	-	-

Figure 1: A Web page with the Italian stock market data

1. The user analyzes the information source (a set of Web pages) and individuates the structures containing the relevant data to be extracted.
2. Considering the data base schema and the source structure, the user writes a Web-OEM-QL query.
3. The system processes the query in two steps: (i) Web pages are automatically parsed and a Web-OEM description is generated; (ii) data are extracted from the description of the pages according to the specification of the query.

This framework can be useful in several applications. One example is monitoring stock market data, that are daily published by many specialized Web sites. Observe that these data are presented in several different ways by the Web sites. Moreover, within a single source, the Web pages usually change their contents over time, but not their structure.

This task can be performed by generating customized wrappers that are in charge of extracting relevant data from the given Web sites. Specifically, the user analyzes the HTML structure of the relevant pages and, by knowing the data base schema, s/he writes a query expressing which data are to be extracted and how this must be done. A "compilation" of this query corresponds to the generation of a customized wrapper and its execution allows for actual extraction of specified data. Assuming that sources do not change their structure over time, it is possible to daily run such a wrapper in order to monitor a specified set of shares.

In [Fig. 1] a portion of a Web page containing data from the Italian stock market is shown. The following query allows for extracting the company name (first column) and its current price (second column).

```
SELECT x1.text, x2.text
FROM Page:p, Table:t, TableRow:r, Text:x1, Text:x2
WHERE p.url="http:\x.y.z\a.html" AND t IN p.structures.* AND
t.nrows > 20 AND r IN t.rows AND
x1 = r.elements[0] AND x2 = r.elements[1]
```

The query returns the following data:

```
B Agr Mantov 24009.75
B Des-Br r99 3446.56
...
```

Observe that this approach to information extraction from the Web requires the user to explicitly define a model for each information source. Indeed, while writing a query, the user must know where the relevant data are in the Web pages. Therefore a problem to be addressed is the integration of data coming from different information sources. Suppose, for example, that a user wants to monitor shares from different stock markets and that relevant information are published by different sources. The user must write many queries and the results of these queries must be appropriately integrated. In some cases it is possible to adapt the data base schema to the information sources, such that integration is solved by the user when writing the queries. However, in other cases, a more general method (a mediator [Papakonstantinou et al. 1996]) is required for an effective integration of data.

Nevertheless, the Web-OEM approach to generation of customized wrappers has several advantages. To summarize: (i) it allows for quick implementation of simple information extraction tasks, (ii) it is suitable for information sources that dynamically change their data, but not their structure, (iii) it allows integration of data coming from different sources by an appropriate writing of queries.

4. Conclusion

An effective information management within an organization deeply depends on tools for accessing and summarizing relevant data from the information sources. Web information extraction systems thus represent important tools for retrieving interesting data from the enormous amount of information contained in the World Wide Web.

In this paper we have presented a simple data model for representing Web pages and a method for automatic generation of customized wrappers for information extraction from the Web. We believe that the Web-OEM model represents an effective and well-formalized tool for Web information extraction and that this is an important step towards the development of automatic information extraction systems. Moreover, the method is simple to implement and effective in many cases, and it provides for the scalability that is required by such systems.

This research is a first step towards the development of Web *wrapper agents*, that is software agents able to navigate in the Web sites and to extract relevant information. Such an agent should make use of a Web-OEM representation of the Web pages and of the Web-OEM-QL language for automatic generation of queries for data extraction and for their execution in order to populate the data base.

University of Tokyo, 7-3-1 Hongo, Bunkyo-ku, Tokyo 113-8656, JAPAN,
{santi,ishizuka}@miv.t.u-tokyo.ac.jp

Abstract: Changes made in Web repositories occur at unpredictable rates. Besides the target information itself, the changes upon the previously released information are significant and worth being notified to those who perceived the out of date information as soon as possible. Unfortunately, stock type information source has no means to inform its prospective users about the changes. While the stock type information source occupies a large percentage of sources on the Web, it is necessary to have a system that monitors changes on the Web, and provides comprehensive presentation to the prospective users. This paper proposes a mechanism that incorporates change monitoring and presentation service for a user community. The service keeps improving its utilization factor by several schemes based on the decision made by game analysis. Thus, the service can be provided to a relatively large group of users.

1. Introduction

The information in Web repositories is changed dynamically without any prior notification. At present, a large number of information sources are stock type. The users access this type of information in pull mode, mostly by Web Browsers. These information sources have no mechanism to bring the changed information to prospective users. The users have to deal with the matter by themselves. Browsing through the sites for new updates is not only time consuming task but also vain in case that there is no change made on the sites once visited. This puts a significant load to the users besides exploring brand new information.

This paper considers the evolution of mechanism that detects and evaluates changes on the Web, as well as provides it in comprehensive form for prospective users. With this system, The ubiquitous stock type information sources on the Web have no need to provide any effort to convey their updates to the users. As a result, the information is seemingly transferred in push mode.

We incorporate shared resource management in our system in order to enable a larger scale of service. The shared resource management plays an important role to make the push mode transfer of changes and differences practical. The system would not be practical if the available resources are used to provide service to a large group of users without an effective resource management processing. The service attempts to increase the utilization factor of the system by several schemes. Each scheme tries to increase identical services in the monitoring process. These identical or virtually identical requests give a significant impact on the utilization of our service. As long as we can implement the service with reasonable resource allocation, more users can have access to our service. At this point, we let the service interacts with user. However, the interaction must be made minimal in order to maintain the level of automatism of the service.

We consider the schemes that deal with user as games. The games are played by users and the service agent. The service agent decides its moves based on experience in the past and game analysis. A useful tool we use here is the game theory. We apply the tool from the viewpoint of our service. Overall, the service agent improves the utilization factor of the service and gets the most out of limited interaction with the users.

2. Architecture of the service

The monitoring service consists of the service provider and user interface. The service is designed so that the service can be accessed from the Internet. Each user accesses the service via the WWW using any browser with

Java Virtual Machine. Requests can be made directly to the service provider. The service provider consists of several modules as follows:

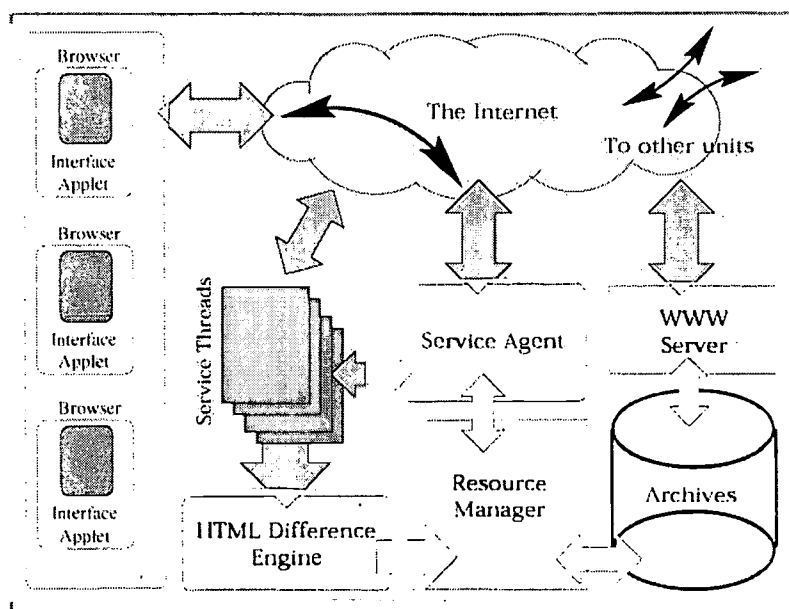

Fig. 1 The architecture of change monitoring service.

- **Resource Manager:** This module handles all resources for the service. Resource Manager will keep the results from the HTML Difference Engine in the archives. It keeps improving the utilization factor of the system by matching all identical or virtually identical requests.
- **Service Threads:** Each Web page monitoring request will be handled by a service thread. The thread keep monitoring and comparing revisions of that Web page.
- **Service Agent:** This is the heart of the service that interacts with other modules in order to retrieve and compare Web pages. It takes requests from the users and consults the Resource Manager to allocate resource for incoming requests. It activates the service threads to start services. When the users query their service profiles, it works as a service broker that retrieves the profiles for the users. The users can edit their service profiles via the Service Agent. Moreover, the Service Agent handles all responses made by users when the service needs to know opinions of the users. The responses from the users are proceeded to the Resource Manager in order to decide how to improve the service.
- **HTML Difference Engine:** The service threads implement the Difference Engine in order to compare the content of updated pages and see whether there are significant changes in them. Running the Difference Engine compares the old and new versions of HTML documents. At the same time, it will summarize the updated information into another HTML document by an innovative algorithm described "Difference and Display" subsection.
- **WWW server:** The page archives contain the old and new version of Web pages together with summary pages constructed by the HTML Difference Engine. When the users are notified by their Service Agent, they can view the summary pages with their browsers via the WWW server.

3. Monitoring the changes

The monitoring service keep monitoring the changes in Web repositories and making comprehensive presentation of the changes available to the users. Once the Service Agent found significant changes, it notifies the users. The consideration for each task is described in detail in following topics:

3.1. Difference and Display

Our HTML Difference Engine implement the algorithm called "Longest Common Tag Sequence"

(LOCTAGS) which is developed from the basic idea of Longest Common Subsequence (LCS) algorithm. The well known LCS has been widely used in comparison of text document revisions for long. When comparing 2 revisions of text with the capability of common subsequence extraction, we can tell the actions made on the new document easily. Unfortunately, the traditional LCS is not applicable to hypertext document. In order to cope with the structured text like HTML, we regard the HTML document as a sequence of tags and context. We use LOCTAGS to find the common subsequence of the new and old version of tag streams. Once we have the common subsequence of tags, we can point exactly which tags were deleted or added. This information helps us in comparing the context pairs at the right place. In other words, the LOCTAGS provides information about which context in the older revision should be compare to which context in the new revision.

Fig. 2 The streams of HTML document.

When comparing context, we apply the traditional LCS. Difference Engine. The tool takes both the old and new HTML documents as its inputs. Both tags stream are fed to the LOCTAGS detector. The result, common tag subsequence, is used as a reference information at the differentiator. Right here, one of the output lines is fed to the HTML Constructor in order to produce a summary page in HTML format. On the other hand, the output is fed to the filtering process that evaluates the changes based on user interests. The result of evaluation is used by the decision-maker. The decision-maker decides whether the changes should be pushed to the users.

3.2. Push it to the users

Once the changes are detected, the difference engine evaluates the content of the changes. The evaluation is necessary because it is no use to push a piece of insignificant information of changes to the user. The evaluation is taken place in the filter based on user interests. If the changes are considered significant, the service provider sends notification to the user and let the user select to show the difference. The criteria used in this process focus on the filtering process, which is based on user interest as described in next topic.

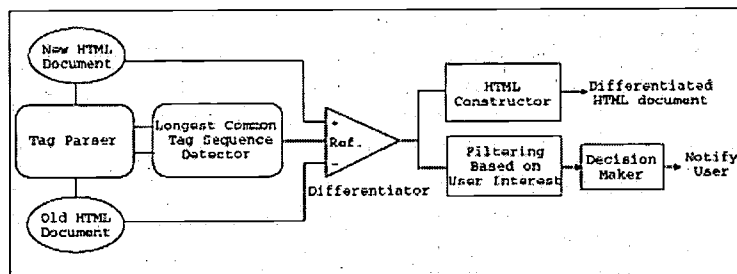

Fig. 3 The HTML Difference Engine with the Decision Maker

3.3. User Interests

We divide the interests of the users into following categories:

- Existence of contents: Many users are curious to know whether the contents they interested in are still exist in or newly added to the document. It is inevitable to check the existence of components again once the document was reviewed. The filter used in our service provider agent deals with this demand by checking the existence of links, images, Java applets, etc. that appear in the new version of document. The filter provides a report of the change in existence of component by comparing with the old version. The service provider agent notifies the user via email with this information in order to tell the user roughly how much the document has been changed.
- Appearance of document: HTML specification includes many tags that control the flow and structure of HTML documents. In some cases, many users are curious about the change in the appearance of the

- documents. We take the appearance changes into account when evaluating the changes.
- Topics in interest: This category is the most important issue when we deal with the user's interests. In real world, people evaluate whether the content they are reading fall in the area of their interest by the context. If we insist to deal with this issue rigorously, we have an expensive processing to pay. The evaluation of relevance to user's interest areas is considered to be heuristic. On the other hand, the process needs natural language processing techniques. We compromised the correctness with computational costs. The filter deals with this issue by the key words that relevant to the interests of the user.
 - Scoring of changes: When the filter found any changes that fall into the first two categories, it evaluates a score of those changes. The score of each category is a fix value assigned accordingly to the importance of the category. However, the third category deals with key words. We assume that the more occurrences of the key word in the document, the closer to the user's interest the document is. The score of each key word is increased as the more occurrences of the key word are detected. Finally, the total score is the summation of all categories of changes. The score is then compared to the specified threshold. If the score is higher than the threshold, the Service Agent notifies the user about the changes.

4. Adaptive Resource Management

When serving a large number of users, we expect to have some identical or virtually identical requests. These requests can share the resource. The more identical or virtually identical requests, the better utilization factor we can get from the service. The Resource Manager deals dynamically with the request matching. The conditions of virtually identical requests change dynamically upon the changes in Web repositories and the parameters of the request made by the users. If we decide to push changes and difference information, we attempt to push the information to prospective users. The fact is that each user has different degree of interest and attitude against the detected changes. In the paper, we define the utilization factor of the service as follows:

Utilization factor:

$$U = \frac{N - M}{M}$$

Where:

N = the number of all request

M = the number of different kinds of requests. M is also defined in term of probability of having different kinds of request (P_{diff}).

$$U = \frac{N - P_{diff}N}{P_{diff}N} = \frac{1 - P_{diff}}{P_{diff}}$$

We can see obviously that if we share resource among users, we are likely to get more profit than serving each user separately. The utilization factor, finally, depends on the P_{diff} , which ranges from $1/N$ to 1. The range tells us that our utilization factor ranges from 0 to $N-1$.

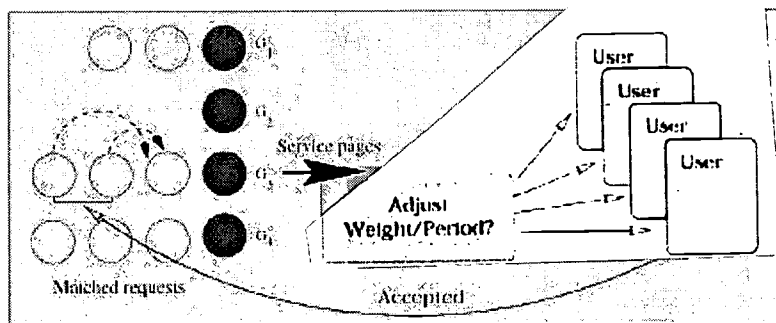

Fig. 4 The Service Agent requests the users to adjust the parameters of services

The amount of identical or virtually identical requests can vary dynamically. This is the case when some

requests among currently identical requests are satisfied by the changed conditions but some are not. For examples, we decide to push changes information to the user if we found that the change score is higher than specific threshold points. Suppose we have 2 users who specified the score threshold for identical page at 1500 and 1000 points. Both requests are considered identical if the change score is 2000 points. However, if the change score fall between 1000 and 1500 points, the requests are no longer identical. The Resource Manager analyzes the characteristic of changes on Web pages. A parameter to check is the notification threshold. In some cases, some users specified high thresholds with high frequency of monitoring. If the Resource Manager found that the change rates of those pages are relatively slow, it may ask the users to adjust threshold weight of notification or monitoring frequency.

Adjusting these parameters has probability to increase more matched requests. Meanwhile, the Resource Manager detects hot requests shared by a large number of users. The hot requests trend to be interesting pages. The Resource Manager may recommend these requests to the users. If some users accept the recommendation, the utility factor of the service trends to be increased according to the increasing matched requests.

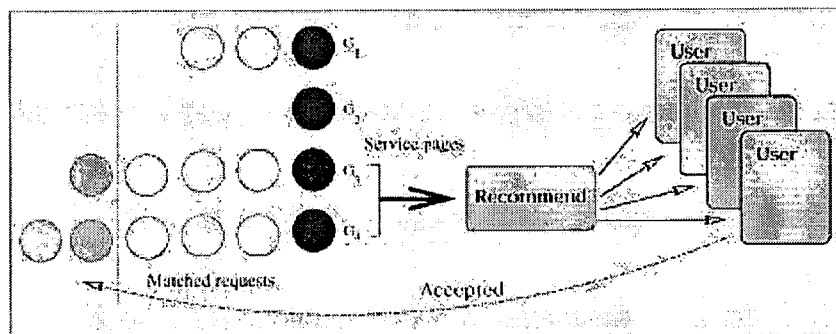

Fig. 5 The Service Agent recommends some hot pages to the users.

However, the Resource Manager has to make decision based on facts and experience in the past whether it should ask the users to adjust some parameters or recommend some hot requests to the users. The Resource Manager makes a decision by investigating the probability of improvement from the pay-off matrix of the game. We will consider how to make decision based on our service games from the following expected pay-off matrix.

		User	
		No Adjustment	Adjust
Service Agent	No Adjustment	p_0	p_1
	Adjust	p_2	p_3

Improvement occurs when:

1. The user obeys the suggestion from the agent, we apply the p_0 and p_3 .
2. When user adjusts while agent does not suggest, we apply p_1
3. The agent suggests but the user does not adjust, we apply p_2

With these policies in mind, we can implement the random equilibrium criteria and derive the probability of improvement. (If P_a is the probability that the agent suggests an adjustment, and P_u is the probability that the user adjusts the service profile)

$$P(\text{improve}) = (P_a P_u) p_3 + (1 - P_a)(1 - P_u) p_0 + P_u(1 - P_a) p_1 + P_a(1 - P_u) p_2$$

But $P(\text{improve}|P_a=0) = P(\text{improve}|P_a=1)$ and $P(\text{improve}|P_u=0) = P(\text{improve}|P_u=1)$

Solve for P_a , P_u then substitute into $P(\text{improve})$ we derive

$$P(\text{improve}) = \frac{(p_1 p_2 - p_0 p_3)}{(p_1 + p_2 - p_0 - p_3)}$$

The service agent checks whether the $P(\text{improve})$ is above 0.5 which means the system has probability to

improve the service more than 0.5, if it asks the user for adjustment. In our service, the probability p_3 can be derived by a function that evaluates how significant a request for adjustment is. The probability p_2 comes from the experience in the past, which is, in other words, how much the user refuses the suggestion. The probability p_1 comes from the improvement made when the user adjusts the service profile without suggestion from the Service Agent. Finally, the probability p_0 comes from the self-improvement rate occurred as the conditions of changes in Web repositories vary in time domain. We can see obviously that the variables used in the game analysis above can be evaluated at ease from the statistic of the service. The Service Agent can make decision to deal or not to deal with the user by calculating the $P(\text{improve})$ based on transactions in the past. Moreover, each decision trends to be more exact as the experience of the Service Agent increases.

5. Related Work

From the standpoint of tracking and viewing changes on the Web, the work that is most similar to ours is that of Douglis, et al. [Douglis 98], [Douglis 96]. They used the AT&T Internet Difference Engine to compare revisions of Web pages of some enterprises from time to time. Their work inspires a great deal in our work. We attempt to improve the service for a larger scale of users. We manage the shared resources among users in order to enable induced push mode of changes and differences. Besides, our difference engine implements the LOCTAGS algorithm, which is capable of comparing context exactly where the revisions should be compared. In addition to a target page, we assume that the child pages are likely to have relevant information. Therefore, the service provider agent can be requested to watch the target down to its child pages. If needed, the agent can also be requested to watch deep down to the grandchild pages. However, the grandchild level is limited to the pages in the same domain of each child page.

The Do-I-Care agent [Starr 96] applies social discovery and filtering to inform the users when changes are detected. Moreover, it takes advantage of training the agent by groups of users where some interesting information may be offered to the user via the effort of others. We agree with the idea but we need a simpler way for evaluation of changes. The scoring method we use is straightforward and can be carried out quickly while providing a way for users to adjust the threshold value upon their experiences. In our system, the social filtering effect occurs when the Resource Manager cooperates with the Service Agent in order to improve the utilization factor.

6. Summary

In this paper, we presented the evolution of the mechanism that notifies the users about changes in Web repositories, as well as preparing the summary of the changes. The shared resource management based on game analysis and experience in the past helps us in providing information pushing service to a large group of user. The effort to improve the utilization factor of the service brings about an adaptive monitoring service. The evaluation of the functions we used to evaluate the probability in the expected pay-off matrix of service games gives a significant impact on the accuracy of making a decision. These details should be considered in future studies.

Abstract: We conducted a transaction log analysis of 51,473 queries from 18,113 users of Excite, a major Web search engine. Approximately 2,500 (approximately 5%) of these queries were from the use of relevance feedback. Given the high level of research activity and historical success of relevance feedback in assisting users in locating relevant information, this is a surprising small percentage of usage. In order to investigate this phenomenon on the Web, we analyzed users sessions that contained relevance feedback queries. We identified states and patterns in these sessions. We also attempt to classify the sessions as successfully or not. This analysis provides insight on the current use of relevance feedback on the Web, its success or failure, and why it is so seldom utilized. We relate our conclusions to system design of information retrieval systems on the Web.

Introduction

Transaction log analysis is a proven analytical technique in information science that can provide excellent data on user searching characteristics (Peters, 1993). In order to gain insight into Web users and their use of advanced searching techniques, we conducted a transaction log analysis of 51,473 queries from 18,113 users of Excite, a major Web search engine. The analysis focused on two levels of investigation, the session level and the query level.

From our analysis, we were able to identify the queries that were a result of a relevance feedback option and isolate the sessions (i.e., sequence of queries by a user over time) that contained relevance feedback queries. Of the over 50,000 queries only about 5% were from Excite's relevance feedback option. This is a surprisingly small percentage of the queries compared to traditional information retrieval (IR) system usage.

Relevance feedback is a classic information retrieval (IR) technique that reformulates a query based on documents identified by the user as relevant (Salton, 1983). Relevance feedback has been and still is a major and active IR research area. Relevance feedback is widely used and reported to be extremely successful in many traditional information retrieval systems. However, why is it not widely used on Web search engines? Is it too difficult for users?

When using the Excite search engine (<http://www.excite.com>), if one finds a documents that is relevant, the user need only "click" on a hyperlink that implements the relevant feedback option. It does not appear to be any more difficult than normal Web navigation. In fact, one could say that the implementation of relevance feedback is one of the simplest IR techniques available. There are more complicated IR techniques that are used more frequently, such as Boolean operators and term weighting. We found it surprising that this highly touted and widely researched IR feature implemented in straight forward fashion was so seldom utilized.

We analyzed the sessions that contained the approximately 2,500 relevance feedback queries to isolate the user characteristics. We identified patterns in these sessions. These patterns are composed of states and transitions from and to the same or other states. From these characteristics, we hope to gain insight into the possible causes of this the low use of relevance feedback and, possibly, methods to increase its use among Web users. These methods could be applied to design of IR systems on the Web. This paper extends finding finds from (Jansen, Spink, Bateman, & Saracevic, 1998).

Review of Literature

Relevance feedback is a well-known IR technique (Salton, 1983) to improve the performance of IR systems. It has been widely researched (Salton & Buckley, 1990), (Harman, 1992), (Koenemann, 1996), and (Dunlop, 1997). It has been reported to successful improve retrieval performance for at least a small number of iterations (Witten, Moffat, Bell, 1994). Although previous studies have focused on a variety of IR systems, we could locate no study that analyzed the use of relevance feedback on a major Web search engine such as Excite.

Background on Excite

Founded in 1994, Excite, Inc. is a major Internet media public company which offers free Web searching and a variety of other services. The company and its services are described at its Web site, thus not repeated here. The search capabilities of Excite are briefly summarized.

Excite searches are based on the exact terms that a user enters in the query, however, capitalization is disregarded, with the exception of logical commands AND, OR, and AND NOT. Stemming is not available. An online thesaurus and concept linking method called Intelligent Concept Extraction (ICE) is used, to find related terms in addition to terms entered. Search results are provided in a ranked relevance order. A number of advanced search features are available. A page of search results contains ten answers at a time ranked as to relevance. For each site provided is the title, URL (Web site address), and a summary of its contents. Results can also be displayed by site and titles only. A user can click on the title to go to the Web site. A user can also click for the next page of ten answers. There is a clickable option *More Like This*, which is a relevance feedback mechanism to find similar sites. When *More Like This* is clicked, *Excite* enters and counts this as a query with zero terms.

Each transaction record contained three fields. With these three fields, we were able to locate a user's initial query and recreate the chronological series of actions by each user in a session:

1. **Time of Day:** measured in hours, minutes, and seconds from midnight of 9 March 1997.
2. **User Identification:** an anonymous user code assigned by the *Excite* server.
3. **Query Terms:** exactly as entered by the given user.

Focusing on our two levels of analysis, sessions and queries, we defined our variables in the following way.

1. **Session:** A session is the entire series of queries by a user over time. A session could be as short as one query or contain many queries.
2. **Query:** A query consists of one or more search terms, and possibly includes logical operators and modifiers.

Overall Statistics

Given the way that the transaction log recorded user actions, relevance feedback option was recorded as an empty query. However, a user entering an empty query would also be recorded the same. Using a purely quantitative analysis, we isolated 2,543 null queries, which represents the maximum number of relevance feedback queries. For this study, we had to remove the relevance feedback queries from the mistakes. Therefore, we reviewed the data and removed all queries that were obviously not the result of relevance feedback. If a determination could not be made, the query remained in the study. The results are summarized in Table 1:

Classification	Number of Queries	Percentage
Relevance Feedback	1597	63%
Mistakes	946	37%
Total	2543	100%

Table 1: Percentage of Relevance Feedback Queries.

As one can see, fully 37% of the possible null queries were judged not to be relevance feedback queries but instead some sort of mistake. This result in itself is very interesting and noteworthy for Web IR system designers. The high level of failures implies that something with the interface or the system is causing users to enter null queries just under 40% of the time. From observational evidence, some novice users "click" on the search button thinking that it takes them to the screen for searching. Additionally, Peters (1993) states that users many times enter null queries. Regardless of the reason for the mistakes, the maximum possible relevance feedback queries was 1,597. These queries resulted from 823 user sessions, implying an average of 1.99 relevance feedback queries per user session.

We then wanted to isolate patterns, if any, in the user sessions. Working with the 823 user sessions, we classified each query in the session as belonging to one of the following states:

- **Initial Query** was the first string of terms that a user entered for a session.
- **Modified Query** was the second or subsequent entry (i.e., query) that was related to the query before it. Related being defined as processing one or more of the same terms or obviously related to the same topic as the preceding query.
- **Next Page** was a request by the user to view the next page of 10 results.

- **New Query** was a second or subsequent entry by a user that was unrelated to the previous query.
- **Relevance Feedback** was the utilization by the user of the relevance feedback option, "More Like This."
- **Previous Query** was the second or subsequent entry by a user that was exactly like the previous entry.

We first analyzed the number of occurrences of each state.

State Analysis

The number of occurrences of each state is listed in Table 2. There were 2148 unique states in the 804 user sessions. As to be expected, relevance feedback occurred by far (872). Ignoring initial query, the next most common state was next page (542). This indicates that there was a number of viewing of subsequent results by users. There were also a large number of modified queries, indicating the addition, removal, or change of query terms.

State	Number of Occurrences
Relevance Feedback	872
Initial Query	804
Next Page	542
Modified Query	467
Previous Query	151
New Query	116
Total	2952

Table 2: Occurrences of Non-Repeating States.

We then examined where each state occurred in the session. The shortest session was two queries. The longest session was seventeen queries. These results are displayed in Table 3.

Type	Query 1	Query 2	Query 3	Query 4	Query 5	Query 6	Query 7	Query 8	Query 9	Total
Initial Query	804	0	0	0	0	0	0	0	0	804
Relevance Feedback	0	371	284	93	63	26	15	8	7	867
Next Page	0	282	63	66	56	26	19	14	5	531
Modified Query	0	132	133	82	38	35	21	12	6	459
New Query	0	19	31	25	14	14	4	3	4	114
Previous Query	0	0	54	48	23	11	8	4	1	149
Total	804	804	565	314	194	112	67	41	23	2924
Type	Query 10	Query 11	Query 12	Query 13	Query 14	Query 15	Query 16	Query 17		Total
Initial Query	0	0	0	0	0	0	0	0		0
Relevance Feedback	2	2	1	0	0	0	0	0		5
Next Page	3	3	0	3	0	1	0	1		11
Modified Query	3	1	3	0	0	0	1	0		8
New Query	2	0	0	0	0	0	0	0		2
Previous Query	1	0	0	0	1	0	0	0		2
Total	11	6	4	3	1	1	1	1		28

Table 3: Frequency of State Occurrence at each Session Level.

Given that there were no one query session in this sample (i.e., the shortest session was Query -> Relevance Feedback, a two query session), we see from Table 3, that there were 239 two query sessions, the largest group. However, there were 251 three query sessions, 120 four query sessions, 82 five query sessions, followed by a fair number of six and seven query sessions.

We see that the distribution of state occurrences shift as the length of the session increase. For the sessions of two and three queries, the relevance feedback state is the dominant state. As the length of the queries increase, the occurrences of relevance feedback as a percentage of all states decrease. Beginning with session of five queries or more, relevance is no longer the state with the most occurrences. This would seem to indicate that relevance feedback was not successful for these users, and they resorted to other means to find relevant information. This is evidence by the predominance of the modified query state in these lengthier sessions.

State – Transition Analysis

Based on this analysis, we could examine the transitions between states in each session. We isolated four patterns that classified all relevance feedback session. These patterns are displayed in Figure 1. Noted that we account for the returning to the same state. With the identification of these four states, it is clear that the IR system interface should be tailored to support these patterns of occurrence, namely in the transitions from one state to a different state.

Session Analysis

Given the low occurrences of relevance feedback queries, we attempted to determine if the session containing relevance feedback was successful or not. Without access to the users, this was difficult and required some assumptions. If the user utilized relevance feedback and quit, we gave relevance feedback the benefit of the doubt and counted it as a success (i.e., the user found something of relevance). Probably, many times these were not successfully, so our count of relevance feedback successes is probably on the high side.

If the user utilized relevance feedback and returned to the exact previous query, it is safe to assume that nothing of value was found. There were some sessions where the user used relevance feedback and returned to a similar but not exact query.

Since one could say that the relevance feedback query could have provide some terms suggestions, we classified these session as less than successful.

Some sessions, could also be classified as browsing, namely the user uses relevance feedback and then returns to the session with a totally new query.

The results are summarized in Table 4.

Classification	Number of Occurrences	Percentage
Success	509	63%
Failure	126	16%
Less Than Successful	135	17%
Browsing	34	4%
Total	804	100%

Table 4: Classification of Relevance Feedback Sessions.

Figure 1: The State - Transition Diagrams of Relevance Feedback Sessions.

As one can see in Table 4, giving relevance feedback the benefit of the doubt, fully 63% of the relevance session could be construed as being successful. If the less than successful are included, then almost 80% of the relevance feedback session provide some measure of success.

The question then becomes, why is relevance feedback used more on the Web search engine? In order to hopefully gain insight to this, we wanted to see if the population that used relevance feedback different from the population at large.

Comparison to Population at Large

We first examined the query construction of relevance feedback users to the query construction of the general population. This is shown in Table 5. The total percentage for each percentage column does not sum to 100% because the relevance feedback queries are not included. There appears to be little difference between the relevance feedback users and the population in general. Assuming that lengthier queries are a sign of a more sophisticated user, it appears that the relevance feedback population does not differ significantly from the general population of Web users.

Terms Per Query	Number in Relevance Feedback Population	Percent of Relevance Feedback Queries	Percent in General Population
1	972	19.80%	31
2	1045	21.29%	31
3	635	12.94%	18
4	310	6.32%	7
5	195	3.97%	4
6	70	1.43%	1
7	36	0.73%	0.94
8	23	0.47%	0.44
9	3	0.06%	0.24
> 10	22	0.45%	0.36
Total	4908	67.46%	93.98

Table 5: Terms Per Query.

Next, we examined the number of queries per user. This data is displayed in Table 6. In queries per user, the relevance feedback population had significantly longer queries than the population at large. The median number of queries per user for the relevance feedback population was approximately 2 and for the general population it was 1. There were also a significant number of relevance feedback users that had session of 3, 4, 5, and even 6 queries. In the general population, there is a steep drop-off at 2 queries per user. This may indicate that relevance feedback were more persistent in satisfying their information need and therefore more willing to invest the time to use not only relevance feedback but more larger sessions in general.

Query Per User	Number of Users	Percentage of RF Users	Percentage of General Population
1	3	0.36%	67.00
2	375	45.29%	19.00
3	223	26.93%	7.00
4	97	11.71%	3.00
5	64	7.73%	1.60
6	34	4.11%	0.80
7	11	1.33%	0.44
8	4	0.48%	0.18
9	8	0.97%	0.20
10	6	0.72%	0.09
11	1	0.12%	0.04
> 12	1	0.12%	0.04
		99.87%	99.39

Summary

We conducted a transaction log analysis of 51,473 queries from 18,113 users of Excite, a major Web search engine. Of the over 50,000 queries only about 5% were from Excite's relevance feedback option. This is an extremely small percentage of the queries. In order to gain insight into the possible causes of this phenomena, we analyzed the sessions that contained the approximately 2,500 relevance feedback queries.

Given the way that the transaction log recorded user actions, relevance feedback option was recorded as an empty query. Fully 37% of the possible relevance feedback queries were judged not to be relevance feedback queries but instead some sort of mistake.

We isolated states within each session, identifying 6 possible states, query, relevance feedback, modified query, previous query, next page, and new query. Of these state, relevance feedback was the most common, occurring 872 times.

We then examined the occurrence of each state at each query in the session. The shortest session was two queries. We saw that the distribution of state occurrences shifts as the length of the session increases. For the sessions of two and three queries, the relevance feedback state is the dominant state. As the length of the queries increases, the occurrences of relevance feedback as a percentage of all states decrease.

Based on this analysis, we isolated four patterns that classified all relevance feedback sessions. These patterns are displayed in Figure 1. Note that we account for the returning to the same state.

Given the low occurrences of relevance feedback queries, we attempted to determine if the session containing relevance feedback was successful or not. As one can see, given relevance feedback the benefit of the doubt, fully 63% of the relevance sessions could be construed as being successful. If the less than successful are included, then almost 80% of the relevance feedback sessions provide some measure of success.

We then compared the relevance population to the population at large. We first examined the query construction of relevance feedback users to the query construction of the general population. There appears to be little difference between the relevance feedback users and the population in general.

Next we examined the number of queries per user. The relevance feedback population had significantly longer queries than the population at large. The median number of queries per user for the relevance feedback population was about 2 and for the general population it was approximately 1.

Conclusion

The data and analysis suggest that relevance feedback is successful for Web users, although only a small percentage of Web users take advantage of this feature. On the other hand, although it is successful over 60% of the time, this implies a 40% failure rate or at least a not totally successful rate of 40%. This may be one reason relevance feedback is so seldom utilized. Its success rate on the Web is just too low.

As for user characteristics of the relevance feedback population, they do not appear to differ in terms of sophistication from the other Web users, but they exhibit more doggedness in attempting to locate relevance information. This could be for several reasons. One may suspect that the subjects they are searching for are more intellectually demanding. A cursory analysis of the query subject matter and terms does not support this conclusion.

There does appear to be four distinct session patterns of relevance feedback users on the Web. If these can be generalized to other Web search engines other than Excite, remains to be seen. However, at the very least it points to the need to tailor the interface to support these patterns if the goal is to increase the use of relevance feedback. Another option may be to automate the search engine to retrieve relevant documents of any result the user examines. This approach would be similar to research by Lieberman (1998). The results could then be presented to the user without the user initiating the process.

Film Theory Meets 3D Internet

A Film Semiotic Approach to the Design and Analysis of 3D Virtual Worlds on the Web

Jens F. Jensen, Department of Communication, Aalborg University, Denmark, jensf@hum.auc.dk

Abstract: The purpose of this paper is to discuss possible approaches through which 3D spaces – and especially 3D Internet – can be studied from a semiotic, or more specifically a film semiotic, point of view. First similarities and differences between 3D spaces – seen as a new form of multimedia – and the film medium are discussed. Then basic concepts from film semiotics are introduced. Finally, features of 3D Internet are described and discussed on the basis of key concepts from film theory such as: *mise-en-scène*, montage, and the relation of sound to image.

A virtual 3D space is characterized by being generated from software and drawn as interactive 3D computer graphics, in this context understood as a way of representing 3D data in 2D so that it can be viewed on a screen. When this space is joined to other computers linked on the Internet, we have 3D Internet. Thus, 3D spaces and 3D Internet exist only in the digital domain of the computers and the computer networks. It is these 3D spaces and 3D virtual worlds (3DVWs) on the Internet that are the primary object of this study. The aim of the paper is to discuss possible approaches through which 3D Internet can be studied from a film semiotic point of view.

Considered as media, films and 3D spaces resemble each other in several aspects:

i) Both films and 3D spaces are representational media, i.e., they use cultural and aesthetic conventions to create ‘texts’ that can exist independently of their sender (similar to books, paintings, sculpture, etc.); in contrast to presentational media that use the body as transmitter and produce acts of communication and are consequently tied to the sender and to the here and now (similar to theater, voice, body language, facial expression, etc.).

ii) Both films and 3D spaces are time-based media, i.e., they include development in time (in contrast to sculpture, architecture, painting, etc. that are articulated primarily in space). But at the same time they also include spatial composition and development in space (in contrast to, for instance, written or spoken languages that deal only with the linear aspect of construction).

iii) Both films and 3D spaces are ‘multi’-media in the sense that they make use of several (sub-)media or sign systems. The French film semiologist Christian Metz points out five channels of information in film: 1) the visual image, 2) print and other graphics, 3) speech, 4) music, and 5) sound effects [cf. Monaco 81]. The same is surely true, *mutatis mutandis*, of computer based multimedia in general and of 3D spaces in particular.

iv) Both films and computer based multimedia, among these 3D spaces, can draw on the majority of the other arts (spoken and written language, graphics, music, painting, dance, etc.) for much of their meaning, aesthetic power and various effects – for one thing because they can record them. That is one of the reasons why computer based multimedia are the most semiotic complex of all media.

v) Multimedia aside, both films and 3D spaces are based on moving images as the dominant sign system.

vi) And last but not least: both films and 3D spaces are composed in three space dimensions and both are screen media that represent the illusion of three-dimensional space on a two-dimensional screen.

However, there are important differences as well:

i) [Monaco 81] writes: “Cinema is not strictly a medium of intercommunication. One seldom holds dialogues in film. Whereas spoken and written languages are used for intercommunication, film ... (as well as language when it is used for artistic purposes), is a one-way communication. As a result, even the most utilitarian of films is artistic in some respect”. Computer media and 3D spaces, on the contrary, are media of intercommunication. In other words, networked media resemble spoken and written languages in that they are used for intercommunication. In fact, one often holds dialogues in 3D Space (e.g. 3D chat). At the same time, multimedia and 3D spaces resemble film in that they are often artistic in some respects. This is another reason why multimedia and 3D spaces are some of the most complex of all media. Or, more precisely stated: film is a one-way-medium whereas 3D Internet is (often) two-way-communication; film is an inherently passive medium whereas 3D Internet is strongly marked by interactivity and human-computer interaction [cf. Jensen 97].

ii) Both films and 3D spaces utilize the illusion of 3D, but in film the fixed movements of the camera are controlled by the film director, in 3D space the user is able to interactively control movements and viewpoint.

iii) Finally, film is primarily an indexical medium (there is a physical connection between the images and the scene they represent) and an iconic medium (the images have a direct similarity to the object); whereas 3D space is first and foremost an iconic medium (on the assumption that the images resemble the object) and possibly a

symbolic medium, because there is no existential bond between sign and object (and in some cases no direct resemblance) but only a contract or convention [cf. Jensen 93]. Thus, while film is a medium with a strong bias towards the indexical, 3D space is a medium with a strong bias towards the iconic and symbolic.

Semiotics – Basic Concepts

According to semiotics, the structure of all media – film, multimedia, 3D space – is governed by the codes that operate within it. A code is a system of signs governed by rules between the members of the user culture. Codes are characterized by the following features: 1) They have a number of units arranged in *paradigms* from which one is chosen 2) The chosen units are combined into a *syntagm*, i.e., a text or message 3) They convey meaning, which derives from the agreement among and shared experience of the user culture.

A paradigm is a set of elements from which one may be chosen to combine with elements from other paradigms to form a syntagm. A paradigm, then, is a set of units that have an overall similarity. A syntagm, on the other hand, is a combination of elements chosen from paradigms to constitute a signifying whole. In a syntagm, the meaning of a unit is determined by how it interacts with the other units, hence the same element may have different meanings in different combinations, whereas, in a paradigm, it is determined by how it is distinguished from the others. So the paradigmatic dimension is one of choice, the syntagmatic one of combination.

These two dimensions are – according to Monaco – of paramount importance for the construction of meaning in film. To produce a film, the film director has to make specific choices. When the significance of a specific shot depends on having “been chosen from a range of other possible shots” then we can speak of meanings produced on the paradigmatic axis. That is, the “sense we comprehend stems from the shot being compared, not necessarily consciously, with its unrealized companions in the paradigm, or general model, of this type of shot” [Monaco 81]. Conversely, when the significance of a specific shot does not depend “on the shot compared with other potential shots, but rather on the shot compared with actual shots that precede or follow it”, that is, the other shots we do see, then we can speak of meanings produced on the syntagmatic axis. The syntagmatic aspect of film is thus associated with editing and montage (cf. below).

“These two axes of meaning – the paradigmatic and the syntagmatic –”, [Monaco 81] sums up, “have real value as tools for understanding what film means. In fact, as an art, film depends almost entirely upon these two sets of choices. After a filmmaker has decided what to shoot, the two obsessive questions are how to shoot it (what choices to make, the paradigmatic) and how to present the shot (how to edit it: the syntagmatic)”. And likewise when we ‘read’ a film, the sense of meaning, “depends on understood comparisons of the image with images that were not chosen (paradigmatic) and images that came before and after (syntagmatic)...”.

In film, however, the syntagmatic dimension seems much more complex compared to, for instance, written and spoken language. [Monaco 81]: “In written/spoken language [sic!] systems, syntax deals only with what we might call the linear aspect of construction: that is, the ways in which words are put together in a chain to form phrases and sentences, what in film we call the syntagmatic category. In film, however, syntax can also include spatial composition, for which there is no parallel in language systems like English and French – we can’t say or write several things at the same time”. Thus, the syntagmatic combination can unfold in time (speech), in space (painting), and in time and space (film). The Danish computer semiologist Peter Boegh Andersen (whom we draw heavily on here) therefore suggests that we speak of “sequential syntagms” [Andersen 90] when elements occur together in a sequential chain, i.e. when the syntagms have an extension in the temporal dimension; and of “concurrent syntagms” when elements occur together in a concurrent chain, i.e. when the syntagms have an extension in the spatial dimension.

The same holds true for multimedia and 3D spaces. Like all other media, a given 3D Space or Virtual World can be conceptualized as a syntagm formed from units from a host of paradigms: objects, actors, architectural design, rules, etc. Examples of concurrent syntagms would be the constellation of windows or views in the 3D browser (chat-window, window for 3D interaction, window with a list of participants, etc.) and examples of sequential syntagms would be a VR walkthrough or a *flythrough* in Quick Time Virtual Reality (QTVR). In computer media and multimedia, however, the paradigmatic axis can also include a spatial dimension for which there is no parallel in language systems or in the film medium. Owing to computer media’s inherent interactive features, a situation with several mutually exclusive options in the temporal dimension is often represented as a paradigm of choices in the spatial dimension. In this case, the paradigm can not be said to be a set of elements that can replace each other in the same place and from which only one is chosen. On the contrary, all the elements in the paradigm of options are in fact chosen and realized simultaneously in the same space. As a distinctive feature of computer media, paradigms are often realized as concurrent syntagms.

Mise-en-scène, Montage, and Sound & Image

Returning to film, [Monaco 81] remarks: “In film criticism, generally, the modification of space is referred to as *mise en scène* ... The modification of time is called *montage*”. And he adds “the tension between these twin concepts of *mise en scène* and *montage* has been the engine of film esthetics ever since ... the turn of the century”. In the following, we will structure the discussion around these two key concepts diverted from film. Both *mise-en-scène* and *montage* are principles of organization. But where *mise-en-scène* concerns the techniques of the shot: setting up the scene, organizing the space, staging the subject in front of the camera; *montage* concerns the techniques that relate shot-to-shot: editing. In short, the domain of *mise-en-scène* is *what to shoot* and *how to shoot it*, the domain of *montage* is *how to present the shot*. Finally, we will supplement this with a short discussion of some of the techniques that relate sound to image.

Mise-en-scène: The Techniques of the Shot

Mise-en-scène is the techniques of the shot. In film theory, a ‘shot’ refers to one uninterrupted run of the camera to expose a series of frames. In the finished film, correspondingly, the shot is one uninterrupted flow of image-frames with a single static or mobile framing. The shot is thus a sort of ‘minimal unit’ in the film medium. In 3D space, it would correspond to one continuous 3D walkthrough or one tour in a 3D space without a change of point of view. A ‘scene’ or a ‘sequence’, on the other hand, is a larger segment of a film relating to the same logical unit of meaning, i.e., it takes place in one time and space and/or involves one complete stretch of action. In 3D space, it would correspond to a series of consecutive actions or interactions in the same time and (3D) space that can be understood as a logical and meaningful unit – without regard to change in point of view.

Mise-en-scène was originally a theater term which reaches back into nineteenth century theater. Here, the concept was applied to the practice of directing plays. The French phrase literally means ‘putting in the scene’ or ‘staging an action’. The term crossed over to film production where it came to signify practices involved in the framing of *shots*. Now, the concept is used to signify “the director’s control over what appears on the film frame”, i.e. the codes that operate within the frame; or rephrased: “In controlling the *mise-en-scène*, the director *stages the event* for the camera” [Bordwell & Thompson 97]. Following from the term’s theatrical origins, *mise-en-scène* includes those aspects of film that overlap with the art of the theater – notably: setting, lighting, figures, movement, appearance, and costumes – within the frame. In recent years, the filmmaker’s control of *mise-en-scène* has been extended to a degree impossible with live actors shot in real time, first by means of animated film as seen in drawn or puppet animation, later by means of computer-generated images and animations. Consequently, settings, figures, and movements created by digital computers are also considered part of the *mise-en-scène*. In the context of computers and 3D spaces, we can define *mise-en-scène* as every element that appears in the scene – and on the screen – and that the designer can control. Naturally, aspects concerning *mise-en-scène* have a special relevance for the new 3D virtual worlds emerging on the Internet [cf. Jensen 98 & 99]. Here, the designer literally has to create or stage a new scene, a new environment, or a whole New World. So, in a way, it is true to say that the emergence of 3D worlds and 3D-interfaces is the fulfillment and culmination of *mise-en-scène* in the computer medium [cf. Andersen 97].

As it appears from the above, each of the general areas under the techniques of *mise-en-scène* offers the designer a range of possibilities for selection and control. However, as mentioned previously, *mise-on-scène* not only concerns the codes of *what is being filmed*, i.e. what is put in front of the camera, but also the codes of *how it is being filmed*, i.e., how it is being inscribed on film. Due to lack of space, we will only comment upon a couple of these codes with special relevance to 3D, viz. depth cues or the illusion of three-dimensional space: our ability to create and perceive 3D depth in 2D representation.

Needless to say, there is no real space extending behind the screen, but arrangement of the *mise-en-scène* and the way it is being transformed for the screen must prompt the viewer to imagine or construct that screen space. In other words, the codes of *mise-en-scène* must provide cues, which enable the viewer to infer the three dimensionality of the screen from the flat two dimensional images projected on the screen. Naturally, some of these codes concerning depth perception are shared with still pictures, notably photography and painting. The most important of these codes to create 3D depth in 2D representation that can be observed in both still pictures, film and 3D spaces are: overlapping planes, linear perspective, relative size (proximity and proportion), height in plane, density gradient, aerial perspective, light, shadows and saturation, and depth characteristics of lenses.

Another set of depth codes with high relevance for 3D space, which is not shared with still pictures but which is relatively specific to film, is the so-called mobile framing or camera movement: the ability to change

the camera's position within the shot, so that the frame moves with respect to the framed material. In some forms of mobile framing, the camera is fixed at a certain point, but is rotated around its own axis. Because the camera and the subject are located in three-dimensional space, there are three types of movements, corresponding to the three axes that intersect the camera [cf. Monaco 81, Bordwell & Thompson 97].

In the *pan shot* (short for 'panorama'), the camera is rotated on the vertical y-axis but the camera itself does not move. In the world of 3D graphics where this rotation is often called *yaw*, a parallel can be found in QTVRs, which are essentially based on this panoramic view of a scene (up to 360-degrees) fixed at a node in space.

In the *tilt shot*, the camera is rotated on the horizontal x-axis but the camera itself does not move. This type of rotation, which in 3D graphics is often called *pitch* has its parallel in QTVRs (and Video Reality) too.

In the *roll shot*, the camera is rotated on the depth (z)-axis that corresponds to the axis of the lens (the horizontal axis that runs into the picture) but the camera itself does not move (also called *roll* in 3D graphics). This axis represents the relationship between the camera and the framed material. While the pan and the tilt shot change the framed material, the roll shot maintains the same focus of attention but turns it around. The roll shot thus destabilizes the subject as well as the horizon and the depicted space. Because of this (and perhaps because it does not correspond to any natural bodily experience in physical 3D space) it is very rarely used in film. In the province of computers and 3D, it can be observed, however, in simulation games based on car races, boat races, etc. where it is used to represent accidents, collisions, overturning, etc. And in this case – if we observe the scene from a first person point-of-view – the rotation actually corresponds to a natural bodily experience.

In addition to rotating around these three axes, the camera can be moved from one point to another within a shot in the form of the *tracking shot*, the *crane shot* and the *point-of-view shot* [Monaco 81].

In the *tracking shot*, the camera itself is moved forward, backward or in any other horizontal direction along the ground. The tracking shot thus generates a feeling of physically entering into the scene, the spatial relations between the objects in the scene continually changes, and – consequently – so does the perspective. As a result, the track shot markedly strengthens the perception of depth.

In the *crane shot*, the camera is moved in the vertical direction above the ground. In the area of 3D VWs, this technique is often used in the form of a so-called 'out-of-body' viewpoint, 'bird's eye', or 'God' view.

The concept of *point-of-view shot* is perhaps best explained with reference to literature. A story is always narrated by someone. This 'someone' can either be a person who participates as a figure in the story – in which case we speak of a *first-person narrator* – or it may be a person who is positioned outside the story – in which case we speak of an *omniscient narrator*. Film can, to a certain degree, mimic these literary codes (in this context, for the sake of simplicity, we will deal only with the images not with a story told on the sound track, cf. below). The vast majority of narrative films are narrated from an omniscient point of view. We might call this a *third-person point-of-view*. In some cases, nevertheless, we see the events from the perspective of a character participating in the story. This is the *first-person point-of-view*. In the context of the film medium, this point-of-view is, however, much more infrequent and, when used, only used on a limited scale. Monaco suggests that if the first-person rule is applied to cinema on a larger scale, it inevitably causes problems. In computer media in general and in 3D applications in particular, the first-person point-of-view has, on the contrary, already been established as a firm convention. A particular version of the first-person-view is the *subjective camera*. In this case, the point-of-view is more or less permanently attached to a character participating in the setting. In other words, you see the world, the scene through the given character's eyes. This version is extremely uncommon in films, but very common in computer media, especially in 3D applications; presumably because of the medium's inherent interactivity, which presupposes that the user controls the action and participates in the events. Examples of first-person-views of this kind – where you constantly see the (3D) world through your avatar's first-person point of view – can be found in most of the 3D virtual worlds on the Web (as well as in computer games).

In 3D graphics, correspondingly, the range of motions available to an avatar or a viewpoint is called *degrees of freedom* (DOF). There are six possible DOFs in 3D. Movements along the x, y or z axes (parallel to tracking, crane shot etc.), which determine the coordinates in the given 3D space, and rotation around any of these three axes: you can move your avatar's or virtual head's viewpoint up and down (tilt/yaw), turn it right and left (pan/pitch), or roll it from side to side (roll) [cf. Wilcox 98].

Montage: The Techniques that Relate Shot-to-Shot

While the concept of *mise-en-scène* refers to the 'shot', montage refers to the techniques that relate shot-to-shot. The original French phrase literally means, "putting together". Montage or editing may thus be described as the way shots are put together to make up a film and, consequently, relates primarily to the temporal dimension.

The precondition for editing is that the human receiver has a tendency to perceive two joined shots as being in some way related, and thus to infer a whole on the basis of parts. In film, these joints can be of various kinds. The most common way of getting from one shot to the next is the unmarked *cut*, the instantaneous junction of two shots, but there are a number of conventional ways of joining shot-to-shot: double exposure, fade-out, fade-in, dissolve, iris, and wipe. In the computer medium, these means of getting from one node to the next have practically exploded, owing to digital technology. A conventional program such as Microsoft's PowerPoint offers more than 40 transitions, i.e., ways of getting from one slide to another. While browsing the WWW, we have a peculiar way of getting from one node to another: the blanking out of the screen for an indefinite amount of time and a more or less slow build up of the new Web-page, i.e., a combination of cut-to-white and a fade-in. Thus the dimension of 'editing' is one of the most annoying aspects of the Web. In 3D Virtual Worlds, joints occur when the user 'jumps' or is teleported from one space to another or from one world to another. Whereas cuts and joints are frequent occurrences in film, they are more rare in 3D space. In the force field between mise-en-scène and montage, 3D Internet definitely has a bias towards the mise-en-scène.

Editing two shots together permits the interaction of qualities (graphic, rhythmic, spatial, temporal) of those two shots. This interaction can be based on differences or similarities, producing abrupt contrast or smooth continuity, respectively. In film, it is the last style of editing that has been established as predominant, in the form of so-called *continuity editing*. The basic principle of continuity editing is to produce seamless transitions from shot to shot – so-called 'invisible cutting' – so that one event follows 'naturally' from another and time and space are logically represented. The prime purpose is to maintain immediacy, to concentrate attention on the ongoing action, that is, to tell a story coherently. This is done by a multitude of different techniques: match cut (which links two disparate scenes via a graphic match or continuity), rhythmic relations of shot lengths, spatial continuity (establishing shot, the 180-degree rule), temporal continuity, and – most generally – by creating a smooth flow and avoiding clashes from shot to shot [cf. Monaco 81]. All of these techniques are also pertinent to 3D spaces.

The relation of sound to image

Sound as a supplement to images is often considered a secondary factor by the viewer. Nevertheless, sound is a powerful technique that influences and codifies the experience in many ways. Sound can guide our attention within the image and focus our perception by pointing to things of particular interest. And sound can thus actively shape the viewers perception, interpretation, and understanding of images. In 3D spaces, in like manner, sound is an important factor, since it can bring about an overall sense of a realistic or convincing environment.

The term '*sound*' usually covers three types of aural phenomena: *speech*, *music* and *sound* effects. In the following we briefly introduce a typology based on the relationship of sound to image, having its source in film semiotics, but of pertinence to 3D spaces as well. Sound has spatial as well as temporal dimensions. It has a spatial dimension because it comes from a source. In this dimension, at the most general level, sound is divided into diegetic and non-diegetic sound, based on the identification of the source of the sound.

Non-diegetic sound is sound that is represented as coming from a source that can not be located in the scene, space, or world. It is often called 'sound over' because it comes from outside the represented visual space of the events. Non-diegetic sound can be subdivided into: 1) *Music* – so-called 'background music', 'movie music' or 'wallpaper music' – that does not issue from, but is added to the scene. 2) *The voice of the narrator*, in this case a heterodiegetic, omniscient third-person narrator, that introduces time, place, and characters but can not be recognized as belonging to any of the characters in the space. And finally 3) non-diegetic *sound effects*.

Diegetic sound is sound that is represented as coming from a physical source in the visually represented space or world. Diegetic sound can be subdivided into: 1) *Actual sound*, i.e., sound that the characters in the given space can or would be able to hear. In other words, we perceive the source of the sound as actually present in the here-and-now of the scene. Actual sound can be subdivided into on-screen and off-screen sound, cf. below. 2) *Subjective sound*, i.e., sound that can be heard only by a single character in the scene (inner voices etc.). And 3) *the voice of the narrator*, in this case a homodiegetic, first-person narrator, that introduces time, place, and events, and can be identified as belonging to a character in the represented events.

Diegetic actual sound can be either on-screen or off-screen.

On-screen sound refers to diegetic sound, perceived as coming from a source that is visible within the frame at the time the sound is heard, e.g. we hear a voice and at the same time we see the lips of an avatar move.

Off-screen sound refers to diegetic sound coming from a source that is not immediately visible within the frame at the time the sound is heard; nevertheless the source is perceived as being present in the scene at the given moment, only outside the actual frame. In 3D applications, environmental sound would be a case in point.

Consequently, off-screen sound can indicate space reaching beyond the immediately perceivable frame and may be used to cue the user's attention on and expectations about off-screen space. This technique is very useful and effective in 3D-applications. For instance, in certain networked 3D shoot'em'up'-games you often hear the footsteps of your opponents before you are able to actually see them in the frame.

Another feature of diegetic sound with strong pertinence and applicability to 3D space is the possibility of *sound perspective* [Bordwell & Thompson 97]. Corresponding to the depth cues that constitute visual perspective, it is possible to create a sense of spatial depth, distance, or location that in turn can model a kind of three-dimensional sound environment. It goes without saying that sound perspective can be produced by stereophonic sound or, better still, surround sound channels. Utilizing these techniques, it is possible to represent a sound's placement in the three-dimensional space – on-screen as well as off-screen. Sound perspective can also be produced simply by volume, because volume by a conventional code is related to the perceived distance. A loud sound is thus perceived as coming from the acoustic foreground close to the listener, a quieter or softer sound is sensed as located in the acoustic background far from the listener.

In the same way that sound has a spatial dimension because it is perceived as linked to a source, sound has a temporal dimension because it is perceived as linked to visual events that take place at a specific time. The most common relation between sound and picture in the temporal dimension involves synchronization [Monaco 81].

Synchronous sound refers to sound that is matched with the projected image, i.e. we perceive the sound at the same time as we see the source produce it. Because of this definitory precondition, synchronous sound relates primarily to diegetic on-screen sound. However, it is also possible, in a more unrestricted manner, to speak of synchronous sound applied to off-screen sound, subjective sound, the voice over, or even applied to background music, sound effects etc.

Asynchronous sound refers to sound that is not matched with the projected image, in short: sound that is *out-of-sync*. This, of course, refers first and foremost to technical inaccuracies and time lags, which are not uncommon in this early stage of the technology. But asynchronous sound can also be utilized for expressive and aesthetic purposes. Again, this type of sound primarily has a bearing on on-screen diegetic sound. In this case, correspondingly, it is possible in a more vague manner to speak of asynchronous off-screen sound, asynchronous voice-overs, as well as asynchronous, or non-contemporary, background music, sound effects, etc.

Conclusions & Perspectives

This paper has analytical, theoretical, methodological as well as practical implications. It is of interest in relation to the analytical and theoretical understanding of this new and rapidly growing medium and in relation to methods of examining these phenomena. The study shows that concepts and categories from the field of film semiotics are highly relevant to the area of 3D applications and it indicates that the concepts presented here can form the building blocks for a semiotics of 3D Cyberspace. However, it also has implications for construction and design aspects since the design of 3D spaces must be based on actual knowledge of the conditions and possibilities for the construction of signs, codes and meaning in the new medium.

Abstract: The paper presents the experiences in shaping virtual lecturing call collected through two years trial within European funded projects dealing with CSWC technology over broadband networks. The models developed and tested in trials with audience in three continents are evaluated and guidelines for further development are briefly described.

1.Introduction

The purpose of this paper is to present the results on large-scale trials of broadband teleconferencing systems carried out during the period 1996 to 1998 that were designed to help shaping virtual lecturing hall. The second objective of the paper is to provide some pointers for future use of this technology within tele-working and collaborative learning field of applications. The systems deployed were designed to support interaction between distant groups of people. At each of the participating locations there was a meeting room or a conference/lecturing hall, with any number of people from two too more than a hundred. It is important here to be stressed that the trials were conducted in two types of environments: a) collaboration of *multiple groups and b) collaboration of a single group* whose members are individually dispersed.

There were 12 trials carried out by two collaborative R&D projects subsidised by the European Union (EU):project NICE, see <http://www.berkom.de/nice> during 1996-7 and project EXPERT see <http://www.snh.ch/expert> during 1998. Both of these projects were part of the EU's ACTS (Advanced Communications Technologies) Programme. The trials followed four years of earlier work by Spanish and Portuguese teams in the ISABEL and IBER projects, beginning in 1992 see <http://www.infowin.org>.

A consortium of partners from EU (European Union) and EEA (European Economic Area) states, assisted by collaborators in Canada, Switzerland, Eastern Europe, Russia and Japan did the work. There were 18 EU/EEA partners, one collaborator each from Canada and Japan, and 11 collaborators from Central and Eastern Europe (CEE) and the newly independent states of the former Soviet Union countries (NIS), (see Gabrijelcic, 1996). The participants were a mixture of private telecommunications operators, academic network operators, universities and governmental agencies. The common goal was to provide enough experience that will enable commercial exploitation of the developed applications, knowledge and services. It will be apparent from the from examples that will be later described that the trials (12 in a period of 2 years) were on a large scale, meaning collaboration of multiple groups dispersed over 3 continents and 15 to 20 sites. There were several reasons for this, partly technical and partly social. It is inherent in the idea of teleconferencing and tele-lecturing to serve widely dispersed users who cannot travel to a central auditorium, for reasons of time or money. Large number of sites were part of the trials because there was need to investigate the problems of scaling up, in the network, in the application software and in the organisation and management of people. The requirement to demonstrate to a big audience also contributed to the wide range of locations. Finally, there was a secondary objective: to transfer knowledge and experience to the colleagues in the CEE and NIS countries so as to create a common capability in this subject.

2. Underlying Network Infrastructure Used In The Trials

To reach the desired locations a variety of bearers: terrestrial fibre, satellite links (both SMS and TDMA), microwave and radio were put together. This was primarily a financial and organisational task, to negotiate the use of links for short periods at prices that could be afforded by the projects. Our consortium was constructed so as to include carriers like Deutsche Telekom and EUTELSAT. Support was provided also from other EU-funded projects such as JAMES and GAMMA who provided pieces of the infrastructure. The result of this ad hoc assembly was that the bearer network was with differing bandwidths in different sections. The core network was either 6Mbit/s or 4Mbit/s, the satellite links mostly 2Mbit/s and other links ranged down to as low as 384kbit/s.

The infrastructure was mainly based on ATM technology, by use of a mix of publicly available ATM services and private switches (see Van den Berg 1997). The ATM service class was Constant Bit Rate (CBR) throughout. The ATM flows over the SMS satellite links were managed using a distributed switch technology known as CADENZA supplied by Alcatel Space & Defence. Over the ATM PVC classical IP was ran. Limited experiments were done with LANE and MPOA technology. The IP structures were usually a mixture of multicast and unicast. The IP network was also used for regular Internet services like WEB applications and IRC

The networks as described above were to provide full interactivity, with all sites having symmetric video and audio capabilities. Outside of the core network were performed experiments with other facilities -

- receive-only watch points within private IP network
- gateways broadcasting to public MBONE
- interactive links outside of core sites, using ISDN

Over this infrastructure a tool enabling the trials was used described in the session that follows.

3. The Application Software

The application software that provided the required support for the trials was the software package called ISABEL, developed at the Politechnical University of Madrid (see Quemada 1995 and ftp2.dit.upm.es/pub/Isabel). ISABEL is enhanced video-conferencing tool designed to operate mainly over broad-band networks with ATM technology. ISABEL provides N to N bi-directional communications for all media exchanged, supports auditorium interconnection and has specific modes for distributing the different types of interactions existing in a, different type of trial like Conference, Workshop or Seminar. ISABEL features multicast efficiently and as a consequence the increase of sites on the network resources is minimal. This enables easy scaling of organised events. ISABEL provides also channels for in-receive-only mode of operation (WatchPoint). This feature enables spread up of the prepared content for the trial to an unbounded number of non-interactive sites at the expense of no extra bandwidth which is especially valuable for countries or region with rather modest communication infrastructure like NIS (the New Independent States). The software acts in two modes: unicast and multicast which is preferred option. The multicast option is used in an advanced agreed network with set up conference management centre that controls the network and monitor the distributed event. The other mode - unicast is used when the participant have agreed to set up a full mesh of point to point circuits. ISABEL was developed on SUN systems but it was later ported to SGI and Linux, (see Peter Akesson 1997).

4. The Models Developed

A. Virtual conference hall

ISABEL was developed as a tool that enables distributed meeting or distributed conference/lecturing to a selected audience. The notions of “meeting” and “conference” overlap and are not useful to make a sharp distinction between them. The key characteristic is that there is some agreed or imposed agenda to which all the attendees are supposed to relate in some way. As the numbers of persons involved gets beyond a small group, a chairman is necessary to manage the agenda and moderate the interactions. With ISABEL the participants are seeing at the screen in advance prepared lectures with usual use of Power Point slides or some other running application e.g. from a WEB page. After the presentation is over the *question mode* appears on the screen and every person from a participating site can invoke his image to appear on the screen and to enter in a dialogue with the lecturer by pressing the button representing the site code.. Other participants can enter also in the discussion and invoke a panel. Other mode of interaction is the use of common *whiteboard*. This type of model was named the *virtual lecturing hall* model as it aims to provide chairmen/lecturer, speakers/contributors and audience in a set of distributed locations with the same facilities as they would have in a single location. This means not only that the audience is distributed but that the chairman/lecture and the speakers/contributors can also be in any of the locations (see Chas P., 1996).

B. Publish-and-subscribe channel

ISABEL can support an alternative model of use and for that reason the techniques borrowed from the world of television combined with teleconferencing software were investigated in the trial enabling access to much larger audience. In this model the audience was offered a channel in which a sequence of programmes was run, rather like a TV channel. For that reason this model was called a *publish-and-subscribe channel*. On one side of the channel were the publishers of programmes, which could be broadcast from one or more of the interactive sites. On the other side of the channel were the organisers of local meetings and conferences, who arranged to incorporate particular programmes from the channel into their own local events (see De Isidro 1997).

5.The trials

There were 10 trials in the period of 3 years. Two of them represent the typical events organised by the project NICE and EXPERT: the CEE/NIS event in November 1997 and Global360 in December 1998 (Global360) see <http://www.isabel.dit.upm.es/>.

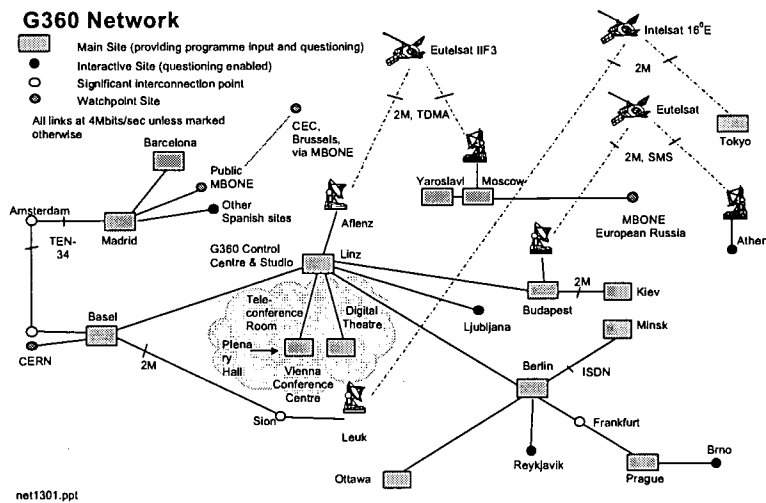

A. The CEE&NIS event and the technical audit

One of the objectives of the NICE project was to transfer knowledge and experience to the CEE and NIS countries so as to create a common capability in this subject. For this reason an event was organised in 1997 and that was completely performed by the Central and Eastern European partners only. The network management centre was set up in Prague within the premises of CESnet and the programme was prepared by the CEE/NIS partners. Four main sites where speakers gave talk had also their local events. Two panels were also part of the programme that applied the conference hall model. Another interesting trial was the Technical Audit in Brussels. For that event 3 partners took part in the conference hall model and special application – the Top Level Certification Authority for Slovenia (SI-CA) which is a part of the European Public Key infrastructure was presented within the conference hall model. The services of the SI-CA see <http://www.e5.ijs.si/si-ca/> from Ljubljana were demonstrated for the technical auditors sitting in Brussels using the conference hall model.

B. Global360, December 1998

Global360 was operated as an extension of the European Commission's Information Society & Technologies conference and exhibition (IST98) in Vienna, from 30th November to 2nd December 1998. It used the publish-and-subscribe model to provide a way of widening the audience for IST98 and to inject into IST98 demonstrations and discussions from remote sites in the special IST98 session published as Digital Theatre. Global360 ran 30 hours of continuous programming over three days. Six of the parallel sessions from the IST98 conference were transformed into teleconferences operating over Global360. The Digital Theatre

session showed the demonstration from external sites and acted as a studio for the Global360 moderator as well as the source of a number of programmes prepared within Global 360 channel. Outside Vienna there were parallel events in other cities, such as Basel and Ljubljana, with content from the IST Conference – Living and

working in the Information Society. The local event in Ljubljana was organised in the Slovenian National Assembly where members of the Parliament and other political people had opportunities to interact with the audience. Global360 interconnected 19 interactive sites, of which no less than 17 acted as sources of programmes. The network of Global 360 is presented on Fig.1

Fig.1. The Global 360 network

Sites were spread across Western and Eastern Europe and in Canada, Russia and Japan, see Fig.2. This was the second Global360 event run by the consortium and by this time both the ISABEL software and the organisation had matured to a point where TV-style production had become feasible. In the distributed event 28 different producers (15 of them outside of the project EXPERT) created the programmes. Control scripts prepared by the program manager for the programmes were automatically converted and loaded into the system, so when the program was ran the director and operators could concentrate on exception conditions. Professional designers were used to create screen graphics for continuity and titling and a professional TV moderator was hired. Other features were: extensive use of side channels for real-time command and control, IRC for technical co-ordination and a telephone audio-conference for co-ordination between the director and the local programme managers was also used.

6. Summary of Results

A. Usability of the developed models

In the course of the trials ISABEL has been permanently improved and by the end of the trials got quite good and rich functional capability. This has been demonstrated by the way in which successfully was shifted from its original model of use (the virtual lecturing/conference hall) to a radically different one (the publish-and-subscribe channel). The most recent trials have shown that ISABEL's reliability is now quite good and could be even better if it is run on a commercially managed platform which is now being negotiated. However, the current public domain version is an academic software and lacks proper packaging, documentation but an increasing number of educational and research institutions are using it as a working tool (in Canada e.g.). The trials have in addition shown that ISABEL systems can also be open to non-ISABEL users. A number of demonstrations were performed using remote ISDN H.321 feeds into ISABEL sites¹ (see also Fig.2), which were useful for including interactive contributions from sites without broadband links. Public gateways broadcasting to the MBONE and to the Web were implemented and tested, so that a much wider audience could follow the distributed events. The experience with heterogeneous networks and external sites shows that it is feasible to run a single teleconference with different grades of service, according to the facilities available at each site.

B. Scalability

¹ The ISABEL site hands over its video input to the external feed. Alternatively it can make up a composite picture with both remote and local images.

The large-scale events performed within the trials helped to understand what aspects can be scaled up in a number of sites simultaneously interacting on screen, 15 to 20 is the current number.. Scalability is also related important issue to understand the technological features as well as the human organisation to deliver a satisfactory service to both the performers and audiences in relation to possible new services. The technology chairmen, but it is not by itself the solution.

C New medium - new issues

others. For example: *distance teaching* relationships of teachers with individual pupils, implying additional channels and data records; *Corporate* require intelligent access to, and manipulation and marking of corporate and external data sets, linked to the progress of the teleconference.

Final Conclusions

There is still need to explore the scalability of this technology in relation to a number of models of use and from primitive level of knowing the identities of the people in the meeting. In such an environment the relevance of the participants to the agenda is more important than their number. Security issues despite that basic security gathered experience shows that when offered it people often do not use it. The whole question of the stimulation and management of interactivity needs further investigation and experiment with different models is certainly the cost/benefit. Clear models and schemes are needed this to be properly defined and evaluated.

Abstract: In this work, a collaborative platform for Internet content selection is proposed. After the execution of the collecting and extracting phases of the platform, the characteristics of all rating groups are learned and can be used to help users to determine which group is suitable for joining. We also design a questionnaire to understand the opinions concerning the Internet content selection of users. According to the statistics of 600 answers of our designed questionnaire, over 72% answers would support the collaborative platform for Internet content selection. Therefore, an enhanced architecture of the collaborative rating system by including one more phase, named distributing phase, to distribute the rating information by using the proxy-based labeling bureau, is further given. Based upon the enhanced architecture, we are proposing a plan to construct a national project, named “Collaborative Platform for Internet Content Selection on TANet”, in Taiwan.

1. Introduction

In recent years, due to the rapid growth of the amount of web pages, web becomes an important media for information communication. It seems that some regulation or content selection for Internet is necessary due to the inappropriate information on Internet.

Some rating systems today were constructed with databases, but it seems almost impossible to rate all pages by human experts due to the extremely large amount of Internet contents. Another approach, the PICS (Platform for Internet Content Selection, <http://www.w3.org/PICS>) protocol proposed by W3C (World Wide Web Consortium, <http://www.w3.org>), provided a systematic and complete architecture for document rating system.

However, to solve the problems that PICS protocol faces, a collaborative platform for Internet content selection is proposed in this work. We first collect the ratings made by the huge amount of users on Internet in the collecting phase. And then, useable rating information of each page is extracted in extracting phase by using *Weight Adjusting Algorithm*. Besides, the characteristics of rating groups are learned by using *Rating Group Discovery Algorithm* to help users to determine which group is suitable for joining.

We also design a questionnaire to understand the opinions of users. According to the statistics of 600 answers, up to 80% answers agree the promoting of Internet content selection, and furthermore over 90% of them would support the collaborative platform for Internet content selection. A national project, named “Collaborative Platform for Internet Content Selection on TANet,” is planned based upon our architecture, and one more phase, named distributing phase, is used to distribute the rating information by using the proxy-based labeling bureau.

2. Background

A survey by Georgia Tech concluded that censorship on Internet is mostly concerned by Internet users[see Georia Tech. 1996]. In fact, different countries with different cultures seem to apply different strategies on Internet content regulating[see Peng 1997]. In [Ellickson 1991], these strategies are divided into five main types: personal ethics, contractual provisions, social norms, organization rules, law, and from liberal to rigid.

PICS protocol is proposed by W3C organization and provided a systematic and complete architecture for document rating system. In addition to the syntax of rating labels, PICS provides the methods of rating and labeling for users.

The rating information can be provided by two methods, self-labeling or third-party labeling. In self-labeling method, the rating information is provided by the content providers for each web pages. In third-party labeling, the rating information is provided by specific voluntary or non-profit organizations.

Once the source of rating information is decided, the most related category should be chosen. After a rating category has been chosen, the rating opinions of rating information providers will be converted into PICS syntax-compliant labels.

There are two methods to distribute the labels. First, the rating labels can be added into the META tag of the HTML. No more requests for rating information will be needed. Second, the labels may be stored in an existing or a newly created labeling bureau, and filtering software will send requests to the labeling bureau to get corresponding rating information. According to the rating information, rating filtering software will decide the access rights of users.

RSAC (Recreational Software Advisory Council, <http://www.rsac.org>), an independent and non-profit organization based in Washington, D.C, empowers the public, especially parents, to make informal decisions about electronic media by means of an open and objective content advisory system [see W3C 1999]. RSACi system [see PICS 1999, RSAC 1999, and W3C 1999], following PICS labeling protocol, was developed by RSAC organization to regulate the contents on Internet. As shown in [Tab. 1], four categories with five levels are defined in RSACi system.

	Violence Rating Descriptor	Nudity Rating Descriptor	Sex Rating Descriptor	Language Rating Descriptor
Level 4	Rape or wanton, gratuitous violence	Frontal nudity (qualifying as provocative display)	Explicit sexual acts or sex crimes	Crude, vulgar language or extreme hate speech
Level 3	Aggressive violence or death to humans	Frontal nudity	Non-explicit sexual acts	Strong language or hate speech
Level 2	Destruction of realistic objects	Partial nudity	Clothed sexual touching	Moderate expletives or profanity
Level 1	Injury to human being	Revealing attire	Passionate kissing	Mild expletives
Level 0	None of the above or sports related	None of the above	None of the above or innocent kissing; romance	None of the above

Table 1: RSACi rating categories and level descriptors

3. Collaborative platform for Internet content selection

To obtain the rating information of all web pages by self-labeling or third-party labeling seems too ideal to apply. The followings are three possible reasons.

- No obligation for content providers to provide the rating.
- Impossible to rate all documents by voluntary or non-profit organizations due to the extremely large amount of documents.
- Hard to design an acceptable automatic rating system.

A collaborative rating system is then designed to solve the above problems, and its architecture is presented in [Fig. 1]:

Figure 1: The architecture of the collaborative rating system.

3.1 Collecting phase

A rating software, named *Rating Toolkit* (*RT* in short) is built to assist volunteer to rate web pages. Before using *RT*, volunteers must firstly choose a rating category, and then provide huge amount of rating data easily. It seems most likely that the documents on Internet can be rated more efficiently and accurately.

There are a variety of ways to divide contents on WWW into several categories. Users can either follow an existing rating category to rate web pages or rate web pages with new rating category if no appropriate category can be applied. Similar to the USENET news group, a new interesting subject can be built up and added with some certificate.

As shown in [Fig. 2], user first needs to make a registration on the specific Web site by providing some basic information, and then download *RT*. An ID number will also be given to identify user when he/she provides rating.

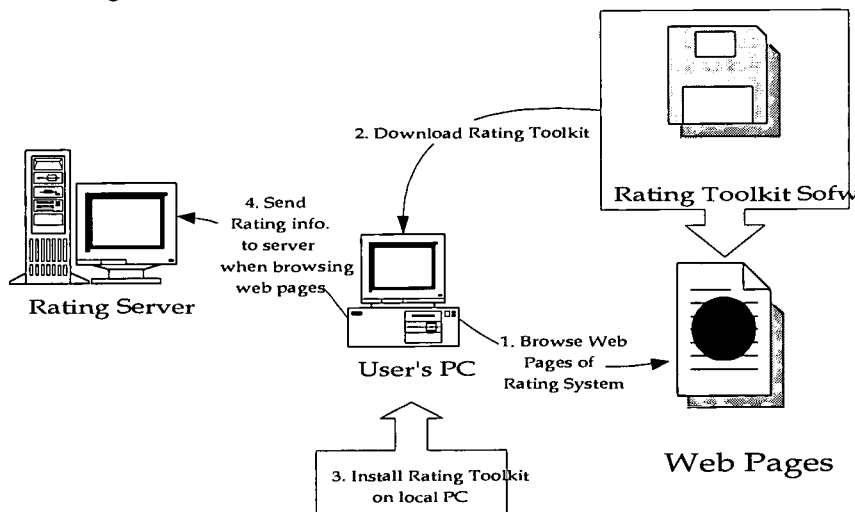

Figure 2: The downloading, installation and operation flow of RT.

3.2 Extracting phase

The purpose of extracting phase is to extract useful rating information from rating data provided by users. The entire flow for extracting phase is shown in [Fig. 3].

BEST COPY AVAILABLE

Figure 3: Processing flow in extracting phase

To extract useful rating information from rating data provided by users, there are at least two different methods: Averaging method and Voting method. Since the users may easily make their decision by the help of the description of each level, a weighted voting method is used in our collaborative rating system.

We would like to note here that for each web page only the last rating of a user will be considered. Each time when sufficient rating data is collected, the extracting phase will be iteratively executed. The level with maximum weighted vote will be treated as the resulting rating level of this page, where the weighted vote of this level can be obtained by the following formula:

$$S_i = S_i' + \sum W_j,$$

where S_i' is the weighted vote of level i in previous iteration, which is 0 at first iteration, and W_j is the weight of user j who rates the page as the level i . Once the content of web page is modified, S_i' will be ignored by resetting as 0.

The following *Weight Adjusting Algorithm* is proposed and will be executed in each iteration to reduce the influence of the participant if whose rating data is much different from the others.

Weight Adjusting Algorithm:

Notations: represents the sum of all votes for a given page P .

l represents the actual rating level of P .

N_i is equal to the number of votes for rating level i of P .

U_i represents the set of users who rate P as level i .

ρ is the threshold for low ratio.

User name	Total#	Noise#	Weight
-----------	--------	--------	--------

is the part of profiles for all users, where $Total\#$ is the number of pages this user has voted and

$Noise\#$ is the number of votes belonging to the levels with ratio $< \rho$.

Step 1: Evaluate the ratio $\gamma_i = N_i / \sigma$ for each rating level $i \in l$.

Step 2: If $\gamma_i < \rho$, then increase $Noise\#$ of u by 1, $\forall u \in U_i$.

Step 3: Increase $Total\#$ of u by 1, $\forall u \in U_i$.

The new weight for each participant can be recalculated using the formula below,

$$weight = (Total\# - Noise\#) / Total\#.$$

The *Weight Adjusting Algorithm* focuses on the majority only, but there may exist other opinions which can't be ignored. A clustering method is proposed in this section to find out some general relation between rating tendency.

First choose some popular websites as benchmark, which have been rated by hundreds of participants. A rating vector with length equal to the number of the above websites is defined to represent his/her behavior, where each element in the vector contains the corresponding rating data.

The distance between rating vectors may be used to represent the difference of users' opinions. For each group partitioned by some clustering algorithm, its characteristics can be learned using some symbolic learning algorithm. And the algorithm was shown below.

Rating Groups Discovery Algorithm:

BEST COPY AVAILABLE

- Step 1:** Find out k most popular web pages, denoted as a benchmark.
- Step 2:** For all users rating all web pages in benchmark, construct their rating vectors.
- Step 3:** Partition these vectors into several disjoint groups by some clustering algorithm.
- Step 4:** Choose some symbolic learning algorithm and set the training attributes for each group by using the personal information of the group's participants.
- Step 5:** Apply the symbolic learning algorithm to find out a general rule to present the characteristics of this group.
- Step 6:** Repeat steps 4 to 6, until all groups have been considered.

After rating groups are clustered, all the rating participants including the new comers will be notified about the characteristics of all groups. This could help the new comers to determine which group is suitable for joining.

4. Experiments and Implementation

Internet services were introduced to Taiwan users in middle 1992. Up till January 1999, there are over 3,000,000 user accounts on Taiwan Internet. There is a national project, "TANet to K12 Schools" will construct campus network for K12 schools to directly connect TANet (Taiwan Academic Network, as shown in [Fig. 4]) and let K12 student use the services on Internet.

Figure 4: Taiwan Academic Network (TANet)

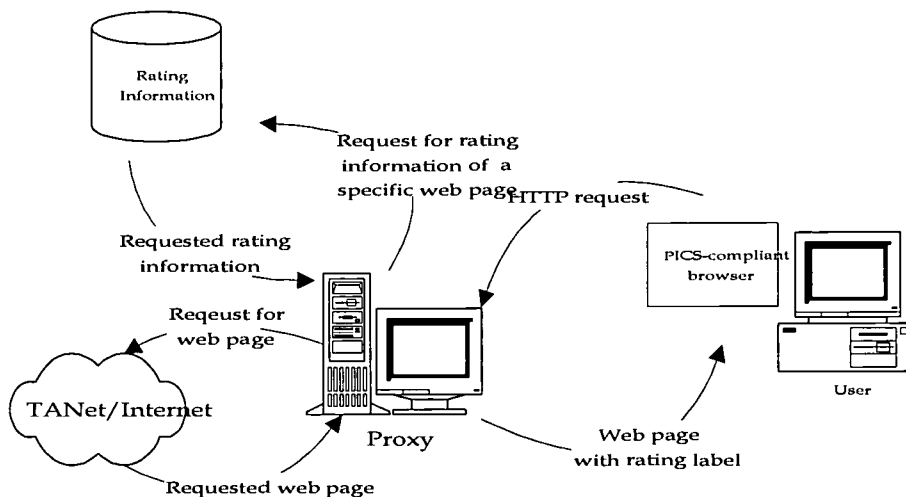

Figure 5: The architecture of the planned collaborative platform in Taiwan.

BEST COPY AVAILABLE

According to the statistics of 600 answers of our designed questionnaire, up to 80% answers agree the promoting of Internet content selection. Among the answerers agreeing to promote Internet content selection, about 70% answerers are willing to be the rating volunteers to assist the work of Internet content selection.

Now, we are planning to construct a national project, named "Collaborative Platform for Internet Content Selection on TANet," based upon the architecture of this paper. In this project, the proxy-based labeling bureaus will be constructed in three national universities, NCU, NCTU, and NSYSU, located in northern, central, and southern parts of Taiwan, respectively. The architecture of the enhanced proxy is shown in [Fig. 5].

5. Conclusion

In order to solve the problems of today's rating system, a collaborative rating system is designed. The system first collects the ratings made by the huge amount of volunteers on Internet and then extract the rating information or label of each page from the rating data obtained by using *Weight Adjusting Algorithm*. Next, *Rating Groups Discovery Algorithm* is used to cluster rating groups, and finally the characteristics of all rating groups could help users to determine which group is suitable for joining.

According to the statistics of 600 answers of our designed questionnaire, up to 80% answers agree the promoting of Internet content selection, and furthermore over 90% of them would support the collaborative platform for Internet content selection. Therefore, we propose a plan to construct a national project, named "Collaborative Platform for Internet Content Selection on TANet," based upon our architecture. In this project, one more phase, named distributing phase, is used to distribute the rating information by using the proxy-based labeling bureau. Based upon our architecture, not only the rating information but also the characteristics of the rating groups could be shared among the users on Internet.

A Study of Students' Perceived Learning in a Web-based Online Environment

Mingming Jiang Information Technology Education and Training
University of California at Los Angeles, Los Angeles, CA, U.S.
E-mail address: mjiang@earthlink.net

Evelyn Ting Center for Learning and Technology, Empire State College
SUNY, Saratoga Springs, NY, U.S., e-mail address: eting@sln.esc.edu

Abstract: The purpose of the study was to find what factors were perceived to be associated with students' perceptions of learning in online courses. Survey data were collected from students enrolled in 78 courses offered through the SUNY Learning Network in the fall of 1997. Correlation and multiple regression analyses were employed. The dependent variable was students' perceived learning that was correlated with eleven independent variables. Results indicated that the amount of student-instructor interaction and the online discussion activity played an important role in predicting students' perceived learning. The implication of this finding is that it is not only important to create an interactive environment for learning, but also important to design discussion activities that can trigger rich and meaningful online discourse.

1. Introduction

As more and more college courses are offered on the World Wide Web, either partially or entirely, quality of instruction and learning is becoming increasingly an issue that needs to be addressed. It is without doubt that the Web is an unprecedentedly rich and convenient medium for instruction and learning, yet, this new medium at the same time poses so many unknown aspects that demand an immediate investigation to ensure quality of instruction and learning. We do not know how various learning activities of a course and the instructor's behaviors are perceived to be related to students' learning achievements. Thus far few studies back their discussions by statistically examining the relations between various factors and students' perceived learning in an entirely Web-based environment (see Jiang, 1998). This study was designed to examine the relations between them. The study used survey data collected from students enrolled in 78 courses offered through the SUNY Learning Network in the fall of 1997. The purpose of the study was to find what factors were perceived to be associated with students' perceptions of learning in online courses.

2. Methodology

The study used survey data collected from 78 Web-based courses delivered through the State University of New York Learning Network in the fall of 1997. Since these 78 courses were in different subject areas and at different levels, it was not possible to use a generic instrument to measure students' learning achievements. Thus, a survey was used to achieve the purpose. An electronic survey, consisting of 14 questions, was administered to all students enrolled in the 78 courses of the fall 97 term. Altogether 287 students responded to the survey; the response rate was 58%. This response rate was based on those students who enrolled and finished the courses, excluding students who dropped off or remained inactive through the semester. This procedure is considered as providing a more direct indicator of a method's response-inducing capabilities than do other methods (Dillman, 1978, Anderson, 1997).

Correlation and multiple regression analyses were employed. The dependent variable was students' perceived learning. Eleven independent variables focused on the contributions of two major online learning activities, two

instructional behaviors, students' interactions with instructor and fellow students. Selection of variables was based on the concepts of collaborative online learning (Harasim, 1990; Kaye, 1992; Hiltz, 1990; McConnel, 1992; Simon, 1992; Hartman et al., 1995; Fabro, 1996; Lundgren-Cayrol, 1996; Berge, 1997), Vygotsky's (1986) interaction theory, Collins et al.'s (1991) cognitive apprenticeship. We also took into consideration the design of SLN courses (see Jiang, 1998). The variables used in this study are summarized in Table 1. Variables for the correlation analysis.

Table 1. Variables for the correlation analysis (N=287)

Perceived learning	Perceived instructor behavior	Perceived Student behavior	Perceived contributions of learning activities	Other variables
perceived learning	instructor-student interaction	student-student interaction	online discussion	learning style
	instructor-student communication	student-student communication	written assignments	prior computer competency
	instructor evaluation			time spent on a course
	Instructor responses			

2.1 Correlation analysis

Results of correlation analysis showed that all the independent variables except one were significantly related to perceived learning (see Appendix: Table 2. Interrelations among the variables for the study). The variable that was not related to perceived learning was prior computer competency. This supports results from our survey on the ease of use of technology (Jiang, 1997). Results of that survey indicated that the majority of the respondents thought the SLN Web environment was easy to work with (Jiang, 1997). That might explain why students' entrance level of computer skills would not influence their perceived learning.

2.2 Multiple regression

In order to find out which variables could best explain the variance in perceived learning, multiple stepwise regression was run. One pair of variables, students' perceived communications with instructor and with fellow students, was dropped off from the multiple regression analysis due to conceptual overlapping with two other variables, students' perceived interactions with instructor and fellow students. The variable, students' computer competency, was not included in the regression because it was not significantly related to the perceived learning. The remaining eight variables were used for multiple stepwise regression to predict students' perceived learning.

Results of the Stepwise Regression showed that four predictors were entered in the equation: 1) online discussions; 2) instructor-student interaction; 3) time spent on course; 4) written assignments (see Table 3. Summary of Multiple Stepwise Regression analysis for variables predicting perceived learning).

Table 3. Summary of Multiple Stepwise Regression analysis for variables predicting perceived learning (N = 287)

Variables in the Equation			
Variable	B	SE B	β
Online discussions	.19	.06	.18***
Instructor-student interaction	.32	.04	.41***
Time on course	-.10	.04	-.11*

Written assignments .16 .06 .13**

Variables not in the Equation

Variable	Beta In	Partial	Min Toler
Evaluation	.10	.11	.73
Student-student interaction	.08	.08	.64
Instructor responses	.06	.06	.69
Learning style	.09	.10	.76

Note: $R^2 = .33$

*** $p < .001$, ** $p < .01$, * $p < .05$

The multiple coefficient between the criterion (perceived learning) and the best linear combination of the four predictors was $R = .58$. It can be said that 33% of the variation in students' perceived learning could be predicted on the basis of the four predictors. An F of 34.60 on four predictors and 275 df was significant beyond $p = .05$, and we conclude that we can predict at better than chance levels.

3. Discussion

Results indicated that students valued their interaction with the instructor, their online capable partner. It has the largest regression coefficient, $B = .32$ ($p < .001$) and an increment of $.28$ (R^2). The significant correlation between students' perception of learning and their perceived interaction with their instructor ($r = .53$, $p < .001$) also indicates the important and indispensable role of the instructor in online environments. The finding is congruent with Vygotsky's concept of the role of interaction with a capable partner in the learning process.

The learning activity, online discussions, has the second most significant regression coefficient $B = .19$ ($p < .001$). The correlation analysis found a significant correlation between students' perceived learning and their perception of the contribution of online discussions ($r = .38$, $p < .001$). It seems that the more students found their participation in online discussions had contributed to their learning, the more learning they perceived to have experienced. This finding is in line with our earlier finding that students' perceived learning was significantly correlated to percent of grade weight assigned to students' participation in discussions (Jiang, 1998; Jiang and Ting, 1998). The implication of this finding is that it is not only important to create an interactive environment for learning, but also important to design discussion activities that will trigger rich and meaningful online discourse.

Written assignments were also found to be a significant contributor to perceived learning ($B = .16$, $p < .01$). This contradicted findings in our earlier studies. It was found that percent of grade weight assigned to written assignments was not significantly related to students' perceived learning. Our argument was that online written assignments were not much different from the traditional classroom written assignments that are common and major learning activities for students in college courses. We believed that that was of the reasons why the percent of grade for written assignments did not significantly influence students' perceived learning. Another reason might be the small sample size ($N = 17$) for that study. In this study which was based on survey data, students perceived written assignments as contributing to their learning nearly equally as they did the discussion activity, though students seemed to value a little bit more the interactive learning activity - online discussions - than the written assignments in this online environment.

Time spent on course has a significant but negative regression coefficient ($B = -.10$, $p < .05$). The correlation analysis also revealed a significant but negative coefficient ($r = -.18$, $p < .01$). These findings seem to contradict our common sense expectation. In a classroom setting, we would normally expect better learning if students spend more time on a course. One possible explanation for the negative coefficients is that these courses were online courses and there were many extraneous factors related to the amount of time spent on a course such as ease of navigation in a course, speed of students' equipment, instructional design of learning activities, clarity of instructions of how to work on learning activities. Since we did not inquire how students had spent their time on a

course, it remains a question for future study to find out why time spent on course was negatively related to students' perceived learning.

4. Conclusions

SUNY Learning Network used one single template for all the 78 courses offered in the fall of 1997. This unique feature offered a good opportunity to make inquiries about students' perceptions of their learning in this online environment and to find out factors that were associated with their perceived learning. Since the courses were of different subjects and at different academic levels, a generic measurement of learning achievements was not feasible. Although a survey study like this has limitations in reflecting students' learning achievements, it provides us with some information about how students thought about various learning activities, instructional behaviors and their relations to students' perceived learning. Such information will provide some basis for improving design of future Web-based courses. The findings of the study indicate the importance of an interactive learning environment and the online support from an instructor. Future design of web-based online courses should emphasize the role of online discussions and create an environment to ensure meaningful discourse among students and the instructor.

Abstract: This empirical study compared a graduate online course with an equivalent course taught in a traditional face-to-face format. Comparisons included student ratings of instructor and course quality; assessment of course interaction, structure, and support; and learning outcomes such as course grades and student self-assessment of their ability to perform various Instructional Systems Design (ISD) tasks. Results revealed that the students in the face-to-face course held slightly more positive perceptions about the instructor and overall course quality although there was no difference between the two course formats in learning outcomes. The findings have direct implications for the development and delivery of online instruction.

1. Introduction

New advances in Internet-based technology have brought challenges and opportunities to education and training, particularly through online instruction. While online instruction is gaining popularity, it is not free from criticism. Many educators and trainers do not support online instruction because they do not believe it actually solves difficult teaching and learning problems (Conlon, 1997). Concerns include the changing nature of technology, the complexity of networked systems, unstable online learning environments, and the limited understanding of how much students and instructors need to know to successfully participate (Brandt, 1996). Online instruction also threatens to commercialize education, isolate students and faculty, reduce standards, and devalue university degrees (Gallick, 1998). While these concerns may be unwarranted, there is little research to fully understand the benefits and pitfalls of online instruction, especially when compared to face-to-face learning environments. Gaining knowledge about the processes and outcomes of online instruction as compared to face-to-face environments will help educators make more informed decisions about future online course development and implementation.

1.1 Problem Statement

Although the popularity of online programs has increased in recent years, the capabilities and efficacy of such programs have yet to be fully investigated. Most effort in this area has been devoted to program development and much of the research has anecdotal in nature. With little empirical knowledge of Internet-based education outcomes, the need for research in this area is not only timely, but also imperative. The primary purpose of this study was to compare an online course with an equivalent course taught in a traditional face-to-face format. Comparisons included student ratings of instructor and course quality; assessment of course interaction, structure, and support; and learning outcomes such as course projects and student self-assessment of their ability to perform various ISD tasks.

1.2 Research Questions

This study was designed to answer the following research questions:

1. What differences exist in satisfaction with the learning experience of students enrolled in online vs. face-to-face learning environments?

2. What differences exist in student perceptions of student/instructor interaction, course structure, and course support between students enrolled in online vs. face-to-face learning environments?
3. What differences exist in the learning outcomes (i.e., perceived content knowledge and quality of course projects) of students enrolled in online vs. face-to-face learning environments?

2. Background

There are many assumptions about Internet-based education, most of which are positive and optimistic (Relan & Gillani, 1997). The many challenges associated with creating meaningful learning environments via the Internet (Hill, 1997) include how to meet the expectations and needs of instructors and students and how to design courses so they provide a satisfying and effective learning environment. From program developer and instructor perspectives, understanding these issues is critical for the development and implementation of quality online instruction.

While few experimental studies have compared the effectiveness of online instruction to the more traditional face-to-face offering, two recent studies provide encouraging results for developers of online instruction. Schutte (1997) conducted a small scale experiment in which he divided a class of 33 students into a traditional section and a virtual section taught on the World Wide Web (WWW). Schutte's results showed that instruction provided online can result in improved performance. LaRose, Gregg, and Eastin (1998) conducted a similar study that compared the learning outcomes of students in a traditional lecture section to course section that provided pre-recorded audio via the WWW along with detailed course outlines and related course pages accessed on the Web. Results showed that the Web group had test scores and student attitude ratings equal to those of the traditional section. While these types of quasi-experimental studies present methodological challenges (e.g., dealing with small sample sizes, the effect of prior knowledge, etc.), they do provide an important first step into better understanding the effect of online instruction on learning outcomes and student satisfaction.

3. Method

3.1 Subjects and Instructional Setting

This study compared outcome data obtained from students enrolled in one of two versions of a graduate level instructional design course for human resource professionals. One version of the course was taught using a traditional face-to-face format while the other version of the same course was offered totally online, with no direct face-to-face contact between the instructor and the students. Both courses were taught by the same instructor using the same content, activities, and projects. Nineteen students, most of whom are pursuing a graduate degree in HRD, were enrolled in the on-campus course. Nineteen students were also enrolled in the online version of the course. These students are also pursuing a graduate degree in HRD through a degree program that is taught completely online.

3.2 Instrumentation

The *Course Interaction, Structure, and Support* (CISS) instrument was used to assess student's perceptions of the quality of various instruction-related variables. This instrument is a hybrid of the *Distance and Open Learning Scale* (DOLES) and the *Dimensions of Distance Education* (DDE) (Harrison, Seeman, Behm, Saba, Molise, & Williams, 1991; Jegede, Fraser, & Curtin, 1995). CISS consists of 11 items for the dialog construct, 8 items for support, 8 items for course structure, and 4 items for transactional distance.

3.3 Procedures

All data were collected at or near the end of the semester. The on-campus students completed paper versions of the instruments while the online students completed equivalent online version of the instruments. All instrument

data were entered into a statistical analysis package for later analysis. Statistical analysis was conducted using independent sample *t*-tests with a significance level of .05.

The search for differences in learning outcomes between students enrolled in the online vs. face-to-face learning environments was conducted using two primary sources of data. The quality of a major course project was the first indicator of learning outcomes. Students in both courses were required to complete a training package that included all training materials and instructional aids as well as all student materials needed to conduct the training. A blind review process was used to evaluate the quality of the course projects. Three HRD doctoral students with instructional design experience were asked to independently evaluate each project in terms of the presentation quality, course organization, degree of detail provided, and overall quality. The reviewers were not told that the purpose of the review was to compare the two course formats and they did not know which projects came from online or face-to-face sections. The reviewers rated each project on a four-point scale for each of the four quality characteristics. Analysis of variance was used to examine ratings of the projects using a significance level of .05.

A self-assessment instrument was also administered at the end of the course. This instrument asked students to rate their level of comfort at performing various ISD tasks. A total of 29 items were developed from the course objectives. Individual *t*-tests were conducted to examine differences between the groups on each of the task items.

4. Results

The following results are from comparisons of the face-to-face and the online students' perceptions in the areas of satisfaction, course interaction, course structure, and support. Further analysis compares student learning outcomes in terms of course project quality and a self-assessment of their ability to perform various ISD tasks.

4.1 Student Satisfaction

Student satisfaction was assessed using two items on the CISS instrument that corresponded to the global items used by the university to evaluate all campus courses. These items asked students to rate, on a five point Likert scale (5 = exceptionally high rating), the overall quality of the instruction and the course.

Both groups provided positive ratings, although the face-to-face group displayed more positive views than the online group. The instructor's overall teaching effectiveness received a mean rating for the face-to-face group of 4.21 ($SD = .79$) while the online course mean was 3.58 ($SD = 1.07$). A similar, though non-significant, difference was found for the overall course quality rating, with the face-to-face group ($M = 4.32$, $SD = .73$) providing a slightly more positive rating than the online group ($M = 3.79$, $SD = .92$), $t(36) = 1.94$, $p > .05$.

4.2 Perceptions of Course Interaction, Structure, and Support

The CISS instrument assessed student perceptions regarding course interaction, structure, and support throughout the semester. Using a four point Likert scale, the students indicated the degree to which they *Agree* (4) or *Disagree* (1) with various statements. Overall, both groups of students had positive perceptions, with the face-to-face students having significantly more positive views for interaction and support.

4.2.1 Student Interactions

Interaction among the students was assessed using 5 items that represented characteristics of a learning environment that support student communications, shared learning experiences, teamwork, building a sense of community, and promoting an increase in student contacts. As shown in Table 1, there was a significant difference in the between the two course formats, $t(33) = 3.847$, $p < .05$.

Students enrolled in the traditional face-to-face course had a more favorable opinion of the amount and type of interactions among the students. Analysis of the individual items revealed no difference in the amount of contact among the students but a significant difference in terms of communication with other students in the class, sharing learning experiences with other students, perceptions of a sense of community, and being able to work in teams.

4.2.2 Student & Instructor Interactions

There was a difference in the perception of interaction between the instructor and the students as assessed using items covering teaching style, interaction with the instructor, instructor feedback on student progress, and the instructor's treatment of the students. Analysis of the individual items revealed a significant difference relating to students being informed about their progress in the course, student and instructor interactions during the course, and the treatment of the students in the course, with a lower rating by the online students.

CISS Instrument Sections	Face-to-Face *	Online *	<i>t</i>
Student Interactions	3.23 (.51)	2.65 (.37)	3.847**
Student & Instructor Interactions	3.11 (.49)	2.74 (.41)	2.455**
Course Structure	3.16 (.41)	2.94 (.40)	1.641
Instructor Support	3.17 (.43)	2.75 (.53)	2.690**
Departmental Support	2.15 (.56)	2.66 (.46)	-2.921**

Note: *Group means determined using a 4 point Likert scale ranging from Strongly Agree (4) to Strongly Disagree (1). Mean value above 2.5 indicates a positive perception among the students. A positive *t* value indicates a more positive perception among the face-to-face students. Standard deviations in parentheses.

** $p < .05$

Table 1: Perceptions of Course Interaction, Structure, and Support.

4.2.3 Course Structure

There was no difference in the variable that examined issues of students being allowed to work at their own pace, quality of the course syllabus, structure of class activities, organization of the content, student input in the topics selection, teaching methods, and student assessment.

4.2.4 Instructor and Departmental Support

Instructor support included comprehensiveness and usefulness of feedback, student encouragement, and the instructor being able to help students identify problem areas with their studies. The students in the face-to-face course rated the instructor significantly higher for instructor support than the online students. Analysis of individual items showed no difference in the amount of encouragement the instructor provided to the students. These differences relate to the characteristics of instructor feedback and the ability of the instructor to assist students to identify weaknesses in their course preparation.

Departmental support included information the department provided to the students, inquiring about their learning needs, and providing a communication link between the students and the instructor. The online students rated the departmental support significantly higher than the students enrolled in the face-to-face course. Analysis of individual items showed no difference in the departmental staff inquiring about the student satisfaction with the services provided and the departmental staff serving as facilitators between the instructor and the students. The differences related to students being informed about the support services, and about their learning support needs.

4.3 Student Learning Outcomes

Although student perceptions are important, the ultimate indicator of course effectiveness is the degree to which students reach the objectives. The following analysis examines differences in the quality of the final course projects and a comparison of the students' self-assessment of their ability to perform each element of the ISD process.

4.3.1 Blind Review of Course Projects

A primary outcome of the instructional design course was the completion of a complete training package that served as evidence that students had gained the knowledge and skills required of instructional designers. Since some of the students choose to work together on this project, the number of projects produced does not match the class enrollments. A blind review process was used to evaluate the quality of the course projects to compare the outcomes across the two course formats.

Overall, the thirty projects were rated very favorably ($M = 3.43$, $SD = .60$). The overall mean rating of the face-to-face class projects was 3.47 ($SD = .60$) and the mean rating for the online class projects was 3.40 ($SD = .61$). The difference in the project ratings for the two groups was not significant.

4.3.2 Self-Assessment

A self-assessment instrument assessed students' reported levels of comfort at performing various instructional design tasks. Each task was rated on a four point scale from Very Comfortable (4) to Very Uncomfortable (1). Significant differences were found on only five of the 29 items on the self-assessment instrument. The online group felt more comfortable than the face-to-face group when distinguishing among various ISD models while the face-to-face group felt more comfortable performing a learner analysis, preparing a content analysis, writing instructional goal statements, and writing terminal objectives in comparison to the online group upon completion of the course.

5. Discussion

As discussed in the opening sections of this paper, the effectiveness of online instruction is unclear. The results of this study show that student satisfaction with their learning experience tends to be slightly more positive for students in a traditional course format although there is no difference in the quality of the learning. These results suggest that online instruction can be as effective as traditional face-to-face instruction.

Students from both groups provided positive ratings of the instruction and the course. Although the face-to-face group provided a slightly more positive rating of instructor quality than the online group, the reasons for this difference are not evident. It is possible that the instructor was more effective in the traditional format, although the lack of difference in the learning outcomes does not support this. Another possible explanation is that student ratings may be higher when there is a personal connection between the instructor and the students, something that may not occur in an online course. Another possibility is that the response set of online students tends to be lower than the response set of students in a traditional format. Clearly, additional study of the influence of online instruction on student ratings is needed.

Generally, the face-to-face students indicated a more positive perspective on the learning environment characteristics than the online students. Considering the fact that the face-to-face class met in person once a week for a 3 hour period throughout the semester, the differences in student interaction levels are to be expected. Students in face-to-face courses can more easily get together for an extended period of time to discuss class projects, work out any differences of opinion, and build social relationships. In contrast, online students do not have similar opportunities, although the technology provides a surrogate form for similar interactions. This suggests that the online environment may lack the strong social dimension that is beneficial to face-to-face classroom experiences.

Differences between the online and face-to-face groups were significant for instructor and departmental support. Students in the face-to-face course reported higher levels of instructor support than did the online students. A more detailed item analysis reflected that the differences stemmed from the characteristics of instructor feedback. This makes sense in view of the differing contexts of the two classes. The face-to-face setting allowed the instructor to vary the nature and type of feedback as needed. In the online course however, the instructor feedback was limited largely to e-mail, fax, uploaded files, and periodic telephone conversations as a means of delivering feedback. The face-to-face students received live and dynamic forms of support from the instructor while the online group received support in a form of one way static communication. In terms of departmental support, the online students reported higher ratings than the face-to-face students. This difference is easily explained by the fact that the face-to-face class had direct contact with the instructor and a part time teaching assistant, therefore they had little need for support from the department. In contrast, given the complexities of online technologies, the online class had more need for technical support, a service that was provided by the department.

The lack of difference in the learning outcomes from the two course formats supports the continued development of online programs. Using a blind review process to judge the quality of the major course projects, the ratings of three independent reviewers showed no difference in the quality of the projects across the two course

formats. While there were significant differences on five of the 29 self-assessment items, examination of the results as a whole indicate the students in both groups are equally comfortable in performing the instructional design tasks. Four of the sets of means fell between the “comfortable – very comfortable” range and one set of means fell between the “uncomfortable – comfortable” range. Overall, both groups indicated a level of comfort at performing the tasks. It is worth devoting some discussion as to why these few differences did exist.

5.1 Implications for Future Online Programs

The ultimate question surrounding online instruction is whether or not it is as effective as traditional face-to-face modes. The findings of this study show that online learning can be as effective as face-to-face learning in spite of the fact that students in online programs are less satisfied with their experience than students in more traditional learning environments. In view of these findings, several implications emerge pertaining to future online programs.

First, this analysis suggests that the development and use of online programs should continue. Further examination of feedback and student progress are needed to improve overall student/instructor communication. This includes identifying and implementing new communication measures to facilitate student/instructor communication at appropriate points in the course. Second, a better understanding of why online learners report lower levels of comfort with their learning is needed so specific strategies for improving delivery of online programs that increase student confidence levels can be developed. Finally, educational practitioners who may enroll in or develop online courses need to be familiar with the limitations of online programs. Such an awareness will ensure that the expectations of learners are met and the intended course goals can be attained. For instance, the findings in this study suggest that online instruction may not be suitable for courses that require high degrees of student instructor interaction and feedback, such as performance-based training methods courses that rely on considerable mentoring and coaching. Until the technologies for online instruction better simulate real time interaction, program developers need to avoid courses that require frequent socialization between students and the instructor.

Student Use of Computer-Mediated Communication in a Distance Education Course

Miriam McNown Johnson

College of Social Work, University of South Carolina, Columbia, SC 29208, U.S.A

Tel: 803 777-2363, Fax: 803 777-3498, E-mail: miriam.johnson@sc.edu

Abstract: Students enrolled in a graduate level social work class offered through distance education were encouraged to use e-mail and a class listserv. Analysis of the sources and content of course-related electronic transmissions revealed that distant students were significantly more likely than on-campus students to use e-mail and a course listserv. Students used the technology most often for practical reasons, such as asking for clarification of course expectations or requesting exam results. They seldom used the listserv for extended discussions of course content or related topics. In responses to a survey about their use of computer-mediated communication (CMC) they reported significant increases in self-assessed competence, and expressed positive opinions about these technological supports.

1. Background

Distance education, defined as education or training courses delivered to off-campus sites via audio, video, or computer technologies, is being increasingly utilized in institutes of higher learning (The Department of Education, 1997). There were an estimated 753,640 students formally enrolled in distance education courses in the 1994-95 academic year. A third of higher education institutions reported offering some type of distance education courses, and another quarter planned to offer distance education within the next three years.

With an expansion in the use of this teaching modality, educators are searching for ways to reduce students' feelings of isolation by increasing interaction among students, and between students and instructors. Both students and faculty seem to prefer being able to interact directly with each other, and reportedly miss this convenience in distance education classes (Dillion, 1989; Fast, 1995). Studies suggest the value of learner-learner and learner-instructor interactions in distance education settings (McGiven, 1994; Wagner, 1993; Shale & Garrison, 1990). Learner-learner interaction may be the most challenging type of interaction to implement in distance education (Moore, 1989). While students in traditional settings can easily interact with their instructor and peers, these same type of interactions must be carefully planned and structured by teachers of distance education (Parker, 1997). The use of computer-mediated communication (CMC), such as electronic mail (e-mail) and a class listserv in distance education courses are two ways to increase student interactions.

Computer-mediated communication has been used as an aid for distance education (Mason & Kaye, 1980; Romiszowki & de Haas, 1989) to foster a sense of community among students, encourage group interaction, and extend discussion beyond class time (Folaron, 1995; Karayan & Crowe, 1997; Latting, 1994), to facilitate or enhance student/instructor contact (D'Souza, 1991, 1992; Latting, 1994), and to simulate a debate (Flynn, 1987). Most instructors report successful experiences, with some notable exceptions (e.g., Latting, 1994). Flynn (1987) suggests that e-mail is particularly beneficial "in a learning environment populated by persons on the move who have a variety of competing commitments. Students today often commute large distances for education and training on a part-time basis or while holding down a full-time job. Traditional methods anchored in the classroom are insufficient" (p. 18). What he is describing, of course, is the typical student enrolled in a distance education class.

Rogers (1981) suggests that the successful diffusion of an innovation throughout a social system begs the question of whether it has desirable effects. He notes that studies of effectiveness are hindered by several factors: most researchers interested in the topic share a pro-innovation bias, that there is a tendency for diffusion research to side with the change agencies that promote innovations rather than with the audience of potential adopters, conventional attitude surveys fail to measure outcomes, and often consequences are confounded with other effects. Sliwa (1994) cautions instructors against the temptation to embrace all available technology without question. Instead, educators are encouraged to accept only those strategies that improve the quality of learning, and to carefully evaluate any technological tools they choose to use in the classroom. The emphasis must remain on

effective teaching and learning. In accordance with this, the objectives of this study were to analyze the students' actual use of e-mail and the class listserv.

2. Study Setting and Methodology

The study was conducted in a graduate level social work program in a large public university in the southeastern United States. The study population consisted of 76 first year, part-time students enrolled in a distance education course during the spring 1998 semester. Thirty students attended class in a studio on campus and 46 attended at 12 other sites around the state. Distant students were required to be present on campus only three times: for the course introduction, the midterm exam, and the final exam. All but one of the students had been enrolled in two distance education courses the previous fall. The instructor of one of those courses used a listserv and also assigned "e-mail journal partners" to facilitate interaction between students.

The majority of the students were white (61%) and female (85%). Almost all were part-time students who held full-time jobs. There were no significant differences between the groups with respect to student enrollment status (full or part-time), work schedule (full or part-time), ethnicity, gender, or age.

The course was offered via two-way audio and one-way video instruction. Students at the distant sites could see the instructor on television monitors and could hear her and the students present in the studio. They could call in to the studio with questions and comments via an 800 number. The instructor could not see them.

The instructor used a class listserv to post her lecture outline and study questions every week. Ten percent of the semester grade for the course was based on class attendance and participation. Students could enhance their participation scores either by speaking up during class and/or by sending messages to the class listserv. The instructor offered no guidelines on what constituted an unacceptably low level of participation. The instructor provided students with information on how to reach her by phone as well as by e-mail.

The author was interested in how students used e-mail and the listserv within the context of the class or, specifically, whether there were any differences between the distant and campus students in their use of the class listserv and e-mail in these courses, and for what purposes the students used computer-mediated communication.

The author analyzed all computer-mediated communications related to the course that were sent by the students to the instructor via e-mail or the listserv. (E-mail transmissions exchanged directly between students were not available for analysis.) The texts of the transmissions were downloaded and printed in a single document totaling more than 650 pages. The transmissions were coded by source and sender, and by message content.

3. Findings

3.1 Sources and Senders of Transmissions

Of 369 transmissions generated by students, 274 (74%) came via individual e-mail to the instructor, and 95 (26%) were shared with the instructor and classmates via the listserv. Only 58 (15.7%) of the 369 transmissions came from campus students even though 39% of the students enrolled in the course attended class on campus. This was a statistically significant difference (chi square with 1 df = 86.9, $p < .001$). Seventeen students sent no transmissions at all; 16 of those students attended class on campus. Another 11 students sent only one message each. Of the total 369 student transmissions, 264 (71.5% of the total) were sent by only 10 students, all of whom viewed the class from distant sites.

3.2 Topics

The manifest content of the students' messages was coded into 14 topic categories: logistics (e.g., requests for information about the class meetings, pleas for extensions on due dates), questions about the assignments (e.g., selecting a topic for the term paper), actual assignments (papers) sent via e-mail, requests for individual exam results and grade reports, problems with the listserv, problems with e-mail, comments related to class content, requests to classmates for assistance, sharing of information (about course-related events in the news or outside resources),

comments about that outside information, comments regarding the listserv in response to a request for input from the instructor, unsolicited comments and evaluative feedback offered to the course instructor and guest lecturers, and acknowledgment of messages

Topic code	Number and percent of all messages	Number and percent of all e-mail messages	Number and percent of all listserv messages
Class logistics	66 (17.0%)	50 (17.0%)	16 (16.6%)
Questions about assignments	31 (7.9%)	27 (9.2%)	4 (4.2%)
Assignment attached	35 (9.0%)	35 (11.9%)	0 (0.0%)
Requests for grades	79 (20.0%)	79 (27.0%)	0 (0.0%)
Problems with listserv	26 (6.7%)	22 (7.5%)	4 (4.2%)
Problems with e-mail	5 (1.3%)	4 (1.4%)	1 (1.0%)
Comments related to class content	10 (2.6%)	6 (2.0%)	4 (4.2%)
Requests to classmates for assistance	10 (2.6%)	0 (0.0%)	10 (10.4%)
Sharing of outside resources	25 (6.4%)	1 (0.3%)	24 (25.0%)
Comments about outside information	11 (2.8%)	0 (0.0%)	11 (11.5%)
Feedback regarding the listserv	15 (3.9%)	6 (2.0%)	9 (9.4%)
Feedback to the instructor(s)	16 (4.1%)	16 (5.5%)	0 (0.0%)
Acknowledgment of messages received	42 (10.8%)	35 (11.9%)	7 (7.3%)
Duplicate transmissions	17 (4.4%)	12 (4.1%)	5 (5.2%)
Totals*	388	292	96

*There were a total of 369 transmission, but several contained multiple messages, bringing the total number of messages to 388.

Table 1. Topics of student messages, as a percent of all messages, all e-mail messages, and all listserv messages.

or information received, and duplicate transmissions. Because 17 of the transmissions contained two or three clearly distinct topics, the total number of student messages coded was 388, nineteen more than the number of

transmissions. Details of the results of the content analysis are shown in the Table 1.

The most common message topic was requests for grades, accounting for 29% of individual e-mail messages and 20% of all messages. The most common topic for the listserv was sharing of outside resources; this category accounted for 25% of listserv messages. Discussion of class logistics was the second most common topic for both the listserv (16.6%) and e-mails (17%). Comments/discussion directly related to class content accounted for only 4.2% of listserv messages and 2.6% of all messages sent. Messages about problems using the listserv accounted for 6.7% of all messages, and messages about problems with e-mail accounted for 1.3%.

4. Discussion and Recommendations

Limitations of the study include the usual restrictions that apply to educational research: 1) the use of a convenience sample in defining the study population; 2) the use of pre-existing, non-equivalent groups without random assignment; and 3) the potential for bias on the part of both respondents and researchers. In addition, the effectiveness of the instructional use of computer-mediated communication may have been limited due to the relative lack of technological expertise and experience on the part of the instructor.

Consistent with the finding of other studies of computer-mediated communication in social work education (e.g., Folaron, 1995; Latting, 1994), problems reported by students included information overload, access problems, a division within the class between the "haves" and the "have-nots," and insurmountable technological challenges. Technology problems and lack of computer accessibility and were the most common negative comments. For example, one student wrote, "It took many tries to get on the listserv and it was inconvenient for me. I don't agree that e-mail should be required. Older students don't all have computers. It causes unnecessary stress and frustration."

Analysis of the sources of course-related electronic transmissions revealed that students attending at distant sites were significantly more likely than were campus students to use e-mail and the class listserv. This finding suggests that this technology is particularly appealing to those students who do not have regular face-to-face contact with their instructor. In other words, it was used to remedy some of the inherent short-comings of distance education rather than to augment learning. Students used the technology most often for practical reasons, such as dealing with logistics, requesting grade reports, or clarifying expectations related to assignments. In a classroom setting these issues might be handled by the instructor before or after class, or during a break. The students seldom used the listserv for extended discussions of course content or related topics; in fact, these purposes comprised less than 6% of all messages sent. At the same time 8% of student-initiated messages were about problems they were experiencing with the technology.

The instructor personally found the listserv helpful in exchanging information (e.g., expectations, lecture outlines, and information about assignments) with students, thus preserving more of the in-class time for instruction and learning. Negative consequences included the high volume of incoming electronic transmissions (including an additional 72 transmissions from "the system" and the university's listserv coordinator related to the course), and time spent trying to help students who had repeated difficulties in using electronic mail or the class listserv. As noted above, not all students had equal access, knowledge, or skills, and there were multiple software and server "glitches" that needed to be addressed. The author found that the availability of competent support staff was crucial to the successful use of these teaching tools.

The vast majority of student comments were very positive. One wrote, "[The listserv] is one of the greatest advantages that distance ed student have. It keeps us informed, allows [us] to assist each other, ask questions, and just to feel as part of the overall class. It may be frustrating at the beginning of the semester getting subscribed and so forth, but it is more than worth the trouble. The good definitely outweighs the bad." Another said, "I love having access to the listserv and e-mail. It makes communication with you much easier. It also helps to get the outlines before class. I feel I have an advantage over the other two students at my site because they have been unable to access the listserv and do not get all of the pertinent information. I share with them as much as I can! It is interesting to read all of the communication among the other students. I don't have much time to chat with them, but I do enjoy reading their communications." And a third wrote, "I do enjoy having the listserv with all of the benefits of interacting with fellow classmates and the instructor. This service helps those of us at distance ed sites feel like we are a part of the class. There are times when you feel very detached from the larger group in the distance education program. I am so thankful for the listserv." Another concluded, "Thank you for taking the time to communicate with us through listserv. I hope you pass the word around the all of the other professors so they will use it for their classes."

The author recommends that educators employ computer-mediated communication to enhance student/instructor and student to student contact, particularly in distance education courses. Guided practice, along with simple written directions on the use of e-mail and the listserv, should be included in a general orientation session and/or at the first class meeting if at all possible. During the first several weeks of class, extra time and emotional support should be provided to students who experience technological difficulties (see Romiszowski & de Haas, 1989). Facilitating direct contact between students and the listserv coordinator (technician) may free the instructor from time-consuming and nonproductive exchanges regarding the intricacies and frequent technical malfunctions of computer-mediated communication. Instructors should develop specific expectations or course requirements related to CMC if they want students to use e-mail and/or a listserv to supplement other modes of learning.

Given the wide availability and growing familiarity with e-mail and listservs, computer-mediated communication presents an opportunity for effective and efficient contact with distance education students, both individually and as a class group.

The case for patterns in online learning

David Jones, Sharonn Stewart
Research Centre of Open and Distance Learning, Central Queensland University
Rockhampton, Australia, 4701
{d.jones|s.stewart}@cqu.edu.au

Abstract: The current practice of online learning, especially at an institutional level, can be characterised as being complex and expensive with limited sharing of ideas and experience leading to a large amount of reinvention. Patterns, simple and elegant explanations which capture solutions that have developed and evolved over time, are abstractions being used to increase reuse and quality in a variety of fields including architecture, software engineering, hypermedia, and teaching/learning. This paper will introduce the concept of patterns, suggest that they offer advantages for online learning and describe how they are being used at Central Queensland University.

Introduction

Central Queensland University (CQU) is a multi-campus regional institution with four branch, three interstate, and several international campuses. Fifty percent of CQU's students learn using a primarily print-based distance education approach. As with many other institutions CQU is increasing its use of online learning technologies for a variety of reasons both good and bad. In making widespread use of online learning CQU faces the same problems as other institutions. This paper describes what these problems are and suggests a process for the development and use of patterns in online learning as a possible step towards addressing these problems. In doing so the paper describes patterns and how they are being used at CQU.

The problems

The perceived need for the development and use of patterns for online learning (or possibly even traditional teaching and learning) is being driven by the observation of a number of problems with existing practice in online learning. These problems include

- **The innovator/practitioner gap.** Every year the literature includes hundreds, if not thousands, of good ideas associated with online learning. Most of these ideas are due to the work of a small group of innovators and researchers at individual institutions. At some institutions these ideas may come out of established centres for the support of and research into teaching and learning while at others they are the work of lone-ranging innovators. Few if any of these ideas find widespread use within their home institution and even less find widespread adoption amongst other institutions. Collis and Oliver (1999) report in their analysis of the papers submitted to EdMedia'99 that the majority of papers report on prototype development and evaluation with few ideas going beyond this stage. Additionally there is a long history of failed technology-based innovations (Reeves, 1999). There is a gap between the research and innovation in teaching and learning and the everyday practice.
- **The field gap.** The design and development of online learning requires input from professionals in a number of fields including computing, graphic design, instructional design and instructors. One of the problems with such group development activities is the limited understanding and appreciation of the disparate fields involved in the process. The gap in understanding and respect between the professionals of different fields can reduce the quality of the outcomes.
- **Online learning is new.** The new medium is different from traditional forms of teaching and learning, face-to-face and print-based distance education. It has different requirements and needs new methods to make most effective use of it. However, many if not most, applications of online learning continue to reuse methods and approaches from more traditional forms of teaching and learning. A contributing factor to this is that people are not aware of what can be done with the new medium and are falling back on what they know.
- **The relative unimportance of teaching.** Most Universities continue to be research focused with little but lip service being paid to the importance of teaching and learning. Evaluation of teaching and learning and

subsequent rewards for innovative and effective practices is limited. Subsequently it is no surprise when teaching staff pay little heed to adopting new approaches to teaching and learning.

- **Inflexible support systems.** A combination of these factors along with the complexity of online learning leads to the development of large support structures and procedures to support and implement online learning. Most of these structures and procedures, like those associated with institutionalised print-based distance education, are inflexible and cannot adapt to changes in the environment or to the requirements of individual courses, staff or students.
- **Limited quality.** All these factors contribute to most online learning being limited in quality. Surveys of websites for teaching and learning (LaRose & Whitten, 1999; Mioduser, Nachmias, Oren & Lahav, 1999) show that the majority of sites make less than effective use of the medium.

Requirements for a Solution

The overall aim of a solution to these problems is to increase the quality of online learning at an institution. To achieve this it is suggested that such a solution will have to

- **Reuse expertise and experience.** It should capture and enable the reuse of the expertise of researchers made available in the literature and of the current practice of the innovators at an institution. It should enable, improve and reward the continued innovation of the innovators.
- **Provide training and raise awareness.** Provide a forum where people from all the fields involved in the development and implementation of online teaching and learning can discuss ideas, learn about the new medium and become aware of the requirements of each field.
- **Encourage reflection and evaluation.** An essential component of any solution should be to encourage people to reflect and evaluate the quality of teaching and learning and reward people for participation in the process.
- **Provide an adaptable, appropriate support system.** The characteristics of online mean that a support system will be required. However, the support system should be able to adapt to changes in technology and to the individual requirements of courses, staff and students.

A possible solution is to provide a common language which enables collaboration and sharing of ideas. The provision of a common language facilitates the process of understanding and may decrease the amount of reinvention. If everyone involved is speaking the same language it facilitates the process of understanding. However, providing a common language is not enough. An environment which emphasises the discovery, collaboration and reflection in which to use this language is also required. We suggest that 'patterns' and their appropriate application may be one possible answer.

History of patterns

Christopher Alexander appears to have first proposed the idea of patterns for application in the field of architecture in the late 60s early 70s. In the late 80s early 90s programmers struggling with object oriented programming discovered the concept of design patterns and adopted them for use in designing object-oriented programming systems. The use of patterns has since exploded into a wide range of different fields including: pedagogy (Erickson & Leidig 1997; Manns, Sharp, Prieto, & McLaughlin 1998); analysis (Fernandez 1998); hypermedia (Nanard, Nanard & Kahn, 1998; Rossi, Garrido & Carvalho 1996); structuring organisations; re-engineering systems; project planning; and a range of other different areas.

What is a pattern

A pattern is "a generic approach to solving a particular problem that can be tailored to specific cases. Properly used, they can save time and improve quality" (Fernandez 1998). As Alexander (1977) puts it: "Each pattern describes a problem which occurs over and over again in our environment, and then describes the core of the solution to that problem, in such a way that you can use this solution a million times over, without ever doing it the same way twice". At a simple level, a pattern is a way to record the knowledge and experience of experts. A way of reusing best practice and taking into account the lessons others have already learned.

The use of patterns provide a number of benefits including making it easier to reuse successful designs, make proven techniques more accessible to developers, enable choice between alternatives, and improve the documentation and maintenance of existing systems (Gamma, Helm, Johnson and Vlissides, 1994).

In practice, a particular pattern format is used to describe the decisions, alternatives and the trade-offs which contributed to the development of the pattern. The use of consistent format for the description of patterns makes it easier to learn, compare and use patterns (Gamma, Helm, Johnson and Vlissides, 1994). There are a number of common formats which have been used to describe patterns in different applications.

Writing a pattern

Writing a pattern is a difficult, creative, and usually collaborative process. A major contributor to the difficulty of writing a pattern is extracting and abstracting expert knowledge and experience from a situation. Additionally, actually achieving the qualities of a well written pattern can be extremely difficult. The process usually starts with pattern mining, that is, searching for patterns to document. This could be undertaken by searching the literature, attending conferences, or reflecting upon personal practice to abstract practices which work. The pattern author is not necessarily the original innovator, although that can be the case.

Patterns are usually developed in a writers workshop, a practice adapted from creative writing. Writers workshops are a collaborative way of producing and improving upon patterns. A writers workshop is a positive, friendly and collaborative group process led by a moderator with the author actively participating at designated times. In short, the group forms a circle, reads the pattern, offers positive comments then suggestions for improvement, finally the author asks for clarification.

At some point in the future the author rewrites the pattern based on the feedback from the writers workshop. Once a pattern has been identified, written and moved through a writers workshop it is then stored in a pattern catalogue. A pattern catalogue is a collection of good patterns.

Typically, at least in programming and a number of other fields, conferences are held where writers workshops are conducted. Pattern Languages of Programming (PLoP) design conferences are one of the key areas where programming design patterns are produced. There is non-anonymous review and careful editing. PLoP conferences are held around the world annually EuroPLoP (<http://www.argo.be/europlop>), PLoP USA (<http://st-www.cs.uiuc.edu/~plop/plop99/>), Chilli PLoP (<http://www.agcs.com/patterns/chilliplop>). Additionally, at regular intervals PLoP conferences produce edited books of the best patterns from conferences (Coplien and Schmidt 1995; Vlissides, Coplien & Kerth, 1996).

The mystical aspects of patterns

It could be argued that patterns and pattern workshops are basically a collaborative process for producing a number of papers which follow a fixed format. Patterns, particularly when they are grouped together in a pattern language (described below), are intended to be much more. Three of the aspects of patterns which make it more than a specially formatted paper are: generativity, piecemeal growth, and the quality without a name (QWAN).

Generativity

Patterns are not simply descriptions of good systems, they are meant to generate new systems. When a pattern is applied the system moves from one particular context to a new context. Ideally, by the continual applications of related and well designed patterns a living structure is generated capable of dynamically adapting to changing needs and demands. Using an analogy from architecture, patterns are designed so that rather than building only a single room, it can be added to and generate a new environment which can be adapted to different means. The intent is that as a number of small patterns are applied, the well designed pattern language will move the user to a larger solution addressing larger problems.

Piecemeal growth

Piecemeal growth is the assumption that every environment whether it be for a building, a learning environment or a computer program is continually changing. Piecemeal growth is the opposite of traditional practice, particularly in architecture, which relies on design for replacement. For example a building is created with one purpose in mind. Twenty years later when there are more people it is torn down and replaced with a different building which better suits the current context.

Piecemeal growth is an approach which emphasises design for repair, not replacement. As the environment changes new patterns are selected and applied continually moving the design from one context to another, replacing older designs with more appropriate designs. An example of this is the story about the most beautiful house in the world (Rybczynski 1990). Rybczynski, a professor of architecture, sets out to build a dwelling in which to house the construction of a boat. However, as building proceeds the environment changes and the purpose of the dwelling changes. Eventually, rather than using it to build a boat the structure becomes a place to live. This is an example of piecemeal growth, continually applying patterns to achieve something that you probably would not have predicted in the beginning.

Quality without a name (QWAN)

The QWAN of a pattern is the incommunicable beauty that gives immeasurable value to the structure. Again using the architecture analogy QWAN is that experience of walking into a room that is well designed and just 'feels' right. The quality is without a name because it is meant to include concepts such as beauty and order, recursive centres of symmetry and balance, life and wholeness, resilience, adaptability, durability, comfort, satisfaction, and resonance (emotionally and cognitively). These concepts form QWAN as described by Alexander (1979) for architecture. QWAN for online learning may include some of these qualities but may also require more specialised qualities.

QWAN is one of the three foundation concepts for the pattern based approach to architecture proposed by Alexander (1979). The other two foundation concepts are "the gate" and "the timeless way". In summary, "the gate" (a pattern language, described below) provides the path by which you can use "the timeless way" (piecemeal growth)' to achieve QWAN.

Pattern languages

A pattern language is more than just a pattern catalogue (a collection of patterns). It is a cohesive collection of patterns and rules (guidance) on how to combine these patterns into a style or philosophy that enables you to achieve the QWAN. A pattern language is not meant to be a simple to follow prescription or recipe. Instead it is a language which enables an infinite variety of solutions limited only by the creativity and ability of the user of the pattern language. A good pattern language guides the designer toward useful or 'good' architectures (Coplien 1996).

Theories, Golden Rules, Patterns and Templates

Nanard, Nanard and Kahn (1998) talk about the relationship between golden rules, patterns and constructive templates in relation to using design patterns in hypermedia. In designing a hypermedia application there are collections of patterns that can be used which have been influenced by the golden rules. For example short term memory effectively holds seven plus or minus two entities, this is a golden rule in interface design. Therefore when interfaces are designed they should only have seven plus or minus two choices on screen.

Constructive templates are approaches or ways in which patterns could be implemented. Remember patterns are meant to be abstract whereas constructive templates are more descriptive enabling patterns to be put into practice. Typically a pattern may be related to numerous constructive templates due to the variability of a good pattern.

The authors would like to expand the Nanard, Nanard and Kahn (1998) model to include a higher principle relating to the education field, that is the philosophical stance that the educator brings to the entire experience. This is the set of beliefs the educator has about how teaching and learning occur, for example the constructivist

philosophy. It is suggested that the beliefs an educator has will inform the golden rules which in turn inform the patterns that are implemented using the constructive templates.

The demise of experts

A misconception that arises when discussing the application of patterns is the possible demise of experts. If there is a pattern catalogue available to novices which describes how to design a good system, surely the experts will no longer be necessary? The reason this may not occur is that applying patterns requires a great deal of knowledge and creativity. To create and apply patterns in online learning a knowledge of the context of application is required in addition to a familiarity with the environment and the implications of actions. For example a knowledge about the students' situation and the content is essential.

There also needs to be an understanding of patterns and creativity in their application and combination. The application of one pattern will not solve all problems, by their very essence they are meant to encapsulate one issue. Further, continually creating patterns requires a community of experts contributing to and evaluating patterns. Therefore patterns are not a way to eradicate professionals, rather they "channel creativity; they neither replace nor constrain it" (Coplien 1996). Importantly, once experts start using pattern languages they are not straight-jacketed into a regime. Patterns and pattern languages are designed such that there is enough variability that they can be applied creatively in an infinite number of ways.

Patterns, online learning and current work

We are currently setting up a patterns group at CQU which hopes to develop a pattern catalogue for online learning. It is hoped that the pattern catalogue and the process used to construct it will develop into an approach for implementing and evaluating online learning which will address the problems outlined earlier. The process we are using includes the following steps

- **Pattern Mining.** This includes sifting through the existing literature and also practice at CQU for examples of good practice. Pattern mining helps bridge the gap between research and practice. By mining the literature we are finally attempting to put into practice many of the good ideas which have been discussed in recent years.
- **Pattern Workshops.** Over a period of six months individuals from a number of fields including: instructional design, graphic design, web masters and instructors will come together in a number of pattern workshops. Each person will be responsible for creating patterns from the results of the pattern mining process. The collaborative, group development process which makes up a patterns workshop will provide an opportunity to share knowledge, experience and ideas amongst a varied group of staff. Participation in this process is a form of professional development and will help expand the participant's awareness of the ideas of other areas and their understanding of online learning.
- **Pattern Catalogue.** The patterns which are produced by the patterns workshops will be placed into a Web-based pattern catalogue which offers a number of different ways of searching for patterns. Being able to easily search and view patterns may make it easier for other staff to identify good practice applicable in their situation. Additionally, the patterns produced by this process will be published in a book which will contribute publications which count towards promotion and provides extra incentive to the workshop participants.
- **Constructive templates** (Nanard, Nanard & Kahn, 1998). To increase the ease by which these patterns can be adopted by other staff a number of the patterns will be implemented as constructive templates into a web development tool currently used by the Faculty of Informatics and Communication (Jones, 1999).

In the longer term it is hoped that pattern mining and construction can become an entrenched part of the teaching and learning practice at Central Queensland University.

Conclusion

Patterns are a basis for codifying and using innovation. Creating patterns requires a collaborative process which emphasises the continual reflection and generation of new patterns based on experience. We are suggesting that the incorporation of a pattern generation process into standard practice will address many of the problems associated with online learning. Eventually, when a pattern language for online learning has been produced, it may

be possible to generate an online learning experience which demonstrates the quality without a name.

Abstract: This paper presents a reference model for the design of Intranets. The reference model is part of a detailed project model called PROMET I-NET, which logically and timely structures the implementation of Intranets. In designing an Intranet we distinguish between an Intranet as a whole (macro level) and its constituting I-NET applications (micro level). The project model covers all phases of an I-NET project starting from requirements analysis to the implementation of a system not only on a technical level but on a strategic and organizational level as well. It doesn't replace existing methodologies but embraces them in its framework.

1. Introduction

In the last couple of years the implementation of Intranets proved to be an efficient and economical means to integrate distributed and heterogeneous data sources. I-NET applications became very popular because of the ease of implementation, too. However, there is a lack of systematic approaches for the realization of I-NET solutions. In general, existing techniques and procedures are based on results of research work within the areas of hypermedia, database design and software engineering (e.g. HDM [Garzotto et al. 1993], OOHDM [Schwabe & Rossi 1995], RMM [Isakowitz et al. 1995], W3DT [Bichler & Nusser 1996]). These works usually concentrate on isolated, mostly technology-oriented questions. So far a comprehensive approach which also includes organizational aspects and project planning in the conception phase of I-NET applications is missing.

This paper presents a reference model for the design of Intranets. It is part of the project model PROMET I-NET, which logically and timely structures the implementation of Intranets. The project model covers all phases of an I-NET project starting from requirements analysis to the implementation of a system not only on a technical level but on a strategic and organizational level as well. The goal is not to replace existing methodologies but to integrate and embrace them into this I-NET specific approach.

Both, the reference model and the project model were developed in the context of a research project in cooperation with leading German and Swiss enterprises where it has been validated in several projects.

2. Fundamental principles of I-NET applications

2.1. Terms and Definitions

I-NET technology describes a group of software and hardware components which implement protocols (e.g. TCP/IP, HTTP), naming conventions (e.g. URL, DNS), languages (e.g. HTML) and interfaces (e.g. CGI), that were originally developed for communication purposes and for the exchange of information on the Internet [Kaiser et al. 1996]

An *I-NET application* is a client/server-application which consists of at least one I-NET client and one I-NET server communicating over a standardized TCP/IP application protocol (e.g. HTTP, FTP, NNTP, ...). A client/server-application using a proprietary protocol on the application layer (e.g. SAPGUI with SAP R/3 or Lotus Notes Client with Lotus Notes) is not considered as an I-NET application, even if it is TCP/IP-based.

In this paper web applications are of special interest. *Web applications* are I-NET applications which communicate via HTTP. The corresponding client and server components are usually referred to as *web browser* or *web server*. The reason for their importance is that they provide interfaces (e.g. HTML, Java API, CGI) which can be used for the development of business applications.

2.2. I-NET Architecture

An *architecture* is a formal description of a system. It serves as a plan for the implementation of a system and offers a base of discussion when developing its structure during the conception phase. An architecture consists of several components (building blocks) which interact with each other. The *components* of an architecture provide a set of functions, which can be used over well-defined interfaces. The implementation of components in software can be done in different ways and to various extent.

The I-NET architecture of an enterprise can be described on different levels, which differ in extent and level of detail. The *macro level* describes the whole I-NET as an infrastructure consisting of network, hardware, software, middleware and application components. The description covers all regarded organizational units and locations of the business (enterprise-wide architecture). The *micro level* describes the architecture of an individual I-NET application and its interfaces to other applications and data sources (I-NET and non-I-NET applications). It concentrates on an I-NET application's components and their interaction (application-specific architecture).

3. I-NET Reference Architecture

3.1. Macro Level

On the macro level the structure of a physical I-NET can be described from three different points of view: a technical, an applicational and an organizational view.

3.1.1. Technical View

The *technical view* describes individual I-NET components and their respective relationships on a technical level. It focuses on platform components (e.g. clients, server), their functionality (e.g. productive, staging or backup system), their LAN- and WAN-connections and their middleware and hardware services. The goal is to show the relationship between components, especially connections between public networks and corporate networks as well as security issues. [Fig. 1] gives an example of the technical view on an I-NET architecture.

Figure 1: Technical view on an I-NET architecture

3.1.2. *Applicational View*

The *applicational view* describes the applications and data sources of an I-NET and their relationships. Each data source has a relation to an application which is responsible for its data. It also shows how applications exchange data with each other over interfaces as well as components shared between applications. This view concentrates on web applications in particular. Applications which are developed with ordinary technology are only considered if there is an integrational relationship to a web application. [Fig. 2] shows an example for this view.

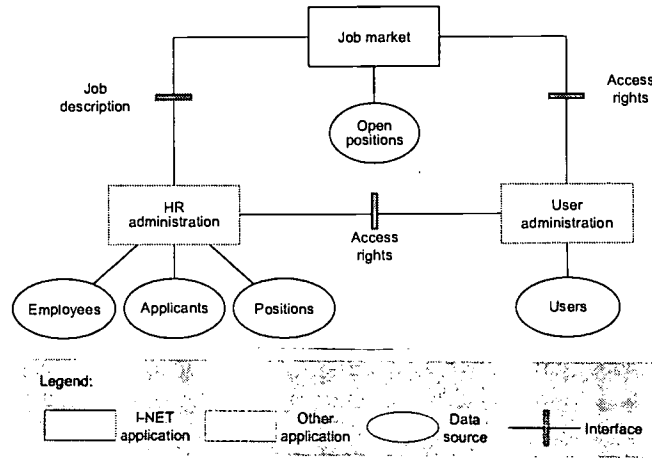

Figure 2: Applicational view of an I-NET architecture

3.1.3. *Organizational View*

The *organizational view* describes an enterprise's organizational units and locations connected to the I-NET. Neither I-NET components nor applications nor data and their distribution are considered here. Only the relationships between organizational units and locations of an enterprise's I-NET are relevant. The view can be illustrated as an organizational chart as shown in [Fig. 3].

Figure 3: Organizational view of an I-NET architecture

The following diagram shows the I-NET reference architecture on the macro level. It consists of those I-NET components which are used in the specific organizational units and locations. Moreover, the diagram includes the

relationship of the organizational units to the outside world. Therefore, the reference architecture on the macro level serves as a model which supports the planning of an enterprise's I-NET. In the diagram the terms *I-NET client* and *I-NET server* are used for different types of client/server components such as a web client, mail client, etc. or respectively a web server, mail server, etc. The term *gateway* describes a set of components facilitating the transition between two subnets. Within such a gateway, functions as encryption, filtering or caching can be implemented [see Fig. 4].

Figure 4: I-NET reference architecture (macro level)

3.2. Micro Level

When designing an I-NET application, there is an I-NET-specific part (surrounded by a dark gray box in [Fig. 5]) and a conventional part which can be worked out using classical methods like OOAD. Therefore, we focus only on the I-NET-specific part. This basically contains the application-relevant business processes and, from the physical point of view, all application parts to be implemented on the web client and the web server. Logically, this is the presentation layer (i.e. the graphical user interface and its components) and the part of the application layer to be implemented on the web client (e.g. Java applets). The rest of the application layer and the data layer are not within the scope of our model because they may be considered as external systems in terms of I-NET technology.

Figure 5: I-NET reference architecture (micro level)

First of all, interactions between users and the system are considered (1). Then we define structures for the graphical user interface in order to identify GUI components (2). Note that functionality to be implemented on the client is covered in the GUI components as well. Interactions between GUI components are given by the static and dynamic navigation structure (3). The actual interface between I-NET-specific and non-I-NET-specific parts are so-called *services* which are part of the middleware components (esp. a web server) (4).

4. PROMET I-NET

Any I-NET project requires a methodical approach, starting off with an analysis on potential advantages of I-NET technology for the enterprise, over process analysis to the final implementation of a solution on a technical and organizational level. PROMET I-NET is a project model covering all phases of an I-NET project. It is based on the principles of Method Engineering [Gutzwiller 1994].

The method's procedure model consists of both an enterprise-wide part and a business process-specific part. The enterprise-wide part includes the specification of an I-NET strategy, I-NET architecture as well as structures for operation and maintenance of the I-NET. The business process-specific part focuses on individual I-NET applications, each one supporting one or more business processes with information and knowledge. It is based on the enterprise-wide specifications. Usually both parts are realized as separate projects.

PROMET I-NET divides any project in the four phases project setup, analysis, design and implementation each of which including several activities. In parallel to these other project and change management activities have to be carried out. As these phases are not I-NET specific, they are not considered in our project model. Of course, the overall structure of the procedure model does not differ from traditional projects, however, it is the activities within each phase, which are specific to the use of I-NET technology.

[Figure 6] shows PROMET I-NET's procedure model in a simplified form. Light gray boxes represent major project activities. For each box PROMET I-NET provides a step-by-step technique describing how to develop a solution adequate to the enterprise's requirements. The activities are shown in a temporal and logical sequence and matched with the project phases. Activities that concern enterprise-wide questions are drawn on the left side, business process-specific activities on the right side. Arrows depict logical relationships and dependencies.

Figure 6: PROMET I-NET model

Below we describe the activities in more detail.

- *Potentials and strategy analysis*
The first step in developing an I-NET is the identification of application areas within the enterprise. This requires an analysis of business and IT strategies, current business processes and technology capabilities.
- *Strategy development*
After identifying application areas existing strategies, standards and policies within the enterprise must be reviewed and revised for reflecting the properties of I-NET technology. This includes security rules, design standards, legal issues, etc.
- *Operation and maintenance planning*
Like traditional IS an I-NET and its applications require technical services. However, there are some I-NET specific tasks (e.g. access rights, usage control, security audits), which usually are under central control. In this step suitable procedures for these tasks are planned.
- *Infrastructure design*
Infrastructure design summarizes all technical design activities relevant to the enterprise as a whole (e.g. web

browsers, web servers, search engines, etc.). It is based on the I-NET reference architecture [see Macro Level]. The main steps are the design of logical and physical structures and derivation of a list of components that have to be added, replaced or removed by comparing the current and future architecture.

- *Security planning (macro)*
Due to its importance there are separate activities to analyze possible security risks and threats. Based on a detailed assessment a set of required measures (e.g. firewalls, network segmentation, cryptography standards) is defined and the infrastructure is adjusted to prevent security problems.
- *Information structure analysis*
Before starting with the design of an I-NET application, a business processes' information needs has to be analyzed (unless already done in earlier projects). This includes analysis of process activities, organizational structures, information structures, information flows, and identification of current deficits.
- *Information structure design*
In this step the future information architecture is being designed. Required information objects and meta-information objects are specified, improved information flows between business processes are designed, conceptual data models, and navigation structures for the planned I-NET application are derived.
- *Content management planning*
It is crucial for the success of an I-NET application to provide for content management in advance. Processes for creation, distribution, maintenance and removal of content must be defined and linked with a set of suitable roles (author, editor, content manager, etc.).
- *Application design*
In this activity the actual application is being designed. It is based on the I-NET reference architecture [see Micro Level]. The main steps are the specification of user interfaces, application functionality and middleware services as well as integration links to existing systems and applications.
- *Security planning (micro)*
While security planning (macro) specified security measures that affect the enterprise-wide I-NET infrastructure, security planning (micro) deals with application-specific security issues (e.g. access rights).

For a detailed case study of the project model's application at LGT Bank in Liechtenstein see [Kaiser et al. 1998].

5. Summary

Planning and implementation of I-NETs require a certain methodology covering all project stages. Our methodology PROMET I-NET is based on a reference model which describes the components of an I-NET application and their interactions in a typical ideal architecture. The model covers both the enterprise-wide I-NET infrastructure (macro level) and the architecture of a single application (micro level). Based on these models we described an iterative procedure to design an I-NET. The procedure model is not just restricted to the technical solution realization, it also considers the organizational context in the enterprise processes.

Abstract: The exponential growth of documents on the WWW has made it difficult to find information on the WWW by browsing hypertext documents. Various search engines and indexing techniques have been developed to overcome this difficulty. This paper describes *SynSeek*, a meta-search engine. *SynSeek* demonstrates the effectiveness of interactive boolean query enhancement using senses and synonyms derived from a static manually generated semantic thesaurus WordNet in searching the Web. Interactive boolean query expansion is used so users can easily express or enhance their query. The meta-search engine provides for better coverage of the Internet, so users do not have to try and retry their queries across different search engines. Filtering options are also provided so the user can filter the returned results.

1. Introduction

The exponential growth of documents on the WWW has made it difficult to find information on the WWW by browsing hypertext documents. Various search engines and indexing techniques have been developed to overcome this difficulty. However, anybody who has done some serious search for information using existing search engines knows how frustrating and time consuming the search can get. A primary reason for the poor results is the simplistic approaches that most search engines today employ to satisfy user queries. WWW search engines (like Yahoo, WebCrawler, InfoSeek, etc.) maintain an indexed database of a subset of all web pages on the Internet. Different search engines use different indexing and web page classification techniques to categorize their subset of web page information.

When a user queries the search engine, this index is used to create a list of web documents containing matching words or phrases. Considering the mammoth size of the web and the inherent ambiguity (presence of homographs i.e. words that have the same spelling but different meanings) and vastness of the English Language, a simple text search may not yield satisfactory results. Unless a query is well defined, search engines cannot do much about the quality of results. Once the result set is determined, ranking algorithms frequently rely on quantitative approaches (like term frequency) to rank a document. If the result set is poor, ranking cannot help.

The focus of our study is the keyword based boolean query approach that relies mostly on full text indices. This boolean query approach is unfortunately error prone because of the breadth (different words with the same meaning) and ambiguity (the use of the same word(s) in different senses based on the context) of the English language. This problem is compounded by the fact that the average searcher is lazy. Searchers seldom think of alternative terms for improving their query and usually only use one or two terms for defining their query (last year's average was 1.5 words (Lusk, 1997)).

We present here *SynSeek*, sense/synonym based interactive boolean query enhancement meta-search engine. *SynSeek* uses WordNet, a manually constructed general purpose thesaurus from the Department of Cognitive Science, Princeton University, and the services of three Internet search engines: AltaVista, InfoSeek, and WebCrawler.

In *SynSeek*, the problem of expression and enhancement is alleviated using WordNet. Senses or synonyms of keywords from WordNet are presented to the user, so he can easily add terms to his query by simply checking an HTML checkbox associated with a synonym. The options provided allow the user to either specialize the query to

return more specific results, or add additional terms to broaden the scope of the query. The searcher knows the best what he is looking for. Once the sense or ambiguity problem is eliminated, synonyms or other terms that describe that sense provide an excellent source for query enhancement. The underlying assumption is that there is a high probability that documents closest to the true sense of the search will contain some or all of the terms or synonyms that describe that sense.

Section 2 looks at related work done in the areas of the semantic database WordNet. Section 3 describes *SynSeek* from the user's perspective. Sample snapshots of *SynSeek*'s user interface, and an example is used to describe the features of *SynSeek*. Section 4 is a performance evaluation of *SynSeek*. Section 5 concludes that *SynSeek* meets its goal of providing the searcher a more effective and easier way of searching the Web. Ideas for further work for improving *SynSeek* are also discussed.

2. Previous Work

This section discusses related work done in the areas of the semantic database WordNet. WordNet is an English language semantic database developed by the Cognitive Science Laboratory at Princeton University [<http://www.cogsci.princeton.edu/~wn/>]. WordNet has been used in various information retrieval and natural language processing projects (for a comprehensive list of WordNet related projects, please refer to <http://www.cis.upenn.edu/~josephr/wn-biblio.html>), a few of them related to the Internet.

Chakravarthy and Haase (1995) have used WordNet and an on-line Webster's dictionary for finding information archives on the Internet using natural language queries. Their program 'NetSerf' focuses on using semantic knowledge to match queries against a list of available generalized descriptions of information archives. Compared to SMART (a standard information retrieval system), on a test set of 75 queries, NetSerf showed an improvement of 28.3% to 70% depending on the number of hits considered. However NetSerf, does not involve any interactive query enhancement approach and does not query Internet search engines.

Burke, et. al. (1997) uses semantic (WordNet) and statistical techniques for matching natural language queries against questions and answers in FAQ files. They showed that a combination of semantic and statistical techniques works better than any single approach. However, this again, does not involve any interactive query enhancement approach and does not query Internet search engines.

3. SynSeek: User's Perspective

SynSeek's welcome page gives a brief description of how *SynSeek* works and has a text box where the user can type in his search keywords and submit them to the server for senses and synonyms. Figure 1 shows the welcome page.

On receiving the sense and synonym request, *SynSeek* looks up senses and synonyms for the requested keyword from WordNet, and sends back a dynamically generated HTML form (Figure 2) containing the senses and synonyms of the keyword.

Synonyms are associated with senses, namely each sense has a list of synonyms. The sense and synonym page provides the user the option of adding terms to his query by simply checking the check-box adjacent to each synonym. The user has three ways for adding terms to his query:

1. "Match All Words" is equivalent to the boolean operator 'AND'. This is suitable for narrowing the scope of a query and also making it more specific to particular sense. For example, if a user is searching for information on the island of Java, picking the 'island' sense with the "Match All Words" will construct a query (+Java +Island) i.e. (Java AND Island) restricting the result set to documents that contain both the keywords: Java and Island.
2. "Match Any Word" is equivalent to the boolean operator 'OR'. This is suitable for broadening the scope of a query and also making it more general. For example, if a user is searching for information on the 'United States of America', he would usually also be interested in documents that contain 'USA', 'U.S.A.', 'United States', 'US', 'U.S.', 'America'. Using "Match Any Word" will yield a query "United States of America", OR "USA", OR "U.S.A.", OR "United States of America", OR "USA", OR "U.S.A."..... The user can easily try different combinations of synonyms by simply clicking on the 'Back' button of his browser and checking or un-checking synonyms.

- The third option is explicitly excluding senses or synonyms from the search query, and is equivalent to the boolean operator 'NOT'. This is suitable for further narrowing down the scope of the query and making it even more specific. The user searching for information on the island of Java can further restrict his query by checking the "object oriented programming language" sense of the keyword java in the "Exclude from Search" section. This will add -"object oriented programming language" to the query i.e. NOT "object oriented programming language".

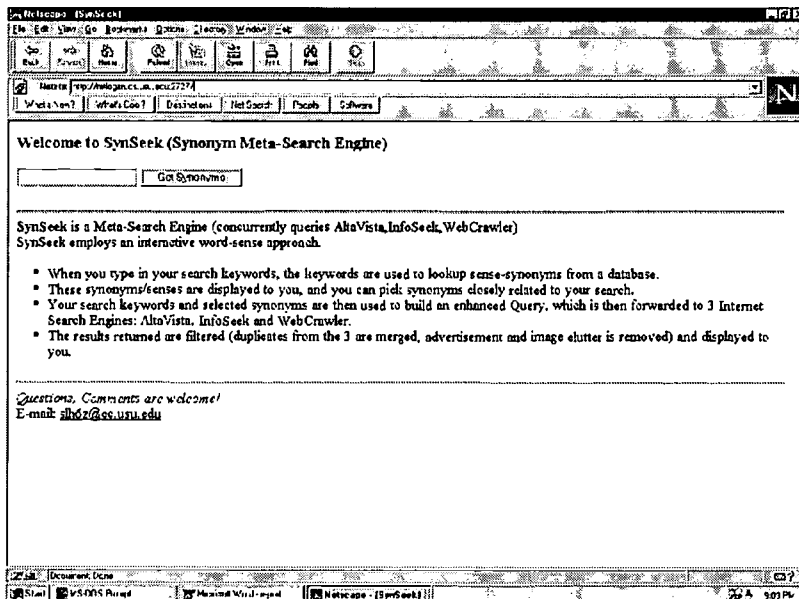

Figure 1. SynSeek's Welcome Page

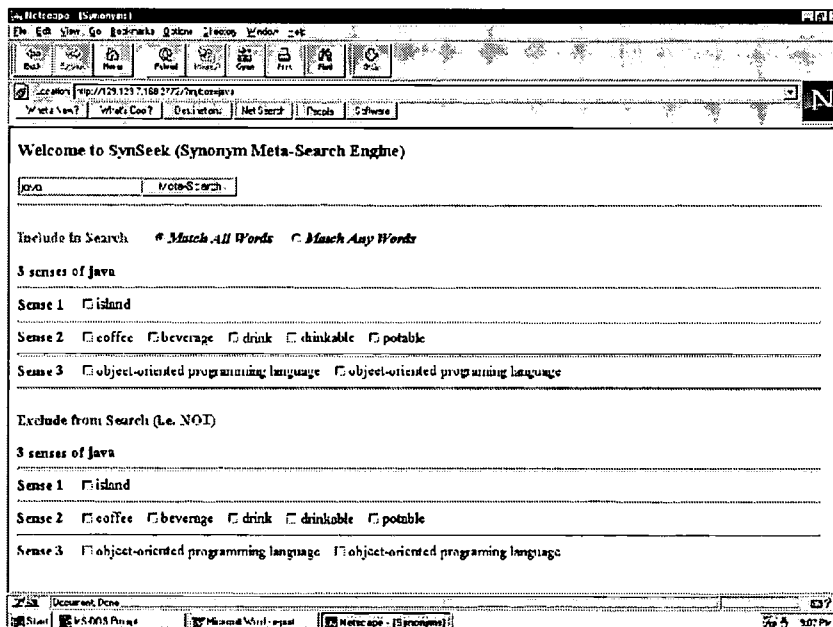

Figure 2. Senses and Synonyms returned by WordNet for the keyword "java"

SynSeek builds an enhanced query from the terms picked by the user, and concurrently submits them to three search engines: AltaVista, InfoSeek and WebCrawler. The results returned by each of these three search engines are filtered. Filtering consists of:

1. Removing advertisement and image clutter
2. Merging duplicates (if any) from the three search engines and promoting their ranking for the simple reason that multiple search engines returning the same result is a strong indication that the result is a good.

A fresh page (Figure 3) with the filtered search results is dynamically generated and sent back to the client.

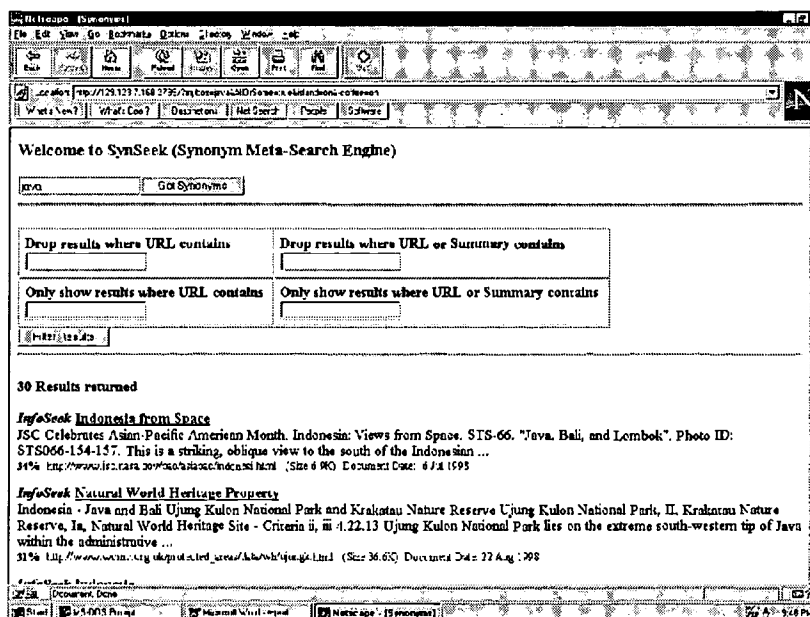

Figure 3. Results returned from a search query

The optional filter process can filter results based on user requests for the presence and/or absence of specific keywords in the URL and/or the summary of the result. *SynSeek* gives the user this very desirable ability to filter results. The user can do things like perform a search on a keyword, and then view or drop results from sites that contain that keyword. For example, if a user wants information about Microsoft from sources other than Microsoft Corporation, there is no way of expressing that in the form of a query. With *SynSeek*, the user can submit a keyword search on Microsoft and then submit a filter request to drop results with URLs containing 'microsoft.com'. This will yield a filtered list of results from sites other 'microsoft.com'. The user has four options for filtering results:

- Drop results where the URL contains
- Drop results where the URL or Summary contains
- Only show results where the URL contains
- Only show results where the URL or Summary contains

4. Effectiveness in Web Searching

Query results from three different Internet search engines (AltaVista, InfoSeek and WebCrawler) were compared to the results returned by the same search engines when using *SynSeek*. Both boolean query scope expansion and boolean query scope reduction techniques were tested.

A survey involving searchers of various levels of expertise was conducted. The results of the survey have been favorable: most users found *SynSeek* helpful and easy to use. Searchers who did not find synonyms for their keywords commented that the database should be expanded to be more effective.

Table 1 shows the summary results from a total of 110 participants:

Survey Question	Result Value	Result %
Experience with On-line Searching:	16.57 months	
Experience with Library System:	2.24/ 5.0	(44.8%)
Experience with Search Engines:	3.65/ 5.0	(73%)
Used Boolean Operators:	45	(40.9%)
Experience with Boolean Operators:	2.09/ 5.0	(41.8%)
Had to go back and change query:	103	(93.6%)
How often was query changed:	3.19/ 5.0	(63.8%)
Tried Multiple Search Engines:	91	(82.72%)
How Often were multiple engines tried:	2.72/ 5.0	(54.4%)
Did SynSeek Find any synonyms:	103	(93.6%)
How helpful were the synonyms:	3.92/ 5.0	(78.4%)
Did you use any of the Synonyms:	83	(75.4%)
Was it hard(1) or easy(5) to improve query using Synonyms:	4.03/ 5.0	(80.6%)
Only tried "Match All Words":	66	(60%)
Only tried "Match Any Word":	0	
Tried Both "Match All Words" and "Match Any Word":	44	(40%)
Tried going back and changing synonym choice:	57	(51.8%)
Used Both "Match All Words" and "Match Any Word", and tried changing Synonyms:	29	(26.3%)
Used the Result Filtering:	58	(52.7%)
How helpful was Filtering:	4.0/ 5.0	(80%)
Found Senses Synonyms more Helpful:	17	(15.4%)
Found Meta-Searching more Helpful:	21	(19%)
Found both Synonyms and Meta-Searching Helpful:	72	(65.4%)
Overall Effectiveness of SynSeek:	4.3/ 5.0	(86%)

Table 1: Summary of Survey Results

While only 40.9% of the participants had used boolean operators before using *SynSeek*, 75.4% of them used the synonyms displayed by *SynSeek* and therefore indirectly used boolean operators.

While 93.6% of the participants said that they had to go back and change their query with other search engines, only 51.8% tried it with *SynSeek*. An improved quality of results on the first try was perhaps one of the reasons for the drop. This is further supported by the fact that *SynSeek* was rated to be much more effective than other search engines. Participants liked both the term suggestions and the meta-searching features and found it quite easy to extend their query based on the term suggestions.

5. Summary

5.1 Summary and Conclusions

This paper explains the motivation behind the design and implementation of *SynSeek*: an Interactive Boolean Query Enhancement Meta-Search Engine for the Internet. Details of the design and implementation are provided, and results of performance testing and a user survey are also provided.

The results show that *SynSeek* meets its goal of providing the searcher an effective and easy to use program for searching the Internet.

5.2 Improvements and Further Work

SynSeek is a good first stab at alleviating the problems faced by Internet searchers. There is a lot that can be done to make *SynSeek* more effective:

1. Dynamically update the Thesaurus, and improve it based on user feedback.
2. To overcome the limitation of single keyword thesaurus lookups, NLP (Natural Language Processing) could be used to detect or improve the quality of terms suggested for user feedback (provided there is adequate context for it).
3. By using an applet the result filtering can be performed on the clients machine rather than the server. This could speed up filtering at the cost of restricting access to *SynSeek* to Java enabled browsers.

Abstract: This paper reports our current and on-going R&D efforts towards the design and development of advanced web-based courses, which are used in parallel to existing classes offered by our institution, aiming at enhancing their effectiveness. We outline the instructional design methodologies that have been adopted and the software tools that have been utilised. We discuss issues related to the functionality and the user interface of the courses, as well as their adaptations for meeting diverse student requirements.

1. Introduction and Background

The rapid evolution of information and telecommunication technologies (IT&T) offers numerous new opportunities for the improvement of the educational process. The adoption and exploitation of the emerging IT&T applications and services, and in particular web and internet technologies, is expected to have significant impact on the quality of education and life-long learning offered to the citizens of the information society.

In this context, our institution has recently initiated an R&D effort towards the development of web-based courses which aims at enhancing existing classes. This paper reports on the web-based courses that have been designed and developed in the subjects of Data Bases and Decision Support Systems. The courses are currently used in parallel with "traditional" classes; however, it is also planned that they will evolve into "self-contained" educational material, which will be used explicitly for distance learning.

The paper begins by outlining the design methodologies and software tools that have been utilised. Subsequently, the functionality and the user interface of the courses are addressed, which may have significant impact on the effectiveness of the courses on the educational process. Specific emphasis is given to the range of adaptations supported by the current version of the courses, as well as the ones that are planned for the near future, in order to meet the diverse requirements of different student and instructor groups. The paper concludes with some thoughts concerning our future work in this field.

2. General Design and Development Issues

The design of the courses under discussion has been realised by a multi-disciplinary group, which includes experts from the domains of educational technology, human-computer interaction, web and internet technologies, etc. A student-centred approach has been adopted, i.e. the courses are designed so that the student is actively involved in the educational process, rather than being passively receiving information.

The development lifecycle has followed the waterfall model of software development, where continuous evaluation with students and instructors of our institution has provided significant feedback during all the phases of design and development. For example, the screen layouts and the functionality provided at each stage of the courses have been evaluated by students and instructors, mainly through paper mock-ups and early software prototypes.

The design and development of the courses has been mainly based on, and influenced by, the results of the Instructional Management Systems project (www.imsproject.org). In particular, the requirements, specifications and meta-data specifications produced by the IMS project have formed the basis of our design and development decisions concerning several aspects of the courses, including content quality, functionality, navigational support, etc; as well as implementational issues, such as openness, interoperability, etc.

The software tools that have been mainly used include the Allen Communications' Designer's Edge (www.allencomm.com/software/designer) for the design of the courses; as well as the University of British Columbia's WebCT (homebrew.cs.ubc.ca/webct) for the implementation of the courses. The use of these tools has proven to significantly assist the design and development process, and has enabled the development group to incorporate their expertise into these processes.

The layout used and the functionality provided at each section of the courses has been based on a set of "templates", which have been designed according to common "patterns" found in similar educational applications. In particular, a survey of existing computer-based courses has been conducted, with emphasis on the types of screen layout and functionality provided for the presentation of specific information / content types [Karagiannidis & Tarabanis 1999a]. A respective set of "rules of thumb" has been devised, which are being continuously evaluated by students and instructors of our institution, and has formed the basis for the design of the courses.

It should be also noted that the design of the courses has put specific emphasis so that the educational material is available in different media (i.e. being "media-independent"). This has been considered important, so that the courses are not bound to specific student abilities, machine configurations, etc. For example, the courses are designed so that the whole material can be presented in pure text, which can be used, for example, by blind students utilising text-based browsers, or by sighted students utilising a slow network connection, or a slow machine (see also section on adaptability below).

3. Functionality and User Interface

Specific emphasis has been given on the functionality of the courses, particularly for assisting the user in navigating in the hypermedia information space of the courses. Part of this functionality has been directly provided by the development tools utilised (e.g. chat, e-mail and bulletin board facilities provided by WebCT), while other parts have been programmed by the development team. Examples include:

- graph-like maps of the educational material, where specific paths are suggested according to the student's expertise, background, interests, etc (see also section on adaptability below);
- bookmarking and annotation functions for every educational section;
- history functions, where, for example, the path followed by the student is presented as a graph, in order to provide ;
- specific functions for students (e.g. present all the quizzes of a specific section) and instructors (e.g. statistics concerning the success factor of each quiz, the average scores for each student);
- simultaneous multimedia presentations of the same educational material; for example, the material that is presented through audio, can also be shown in parallel through a scrolling text field, so as to assist the student if the quality of the audio is not acceptable;
- different types of questions, in addition to the ones that are provided by WebCT, e.g. questions where the student is required to insert the missing words into sentences; etc.

Moreover, the courses provide extended functionality for assisting the educational process, such as different course structures and levels of help according to the user's expertise, continuous feedback concerning both the educational process itself (i.e. the educational subject), as well as the user's interaction with the system, etc (see also section on adaptations below).

Central to the design of the courses has also been the requirement for easy access and high quality of interaction, so as to enable the student and instructor focus on the educational process itself, without spending much time on learning the use of the system. To this end, specific emphasis has been given to the user interface of the courses, which follows the general user interface design and development guidelines and recommendations. In particular, after the requirements analysis phase, the design and development of the courses has concentrated on the satisfaction of specific usability requirements, such as the provision of continuous feedback and special help facilities. Finally, specific emphasis has been given on the careful selection of media for presenting information,

interaction techniques and objects, input/output devices, etc.

4. Adaptability and Tailorability [1]

In addition to the above, and in order to meet the requirements of different student groups, special care has been given so that the courses provide adaptability and tailorability features. In the current version of the courses the user/student can specify whether she considers herself to be an expert, or novice in the educational subject, and in computer-based courses, in general. According to this selection, the courses are adapted at different levels, and in particular:

- specific sections of the educational material are presented, while other ones are omitted, resulting into two different courses, an “introductory” and an “advanced” one; the material presented to the student, the respective quizzes and their time limits, etc, are adapted accordingly;
- the help provided at each stage, both for the educational material, and for the user interface, is adapted accordingly; “novice students/users” are provided with more extensive details than “expert students/users”;
- specific “paths”, i.e. course structures are suggested, according to the student’s abilities, background, interests, etc.

Additionally, the user (i.e. student or instructor) can specify the machine capabilities (i.e. slow or fast machine) and the connection bandwidth, so that the courses can be adapted accordingly; for example, in the case of a slow internet connection, or a slow machine, the presentation is adapted so that animation and video files are not downloaded, and the presentation is text-based. Alternatively, the student can specify through the “preferences” function that a text-based presentation is preferred, independently from the network connection or the machine capabilities.

These parameters are explicitly specified by the user upon initiation of each “educational session”, through a respective dialogue box. Alternatively, they can be inserted to the system through the “preferences” function. It should also be noted that, for the cases that the student does not specify any set of parameters, there is a “default” set which is used for the selection of the appropriate adaptations.

5. Adaptivity [2]

For each student interacting with the system a log file is created, containing information at the “interaction level”, and at the “educational level”. In particular, log files contain:

- “low-level” lexical information, concerning the student’s interaction with the objects comprising the user interface, such as push buttons, fill-in forms, etc;
- as well as information at a “higher-level”, such as the sections that have been visited by the student, the quizzes taken and the respective results, etc.

In the current version of the courses, these log files are provided to the instructor as a form of additional information concerning the progress of each student. Also, they are used by the system, in order to provide some adaptive features, such as:

- inform the student that the same sections has been visited many times, and suggest subsequent paths in

[1] It should be noted that, in the context of this paper, adaptability refers to the automatic (i.e. system-initiated) selection / modification of selected aspects of the courses, which are based on parameters / characteristics that are considered to remain unmodified during the same “educational session”, such as the user’s abilities, the terminal type, etc. Tailorability, on the other hand, refers to the student-initiated modification of selected aspects of the courses, through “preferences” function.

[2] Similarly, in the context of this paper, adaptivity refers to the automatic (i.e. system-initiated) selection / modification of selected aspects of the courses, which are based on parameters / characteristics that are considered to be continuously modified during the same educational session, such as the student’s familiarity with the educational subject, or with the user interface of the system, etc. The state of these parameters is determined by an “assessment process”, which extracts this information through monitoring of the student’s interaction with the system [Karagiannidis et al. 1998].

- the educational hyperspace;
- suggest further sources of information, when the student visits the same educational section several times;
- provide extensive help on a specific educational topic, if the rate of correct answers to the respective quizzes falls below a specified threshold; etc.

It is planned that future versions of the courses will also use this information at run-time, in order to extract high-level conclusions concerning the student's progress with respect to the educational subject (e.g. the student has understood a particular section, while she is not familiar with another one), as well as the student's familiarity with the functionality and the user interface of the system (e.g. the user cannot initiate a specific function, or the user is not familiar with web-based applications). Subsequently, it is planned that this information will be used for the selection of run-time adaptations (adaptivity), aiming at enhancing the effectiveness of the educational process, as well as the usability of the user interface.

6. Conclusions and Future Work

This paper has reported on our R&D efforts towards the design and development of advanced web-based courses which aim at assisting existing classes offered by our institution. It has outlined the design methodologies and software tools that have been utilised, and discussed issues relating to the functionality and user interface of the courses. The paper has also presented our current work for the provision of adaptability, tailorability and adaptivity features.

Our current and future R&D work in this field involves the development of methodologies, techniques and tools for the construction of *personalised* web-based courses which can be automatically adapted to the individual characteristics of diverse student and instructor groups; to this end, we investigate the automatic, run-time assessment of the educational process, through the monitoring information contained in the log files created by the courses, and the design of respective run-time adaptations, which aim to assist the educational process; as well as the development of evaluation techniques for adaptive web-based courses, with respect to their effectiveness in the educational process, and their costs.

Also, our current work involves the design, development and evaluation of new multi-metaphor environments for web-based open and distance learning, which enable the full exploitation of the new opportunities provided by the emerging information society applications and services.

Abstract: While developing a distributed infrastructure for personal agents we want to give all kinds of agents a possibility to communicate with their user by means of a central and consistent user interface integrated in their web browser. New agents should be able to join this infrastructure in a dynamic manner without need to change the framework and there should be no built-in restrictions to the complexity of the user interface. We describe a special user communication agent that allows agents to describe their user interface dynamically, display the user interfaces for any number of agents in a special applet and handle remote event delegation. The result is a new kind of ultra-thin client where the web browser and Java Applet merely works as a generic display server.

Introduction

Our research group is currently studying different aspects of software agent systems in a project called CIA [Kargl et.al. 99]. We are developing an infrastructure into which software agents can easily be integrated. In our project all agents belonging to one user form a so called Agent Cluster. This cluster supports the agents with all kinds of commonly needed services like different communication models, persistent storage capabilities, security services etc. The agents are able to communicate via a software bus system called Agent Bus which we implemented on top of the iBus system [Softwired 1999].

For interaction between users and agents we identified a number of possible mechanism:

- Each agent has a local user-interface. The major disadvantage of this solution is that a user always has to be at the computer the agent is running on if he wants to interact with it.
- Each agent has a specific control applet. Now a user is able to control each agent from within his Web Browser. However there is no integration of the different agent user interfaces. If a user wants to control many agents at once he has a lot of windows on his desktop. Interaction between the different agent UIs is difficult as well.
- There's a central control application for all agents that is accessible via an applet. This approach can be found e.g. with most current network administration systems. Agents collect data on all the managed hosts and transmit it to a central management application. The user can attach to this single application using an applet or a standalone user-interface application. This approach works only if you have similar agents running on many hosts. However if your agents are very heterogeneous and new agents with new capabilities and new user interfaces will occur on a regular base, the central control application has to be adapted each time.

- There's a generic display application or applet that is independent of the agent's user interfaces. The agents use the display application to display their user interface and relay user input back.

We have chosen the last approach as we wanted to avoid the disadvantages of the other approaches. It is realized in the User Communication Agent (UCA). This agent handles display of the graphical user interface (GUI) integrated into the web browser, user authentication and many things more. On the other hand, the UCA has no knowledge of the specific details of the different agents in the cluster.

Within an Agent Cluster there is an always changing number of different agents. Each of these agents has different demands regarding its GUI. Some agents may want to display only a simple status message or a text list and have no user interaction whereas others need the user interface of a full scale application with different windows, menus, interactive elements etc. The user interfaces of different agents shouldn't interfere inadvertently. If explicitly needed communication between different components of different user interfaces should be possible. There is a common part in the user interface that's independent of single agents. Functions like listing all active agents, connecting/disconnecting from the Agent Cluster, user authentication etc. fall in this category. This functionality should be realized directly in the UCA without need to reimplement it for each agent.

General Design

The UCA is partitioned into a generic Java Applet that runs in the user's web browser and a server module that connects to the Agent Bus and handles communication with other agents. [Figure 1] shows the principal architecture of the whole system. The details will be explained throughout this text.

Figure 1: System Architecture

For maximum flexibility we modeled our system in accordance to a modified distributed Display-Control-Model (DCM) design pattern [Buschmann et.al. 1996]. The UCA is responsible for the display part. The control and model parts are usually implemented in the agent in form of the GUI Control and the Agent Code itself. For performance reasons parts of the GUI Control may be transferred to the applet in form of Java Beans. Our framework provides for the seamless communication between the parts hiding nearly all aspects of distribution.

In effect the whole system resembles a little bit the X11-system [Scheifler et.al. 1992] with the agent being the X11-client and the UCA being the X11-server. In contrast to X11 our system is written entirely in Java, is completely object-oriented and uses advanced communication mechanisms like software buses and Remote-Method-Invocation (RMI). Another major difference is that we are able to transfer mobile code to the display applet which can be used for enhanced functionality of performance.

While designing the general layout of this model, we identified three major problems:

- The applet must be flexible enough to display any user interface imaginable for any number of agents in parallel.
- The agents need a way to describe the composition and structure of their user interface at run-time.
- User interaction generates events like button pushes etc. that must be delivered to the appropriate agent.

Our prototype implementation of the infrastructure is based on Java 2 so a Java 2 solution to these problems had to be found.

UCA Applet

[Figure 2] shows the applet with an active diary agent displaying its user interface. Each agent is assigned a separate tab where it can display its user interface. As this tab is a general container that makes no pre-assumptions, agents are completely free to build their user interface. They can even spawn new windows that are totally independent of the rest.

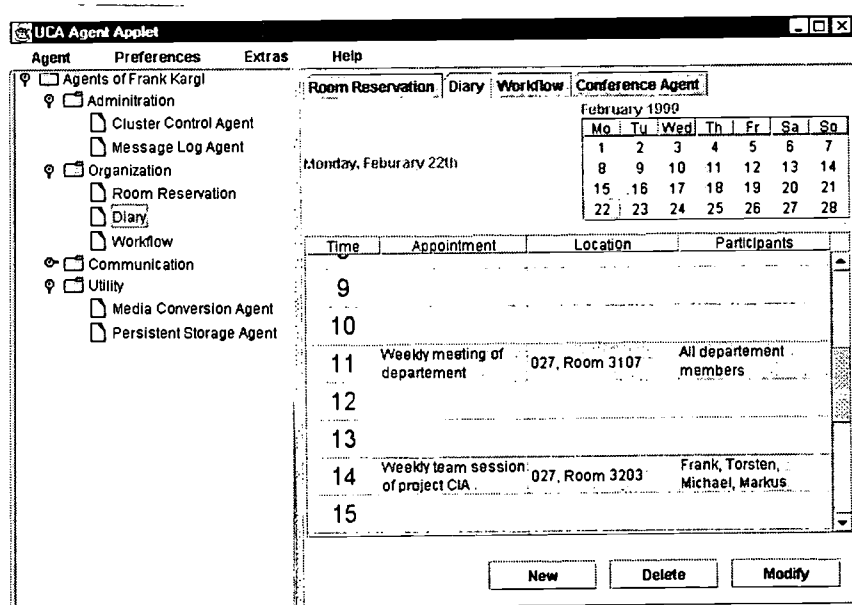

Figure 2: The UCA Applet

UCA Server

The server part consists primarily of two proxies, the GUI and Event Proxy, that translate Agent Bus events to RMI calls and vice versa. When an agent wants to do any changes to its user interface, it generates specific Agent Bus events that are translated to RMI function calls in the GUI Proxy. In reverse direction events generated by the user interface are caught by RMI event-handlers and are then translated to Agent Bus events in the Event Proxy.

Dynamic Interface Construction and Manipulation

As explained above, each agent is assigned an empty container within a tabbed pane in the UCA applet where it can construct or manipulate its user interface. It does so by using our *Dynamic Interface Construction and Manipulation* mechanism (short DICM) which supplies the following possibilities:

- Creating new components using *create()*
- Manipulating existing components using *call()*
- Integrating existing Java Beans at runtime into the applet

All these mechanisms work locally as well as remote via the Agent Bus or RMI. For ease of use we have encapsulated DICM in a complete set of remote components, so a user just needs to build a local component hierarchy that is automatically mirrored and displayed in the UCA applet.

Creating new components using *create()*

Starting from the initial container, remote objects can create new components in the applet using the *create()* call. The call takes three arguments: a base container where the component is added to, the class of the component to create and a name that is assigned to the newly created component. As every AWT component has a name attribute and all components are arranged in a hierarchy, we can access every component starting from a single container. An example usage of *create()* may be:

```
guicont.create("startcontainer.firstpanel", "javax.swing.JButton", "okbutton");
```

This will create a new *JButton* component, name it "okbutton" and add it to the component named "firstpanel" contained in "startcontainer".

Modifying existing components using *call()*

If we want to modify existing components we can use the *call()* method. We need to supply three arguments: the name of the component to modify, the method to call within the component and an argument list to the method. Call invocation is done using the Java Reflection mechanism [Sun 1999]. The following code will set the text attribute in the button created above:

```
String[] args = { "new buttontext" };  
Object result =  
    guicont.call("startcontainer.firstpanel.okbutton", "setText", args);
```

Transferring existing Java Beans

Both *create()* and *call()* work well for small graphical interfaces or slight modifications to existing ones but it is quite cumbersome building large user interfaces this way. Consequently there is a third way for an agent to display and manage complex structures in the UCA: mobile code. A complete user interface or complex subparts

of it can be developed as one or several Java Beans. An agent then transfers the complete bean into a Bean Repository located in the UCA applet and instantiates it as needed. Subsequent method calls to this bean are again done using the *call()* method described above. The transport of bean code to the applet is a quite complex process. In our current prototype the agent transmits the bean code (read in from the class file) to the GUI Proxy via the Agent Bus. The bean is then sent to the Beans Repository in the applet. There's a custom classloader for instantiating any of the beans in the repository.

In a future implementation we will use Java Spaces [Sun 1999] for the same purpose. Beans can then even be stored in a Persistent Object Space (POS) [see Kargl et.al. 1999] and can be retrieved as needed. Beans are instantiated in the applet using a custom class loader.

Remote Event Model

Now that we have constructed our remote interface we need a way to relay user generated events (like menu selections etc.) back to the agent. Starting with version 1.1 Java uses an event delegation model. Components (like buttons, menus etc.) generate events that are delivered to previously registered event handlers. We have extended this model so event handlers can not only be local (that is within the same virtual machine) but also remote event handlers can be used. This requires slight modifications of the standard API (making event handlers throw *java.rmi.Remote* exceptions) but works absolutely fine otherwise. The changed standard API is only used for the proxies and the applet. Agents are developed using the normal JDK. Now an agent simply registers its event handler routine with the respective component in order to get notification of all events generated by this component. There's a event proxy for translating the RMI calls to Agent Bus events, so the remote event mechanism is even independent of the underlying transport mechanism.

We have conducted various performance tests that show the effectiveness of our approach. [Table 1] shows the results measured in calls per second. The first test called *Local Event Handler* creates a component and fires action events to a local event handler routine. *RMI no argument* calls a method using RMI and passes no arguments. *RMI ActionEvent argument* does the same but passes an *ActionEvent* object to the method called. Finally *Remote Event Handler* does the same as *Local Event Handler* but calls a remote event handler routine. All tests were done using 200MHz Pentium Systems running Windows NT 4.0, JDK 1.2. The machines were connected to a local 10 Mbit Ethernet segment.

Calls/s	Local Event Handler	RMI no argument	RMI ActionEvent argument	Remote Event Handler
local	6405	839	372	386
remote	N/A	831	358	358

Table 1: Performance Tests

How can we interpret these results ? Remote event handlers have a potential throughput of about 350 events per second. As the *RMI ActionEvent argument* and *RMI no argument* tests indicate, this seems to be primarily due to the RMI call and marshaling/unmarshaling of the Action Event argument. Using such RMI calls for Event Handlers adds no additional overhead. Although 350 events per second are much less than the maximum of 6400 in a local scenario, it is enough given typical user interface scenarios. Normally events are generated by mouse-clicks and no user will produce more than one or two clicks a second. Even resize events that affect many components at once aren't critical given that there are seldom more than 50 components in one user interface. Our prototype confirms this as an ordinary user can't detect any significant difference between local and remote event handling. If any user interface would get into performance difficulties due to event handling, it can still be integrated into a bean which can be executed locally in the applet.

Conclusion and Outlook

Display systems like the one described in this paper may become necessary whenever you want to control or operate a distributed system of heterogeneous applications (not only restricted to software agents) from within one application or applet. Other agent systems like IBM Aglets / Tahiti [IBM 1999] often don't address this problem, as they only allow the display of user interfaces from agents residing on the local host.

As our work clearly indicates it is possible to realize ultra-thin clients with Java that have practically no application specific logic built-in. Instead they merely represent a highly-functional display server similar to the well established X11-servers. Due to the broad availability of Java enabled browsers our system can be used nearly everywhere. By using a set of remote components, applications can use this "display server" in a nearly transparent manner through an easy to use interface. When transferring complex components to the display application the communication overhead can be minimized.

When realizing the bean transfer and remote event model you often interfere with the security mechanisms in Java applets so policy files are necessary for granting certain rights to the applet. The efficient installation of these policies at the user is one of the unsolved problems yet.

Our next extension will be an even more generalized DICM mechanism so user interfaces described by agents will automatically adapt to a wide range of possible displays like PCs, PDAs or possibly even voice control.

Web-Based Training in Banking and Finance: Requirements and Strategies

Michael Klemme & Joachim Hasebrook,
Bankakademie e. V., Oeder Weg 16-18, D-60318 Frankfurt/Main (Germany),
URL: <http://www.bankakademie.de>, email: klemme@bankakademie.de, hasebrook@bankakademie.de

1 Introduction

Due to the high rate of innovations in products and procedures traditional means of education are not adequate for life-long learning of the banking staff. The short life time of modern financial products requires immediate marketing and therefore quick and complete education of the personnel involved in selling this product.

German banks are expanding beyond their traditional market place. Therefore, the marketplace for educational services in the financial sector will be European and global, with great increases in the quality of education available to the individual at lower real costs per capita than conventional education today. Today, in-depth banking knowledge is needed outside the core financial industry (the so-called near- and non-banks) as well. In order to implement complex financial transaction systems the programmers of financial software need to be trained in the subject matter.

1.1 New means of communication and training

We consider electronically mediated education as a major source for ongoing education in the international knowledge-based economy. Computer, television, satellite, fibre optics and other technologies combine to create a vast interactive communication and information network.

The banking sector is leading in the development and adoption of electronically supported workplace training and is now moving towards distance education and integrated multimedia learning environments to cope with the scale of vocational training and communication requirements. As of today, many distance learning projects are realized by means of conventional media, such as printed matter and telephone tutoring. We consider electronic performance support systems (in the form of on-line media and self-directed learning environments) to be the only effective solution in terms of cost, time and logistics.

From an economical point of view it seems clear that costs can be reduced drastically. Little is known, however, about the effects of tele-cooperation upon corporate identity, learning behaviour, and communication processes (Sproull & Kiesler, 1991). Several studies compared computer conferencing via e-mail, video conferencing, telephone conferences, and personal communication. They ascertained that video conferencing is much more like telephoning than like personal communication. But simple e-mail conferences can provide several advantages as Sproull and Kiesler (1991; Kiesler, 1992) discovered: Personal communication takes less time but electronic mailing leads to agreements more frequently. Additionally, conferencing by e-mail allows for a more symmetrical participation than personal discussions. Banks and their departments for human resources development aim to take advantage of these new technologies.

2 Requirements for Web-Based Training (WBT) in German Banks

Learning to learn and learning to select and process information effectively will be key skills in the information society. Major objectives for new learning environments are: supporting and understanding how to cope with a rapidly growing amount of information, helping to manage the learning processes, supporting active, self-paced learning, and finding effective models for assessment and evaluation of the learning and teaching processes. The research on constructivism and situated cognition supports the idea of a new role for teachers and interactive learning systems. The main idea of constructivism and situated learning is learning as an active construction of knowledge instead of passive absorption of knowledge. Additionally, physical and social aspects of the learning situation have to be considered (an overview is provided in Duffy & Jonassen, 1992).

All media provided in the learning process should be linked to well defined learning goals, pre-knowledge of the students, and appropriate amounts of information. Positive pedagogical effects can only be elicited by the

careful use of multimedia: New technologies solve technological problems, but they do not solve pedagogical problems. We can take advantage of new technologies by transforming the traditional classroom setting and initiating a smooth transition from classroom settings to fully interactive electronic learning environments using digital TV, World Wide Web, and electronic feedback devices as a technological basis. The benefits of this approach are:

1. By eliminating travel and lost production costs, we can reduce overall training costs.
2. By creating virtual classrooms, we extend single learning facilities to an integrated international learning environment.
3. We foster on-the-job training to reduce the amount of time spent away from the job and thus help to improve worker productivity.
4. By making training more timely and accessible, we increase skill transfer and improve effectiveness.
5. By providing managerial expertise, we can track and store training information and multimedia material for the corporations.

This new approach to learning needs to be reflected in the infrastructure used for education. Traditional Computer Based Training (CBTs) provide self-contained learning environments and often strong guidance for the user (e. g. by providing learning paths based on tests). In the open world of the Internet and corporate Intranets this strategy is no longer enforceable. Furthermore, external resources, such as real-time data and corporate manuals can be integrated into the learning process. But even more interesting is the integration of learning into every-day work: Education is available on the spot and will be integrated into other information resources.

Communication is an integral part of learning. This was widely neglected by many CBTs (where the learner could only "talk" to the program). Since the learning system is part of the Intranet infrastructure it can easily interface with communication systems such as electronic mail and discussion boards. As part of the Intranet the system has to integrate into the design style guides. It is desired (and often strictly enforced) that most of the applications found in the Intranet provide the same basic structure and design (e. g. style guide and corporate design).

Most of the bigger German banks have been working to establish corporate Intranets for quite some time. These networks are slowly evolving from a domain of the IT departments to a widely available resource with a unified user interface and structure, and central organization. They are slowly getting accessible to people outside the corporate headquarters, although bandwidth outside the headquarters is still a major issue.

It is still undecided where the employees are supposed to learn. One of the main advantages of WBT often cited is its ubiquitous availability allowing employees to learn during their breaks or in off-peak time at their workplaces. We question that those short intervals will be appropriate for effective learning. Rather, we suggest allocating longer and uninterrupted periods of time for first time learning. Some banks have installed learning computers in their major branches where the employees can retreat for learning a subject the first time. The refreshing of knowledge, however, can ideally be done directly at the workplace.

3 First Systems and Results

Bankakademie is a non-profit organization with a membership of about 3.500 German banks and key player in the educational market for the German banking industry. We were asked by a major German commercial bank to study the requirements and effects of Intranet Based Training. It included a study of the previous situation, a prototypical implementation of a course on currency management and the evaluation of a first group of 80 learners. The system was based on an early beta version of the Hyperwave Training Space (formerly known as GENTLE, Dietinger, 1998), an application that runs on top of the Hyperwave Information Server (Maurer, 1998).

Content and Design. The general layout and design of the system had to be adapted to the corporate Intranet. It turned out that the existing Intranet style guide was not fully applicable to the new learning system, since it was targeted on systems for information consumption rather than learning and communication. Therefore, a modified style guide for WBT was developed and approved. The system is fully integrated into the Intranet: It features as part of the bank's "Virtual Learning Centre" and can be accessed from any computer within the bank.

The content was developed by a CBT author in cooperation with the subject expert group. The pages were the programmed as normal HTML pages containing Java and JavaScript interactions. On request of the bank, the content is quite "CBT-style": There are questions and interactive images on about every second page. Due to the anticipated bandwidth problems we refrained from integrating video. Audio was only used in communication

exercises.

Online Evaluation and Testing. Every module came with a test. Taken as a pre-test, it allowed the students to assess which modules they needed to see. Taken as a post-test, it showed the students whether they had understood the content of this module. No automatic actions such as prescribing a certain learning path were undertaken, for privacy reasons the test results were not stored. A short evaluation questionnaire was offered on-line after each module. The students were asked whether they regarded the module as appropriate and how they rated the quality of the material. The summative rating of all fellow students was displayed with the questionnaire.

Notes and Forum. As mentioned above, the integration of communication facilities is one of the main advantages of WBT over classical CBT. Communication was realized by notes and forums. The student could add a note to any point of the text (Figure 1). Every note could be labelled *private*, to be seen by the student only, *learn-*

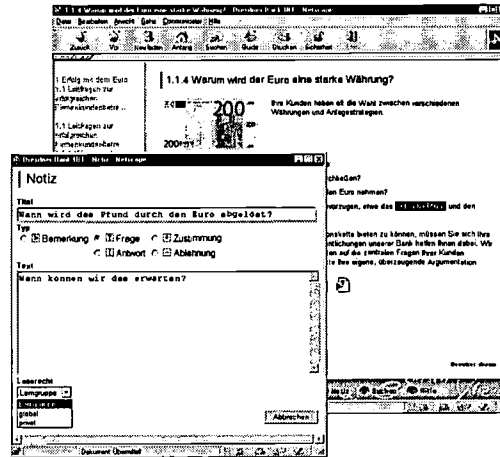

Figure 1: Note taking on-line: The note is connected to the highlighted text area.

ing group, to be seen by the student and his virtual learning group or *public*, to be seen by all identified users. It is one of the main features and advantages of Hyperwave that all pages are personalized on the fly: Every student is presented with the notes he is supposed to see, at their defined positions. Every note is typed. For the prototype we defined *remark*, *question*, *answer*, *agreement* and *disagreement*. All notes marked as *question* are automatically forwarded by email to the tutors in charge of this module. The tutor can then jump directly to the page in question and enter the answer directly into the system. In a future system the students will be informed by email on every response to their note. During the prototype test this was not possible due to privacy requirements of the contestants.

All notes tagged as *learning group* or *public* are automatically integrated into the forum of this course. This allows for an overview of the activity within the course and shows which answers have already been answered. It turned out that the notes are a very valuable tool for the long-term maintenance of the material, since the notes are directly connected to the passage that was wrong or mis-understood.

Search and Background Library. The entire system can be searched. All HTML pages are indexed in Hyperwave's built-in fulltext server. Only the text that appears in animations (i. e. presented by Java applets) cannot be searched. Since notes are documents stored within Hyperwave, they can be searched as well. Students can either search the current lesson or the entire CBT. Each lesson can be complemented by a background library that contains additional material, such as the text of the relevant laws, corporate handbooks, etc. Section 5 illustrates this in detail.

3.1 Results

Different groups of altogether 80 users, each working with different versions of the bank training system, participated in the study. Two traditional two-day seminars were surveyed to compare traditional and Intranet learning.

The evaluation indicates that Intranet-based training equals or is slightly superior to classroom teaching-tak-

ing only 50% of the study time of classroom learning. The learning results did not differ substantially for the different settings tested. Additionally, we examined the following factors:

- Self tests and surveys were presented with and without direct feedback. Providing direct system feedback for inputs into surveys clearly supports the acceptance of the respective facility.
- The learners were either asked to read all pages in sequential order (sequential learning) or to decide if and what to read after studying a summary and doing a self test (selective learning). Furthermore, the learners were asked to work on their own or to collaborate in a five-person learning group. The learners preferred a traditional learning style, that is sequential and individual learning.
- Half of the students were presented graphs and animations with additional explanations, which are provided as additional texts or audio files. Using sound and animation marginally enhanced acceptance ratings and test scores.

The analysis of the users' notes and the module surveys revealed that the content was too specialized for some and too general for others. The course will be re-structured to cater for the different learning needs and was rolled out for a larger trial with a target audience of 1.500 employees in July 1999.

4 From CBT to WBT and KM

CBT has been around for quite some time and is widely employed. However, there is a need to integrate CBT into a larger management framework in order to distribute and use it over networks.

First standards for interfacing traditional CBT are emerging: The *Aviation Industry CBT Committee*¹ defined standards for interfacing CBT modules to a management system and to each other. The IEEE and the European Union are jointly developing standards for meta information for computer mediated instruction². This shows a trend towards integration of small CBT units into a greater framework. However, these structures can only handle on a very coarse level of granularity. But this is exactly one of the strengths of the World Wide Web: different documents can relate to any other document within the Intranet or the world-wide Internet. WBT allows for better adaptability: Different target groups may use different parts of the same training material. Easy and unified access mechanisms (e. g. by search engines and directories) allow for immediate access to the entire corporate learning resources.

Systems are under development that aim at integrating and controlling the entire corporate learning process, from training needs analysis to production and deployment on a general level as well as registration, budgeting, and the training itself on the personal level. The system Columbus by Deutsche Bank is a first system of this kind and will be deployed soon. The investment in traditional CBT will need to be preserved by integrating them into the new learning architecture. But on the long run we expect this technology to be replaced by true web applications (see section 4.1). The other trend is the integration of many resources into corporate Intranets and the unified administration and access mechanisms as part of the Knowledge Management (KM) cycle. As will be demonstrated in section 5 below, training resources will be an integral part of these networks. Therefore, we have to make sure today that the interfaces of our systems are open to be integrated into these frameworks.

4.1 Migration of Content and Infrastructure

Most of the traditional CBTs have been developed by multimedia authoring systems. A large number of developers have been trained in using these systems and large libraries of components have been developed. The supporters of these systems propose integrating the CBTs as downloadable modules into the Intranet. For example, Shockwave is a file format that can be generated by the authoring system Macromedia Director. These files can then be loaded from an Intranet server as any other document and displayed by special add-on programs (plug-ins) to the users' Web browser. This preserves the investments into the CBT, it can be fully re-used in the Intranet. Specialized servers, such as Asymmetrix Librarian provide a framework for the delivery of these modules. However, there are a couple of disadvantages connected to this approach:

- There is not one single standard for CBT delivery. Different authoring systems produce different file formats and require different plug-ins.
- Plug-ins are generally not favoured by the corporate IT departments, because they are seen as additional cost

[1] <http://www.aicc.org/>

[2] IEEE P1484.12 Learning Objects Metadata Working Group (<http://ltsc.ieee.org/wg12/index.html>)

for system maintenance.

- These modules are usually quite large. They have to be loaded entirely before they can be displayed.
- The content of these modules generally cannot be indexed by search systems and therefore does not integrate into the overall infrastructure. If the modules are indexable then the single units of information (screen page) are not directly accessible to the interested user (imagine pressing "page forward" 100 times before you reach the needed page).

In a project for GMAC European Operations,¹ Bankakademie and Raytheon chose a different way. The CBT

Figure 2: Table of Contents for GMAC CBTs. The traffic lights indicate the learning progress.

content is produced as HTML pages (including JavaScript and Java animations and interactions) and then installed into the Hyperwave Training Space. In the near future, the training modules will be available in 5 languages and centrally administrated and maintained within the server. The pages are then extracted by a special tool from the Hyperwave Training Space (taking advantage of the personalization features of Hyperwave). Some special features, such as bookmarks and a search engine have been implemented using Java and JavaScript. This conglomerate is then transferred onto CD-ROM. The end-user can access the CBT by a standard Netscape browser.

As soon as the corporate Intranet will be ready, the learning system can go on-line right away. Communication features as described earlier can be added at this point. There is no need for changing the content pages. All necessary changes will be done within the Hyperwave framework.

5 Integration into Knowledge Management

The integration of Intranet resources into education is not a one-way process. There is not a separate educational framework available in future Intranet designs, but the education modules are integrated into the information interface. Learning is tightly integrated into the personal working environment.

Bankakademie is pursuing this idea by integrating its educational resources with other available material into one unified system of delivery. Bankakademie's printed base material is a 4.500 page loose-leaf body of material called "Studienwerk". This work has been converted to SGML and is now available for Intranet use. Based on the consolidated index of Studienwerk, we are developing a hierarchical thesaurus of banking knowledge. Into this thesaurus other materials of Bankakademie will be integrated as soon as they are available. However, this structure is open for other materials such as bank-internal manuals and handbooks. Additionally, a full-text search will be available for all materials. The users can personalize the material by adding notes and bookmarks.

As stated above, this architecture has to be open for the integration of resources of divergent origins. Formats based on open standards such as SGML and systems that preserve content structure and meta information (such as Hyperwave) guarantee that the content developed today can be re-used in future systems.

Examinations and self tests are another area of our activities. In the process of dealing with over 12.500 students a year, huge amounts of exams and other testing material is produced and distributed. We developed the

[1] General Motors' financing subsidiary for Europe, e. g. Opel-Bank in Germany, Vauxhall Finance in Britain

question and test database CertiFire[®] to streamline this process. CertiFire comprises three modules: authoring, administration and testing. Most of the questions can be evaluated automatically, but we also provide essay-type questions that have to be evaluated by the students themselves or a tutor. Every question can be assigned to multiple contexts, described by mode, target group and subject area, but it only has to be maintained once. Based on these contexts exams or self-test modules can be generated. These tests can be delivered in four different ways:

- by our electronic testing environment on a (stand-alone) Windows PC, all results can be fed back into the administrative database;
- via a CGI program through any browser, the results are fed back into the database;
- by a Java applet that retrieves exam files from a Web server;
- on paper (still requested by many of our customers).

Therefore, tests generated by CertiFire can be integrated directly into the learning environments described above, without creating additional administrative costs. An evaluation study conducted in 1998 examined the impact of Intranet-based testing and simulation tools within a bank training framework. The results of the study confirm that using testing and simulation tools does not affect the actual test results in comparison to paper-and-pencil work. The use of multimedia tools, however, was able to enhance acceptance judgements and self confidence of the users.

6 Future Work

Future research has to focus on the interaction of key aspects of learning. This implies that simple experimental settings, which aim to study main effects, such as comparing two types of media, are not too promising. Relevant advances in networked multimedia computer environments will emerge, if recent results of basic research are applied explicitly and the evaluation criteria meet the demands of the practical use of computer environments. Furthermore, the necessary network infrastructure is not in place yet. If existent, it is often inappropriate for "full multimedia", including audio and video. But nevertheless, it is possible to develop and deploy the module of the new architecture already today. Systems and standards have to be open for the likely case that our ambitions will outgrow the systems that we are developing today. For the future we do not expect to see CBT in a new networked gown, but as an open, adaptable and extensible platform, that allows for integrated learning, information, and communication services.

jCentral: Search the Web for Java

{Reiner Kraft, Gabi Zodik, Daniel Ford, Ron Pinter, Dirk Nicol} IBM
{Qi Lu, Matthias Eichstaedt} Yahoo

Abstract: jCentral (<http://www.ibm.com/developer/java>) is the largest repository of Java resources on the Internet. It provides advanced, Java-specific search, orientation, and notification services for application developers to locate and subsequently use Java resources such as applets, beans, source code files, newsgroup discussion articles, FAQ's, and other related documents. We present the design and implementation of jCentral, and offer insights and highlights from the experience we have gained so far.

1 Introduction

Java has become the language of choice for application development. It has also emerged as a possible open environment for component-based network computing due to its platform independent bytecode standard and built-in support for programming applets (small applications that can dynamically migrate over the network and execute on the fly on the user's client machines). Java has also benefited tremendously from the explosive growth of the Internet: unlike any other programming language, information and artifacts about Java such as manuals, FAQ's, source code files, are widely available on the World Wide Web in large amounts.

Furthermore, the combination of the world wide accessibility of the Internet and the abundance of Java artifacts on the Web has given rise a historic opportunity to address the challenge that has faced the software engineering community for decades: how do we effectively locate, trade, and reuse existing software artifacts to significantly improve the productivity of software development? A number of online Java resources web sites, such as Gamelan, Java boutique, and others, have been developed. However, these sites rely on users' submissions as the basic means of obtaining their Java resource repository, and are thus unable to include the vast amounts of useful Java resources that are out there on the net. In addition, they typically provide only textual search and retrieval facilities that are insufficient for Java developers to accurately find the classes/applets they can use, or the source code they can look at as examples. For example, a programmer looking for a radio button applet or a sort method with a certain parameter-result signature, would like to express his or her query in such a way that resources that are directly related to these concepts will be matched by the search engine based on their content and usage context, not just the appearance of certain strings in their descriptions.

jCentral addresses these challenges by providing the Java developers community with a comprehensive online Java resource center targeted to the specific attributes of this domain. Currently, jCentral is the largest Java resource center containing almost every Web accessible Java applet, Java source code file, Java bean, Java newsgroup article, and any other Java related document, such as FAQ's and product news, that are available on the Internet. It is designed to find and store information about an unlimited amount of Java resources, to offer an effective, extendible, and Java specific search engine, and to help the user evaluate some important attributes of the resources it finds. It knows how to find Java related resources by means of content directed crawling, it provides a mechanism for contributors to submit their own resources in addition to what is available through regular crawling, it features an innovative user interface to describe Java resources in a domain specific fashion, and it offers ways to view the resource it find in context so to enable their effective usage in the user's application.

The jCentral project started in the summer of 1997 and our site was officially launched at the JavaOne conference in March 1998. Since then, we have received an overwhelmingly positive response from the Java developer community. This paper is a first-hand report about both the technologies behind the jCentral site as well as insights and experiences gained on how jCentral is able to help Java developers to find the Java resources they need and enhance their productivity.

2 System Architecture

The jCentral system consists of three main components, the Java resource gathering facility, the Java resource repository, and the search/notification/navigation frontend. This section will describe the overall functionality and structure for each of the components; and highlight the technical challenges in the development of those components. Specific technical details will be provided by subsequent sections.

jCentral's Java resource gathering facility is built upon the IBM Grand Central Station (GCS) System. GCS inherits the distributed Gatherer/Collector architecture pioneered by Harvest. Each Gatherer functions as a much extended crawler that gather and summarize resource from a variety of data sources, such as Web server and database servers, in a variety formats such as HTML and relational database tables. jCentral extends the GCS Gatherer with mechanisms that are specific to the needs of gathering Java resources over the Internet. Among the many technical hurdles we have to overcome, the following two challenges stand out. The first is how to efficiently gather Java resources from the Internet where there are more than three hundred millions of Web pages. Second, Java resources such as Applet and Beans are linked to the Internet in special structures much more complicated than normal HTML pages. We must develop new techniques that can systematically discover and collect all publicly accessible Java resources on the Internet. Detailed discussions on these issues are in section 3. Large-scale resource gathering is only the means of building up the jCentral Java resource repository. Note that the jCentral repository does not directly store the original content of the gathered resources. Instead, for each Java resource, whether it's an applet, a bean, a source code file, or a newsgroup article, we create a meta-data stored in the XML format that contains salient features useful for searching Java resources. The technical challenge here is developing analysis mechanisms that can understand not only the data format of the each of the Java resources but also the semantic relationship among different resources so that meaningful and descriptive features can be automatically extracted and stored in the repository. Section 3 will discuss the specific details.

Even with a large collection of Java resources, how to enable users to conveniently and effectively search and locate the Java resources of their interests or needs still presents plenty of challenges. First, Java resources such as applets and beans are very complex objects, where simple text search will not be sufficient in finding accurate Java resources. jCentral designed new advanced search facilities that allow Java developers to query resources with Java specific feature constraints. Second, multiple Java resources, although may physically be located on separate servers or container files, can be semantically related to one another. For example, the class and sources files of a popular applet (e.g. the lake applet) can appear on thousands of Web pages. When the user finds one of them, it is highly desirable that there are mechanisms to help guide the users to locate other resources that are related in some ways. Finally, the Internet and online Java community evolves at a rapid pace. Even if the Java resource sought by a Java developer in jCentral does not exist in resource repository, it may show up the next day as jCentral crawls the Internet continuously. Therefore, jCentral offers a notification service so that the Java users can simply tell what resources they are interested in and jCentral will automatically notify them via email as soon as one matching their needs is found. The technical details of the jCentral searching, navigating, and notification mechanisms are presented in sections 3, 4 and 5.

3 Java Resource Gathering

Efficient large-scale Java resource gathering faces the following two main technical challenges. First, we need to be able to control a collection of distributed gatherers and direct them to destinations that tend to lead to Java resources. We address this problem with a scalable distributed team crawling scheme [3] that prioritizes the discovered links to quickly get to sites that contains Java resources. Given the relatively low percentage of Java relevant sites, our gatherer dramatically increases crawling efficiency by prioritizing the URLs before actually accessing the web pages.

Second, the gatherer must be able to follow the Java-specific links such as applet class references to chase and gather relevant resources. This problem is solved by integrating a specialized Java resource analyzer into the gatherer. This analyzer understands the structure of each kind of Java resources, applet, bean, source code file, or a Java newsgroup article.

3.1 Java Resource Analysis

For each gathered Java resource, jCentral runs through an analysis phase to extract all the key features and store it an XML meta data file in its repository. jCentral includes four main analyzers for the following types of resources: Applet, Bean, Source and News.

3.2 Search Interfaces

The jCentral resource repository consists of a variety of contents from simple text documents in Java newsgroup articles to complex objects such as a Java bean. Therefore, the traditional textual keywords-based query interface is not sufficient for the users to quickly and accurately find the Java resources they want. jCentral's approach is to provide a suite of search facilities that can address different aspects of the users search needs.

The jCentral user enters a query from its Web Browser in a HTML form. There are currently three types of HTML based forms available:

1. Basic Search (<http://www.ibm.com/developer/java>)
2. Power Search (<http://jcentral.alphaworks.ibm.com/power.htm>)
3. Advanced Power Search (<http://jcentral.alphaworks.ibm.com/powersearch.htm>)

Basic Search

The Basic Search provides only one line for text input and looks similar like other search engine's user interface. Boolean operators and other common search primitives are supported (wildcard search, stemming, etc.) [8].

Power Search

The Power Search allows the user to search using Java specific search attributes. The form is divided into five categories where the user can search in (Applets, Beans, Source Code, related newsgroup articles and other Java resources).

4 Notification Service

The notification service allows registered jCentral members to submit a persistent query and monitor the Internet for new Java resources. Each resource type belongs to one of the five channels Applets, Beans, News, Java Source and Other Resources and enables users to set up a fine-grained interest profiles. The following user profile gives an example of a typical subscription profile.

Applets: Network or 3D or VRML or proxy

Beans: Enterprise or database

News: e-commerce

Java Source: Jdbc or class loader

Other Resources: Servlet Express

When a sufficient amount of new resource items has been collected, the system sends out e-mail summaries showing any matches for the interest profile.

The foundation for our information dissemination technology is a scalable webcasting system [4], [5], which is able to efficiently match diverse data against a large set of user profiles. The heart of the webcasting system is the profile engine, which maintains a large profile database and matches any incoming data item against all user profiles. Data satisfying certain profiles is temporarily stored on disk until a notification message has been mailed to the user. The key concepts of the profile engine are the compact representation of the user profiles and the efficient evaluation algorithms. Internally, the profile engine represents each user profile as a graph where the Boolean operators of the profile language are mapped to inner nodes and the text predicates are mapped to leaf nodes of the graph. The graph structure parallels the logical structure of the Boolean profiles. The profile engine absorbs new subscribers without severely degrading performance because text predicates and common sub-expressions are shared among all subscribers. The user profiles from our current deployment shows that users have shared interests. After reaching a certain scale, most common interests are represented in the system. As a result, the performance degradation incurred by admitting new users will be limited.

The matching algorithms dynamically monitor the evaluation process and adjust to evolution in the digital content. This allows the system to sustain high performance over time. To be able to process all collected data items in a timely manner the profile database can be partitioned and distributed across multiple machines.

5 jCentral Class Navigator

The Class Navigator is a tool for visualization of the search results. This tool, implemented as an Applet, visualizes many additional relationships of the selected result compared to regular search engines. Among these is the class hierarchy, reference relationships, and various OO class characteristics. All this information is presented to the user in a compact way, creating a comprehensive understanding of the results.

5.1 Motivation

The following reasons have led us to integrate the Class Navigator as an additional means for visualizing search results. First it provides the user with all the information required, in order to allow him to reach a Go/No

Go decision as fast as possible. The second advantage of this tool is the ability to navigate the very large repository of classes available in jCentral. Third, the Class Navigator is capable to present the inter-results relationships to the user.

6 Experience

Over the last 6 months the jCentral repository has been continuously grown in terms of content. From an initial size of 100,000 Java resources it went up to over 350,000 Java resources (Java Applets, Java Beans, Java Source Code, Java related Newsgroup articles, and other Java related resources) by the beginning of October. For this reason we were able to gather a lot of feedback, experience and data of the queries the user issued as well as interesting facts about the Java resources currently out on the web.

Typically all traffic on a web site is logged into some log files of the web server. We developed some tools to extract this information out of these log files and transform the user queries into a computer interpretable format (based on XML) and store these in a database so that we can use to create interesting statistics about the user behavior. This

section presents statistical material about the current jCentral repository and also about the user queries we experienced during the last six months.

6.1 Repository statistics

In this part of the chapter we will present information and interesting facts about the current jCentral repository as of beginning of October 1998.

Distribution of categories in repository

The repository consists currently of 358,120 Java resources. These resources are distributed in the following categories:

Category	Number of resources
Java Applets	35,198
Java Beans	209
Java source code	86,298
Java related newsgroup articles	235,415
Other Java resources (white papers, tutorials, etc.)	767
Submitted Java resources	364

An interesting fact is that the Java source code is dominating. We didn't expect that there's so many source code available on the web in relation to Java applets.

Size of Bytecode (Applets)

After compiling Java source code the result is called bytecode, which is an intermediate format used for the interpretation of the Java virtual machine. Typically applets tend to be very small in size. These statistics presents the minimum, average and maximize size of the bytecode (measured in bytes) which is currently in our repository.

Minimum size of bytecode	343 bytes (0.3 Kbytes)
Average size of bytecode	4,519 bytes (4.4 Kbytes)
Maximum size of bytecode	142,668 bytes (139.3 Kbytes)

Classes used per Applet (associated classes)

A Java applet is a class file, which will be downloaded into the users web browser and there executed within the browser's environment. An applet however need not necessarily exist of only one class file. There can be many class files involved, which build together the applet. Class files can be bundled and distributed using a JAR archive file format (similar to the UNIX tar utility). The browser will download this archive and execute the main class and the associated classes.

Average number of class files per applet: 2
 Maximum number of class files per applet: 29

Copyright protection

Some of the people who put their applets, beans or source code on the web want to have their copyright rights protected. Whereas there are other developers who are not concerned about legal issues. We were interested about the more general trend whether developers care much about copyrights when they make their intellectual property available public on the web. Note that jCentral in the case there's a copyright notice only exhibits general properties of this resource (title, description, etc.). However, for non-copyright protected resources it will present

the full information, which is available from the bytecode or source code. An interesting result is that less than 10% of Java developers are concerned about copyright issues. The percentage of Java applets found with copyright protection is 7.8 %.

Distribution of network domains

Another interesting aspect is the distribution of the Java resources (Java Source Code, Java Applets and Java Beans) within the top level Internet network domains (.com, .edu, .gov, etc.). It turned out that most the Java resources are hosted on academic and educational organization's servers (almost 40 %). Commercial sites do only host around 12.5 % of all Java resources of the jCentral repository. The rest is distributed almost equally (around 0.5 to 2.0 %) to the country domains. To mention here is that Japan, Germany, Austria, UK and Canada have a higher percentage than other countries. Note that these numbers only represent the distribution of the jCentral repository.

Category	%
.EDU	38.9
.COM	12.5
.JP (Japan)	7.2
.DE (Germany)	6.1
.AU (Australia)	4.4
.UK	4.3
.CA (Canada)	3.6
.GOV	2.6
.NET	2.3
Miscellaneous	18.1

1.1 Top 20 frequently used keywords in search

An interesting aspect is analyze what kind of keywords the users are looking for. Surprisingly the most used keyword in all searches was Java, since this is a Java only repository. The following keywords have ranked in the top 20 places : java, jdbc, servlet, applet, swing, rmi, for, html, visual, file, server, image, database, sun, visualage, notes, text, beans, francisco, search.

2 Future Directions

jCentral, as described in this paper, has already changed the way many Java application developers work. Rather than hunting for resources in a manual and unfocused manner, using inappropriate search engines and inadequate result viewing mechanisms, they can now direct their attention to the subject at hand and use the resources they find in an effective manner. Both our scaleable design and effective interfaces position jCentral as a robust framework that will serve the Java community well for quite some time.

There are several directions we are pursuing as a continuation of this effort. In many ways, jCentral is the first step towards an integrated web based application development and resource management environment for Java. Once found, resources can be filtered (according to a variety of criteria) and integrated into the user's applications. Tracking of enhancements, bug fixes, and other changes can also be made part of such an environment.

In addition, several other aspects of the repository can be enhanced to provide services found in search engines and sites that cater to other domains. First, a classification of resources according to evolving taxonomies is desirable; this will have to be done in an automatic fashion, given the sheer size of the domain, and requires some further research. Other services include facilities for trading components and establishing ways to e.g. charge for royalties of licensed resources. Finally, similar systems directed towards other domains can be constructed using the concepts and techniques from our design.

Abstract: This paper focuses on the impact of the Internet in relation to our understanding of geography. The growing reach of the Internet will soon see total global coverage. This relegates geographical barriers to secondary concerns when establishing sociopolitical and economic linkages. However, the question of whether geography will cease to matter is still unresolved. To answer this, the rise of the Internet is discussed from a geographical perspective. The paper then considers the Internet's impact on the way we conduct business, form communities, and establish new political identities. The discussion concludes with a call for greater geographical analyses of the present and future impacts of the Internet.

1. Introduction

"Soon geography will be irrelevant. Our ability to manipulate technology will play a larger and larger role in determining where and how we live." (Ogden, 1995, pp. 25)

The veracity of Ogden's prediction is a matter of debate, but it is a fact that the Internet questions our traditional notions of geography. Indeed, as reported by ABCNEWS.com on October 13 1998, Tristan da Cunha, the remotest inhabited island on Earth has an Internet connection ([ABCNEWS](http://ABCNEWS.com), 1998). No other communicative medium has as great an impact in as broad a scope, in the way we conduct our lives, as the Internet. It changes the way we interact with other people, establish relationships, conduct business, educate our young, form communities with common interests, and even travel the world. In each of these aspects, traditional concepts of geography are being complemented, and at times replaced, by a newer notion of the connected world. At one extreme, the Internet is seen as the ultimate form of democracy, bringing individuals from different backgrounds into the leveling field of electronic communication and network. Yet, many sayers caution of the social ills of retreating into electronic cocoons, claiming physical interaction and socialization are necessary elements of community survival. Underlying these opposing views is the changing dynamics of our understanding of place, space and geography.

The task of understanding the impact of the Internet on geography is an onerous one. Unlike the influence of other technologies, the Internet is a rapidly evolving medium. Though it boasts a history of several decades, its direct impact on humanity spans less than five years. Hence, studying its impact requires a flexible approach, where conclusions of today become historical artifacts of tomorrow. But, some form of preliminary analysis is necessary lest the rapidity of change and the growing ubiquity of the Internet leaves us in its wake. Mapping its history, growth and influence in several key aspects in the way we conduct our lives will indicate how the Internet is affecting and shaping our notions of geography.

2. The Internet

Vinton Cerf, in the foreword to Gilster's (1993) book defines the Internet as

"a virtual space of software, networking, and computers, the Internet is infinitely renewable and infinitely adaptable, and it grows and changes every day." (Cerf in Gilster, 1993, pp. xix)

This definition encapsulates both what the Internet is and what it can become. Underlying the concept of the Internet, though, is its interplay with geography. The Internet can be seen as redefining our traditional notions of space. It creates a more dynamic form of connectivity, where proximity is a function of electronic linkages rather than physical distances. To understand how this fluid concept of space affects us now and in the future requires looking briefly at the rise of the Internet.

The history of the Internet began well before the notion of an interconnected global network of computers. In one sense, it is the culmination of developments beginning with the discovery of mathematics. In another, it is a way station in the progress of computing, before a new and fundamental change in telecommunication occurs. This can be seen from the different versions of the Internet's history found in cyberspace.

However, for the purpose of this discourse, the Internet's history can be traced to the development of the ARPANET in 1966 (<http://www.darpa.mil>). Devised as a command and control network that can survive the possibility of a nuclear strike, it used geography as the key to its functionality and feasibility. Hence, from the very beginning, geography played a critical role in the development of the Internet. The early concerns were issues of overcoming distances via computer networking to enable time and resources sharing among scattered mainframes. The main aim was to ensure effective communication even in the instance when one or more of the nodes in the network ceased to function. Geography, therefore, played opposing roles in the formation of the fledging Internet; a barrier to overcome for the parts, but yet an asset to utilize for the effective operation of the whole.

While the ARPANET laid the foundation of the Internet, the latter only took off when it filtered into the public domain. Much of this transition from predominantly military and academic applications of the Internet into general use is attributable to the development of World Wide Web in 1993 (Reid, 1997). This interactive medium coupled with growing commercialization and rising popularity of personal computers captured the imagination of businesses and individuals alike. The Internet afforded access to geographically scattered collections of data, information and resources. Today, examples like the call by Hans Lombardo (1999) for businesses to leverage the power of the Internet to fast-forward Asia's economic recovery attests to the rapidity of its growth and its importance in our lives.

3. The Internet and Geography

Soon, if it has not already, the Internet will affect our lives to a greater degree than any other technological development. One of the profoundest effects of the Internet is the modification of our accepted understanding of geographical concepts. It is equivalent to the opening of new horizons when the ideas of Renaissance thinkers superseded Plato's version of a flat earth. To understand the impact of this change in how we relate to geography, one must analyze the effects of the Internet in the way we conduct our lives. The Internet's impact on the sociopolitical and the economic realms can provide us with clues to the evolution of spatial concepts and how we employ these new ideas into our world-view.

Perhaps the most visible application of the Internet is in the business sector. Once, when business cards were the norm, today, web sites are a must for commercial survival. Electronic commerce is accelerating credit card transactions and hastening the demise of paper money transactions. Electronic trading is also changing the face of the stock market. Indeed, much of the tremendous growth in stock values is centered on the high-tech industry. Despite recent leveling off of Internet companies stocks, investors are preparing for higher gains in this industry. The offshoot of conducting businesses online, with the attendant online banking, is that geographic locations of neither the customers nor the sellers are of importance. Of greater concern is the security with which such transactions are conducted. Therefore, access to the Internet is beginning to replace specific locations as one of the primary factors for effective business.

The global coverage that telecommunication conglomerates are seeking to provide the individual, together with new technological aids such as the Wireless World Wide Web (<http://www.w4.org/>), allow business transactions to be conducted from variable locations. It also opens a larger customer base that companies would otherwise not have access to. The limits of purchasing goods and services used to be bounded by the physical distances between the producers and the purchasers. The Internet relocates these limits, especially when such goods and services can be accessed via the Internet. For example, computer software can be ordered, paid for and be delivered via electronic means, without the need to leave the comfort of one's home.

By that same token, the Internet also allows certain industries to decentralize from office spaces to home offices. Telecommuting, virtual teams, flexible work plans, and temporary professionals are becoming the new workforce in the Internet era. Large, multi-site global companies in information-rich industries are taking advantage of transboundary professionals to complete tasks at faster and cheaper rates than using in-house staff. Ogden (1995) wrote how the first of these virtual employees were British software developers who offered their services to companies based in the USA at half the latter's rate. The question that arises then is whether traditional geographical models of economic activities can explain the Internet model of production and distribution.

As more people are exposed to the Internet, their spheres of interaction expand exponentially. The Internet serves as a megalibrary of not only data and information, but also ideas and groupings. Where once the physical distances limited users in exchanging ideas with others of like mind, Internet connections in the form of chat rooms, newgroups and forums allow new and virtual communities to evolve on the Internet. These communities cut across national borders and social background. The unifying theme is shared concerns and interests. The notion that networking is a crucial strategy for survival underlies virtual communities that are preparing for Y2K.

The ability to conduct a dialogue, be it via electronic mail, newgroups or other forms of electronic communication, imply a sharing of ideas and consensus building. Coupled with the possibility of working from home, the Internet alters our traditional thinking of neighborhoods, communities and societies. On the one hand, the Internet can create groups that cross political boundaries, social status, educational background, gender differences and age gaps. This can be seen especially when individuals spanning the globe come together on environmental and human rights issues. On the other hand, the Internet can also foster closer ties within local neighborhoods, where people living within a given area establish a common forum to exchange and discuss issues that concern their immediate surroundings. The San Francisco Bay Area Net is one of the earliest example of this. So, how can one understand this inherent paradox in the forming of communities on the Internet? Does this call for a rethinking of social theories and geographical concepts of how communities form and function?

These are important questions, because the Internet is fast growing into a global community. With the forming of any community comes the idea of political grouping. Given the trend that location, and hence place and space, are becoming secondary concerns in the economic arena, and the rise of virtual communities in cyberspace, one must raise the question of the new form of governance that the Internet heralds. Already, the absence of territorial boundaries on the Internet poses difficult questions in formulating and implementing rules and laws for Internet interactions. Consensual behavior such as "netiquette" can only take us so far. The seemingly anarchical terrain of the Internet allows rampant fraud, copyright infringements and defamation. Territory based laws of sovereign states need modifications if they are to serve the citizens of cyberspace. The key to this is to recognize that the Internet is a new form of space with its own boundaries and territories. Its citizens will need to be represented and heard in a newly created political framework if the Internet is to remain a domain of democracy. Traditional geopolitics must recognize the growing importance of "netizens" to resolve international issues such as those in the Middle East and Kosovo.

4. Conclusions

Given the far ranging impact of the Internet on society, we need to look at traditional space in a different light. While we are still rooted in the physical dimensions, our interactions with others, be they for social, economic and or political purposes, will increasingly take electronic forms. In line with this progression, our spheres of interaction will extend from the physical limits of commuting, to the near instantaneous and globally ranging telecommunication form facilitated by the Internet.

One form of the new geography will focus on spaces and locations created by expanding telecommunication and Internet connectivity. Telegeography has been put forward as one alternative (<http://www.telegeography.com/>). While the purpose of this discourse is not to promote any organization, the focus of Telegeography, Inc. raises an interesting question. They define telegeography as the study of telecommunication geography. One of the areas covered by telegeography is the mapping of places and spaces created by telecommunication. The Internet represents, perhaps, the most defined medium of such places and spaces. While statistics and analysis of traffic and proliferation of connections abound on the Internet, studying this growing network from a geographical perspective is still in its infancy.

The key question deals with the choice of paradigms in studying the Internet. The over bearing of technical and quantitative methodologies in understanding the Internet ignores the rich range of approaches available for researchers when studying the rise of this phenomenon. The challenge is to use these approaches in meaningful ways when examining the Internet. Three avenues present themselves when dealing with the Internet; one can use existing paradigms and methodologies, modify them to suit the unique characteristics of the Internet, or strive to develop new models to explain the Internet.

The explosive rate of networking and establishing Internet connections around the world creates a new concept of space that is both paradoxically dependent and yet independent of physical location. Traditional models of geography offer different ways of measuring space, among them the notion of distance in terms other than the physical. Such concepts can be applied successfully to the Internet, but the key issue will be the selection of appropriate indices to measure Internet space. Will focus on the Internet infrastructure yield such indices? Will measuring interconnectivity on the Internet in terms of bandwidth and routers be sufficient, or will new indices than assess the value of content at web sites form the basis for understanding space and place on the Internet?

There is an urgent need to understand the geography of the Internet and how it affects the growing numbers of users. The challenge therefore is to develop acceptable methods of studying the geography of the Internet. History shows that links with physical location determines the rise and fall of civilizations. Geography has, and will continue to play, a crucial role in shaping human ideas and societies. It also plays a powerful role in establishing states and nations, and has been one of the causes for much of human strife. Understanding the geography of the Internet and its hold on its users will prepare us to adapt and function in the ephemeral locations of cyberspace.

Classifying Virtual Environments - Some Implications for the Mass Market

Martin Kurze⁽¹⁾, T-Nova Berkom, Germany; e-mail: kurze@acm.org

Georg Mnich⁽²⁾, lunatic interactive, Germany; e-mail: mnich@lunatic-berlin.com

Abstract: This paper first presents a classification for virtual environments (VEs). All relevant features of a VE are characterised and classified. The result is a multidimensional metric enabling designers of virtual worlds and corresponding applications to position their systems and to rate the appropriateness of the design in the context of a specific target environment. An application of this classification for a real-world application for the mass market is described. This application is based on a highly flexible VRML generator architecture and covers quite a large region in the multidimensional space of the metric. Since the application addresses the end-user (private consumers or small enterprises) certain constraints in terms of system environments and users' VR-experience had to be considered. Finally the application is rated and positioned in the taxonomy and the process of rating is described in detail resulting in an assessment of the rating system (the classification) itself.

Introduction

Virtual Reality (VR), today called more apt 'virtual environments (VE)', becomes more and more common in modern applications. The confusion concerning the term VR/VE is just one indicator for the upcoming problems with this new form of human-computer interaction. The meaning of the word is anything but clear, despite the fact that it is used frequently.

In this paper a qualitative (and partly quantitative) metric for the numerous aspects of systems using VR-technology is proposed. No exact definition of the term 'Virtual Reality' or 'virtual environment' is given. Rather a multidimensional space into which the reader may put his/her applications in their proper place is defined. In addition, the paper describes a system which uses a wide range of possible instantiations in this space, in order to give the user the most appropriate form of interface in several situations.

A multidimensional classification

This section describes a metric referring to a number of more or less independent features which nearly all VEs have. These features have been selected in such a way that they can be measured or at least estimated and thus can serve as axis in the multidimensional space formed by the classification. After a brief description the individual features are ordered in relation to each other using a proposed categorisation according to their relevance and independence.

Degree of immersion: Immersion is one of the key-features of classical virtual environments. Since immersion is defined as the feeling of being part of the scene, it is difficult to measure this 'degree'. A few attempts have been made to quantify immersion, e.g. in [Kalawsky 98], [Louka 98], [MacKenzie & Booth 96]. A completely different way of looking at this aspect can be found in [Kurze 98]: here the attempt to reach immersion (in the classical meaning of the word) is rejected and the user remains *outside* the scene while he controls a 'puppet' which is a part of the scene (in this sense the puppet is 'immersed').

Capability for users to move/navigate: According to a common saying 'in virtual worlds nobody walks around, everybody flies'. This is only partly correct: While the technology enables users to navigate in numerous ways (walk, fly, jump, beam, ...) some applications limit this freedom to a subset suitable for the specific context in which the application takes place (see below for an example). The capability to move can be set to any value on an axis ranging from 'no movement at all' via 'viewpoint hopping' to absolute freedom with no limitations, enabling flying through walls etc.

Model-complexity: This is a more technical property and should be easier to measure. There are at least two independent aspects that can be identified:

Geometric complexity: Geometric complexity can be defined as the number of vertices/polygons/triangles in the scene. However this number is often hard to tell because modern rendering systems accept complex geometric objects as input (like spheres and cones), and do the polygonisation by themselves. Thus the number of vertices can vary from system to system and even within the same system from situation to situation. Still geometric complexity is a relatively good candidate for an axis in our metric.

Textural complexity: The number and resolution of (image or movie or procedural) textures. Textures and in particular image textures need display memory to be rendered. Hi-res images and movie-textures require not only this memory but also a lot of computational power to map the appropriate picture/frame on the geometric object. Texture co-ordinates are used here and add further necessary effort.

Motion/Animation: Objects in VEs can be static like houses, or they can be animated like moving cars, birds and so on. Motion attracts the visitors' eyes, and motions make the scene look vivid. Therefore motion is a valuable tool in VEs. On the other hand motion requires a lot of resources: Not only must a rendering engine be able to draw objects at a different place or in a different position, but moreover the designer of a virtual world must not only design the object itself but also its' animation path.

Interactivity: Interactivity is *the* main feature that makes the difference between an animation and a virtual environment. Without interactivity, a 3D world would be like an old-fashioned museum and in fact its' contents might be better to present in conventional 2D fashion. The most basic form of interaction is user-navigation. In our context user-navigation (e.g. walking) is not considered as being interactive even though the user can choose the way of perceiving the environment by selecting the path and speed at will. This form of intra-personal interaction (the user acts and perceives changes on which he reacts, but these changes are caused only by his perceptual process) would be interesting to explore in more detail, but it is not covered by the present definition of interaction which requires the environment to be active itself. Three forms of interaction can be distinguished: Interaction with objects like buttons or door handles, with other users and with applications outside the virtual environment.

Interaction with objects: This is the most basic form of interaction in virtual environments. Objects like door handles are supposed to be interacted with, even in the real world. Other objects react on the user's actions in a different way than in the real world: Often you can touch a whole object to make it act, this is true for doors too: The door's geometry can be set to react on a touch (i.e. mouse click) by opening (or closing). Very often arbitrary shape react on touch events which cause it to start an animation sequence. (That's why people move the mouse over objects: They want to make them move).

The trigger for objects actions, i.e. re-actions to the user's actions, can be nearly everything: from the time the user is present in an environment to the "enter"-event of a proximity-sensor; even the state of the user (his/her history of behaviours in the environment) can be used as a trigger. In many cases it is difficult to model "natural" behaviours of objects that the user can interact with only by using a pointing device; thus other forms of interaction are used.

Interaction with other users: The basic form of interaction with other users in a virtual environment is communicating. This communication can be performed using gestures or text (spoken or typed). Adding multi-user functionality to a VE results in a huge number of nice options and at least as many potential (conceptual) problems: The other users avatars (3D-representants) can be regarded as objects in the VE, but they must be kept consistent in all its instances. Only one user can control this avatar, the other can only observe it (or interact via pre-defined interfaces). An other problem (and an opportunity) are shared objects: What does a user see if an other visitor opens a door (in what way ever). Can a user pass an object to an other user? How is this performed? As indicated, the multi-user concept is worth a more detailed investigation which can not be accomplished here.

Interaction with other applications: Finally, VEs often are used as the front end of other applications, sometimes more than one at a time. Thus, a VE might be able ore forced to interact with other applications. These other applications can use the VE as the user-interface or they may have their own GUI. Even combinations are possible. The interaction (e.g. a shopping-task in a 3D store based on a conventional E-commerce-application) is done in both applications in parallel. Sometimes the trigger for an action in the VE is released by the background-application without a user's interaction. This can cause confusion if the action results in disappearing objects (e.g. if a desired and currently explored item from a store is out of stock an thus removed from the display). However, it is possible and thus must be considered in a classification covering as many options as possible.

Frame-rate: The frame-rate is very important for a reliable interaction in VEs. Thus this unit for speed must be considered here. Unfortunately, the frame rate is not an independent dimension. Rather it depends on the rendering environment (hard- and software) and on the geometric complexity of the scene or parts of the scene. A number of procedures can be performed to keep the interaction and movement in VEs smooth.

Communication: Communication is in many aspects similar to interaction. In fact one could assume that communication is a special case of interaction where only information is exchanged and no task is performed. Like interaction, communication can take place between users (visitors) of a VE, between users and objects (e.g. bots) and between the VE and other systems (see [Rea 98]). This paragraph will concentrate on the latter. After a VE has been loaded into the users browser, it can contact other systems such like an external server to get additional information or even new elements of the VE. This communication often depends on the users actions, e.g. his path through the VE. The number of communication events and their intensity (the amount of data transmitted) directly interferes

with the smoothness of the VE and with its start-up time: A world can be first loaded in a rather coarse version and then be updated on demand, or it can be downloaded more or less as one big chunk and is then available immediately. Both variants have their advantages. This dimension in our taxonomy is closely connected with the next one, network-bandwidth.

Network-bandwidth: This is always a critical issue. You can never have enough. One of the most charming features of VEs is the flexibility in terms of required network bandwidth. You can build a nice VE with just a few lines of code resulting in just a few bits to be transmitted over the network. On the other hand you can use all the bandwidth available for high-quality sounds and/or movie-textures. Thus network-bandwidth is not just one dimension in the metric, it covers two: The *flexibility* of a VE to use a range of available bandwidths must be considered separately.

Addressed sensory channels: These dimensions of the metric rely completely on the available devices (hardware). Naturally the software must support the devices/channels to create the desired perception. The particular channels are listed below:

Video/Sight/Stereo-Vision: The sense of sight is the main perceptual channel for most people. For virtual environments, a large portion of the field of view should be occupied by the visualisation of the surroundings. A monitor should be able to display as many colours as possible at a high resolution, possibly in stereo (one display per eye). Fortunately, the eye can be cheated more easily than the ear, thus a poor visual quality is often accepted by humans.

Audio/spatial audio: Do the worlds contain audio, and are the sound sources detectable in 3D-space? How many sound-sources are supported? Which formats of sound (sampled sounds/midi/synthetic speech/ ...) can be used?

Haptic/touch: This channel is receiving more and more attention in the VE-community since the lack of tactile feedback and haptic stimulation in most VEs today prevents these VEs from being as effective as possible.

Taste and smell: These are still not used at all in VEs. Only a few attempts have been made to add odour to certain objects in VEs. An enormous effort is necessary to do so, and the results are very limited. In addition the usability of smell-devices is not very high: you can not turn odour off immediately and you can not stop your own olfactory sense at will.

Origin of the VE: In business uses, it is of great importance that VEs are generated automatically from a database or other sources and not generated manually. Thus the VE must be designed once in a way that a particular change in the requirements (or in the database) can be reflected automatically in the VE. This requirement can collide with the multi-user aspect: since in a multi-user-VE the world must be identical for all users, it cannot be generated freshly for each new visitor. Other implications follow from this problem.

Appearance: Finally the appearance of the VE can be different from one instance to the other: The world can look very much like the real world or a real city/house/room as in [Distler 98]. Or the VE can be a futuristic spaceship looking different than all those spaceships the user might have seen before. Eventually the world can be completely abstract with no items that can be referred to as "rooms" or buildings (see [Feijs & de Jong 98]). This is a matter of design and depends on the purpose of the VE (and the owner's taste :-).

Organising these properties

The properties described above span a multi-dimensional space of possible combinations. Before taking a closer look at the interdependencies of these dimensions, the properties/dimensions according to the driving forces that determine the dimension are organised:

Some distinctions between VEs are mainly *technically driven*. These depend on technical conditions such as processor-speed, display-devices or software-interfaces. Technically driven distinctions are: model complexity, motion/animation, the frame rate, network bandwidth, and the origin of the VE.

Perceptually driven distinctions are caused by the way human visitors perceive the VE. Thus they depend on individual human sensations, actions, and thoughts. So they may be hard to determine in advance. On the other hand, once you understand some basic features of human perception in VEs, you can build much more effective and attractive ones. Examples for perceptually driven differentiations are: degree of immersion, sensory channels, and interactivity.

Finally, *task driven* distinctions can be identified. This is a difficult class of dimensions because it actually covers most dimensions in the metric but they are of different importance for the different tasks to be performed in a VE (see [Ishi et al. 98] for an example). In general business tasks require extremely efficient VEs which do not necessarily have to be nice and entertaining. On the other hand, entertainment tasks should be pleasant to explore while efficiency is of less importance. The capability for users to move/navigate, interactivity, communication, and appearance can be placed into the context of task driven distinctions.

Rating the Classification

The properties which determine the dimensions in the classification are not completely orthogonal (In so far they do not really create "dimensions" in the conventional meaning of the word). Some properties depend on others more or less directly: e.g. the model complexity directly influences the frame rate (the more complex the model, the lower the frame rate); these are both technically driven distinctions. If the frame rate is very low the user cannot perceive a real feeling of immersion (a perceptually driven distinction). Immersion plays an important role in some professional tasks (e.g. judging a new cars interior). Thus a high model complexity might prevent the user from judging a car interior presented in the form of a VE from being effective in his/her task. A naive person could now come to the conclusion that a reduced model complexity might increase the frame rate and thus make the task more easy to perform. This would be anything but effective: judging a car interior requires a very high accuracy. Otherwise the results of the observations would be useless.

The relevance of the different dimensions varies widely in different tasks. So the task-based differentiation may be the most important in the described classification. Having said this, one can continue by stating that there is an order of importance for the different dimensions. As mentioned above, interactivity plays a very important role among the features that constitute a virtual environment. Unfortunately the classification in the form described here does not reflect this factor appropriately. This is due to the fact that "importance" is an amorphous property which depends on the given task to a certain degree.

The usefulness of the taxonomy has been tested in a real-world implementation. A framework for software-integration and a common user-interface to make this software accessible utilising an intuitive navigation support has been developed.

Implications for the implementation

The classification described above has been used to design and implement a large-scale virtual environment for the mass market. The objective of the design-project was to develop a 3D environment hosting a conceptually unlimited number of service domains which in turn are represented in 3D as well. The services to be included in the framework were highly inhomogeneous and the requested levels of integration ranged from a simple web-link to a complete merger. The following section covers these and other aspects of the problem and shows how the classification helped to keep the individual aspects in order. These (and other) constraints forced us to pick particular areas in the n-dimensional space set up by our metric.

The target-group of users was inhomogeneous; therefore the application had to be highly adaptive (or adaptable if adaptivity could not be reached). The intended users were mainly private people ("consumers") using their PCs at home. Since the service domains included (among others) a set of games, a video on demand (VoD) shop and a more conventional shop offering telecommunications devices, children, possibly experienced arcade-players, and adults with only a limited experience using a PC or 3D-interaction had to be addressed (and reached). In addition a special version of the application was needed for small and medium enterprises (business users).

The target-platform was not specified precisely; therefore a platform-independent solution had to be developed. To maintain platform independence, it was decided to rely on international standards, mainly HTML and VRML. Unfortunately there are at least two major HTML-Browsers and at least three important VRML-Plug-Ins for them. All these systems cover a big portion of the standards, but there are important differences between them which prevent a working solution that runs on every combination of browsers and plug-ins. Finally, the graphics card in the PC (in particular if it supports 3D-acceleration such as Open-GL or Direct-X) must be considered. Even if the 3D-acceleration technique is well defined (as in the cases of the mentioned systems) the drivers of the cards obviously interpret these definitions at will.

Using a participatory approach complemented by extensive semiformal usability testing and quality-management several versions of the whole system were implemented. At least three stages were frozen and presented to a bigger user group for testing purposes. Finally a combination of "classic" VR, conventional 2D-Webpage, conceptual visionary and cognitively inspiring 3D-animation with vivid and experience-oriented elements was implemented.

In addition to the 3D-world based approach the same technology was used to develop an application that actually *is* 3D even though it *looks* two dimensional in most situations. Here the fact that VRML-worlds have a state and a progressing time and allow a lot more interaction with the user than traditional 2D-HTML-sites was exploited. Only in one situation the spatial nature of the whole application becomes clear: When the user selects a real object (in our case a phone); regularly the application provides a convenient access to a complex set of forms in a business centre.

Figures 1 to 4 show some screenshots of different versions of the application. To make a comparison possible, similar scenes have been chosen in all VEs. The whole application has a lot more to offer than can be seen here.

Figure 1: Version 1 of the application: architectural appearance, high geometric complexity, limited interactivity

Figure 2: Version 2 of the application: medium geometric complexity, high interactivity and communication; the screenshot on the right shows

Figure 3: Experimental version 3 of the application: partly abstract Environment, low bandwidth requirement, highly interactive potentially multi-user, integrated 2D-components.

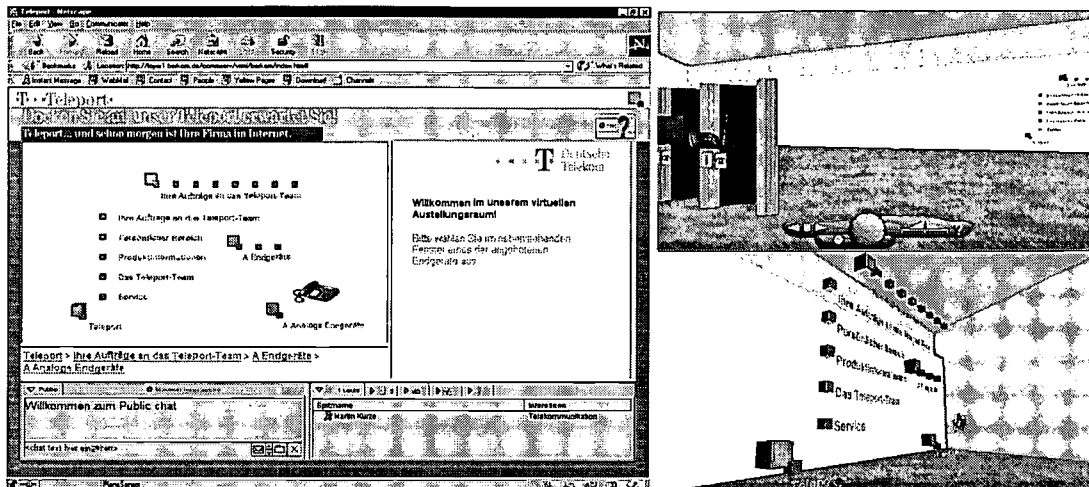

Figure 4: The application in the business centre context: The scene might look flat (left) it is three dimensional which can be seen (bottom right) once the viewpoint changes to show 3D-objects (phones, top right).

Conclusions

Due to the multidimensional taxonomy for virtual environments described above it was possible to determine the positions of the individual instances of our VEs. A sort of similarity and relationship among these applications could be maintained. This reduced the development work for all these systems very much.

Concluding this paper it can be noticed that a classification for VEs is a valuable tool to organise design and implementation work. It makes various VEs comparable and thus uncovers similarities between them which might not be discovered otherwise.

Working with our classification also showed us that the metric is not yet perfect. In particular the number of dimensions seems to be quite high and thus makes working with it difficult. The categorisation helped a lot, but there still remains a lot of work to localise a planned VE or to find out what to change to make it appear at a specific spot in the multidimensional space.

This leads us to the future work that will be performed now: First the classification will be revised and the number of dimensions reduced or grouped differently. A tool to make the localisation of a VE easier will be developed. In parallel to these activities the classification and the rating process will be applied to other VEs found in the VE-community.

Abstract: The *Computer Aided Information Navigation* project provides a new method of adaptive navigation support which aims to increase the World Wide Web's value as a pedagogical tool. This work approaches adaptive hypertext systems, metadata, computer supported co-operative work and recommender systems. The project extends and combines work from these areas in a new way to support learning and initial research tasks by facilitating the navigation process, providing a Rough Guide-like weak hypertext linearization which enables the user to follow a ranked sequence of selected, context specific, World Wide Web pages. This is accomplished by regarding information available on the World Wide Web as an open corpus upon which a new specialized structure is superimposed which provides for a collaboratively built partial representation of the World Wide Web's information space and which also provides a mean of representing user attributes.

1 Introduction

A large volume of information, such as the one available over the World Wide Web (Web) has an inherent application potential in an educational setting. Unfortunately, besides inheriting and enhancing most of hypertext's qualities, the Web also incorporates and stresses common hypertext problems. It is the Web's disorganized nature that mainly prevents its most effective use as a pedagogical tool and, as such, research is needed to develop the means that will help to transform the available data into meaningful information able to support learning or initial research activities.

The *Computer Aided Information Navigation* project (*CAIN*), reported in this document, attempts to provide adaptive navigation support as a way of increasing the Web's value as a pedagogical tool. *CAIN*'s approach is a reactive one as the effort goes into providing a way to deal with the vast amount of useful information available on the Web as is, rather than to try to improve or alter the Web's infrastructure in any way.

In order to help users reach their goals, *CAIN* provides direct guidance navigation support as a form of non-obtrusive *weak hypertext linearization* enabling the user to follow a context specific ranked sequence of selected Web pages without ever needing to perform any search or follow any link if they do not wish to. This approach does not intend to prevent goal-oriented exploration but to provide a sound thread or guideline to help users to retain their focus in the way a *Rough Guide* does.

The system's representation of the Web, crucial to the success of its adaptive features, builds on the *Dublin Core* and on the *Resource Description Framework* (RDF) (Lassila & Swick, 1998). The users' representation combines three user modeling techniques resulting in a hybrid solution that uses stereotypes, overlays and attribute-value pairs.

Navigation support is accomplished by a basic route-finding heuristic which selects context specific Web model items, sorts them using associated qualitative ratings and presents them to the user, one at the time, based on the attributes of the user's model.

Section 2 presents and discusses the problem space, section 3 provides an overview of the related areas of research and section 4 presents the project outline. Finally, section 5 provides final remarks and highlights future research directions based on the work done so far.

2 Problem space

The Web affected and affects the *modus operandi* of many people in areas that range from scientific work to business, including education, and Web usability problems affects many users today (Brown, 1990; Shum, 1996). The fact that the Web is currently perceived as an accessible medium in which anyone can create content results in a community of developers where the majority of authors are new to system development and have little or no knowledge or understanding of human-computer interaction issues.

Further, poorly designed hypertexts are also cited as a problem source (Brown, 1990) since, just as early programmers lacked experience, so do the majority of current Web authors. The consequence is that many Web sites are developed by multiple authors with different goals which tends to result in incremental expansion of their information space without coordinated planning.

2.1 Setting the boundaries

Before focusing on the problem and outlining its context, two questions raised by Theng (1995) must be discussed: are we looking for solutions to an avoidable problem? what if we do the right thing from the start?

These questions defend the position that, when talking about hypertext navigation, most of the effort on the system side is a reactive approach, ie most of the effort goes into providing solutions to problems that result from badly designed hypertext. From this point of view, it is suggested that feasible approaches to avoid or minimize navigation problems include (Theng, 1995): incorporation of good design principles and guidelines; and defining the task and structure of the hypertext applying a user-centered design methodology;

This position is further defended by Berk & Devlin (1991) who argue that the continued emphasis on navigational difficulties is leading to too much attention being given to navigational tools while insufficient attention is being paid to what constitutes good hypertext writing. This point of view is somewhat supported by recent studies reported by Furnas (1997).

The approaches to the problems of navigation and information overload can thus be summarized in two perspectives: *Top down approach* - where the problem is perceived from the reader's stand point and solutions seek to help improve navigation tools to cope with information overload. These include better browsers offering more navigation facilities, better search engines and additional navigation tools such as agents and mediators; *Bottom up approach* - where the problem is seen from the content provider point of view and approaches seek to provide better content layout and improved structural support. These include enhanced authoring tools and improved hypertext system infrastructure.

Nonetheless, even if the *bottom up approach* was shown to be the better one, the fact that there already exists a huge amount of information ready to be accessed and used justifies all the effort invested in pursuit of better, system side, navigation aids. More, an environment such as the Web, in which every reader is potentially also a Web author, makes it very difficult to enforce any author-side methodology or set of guidelines.

2.2 Setting the context

As said before the Web's volume of information has potential application in an educational setting, but its disorganized nature prevents its most effective use and research is thus needed to develop technology that helps to transform the available data into meaningful information as part of a learning or information-retrieval activity deployed either individually or in a collaborative way (Eklund & Ziegler, 1996).

Using the Web as a pedagogical support can be achieved in two, nonexclusive ways (Marshall, 1995): *Closed corpus* - in this case, the technology is mostly used for its hypertext and distance delivery capabilities and, normally, specially designed content is provided; or *Open corpus* - This approach takes advantage of the

large quantity of information available on the Internet whether or not it has been developed for educational or training purposes. In this case, however, an organized structure, static or not, must be superimposed over the addressed information space to enable guided or assisted information explorations which would not otherwise be possible due to the generalized assumption that information producers are mostly passive and that it is part of the reader's role to drive the process.

As suggested by Eklund & Zeigler (1996), applying the results of the research in *Intelligent Tutoring Systems* or *Computer Aided Learning to the Web*, either in *closed corpus* or *open corpus* approaches, is a logical step and is reflected by ongoing research on *Adaptive Hypertext Systems* (Brusilovsky, 1996), a research area which has its roots in *Adaptive Systems* research (Benyon & Murray, 1993). Other researchers (de La Passardiere & Dufresne, 1992; Jonassen, 1992) go even further suggesting that some expert assistance or guidance in the form of, for example, individualized navigational advice, could provide more structure to the information space and more direction for the user as an approach to minimize disorientation problems and prevent readers from becoming lost, skipping important content and looking for visually stimulating rather than informative material.

Nonetheless, evidence exists that the data navigational and structural tools currently available are not sufficient to exploit the available information (Andrews et al., 1995). Additionally, learners tend to make poor decisions in learner controlled systems and, therefore, some direction or knowledge sequencing might be necessary for the World Wide Web to become an effective learning environment.

2.3 Subjects addressed in this work

One way to provide such direction is through the use of adaptive navigation techniques used in some hypertext systems and identified by Brusilovsky (1996) as being able to provide features including direct guidance, adaptive annotation, and adaptive link re-ordering and hiding.

However, in order to enable adaptive navigation, apart from modeling the user, information must be available to the system about the underlying information space.

3 Related areas

As closely related subjects, adaptive hypertext systems, metadata, recommender systems and computer supported cooperative work are summarized in this section.

3.1 Adaptive hypertext systems

Adaptive hypertext systems build on the general adaptive system's concepts but there are a number of considerations to be made. Such systems cater for users with different goals and knowledge who may be interested in distinct pieces of information and links contained within a hypertext node. In general, an adaptive hypertext system attempts to overcome this problem by providing either adaptive presentation or adaptive navigation support or both (Brusilovsky, 1996). *CAIN* only provides direct guidance but different alternatives include adaptive sorting of links, adaptive hiding of links, adaptive annotation of links, and map annotation.

Adaptation goals are dependent on the application areas as each application addresses its own set of problems and each goal is only relevant within some specific context. They also usually provide or drive the answer to the *what should be adapted* question. User model features usually include features related to the current application context and to the individual user as also happens with other adaptive systems.

3.2 Metadata

Metadata is *data about data* and in the case of the Web, it can be the domain structure and content model needed to enable the adaptive behavior characteristics provided by a Web access mediator such as *CAIN*.

One of the advantages of using a *new* term to describe Internet resources is that there is no residual meaning attached to it as it would be the case with the *catalogue record*.

In *CAIN*, the *Dublin Core* (Weibel & Lagoze, 1997) is used as the underlying metadata definition and the project's domain model builds on its core elements and qualifiers as they are, on one hand, flexible enough to accommodate ratings and a number of other attributes needed to build the domain model and, on the other hand, they are structured enough to enable automated machine processing. Finally RDF (Lassila & Swick, 1998) provides the model for representing Dublin Core's named properties and their values enabling a syntactically independent way of representing *CAIN*'s domain model. RDF features a layered architecture that progressively offers higher level constructs and on top of which the Dublin Core can be defined.

3.3 Recommender systems

Recommender systems assist and augment the activity of making choices without sufficient personal experience but instead based on recommendations from other people (Resnik & Varian, 1997). Recommender systems may be classified on a number of dimensions (Resnik & Varian, 1997) including technical attributes, domain features, user characteristics, the recommendation density, the recommendation consumers, and the consumer goals variability.

In *CAIN* the contents of a recommendation can both mean that a new metadata record was added to the system or that a referred Web node was visited and that the user volunteered a relevancy rating. Additionally, whereas any system user may submit a relevancy rating, only selected users can actually *recommend* a Web page. The main reason for this constrain is to provide some credibility to the cooperatively built Web domain model as, for the system's success, the stored information must be trusted and reliable.

4 Project outline

As a navigation support tool, *CAIN* aims to support the accomplishment of learning and initial research tasks helping users to move sequentially in a given environment taking most of the burden of deciding where to go next off their shoulders *i.e.*, *CAIN*'s goal is to facilitate the navigation process within a specific subject's context when the target is to acquire or improve knowledge about that particular subject.

As also happens with bookform *Rough Guide* users, potential *CAIN* users rank low in either or both *subject knowledge* and *expertise in Web navigation*. From this point of view and to enable adaptive navigation support, the usage of the Web as a pedagogical support is achieved regarding the large quantity of information available as an open corpus over which a specialized structure is superimposed which caters for:

The domain model - A partial representation of the Web's information space; and

The user model - A representation of a given user's attributes.

As said before, the behavior of the adaptive navigation shell provided mainly results from the combination of these two models. Further, the system's design ensures that users can inspect the adaptivity mechanisms and control their results. This approach aims to improve trust and prevent disappointments resulting from misunderstood changes in the adaptive navigation shell (Höök, 1996). *CAIN*'s domain model, contains Web metadata stored as Dublin Core compliant records.

Used Dublin Core elements include *title*, *description*, *resource identifier* and *date* but intentionally exclude the *relation* element. This happens because explicit linking is not needed as the sequence of Web pages is determined on the fly and only selected available nodes are presented to the user as a thread. Specially important are the extensions to Dublin Core's element set used to provide the storage of the contextual and related ratings needed to enable the system's adaptive behavior. Each metadata record can have one or more associated *contexts* and each context has an associated *depth* and *level* rating and one or more *relevance* ratings. These contexts are a key characteristic of the domain model as they provide the frame of reference for specific Web resource ratings. Finally, the depth, level and relevance ratings all have different grades with well defined semantics.

On the other hand, the user model uses an overlay approach to model the user's interests and knowledge as well as attribute-value pairs to record personal data. User models are user inspectable and modifiable and divide users in two distinct groups:

Moderator - Users that can add metadata records, contexts and ratings to the domain model. Moderator status can also be delegated by *moderators* on *readers*; and

Reader - Identifies every other system user. These ones are restricted to just using the navigation aid provided and to eventually submit relevance feedback information.

Stereotypes can be used to initialize the user model and the more general one is the one describing the user as knowing nothing and having no interests what so ever. Populating and maintaining the domain model is a task shared between users and the system and also a collaborative effort as the system relies on its users to collaboratively populate the domain model either by adding new metadata records, contexts and ratings or by simply providing relevance feedback.

Populating and maintaining user models is also a user and system shared task. The user explicitly fills in her own user model when she uses the system for the first time and from that moment on, the user model is updated either:

- Explicitly by the user when choosing a new context or modifying context specific threshold information; or
- Implicitly by the system when providing navigation support and updating a particular context's record of used resources and thresholds.

Combining the domain and the user models to provide direct guidance is a very simple three step process comprised of *context selection*, *route finding* and *determining what to show next*:

- First, the context element of the metadata records enables the selection of specific context related metadata records;
- Then, the selected metadata records are then sorted by level, by depth and by the relevance average. The result is a context specific ordered list of Web resources in which fundamental ones come first, within them general overviews come first and finally, more relevant material comes first;
- Finally, the route for the selected context is compared against the user's model and the first unread Web page is brought to the user and so are all the following unvisited ones.

The proposed solution was formally specified and to test it, a prototype implementation was developed and an initial empirical study was conducted which provided encouraging results. Finally, although *CAIN* aims to support learning activities, it is not an Intelligent Tutoring System as it is not able to diagnose or correct misunderstandings, or to provide an assessment of the level of achievement of the student.

5 Final remarks

This project's reactive top down stand point is, however, not taken lightly because other approaches that tackled the problem from other angles were also considered. However, all the pro-active bottom up alternatives seem to reduce the Web's successful characteristics resulting in either:

A decrease in hypertext production because if strict publication rules were imposed on authors, a percentage of them would stop or at least slow down delivering Web content;

A bypass of publication rules because if authors can still publish without any additional effort some will; or

A complex publication procedure if rules were imposed in some way and control mechanisms implemented.

CAIN's major contributions are the bringing together of different areas of computer science. Although an initial empirical study suggests that the navigation guidance provided improves the performance of its target Web users, the study is not exhaustive and further development and empirical work need to be done.

The above work provides an initial understanding of how individualized, adaptive and directed Web navigation guidance can be provided over contextualized Web browsing experiences. Following these first steps, future possibilities include:

- Improving the Web model and its modeling devices;
- Improving the user model and the user modeler;
- Improving the route finding heuristic; and
- Understanding the system's application boundaries.

Regarding the latter, besides supporting the accomplishment of learning and initial research tasks, other application areas may be explored namely supporting distance learning courses, assisting project groups and providing contextualized enterprise information.

Abstract: New learning paradigms, the continuous progress in the field of information and communication technology, as well as a stronger commercialization of education and training are relevant pacemakers on the way towards an electronic education market. This article introduces the concept of an Electronic Education Mall (EEM), which supports communication and interaction processes between suppliers and customers in this market. The EEM can be regarded as a virtual center for educational services, which facilitates market transactions by providing a multitude of service functions.

1 Approaching an Electronic Education Market

1.1 Status Quo

Due to continuous progress in the field of information and communication technology, not only companies but also universities in particular are facing new challenges and opportunities. Universities, e.g., have now more opportunities to cooperate with the industry and other educational institutions. At the same time universities' programs and courses can be targeted at new groups. As a consequence there will be an increased market orientation: "We have entered the era of world wide competition among institutions of higher education. In the long run this will also apply to public and private education at all levels and various student services" [Turoff 1999]. In this context universities are trying to open up new financial sources by offering specific media-based learning materials to non-students.

Specific support systems (videoconferencing, groupware, authoring tools, etc.) provide the platform for innovative forms of teaching and learning. Media-based learning resources (MBLRs) directly or indirectly accessible and applicable via the Internet/WWW cover integrated Web-based courses, Web-based information and knowledge pools, electronic references, electronic learning materials (e.g., PowerPoint slides), conventional Computer Based Training (CBT) applications, as well as various forms of synchronous and asynchronous teleteaching/telelearning applications.

1.2 Closing the Gap between Suppliers and Customers

Today there is a myriad of producers and, accordingly, of MBLRs they offer on the WWW. Prospective learners are often faced with the serious problem of having to pick out the right contents out of the enormous supply of MBLRs on a specific demand. Up to now, support provided by the suppliers (content providers) has been insufficient. A study conducted by the University of Erlangen-Nuremberg among about 120 German suppliers of Web-based learning resources revealed that basically only few sub-processes of a transaction between supplier and customer – in most cases parts of the information phase – are supported electronically. None of the suppliers surveyed provided continuous electronic support of all transaction phases, which according to [Schmid 1993, 468] is one of the crucial criteria of an electronic market.

Consequently the coordination of supply and demand on this electronic market for education and training remains a true challenge. In other business sectors structures of electronic markets have already emerged, e.g.,

electronic stock markets, or computerized reservation systems in the tourism industry. Accordingly, in the field of education and training the development towards an electronic market seems possible (cf. [Hämäläinen, Whinston & Vishik 1996]). Flanking developments in electronic commerce (cf. [Kalakota & Whinston 1996]) are expected to force and shape the establishment of an Electronic Education Market.

One important issue is how to design and support coordination and cooperation activities in this Electronic Education Market appropriately. A promising approach is the development of so-called Electronic Education Malls as an analogy to electronic shopping malls. A concept for an Electronic Education Mall (EEM) in the sense of a coordination instrument in an Electronic Education Market is introduced in the following chapters.

2 Concept of an Electronic Education Mall

2.1 Characterization

Systems supporting coordination, cooperation, and transaction processes within an electronic market have to provide a multitude of services. In addition, standardized interfaces for suppliers and customers are needed. Internet/WWW-based electronic (shopping) malls are an approach to fulfil these demands. This leads to the derivative concept of *Electronic Education Malls* for educational contents and services, which provide a technological platform with appropriate value-added services and interfaces for suppliers and customers.

In this sense an EEM can be regarded as a *virtual service center for educational purposes* [Langenbach & Bodendorf 1998a, 290]. An EEM can be built up by a coordinated alliance of service providers within the Electronic Education Market. Concrete examples for those service providers are *certification and quality assurance authorities, marketing units, education brokers, advisory boards, accreditation authorities, technical providers and financial clearing units*. The services provided by this alliance are accessible through a standardized system of *Mall Services*.

Particularly, regarding the establishment of an EEM analogies to virtual corporations/organisations (cf. [Byrne 1993], [Mowshowitz 1997]) can be identified. One possible approach is to set up a fixed consortium of service providers to achieve a long-term collaboration. In contrast, a more dynamic set-up of a loose-tied alliance for a time-limited task-oriented cooperation is conceivable. The decisive difference between a conventional electronic (shopping) mall and these two forms of organizing an EEM is that it is the intermediaries that initiate and run the EEM in the electronic marketplace and not the suppliers.

2.2 Mall Services

Primarily, mall services have to support all phases of an EEM-centered transaction in an appropriate way. This includes customer-initiated transactions (e.g., retrieval, customization, booking, use and payment of MBLRs) as well as supplier-initiated transactions (e.g., production and delivery of new MBLRs).

Figure 1: Approach of an Electronic Education Mall

Mall services are accessible via customer and supplier interfaces (see [Fig. 1]). In addition, communication and coordination mechanisms among the mall service providers are realized by "horizontal" information and data interchange within an EEM. From a conceptual point of view, each mall service can be subdivided in a multitude of functionalities. [Tab. 1] shows some examples.

<p>Accreditation and Administration</p> <ul style="list-style-type: none"> • accreditation and registration of new customers • booking of MBLRs • accreditation and registration of new suppliers • generation of supplier profiles 	<p>Education Broker and Advisory Board</p> <ul style="list-style-type: none"> • pedagogical and didactical advice for customers and suppliers • customizing of MBLRs according to customers' specific needs • mediation of human resources, e.g., coaches, instructors, tutors, speakers, etc.
<p>Quality Assurance and Certification</p> <ul style="list-style-type: none"> • information on quality and certification guidelines of the EEM • certification of new MBLRs • quality assurance measures 	<p>Marketing</p> <ul style="list-style-type: none"> • information on the supply of an EEM (suppliers, contents, certificates, financial conditions, special offers, etc.) • marketing for single MBLRs as well as for the whole EEM • provision of customer profiles and market surveys
<p>Financial Clearing</p> <ul style="list-style-type: none"> • support of pricing new MBLRs • development of individual and flexible payment procedures for MBLRs • negotiation about special conditions within price ranges defined by the supplier • accounting of MBLRs and mall services inquired by the customer or the supplier respectively 	<p>Technical Provider/Support</p> <ul style="list-style-type: none"> • consultation/information related to technical requirements to produce and use MBLRs (bandwidth demand, operating systems platforms, tools, etc.) • technical support during the delivery phase of new MBLRs (setup of server capacities and network connections, etc.) • technical support during the learning process (installation of required tools, setup of online connections, etc.) • technical support of MBLRs (maintenance, re-implementation, software updates, etc.)

Table 1: Mall Services and Their Respective Functionalities

2.3 Market Transaction Support

According to the classical market transaction scheme (cf. e.g. [Williamson 1985, 20]) a customer-initiated transaction within an EEM can basically be subdivided in the phases of information, negotiation and settlement. At a more detailed level the transaction consists of 10 sub-phases, steps (1) to (3) being assigned to the information phase, steps (4) and (5) to the negotiation phase and steps (6) to (10) to the settlement phase. A description of a customer-initiated transaction performed in an EEM is given below. [Fig. 2] illustrates which service providers are involved in each sub-phase to support the respective steps. Some tasks can be fulfilled by just one mall service provider whereas other tasks require coordinated cooperation and/or information interchange of two or more service providers.

Steps of a Customer-Initiated Transaction (example)

- (1) Gathering information about the supply, e.g., on service and price structures, quality of supply, current references and rankings, certification criteria.
- (2) Obtaining educational advice, e.g., information on learning contents from a pedagogical point of view, proposal of an appropriate MBLR or a bundle of resources.

BEST COPY AVAILABLE

- (3) Configuring and customizing individual MBLRs according to customers' specific needs.
- (4) Negotiating prices and special conditions like credits, discounts, etc.
- (5) Booking of the chosen resources according to the negotiated conditions; accreditation of the customer.
- (6) Preparing the technical environment, e.g., reservation of bandwidths, installation of tools, request for keys to access restricted MBLRs.
- (7) Using the booked MBLRs.
- (8) Taking online exams to receive a certificate.
- (9) Accounting and payment.
- (10) Delivering the certificate.

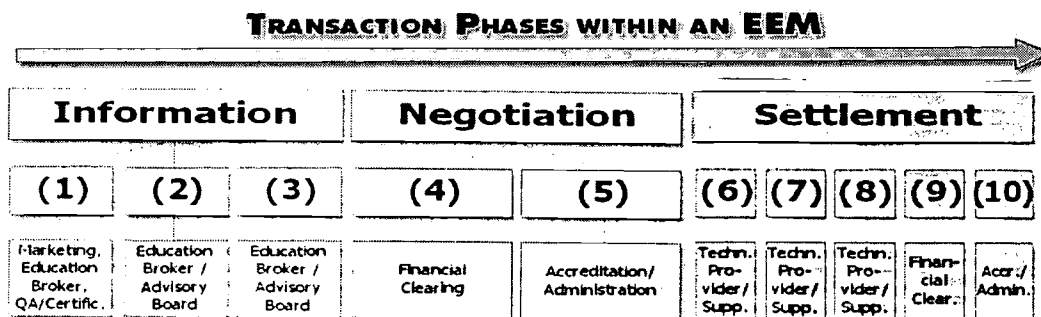

Figure 2: Transaction Phases and Mall Services

3 Implementation

3.1 Mall Service Support Systems and User Interface

Core components of the EEM are so-called *Mall Service Support Systems* (MSSS), which support the individual service provider's tasks electronically. MSSSs can be standard software and hardware (e.g., videoconferencing systems), adapted or customized systems (e.g., payment systems) or specific solutions developed for a certain need (e.g., agent systems, configuration systems). On the basis of the customer-initiated transaction (cf. chapter 2.3) some examples of MSSSs which facilitate the complete electronic transaction support are given below.

The marketing unit offers the customer different self-service approaches for obtaining general information on the EEM and the MBLRs – e.g., electronic product (MBLR) catalogues as key elements of electronic markets [Schmid 1997, 4], bulletin boards, search engines or agent-based search mechanisms, newsletters, and push channels. Besides, the customer can specify his need for information using synchronous (e.g., videoconferencing or chat) or asynchronous (e.g., email) communication channels. The same communication mechanisms can be used for obtaining individual educational advice provided by the advisory board. The advisory board can be supported by case databases and soft computing (e.g., expert systems). (Semi-) automatized advice by using consultation agents is conceivable.

The education broker uses specific configuration systems supporting the MBLR customization and facilitating also the bundling of different MBLRs. For standard requests direct MBLR retrieval by the customer is possible. In the negotiation phase, the financial clearing can use (agent-based) price finding and negotiation mechanisms (e.g., to negotiate on special conditions and discounts within price ranges defined by the supplier). The bookings of MBLRs are supported by electronic contracting processes. The collection of customer data and the accreditation of new customers can be done using CGI- or Java-based forms.

The support given by the technical provider to customers in the phases of preparing and using the MBLRs can be remote administration and installation. If necessary, the customer and the technical provider can communicate with each other synchronously or asynchronously via the channels mentioned above. MBLRs and services are being paid for by means of electronic payment systems using appropriate security mechanisms such as SET (Secure Electronic Transactions).

Also, flexible accounting mechanisms systems are to be deployed to make the payment of heterogeneous

bundles of MBLRs and services easier and more economical. Finally, the certificates are being handed over in the form of electronic documents, providing that their authenticity is guaranteed by suitable cryptographic mechanisms.

The "visible" part of an EEM is to be realized as a Web-based interface, which allows suppliers and customers to access all relevant services offered by mall service providers. In addition, a separate interface for mall service providers has to be implemented, through which they can administer and use their respective MSSSs.

3.2 MBLR Production and Delivery

In addition to the implementation approach of the EEM and its support systems for each service provider the question of an appropriate technical framework for the production and the delivery of MBLRs has to be dealt with. [Fig. 3] shows a layer-oriented reference model. The very top layer contains specific production and application systems for suppliers and customers. The layers underneath are transport layers. The normalization of the framework is achieved by adhering to relevant standards and protocols.

Figure 3: Technical Framework for MBLR Production and Delivery

The WWW serves as a production and presentation platform for the supplier. Web publishing tools like HTML editors or graphic applications are used. In addition, authoring and programming tools are needed. Looking at specific MBLRs, the framework offers a variety of design and realization possibilities. For instance, Web-based teachware packages can integrate Web-compatible media formats (text, graphics, audio, video, etc.) as well as components which are connected via the common gateway interface CGI (e.g., databases, executables for the evaluation of progression tests).

Furthermore, CGI-independent executables like Java applets and servlets, JavaScript and ActiveX modules are also connectable. A lecture-on-demand service can be provided by using a (Web-based) audio/video broadcast server. Multimedia databases are needed to build up electronic references as well as Web-based information and knowledge pools. Electronic instruction and lecture materials and non-Web-based teachware applications are offered for download either from the Web server or from a dedicated download server (ftp server).

Synchronous teaching and learning approaches are usually based on videoconferencing and groupware systems (e.g., the Mbone toolset) which nowadays do not work predominantly Web-based. However, the further development of the WWW to support synchronous multimedia communication can be foreseen.

The customer's access to the Web-based modules is realized by a conventional Web browser which can be extended by plug-ins if necessary. Dedicated clients and frontends facilitate the use of non-Web-based applications.

4 Current Status

Encouraged by the emerging commercial structures in the fields of education and training, especially media-based teaching and learning concepts with promising market potential are being prototypically realized and evaluated at the University of Erlangen-Nuremberg. Since 1994 multilateral synchronous teleteaching scenarios

BEST COPY AVAILABLE

based on broadband data networks, videoconferencing, and groupware systems are being run [Bodendorf, Grebner & Langenbach 1997], covering national and international universities as well as partners from industry and administrative authorities. Examples are distributed lectures, talks, seminars and workshops between university and practice.

Furthermore, in analogy to the well-known video-on-demand a lecture-on-demand service is provided. Talks and lectures are stored in digitized form on a media server for an on-demand retrieval with supplementary learning materials offered via WWW. The media-based teaching and learning program at the University of Erlangen-Nuremberg is completed by a set of Web-based multimedia teachware packages [Langenbach & Bodendorf 1997].

In parallel to the development of media-based learning resources and teaching concepts with relevant market potential the prototypical realization of an university-oriented EEM (called *NOVEM* – Nuremberg Open Virtual Education Mall) is in progress. In addition, a number of MSSS for transaction support have been designed and realized as prototypes. Examples are an electronic MBLR catalogue, a price finding mechanism based on regression analysis, or an education broker toolset for Web-course customization. The prototype of this toolset – presented at WebNet 98 [Langenbach & Bodendorf 1998b] – was nominated for the international software award "Multimedia Transfer 99" of the German Academic Software Cooperation. The whole range of services of NOVEM is accessible for suppliers, customers and mall service providers via a standardized Web-based interface (designed in plain HTML as well as in VRML).

laufer@inf.puc-rio.br

Abstract: This work presents the many forms of communication used in AulaNet <<http://www.les.inf.puc-rio.br/aulanet/>>—an environment for creating, administrating, updating and attending courses through the World Wide Web. This environment ensures the necessary conditions for communication, coordination and cooperation among the participants of a course. These communication mechanisms include administrative procedures, discussion lists, news, agenda, announcements, e-mail messages, chat and videoconference. Almost all the information exchanged is stored in databases allowing for information retrieval.

1. Introduction

Communication in cooperation environments is of fundamental importance in establishing the necessary conditions for effective coordination and cooperation among the participants in these environments [Ellis, Gibbs & Rein 91]. Communication in a determined cooperation environment is one of the main characteristics that defines the profile of such an environment. [Brooks 75] states that Organization is communication.

The popularization of the use of computers in conjunction with the Internet has been transforming the way that people carry out the most varied activities [Tapscott 98]. Computers are being used with increasing frequency to obtain services, for work, education/training, entertainment and many other activities.

Gradually, computers are becoming more like communication devices, with the desired activities installed in the processing capacity, similar to the process installed in a digital telephone or in a bank cash dispenser. When a computer is connected to the Internet, whether through a modem using a telephone line or connected to a LAN, it is not the same machine as the very same computer disconnected. In this context, the computer allows a person to interact with a wide range of objects spread around the world. Computers continue to be machines with many uses, but they are beginning to be increasingly perceived and used as a medium for various types of communication [Perrone et al. 96].

[Poster 94] makes an analysis of the impact that the forms of communication have on society. For example, he analyzes how the concepts presented in tv commercials influence people's behavior in contemporary society. [Melody 94] makes a correlation between information and communication and affirms that the way a society functions depends on information and the efficiency of the communication of this information among its members. [Barlow 94] defines a taxonomy of information and maintains that among other characteristics information is a relationship.

The way in which information is becoming increasingly accessible and the increase in the speed at which information is being updated is creating the necessity for people to be continually learning. Society is heading in the direction of workers having to be constantly updated, thus creating a situation in which working and learning environments are converging.

This new culture of access to information and people has been generating a variety of environments and, more specifically, cooperation environments in which various people can perform activities in groups. These activities are often associated to education/training or work which tends to transform into the same type of activity.

One of these types of environment is designed for distance education. The concept of distance education is not new; it is associated to educating people where distance makes communication difficult between those who are consuming knowledge and those who are transmitting it. In general this type of distance education offers less

possibility for teachers and students to communicate than traditional teaching methods where all participants are present [Romiszowsky 97].

AulaNet is an environment for creating, administrating, updating and attending courses through the Internet. It has been developed in the Software Engineering Laboratory (LES) of the Computer Science Department at the Catholic University of Rio de Janeiro [Lucena et al. 99]. AulaNet offers, among other facilities, various types of communication integrated in one unique environment that allows communication, coordination and cooperation among the participants on a course.

One of the differences between teaching environments on the Internet and traditional forms of teaching with the participants present is the fact that distance courses are offering many new possibilities for communication between the participants in a group. These new environments on the Internet allow participants to interact at a greater level of intensity [Fussel et al. 1998].

2. Computer-Mediated Communication

The development of the Internet and the World Wide Web has introduced new forms of communication into every day life. Nowadays it is possible to communicate with other people, go shopping, make bank transactions and perform many other activities from one's home with a computer connected to the Internet. All these activities have established protocols of communication that may have distinct objectives referring to anything from entertainment to work commitments.

There are a variety of applications on the Internet that allow people to communicate with one or more persons, or to communicate with automatic procedures through the Web like for example buying a CD, transferring a software or enrolling in a course given through the Internet.

The first application to become popular was email which is being used more and more frequently all the time. Some enthusiasts are even calling it the third revolution, the first two being the written word and the printing machine [Nunberg 96]. It is increasingly common for people and companies to have an email address. Email is very accessible and one of its advantages is that it has a very low cost. It uses a small bandwidth of the Internet and nowadays there are even many free email services. In the beginning email was used by the scientific community but it is now becoming more widespread in everyday life. One example is the use of email to swap messages between people as a substitute for the traditional mail services. Email is also being used increasingly at work as a form of communication that substitutes the traditional memo and to request technical assistance as a substitute for telephone calls, etc...

Two other popular communication applications on the Internet are IRC (Internet Relay Chat) and ICQ (I Seek You). IRC is an application that allows various people to communicate through text in real time. ICQ appeared in November 1996 and two years later it already had 2 million registered users. It is a freeware application that allows a person connected to the Internet to know that other people are connected at that same moment using ICQ, thus enabling communication between these people through a type of email with a very short message reply time, giving the impression of conversation in real time. Both IRC and the ICQ have the facility to transfer files.

Videoconference is another form of communication that is increasingly used on the Internet. Examples of videoconference tools used on the Internet are CU-SeeMe, initially developed by Cornell University and currently being commercialized by White Pine Software, and Netmeeting developed by Microsoft. In a videoconference it is possible for various participants to communicate through audio, video and text. The participants of a videoconference can also interact through a whiteboard where various types of material are shared. For example, it is possible for somebody taking part in a videoconference to put a figure on the whiteboard and for someone else to indicate points that should be corrected in the figure. [Laufer & Fuks 98] present an experiment in which videoconference was used in an environment for cooperative learning.

The conjugation of the Web with databases, CGI and Java has been making an ever increasing range of services available on the Internet. It is currently possible to make the most diverse purchases through the Internet, from buying a book or CD to doing your weekly shopping at the supermarket. Nowadays, many banking services are also offered through sites on the Internet that enable account holders to undertake transactions with their accounts from their office or home.

These diverse forms of communication using the Internet are classified according to different criteria. [Long & Baecker 97] propose a taxonomy for the communication tools used on the Internet in which various characteristics are taken into consideration, like conversational synchronisation and style, audience membership and communications media, among others. These tools are analyzed individually but the type of use most suitable for each tool is not taken into consideration.

Each of these tools individually has a suitable use for a certain type of activity, with advantages and disadvantages depending on the activity. For more complex activities it would be convenient for a group of available tools to exist and that each of these tools be used in situations most suitable to its functionalities, thus increasing the potentiality of integrated use of these tools.

3. Computer-Mediated Communication in AulaNet

AulaNet is an environment for creating, administrating, updating and attending courses through the Internet. There are three actors involved in AulaNet: the administrator, the teacher and the student. In order to enter the AulaNet environment it is necessary to register. Once the administrator has accepted a person's registration he may make a request to enroll in one of the courses offered. If a participant would also like to be a teacher in AulaNet, which would allow him to create courses, it is necessary to make a teaching request that is analyzed and accepted or rejected by the administrator.

There are six steps to be followed in order to create a course in AulaNet. First the teacher must define the general course information, for example, the course name and syllabus. Then in the next three steps the teacher defines the communication, cooperation and coordination mechanisms to be used. Figure 1 shows the screen in which the teacher chooses the communication mechanisms of a course.

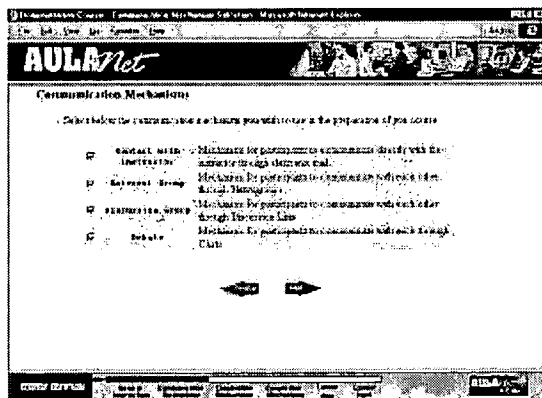

Figure 1: Interface in which the communication mechanisms of an AulaNet course are chosen

In the fifth step to creating a course in AulaNet the teacher defines a lesson plan and finally, in the sixth step, the teacher inputs the course material. The course material is transferred directly from the teacher's machine to the AulaNet server. At the moment AulaNet accepts material on the following formats: html, pdf, powerpoint, shockwave, toolbook, real, gif, jpg, avi and mov.

A course created in AulaNet supplies the teachers and students with various types of communication integrated in one unique environment that allows for communication, coordination and cooperation among the diverse participants of the course. We will now present some of the communication and coordination mechanisms that may be chosen by the teacher for a specific course.

The discussion list allows students enrolled in the course to send a message to all the others members on the course. This message is sent to all the other participants through email and is stored in the AulaNet database. Therefore, when a student enters the AulaNet environment and more specifically the environment of a certain course he can read all the messages that have already been sent to the discussion list through the Web interface.

The course news topics are defined by the instructor and contain subjects of interest to the community. Any community member can post messages in the news feature, however such messages, differing from the discussion list, are only accessible using the Web interface.

The teacher decides where the course discussions should take place, either in a discussion list or a newsgroup. In the postgraduate course Information Technologies Applied to Education given in the Computer Science department of the Catholic University of Rio de Janeiro, general discussions take place on the discussion list. When a theme on the discussion list becomes more important a specific newsgroup is created and the discussion about that theme is transferred to the newsgroup.

There are various possibilities for sending email messages in AulaNet. A student can send an email to the instructor of a course in which he is enrolled. The administrator can send messages to a specific student or teacher or to all the teachers and all the people registered in the environment. The sending of email messages is carried out in the actual AulaNet environment through filling in a form.

Webchat and CU-SeeMe videoconferencing technology are the synchronous forms of communication offered by AulaNet. Consulting the course agenda, students are informed that a chat session or a CU-SeeMe videoconference will take place. Real technology is used for broadcasting lectures.

The agenda has information about commitments established for the community. Announcements are posted by the instructor to inform the community about, for example, the postponement of a course activity.

4. Administrative Procedures

Within a cooperation environment there exists a variety of procedures that need a communication in order to be established. There are various administrative procedures within the AulaNet environment, like for example: participant registration, authorization to teach, the creation of courses, course enrollment, etc... Many of these procedures call for communication between the actors in the environment.

In version 1.0 of AulaNet participant registration was carried out automatically and did not require any authorization on behalf of the administrator. Once a request to register in the environment was made, the participant was automatically given authorization to request enrollment in any of the courses offered. Figure 2 shows a diagram representing a request to register in version 1.0 of AulaNet.

Figure 2: Diagram of Request to Register in Version 1.0 of AulaNet

In version 1.2 of AulaNet participant registration implies in a communication between the administrator and the person wanting to register. When a person makes a request to register in the environment an email is sent to the administrator informing him of the request. From that moment a negotiation process begins between the administrator and the person making the request. Depending on the information exchanged in this communication the administrator may accept or refuse the applicant, which means that this person may or may not have access to AulaNet. Figure 3 shows a diagram representing a request to register in version 1.2 of AulaNet.

Figure 3: Diagram of Request to Register in Version 1.2 of AulaNet

All the messages are sent within the AulaNet environment and are stored in the AulaNet database. In this way it is possible to follow the whole process until the administrator decides to accept or reject the registration request using the actual AulaNet environment. Figures 4 and 5 present the administrator's interface and the applicant's interface respectively.

All the communication related to the administrative procedures in AulaNet is carried out from the Web interface. The information related to this communication is stored in the AulaNet database thus allowing for the communication established during a determined procedure to be retrieved.

Figure 4: AulaNet - Administrator's Interface

Figure 5: AulaNet - Applicant's Interface

5. Conclusion and Future Work

The growing popularity of the Internet and the Web has been generating a variety of cooperation environments where various people can carry out activities in groups. These activities are often associated to education/training or work which tends to transform into the same type of activity.

The way in which information is becoming increasingly accessible and the increase in the speed at which information is being updated is creating the necessity for people to be continually learning. Society is heading in the direction of workers having to be constantly updated, thus creating a situation in which work and learning environments are converging.

Communication in cooperation environments is of fundamental importance in establishing the necessary conditions for effective coordination and cooperation among the participants in these environments. Communication in a determined cooperation environment is one of the main characteristics that defines the profile of such an environment.

AulaNet is an environment for creating, administrating, updating and attending courses through the Internet, that supplies teachers and students with various forms of communication integrated in one unique environment that allows communication, coordination and cooperation among the participants on a course.

The role of the teacher is transforming because in computer-mediated cooperation environments the concept of confinement no longer exists, whereby at a set time and place a teacher presents knowledge to a class of students forbidden to communicate among themselves. Computer-mediated cooperation environments offer a group of possibilities for communication among the participants of a course thus allowing for a more intense exchange of information and personal experiences. Therefore, the teacher changes from being a transmitter of information to a motivator and mediator of a group in a more constructivist form of learning. It is up to the teacher to organize the type of communication among the participants in order to avoid a cognitive overload faced with the volume of information to be dealt with. An adequate choice of the type of communication to be used to perform a certain task may positively influence the coordination and cooperation among the participants of a project [Gay & Lentini 95].

For future work we will observe and study the communication processes arising from the interaction among actors of computer-mediated cooperation environments, with an aim to define communication patterns. Within a cooperation environment there exists a variety of procedures that need a communication in order for them to be established. This

communication often presents a pattern of repetition. [Laufer & Fuks 95] define conversational clichés from conversations that repeat for certain situations. For example, it could be possible to define a group of communication patterns to be configured for each administrative procedure. A cooperation environment could be configured according to certain communication patterns suitable for a specific institution. At the moment, a participant with permission to teach does not need any authorization to create courses in AulaNet. At a certain moment, it could be desirable that course creation be preceded by an authorization on behalf of the administrator, which would result in a communication between the teacher and the administrator.

Taking the study of communication patterns as a starting point we also aim to define ways of registering the information generated during the negotiation carried out during communications, which often defines commitments between the participants of a communication. In this way we could retrieve a record of the processes associated to a determined communication pattern and the options and justifications for reaching decisions within computer-mediated cooperation environments.

Communication in computer-mediated cooperation environments is one of the main characteristics that defines the type of environment. It is necessary for computer-mediated cooperation environments to offer an integrated group of different forms of communication with the possibility of customizing their communication protocols, thus allowing for a more agile generation of environments with different profiles to appear.

Abstract: Harmful events, which occur during the provision of health care, can be costly and deadly. The challenge for clinicians and health professionals is to eliminate or at least reduce occurrence of these events to improve quality of care. This paper introduces a web-based intelligent system for managing the clinical incidents. The development of the system is an integration of rule-based reasoning, case-based reasoning and causal-based reasoning over the net infrastructure. The use of heuristic knowledge, previous cases as well as causal models facilitates the implementation of analysing, browsing and explaining clinical incident knowledge. The resulting system leads health professionals to share knowledge/experience on active and latent human failures and the re-use of such information increases clinical safety awareness.

1. Introduction

More than 80% of needless injury and or death among hospital patients in Australia is caused by human error [Johnson 1999]. For example, with the patient receipt of an inappropriate drug, the error is often associated with incorrectly dispensing or incorrectly prescribing due to similarity of medication names. The challenge for clinicians and health professionals is to eliminate or at least reduce occurrence of these incidents in order to increase care quality and reduce harm to patients. Therefore, it is important that we learn as much as possible from these incidents to prevent mistakes in the future and improve patient care.

Increased interest in quality improvement in health care has led to greater recognition that errors occur. However, the study of clinical errors, accidents or incidents is still in its relative infancy [Vincent et al 1993, Leape 1994, Bhasale *et al* 1998]. It is important to look at all aspects thorough analysis of incidents or accidents. These aspects should include identification of what actually happened; description of how it happened; identification of the causes and contributing factors (why) and determination of preventability and possible safeguards [Bhasale 1998]. It should be noted that although in some cases a negative outcome can not be prevented, but the conditions and factors that created a potential harmful situation are still of interest.

The World-Wide Web (WWW) represents one of the most powerful instruments for the creation and dissemination of information. One of the effects of the Web is a widening of the population of those who publish information. Health care has always been information rich, but has severely been limited by mechanisms for distribution and access to that information [Coiera 1996, 1997]. However, there comes the possibility of sharing such information whenever the need applied [Riva et al 1998]. Therefore, we aim to assist health professionals to explore medical incidents globally in order to identify how and why these incidents occurred in more detail and suggest improvements to prevent and mitigate their effects.

This paper introduces a Clinical Incident Management (CIM) system, a web-based intelligent system, to allow clinicians and/or other health professionals to complete structured incident reports about any event which has caused harm and can cause potential harm. The repository of clinical incident reports provides analyses of individual incidents such as type of incident, contributing factors and possible causes. When a new incident is reported, a set of intervention strategies is recommended to reduce the chances of similar problems occurring. The system enables health professionals to achieve a better understanding of possible underlying causes of specific groups of incidents. The system also performs

statistical analyses to indicate potential or actual harm to general practice patients. In addition to incident analysis knowledge, the CIM provides justification knowledge of suggested intervention methodology to the given clinical incident. The resulting system enables health professionals to share the medical incident information, which has caused harm and can cause potential harm. The re-use of such information may prevent or mitigate human or medical errors.

2. Major Functions of the CIM System

Major functionality of the CIM system includes incident analysis and advisory, explanation and justification, case-base browser, quantitative descriptive analysis and knowledge management as shown in figure 1. This section will concentrate on the description of these functions.

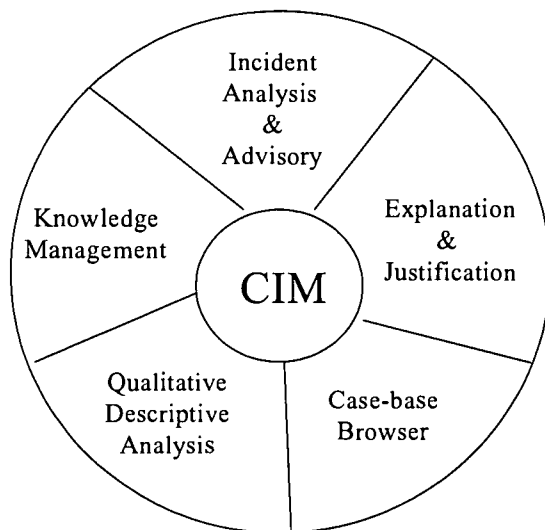

Figure 1. Major functions of the CIM system.

2.1 Incident Analysis and Advisory

The incident analysis and advisory function is based on health professionals providing incident reports in order to investigate the underlying problems in the given incident and suggest interventions for preventing these problems. In reporting the incident, an incident profile is provided by health professionals. The incident profile includes the patient's information (age and sex), incident outcomes (potential harm, immediate consequences and preventability) and general description of the incident.

The CIM system then assists the users to analyse the incident by identifying types of problems involved in, their features and possible causes. The type of incidents can be classified as pharmacological, diagnostic, or other incident types. The incident features consist of factors contributing to incident types. For example, diagnostic incidents can either relate to clinical judgement in assessing the patient or poor communication (between GP and patient, or between health professionals). The possible causes identify the causes relating to the incident features, such as errors in judgement may cause by failure to recognise significant symptoms and signs.

Case-based Reasoning (CBR) and Rule-based Reasoning (RBR) are applied to the incident cases analysis and generation of intervention knowledge. The CIM system searches through the incident case base. If a matched sub-case can be found based on the incident types, features and causes, the interventions in this sub-case are adapted as interventions to the problem. Otherwise, the generalised rules for interventions are applied to produce recommendations using heuristic knowledge.

2.2 Explanation and Justification

The explanation task is to answer how that causes are determined and the justification task provides extra information of the suggested intervention, which leads to potential benefits and advantages of using suggested interventions. Rule-based approach which can be used to represent and reason about the events that lead to major accidents. However, this is of little benefit if analysts cannot achieve a better understanding of the causes of the “errors” [Johnson 1997]. Causal Reasoning therefore is applied to identify causes of an incident that might otherwise be lost in the incident report [Wick 1993].

A frame-based knowledge base representation in the form of a causal graph is used to capture information for explanation and justification. The knowledge bases are represented as a collection of cause-effect relationships illustrated in Figure 2.

Activity:	Contributing Factor (CF)
Index:	CF-1
Text:	“Poor communication between GP and patient”
Inference:	lead to INT-3
Activity:	Intervention (INT)
Index:	INT-3
Text:	“GP can use a clear statement for communication”
Inference:	caused by CF-1, CF-3, CF-4
Activity:	Explanation (EXP)
Index:	EXP-1
Text:	“Patient’s Poor English”
Inference:	determine for CF-1
Activity:	Justification (JUS)
Index:	JUS-10
Text:	“Print prescriptions and provide with a clear medication names”
Inference:	justify for INT-3

Figure 2. A frame-based representation of a causal model.

Using the representations illustrated in Figure 2, the inference transition is possible when relationships are found. For example, if an inappropriate drug incident occurred which was due to the poor communication between GP and patient. The intervention statement therefore leads to as “GP can use a clear statement for communication”. The explanation of the cause may be the patient has poor English. The justification of suggested intervention is to print prescriptions and provide clear medication names.

2.3 Case-Based Browser

In order to maximise the usefulness of accident research, it is important to allow health professionals to browse previous incidents stored in the system. The development of the browsing functionality is based on case-based reasoning. It retrieves relevant incident cases/sub-cases according to users’ queries. Should the user prefer to view certain cases specific to their interest, they can restrict their search in any of the five areas provided:

- Incident Profile
- Incident Type
- Incident Feature
- Possible Causes
- Interventions

Six options in the incident profile are provided for the user to specify their search parameters: patient’s age, patient’s sex, health problem, potential harm, immediate consequence, and preventability. When selected, these parameters are taken to be logically AND with each other. At any time, users can view

the status of their query. The relevance of retrieved incident cases to the query is measured based on an attribute order that specifies the importance order of attributes used in the query [Zhang *et al* 1999].

The advantage of using this case-based browser is that health professionals and end-users can glance over incidents in detail. Such a browsing functionality encourages the sharing and re-using information to identify clinical incidents and to illustrate preventable and especially system causes of such incidents.

2.4 Quantitative Descriptive Analysis

It is essential for the web users to gain an understanding of the type of incidents occurring in general practice and hence areas of potential harm; and to identify areas which might benefit from intervention. Quantitative descriptive analysis is used to provide the main features of the data for all incident cases.

Figure 3 shows four types of statistical analysis, which are provided in the CIM system:

- Age and Sex of Patients [histogram]
- Types of Incidents [pie chart]
- Features of Incidents [table]
- Outcomes of Incidents [table]

Figure 3. An example result of the statistical analysis

The age and sex of patients histogram displays the relative distribution of age and sex of patients in all the cases. The ages are categorised into 8 age groups. All toddlers and babies under 12 months is grouped into the "<1 year" age bracket. The incident pie chart displays the proportion of each incident type as a percentage of total number of cases. This analysis is dynamic and will update the percentages as new cases are entered or new incident types are reported. Ranking from the greatest to lowest, the twelve most frequently occurring incidents feature in the case base. While there may be other less significant incident features, they are not listed here and so as a result, the total percentage will not necessarily total 100%. The outcome of incidents table shows a breakdown of each incident type reported in the case base in the areas of potential harm and immediate consequences. The percentage proportion is shown for each of the 5 degrees of severity.

2.5 Knowledge Management

The knowledge management function is built for the maintenance of the incident case base and domain knowledge. It is designed for the knowledge engineers to access newly reported incident cases and insert appropriate interventions to the given incident. This is done by integrating the input incident

profile with the analysis information and suggested interventions together. When new information or knowledge arrives, knowledge engineers can manually insert the new piece of information or knowledge into knowledge bases for future use. This new information or knowledge can be either based on user's input or new research results. For example, if there is no existing type of medical problems in the incident profile, users can add a new type of medical problem in the "other" column of the list. Knowledge engineers then evaluate the problem type and integrate it into the knowledge bases.

It is important to consider the consistency of the formalisation when managing the domain knowledge. The CIM system provides built-in consistency checking and incoherence checking. The consistency checking is to ensure that new components do not conflict with current knowledge. The incoherence checking is concerned with the representation schemes. For example, the relationships of problem types and contributing factors need to be maintained if a new problem feature is introduced. Therefore, when new problem features are inserted, associated problem types and contributing factors are provided for knowledge engineers to consider further relationships.

3. Implementation on the Web

The CIM system is developed to create web-accessible, distributed medical applications consisting of three main components: a set of inference engines, a long-term knowledge-base and case-base repository, and a graphical user interface. The knowledge bases and case bases consist of incident cases and generalised knowledge for intervention, explanation and justification as well as long-term data storage. The reasoning engines manipulate the objects contained in the knowledge bases and case bases. The graphical user interface provides data collection and representation facilities.

The client-server implementation environment is based on an object-oriented approach using *Java 2* platform. The graphical user interface is implemented using the *Swing* API whereas the database is applied to SQL data base server.

Two types of security are involved in the system because security is also of fundamental importance in health care. The first involves setting up barriers to accessing knowledge-base and case-case files. Only the knowledge engineers can access these files as they are responsible for the maintenance of the repository. The second is the reporting GPs or health professionals who will receive an identification number with password to authenticate that they are privileged to use the system. In the reporting process, the patient's and health professional's names are anonymous as they are confidential information. The general public, however, is allowed to browse the system, but their input will not be saved to the repository.

4. Conclusions

The Web is increasingly being used as a platform to develop distributed applications, particularly in contexts, such as medical ones, where high accessibility and availability are required. In this paper we have introduced the development of a knowledge-based medical application on the Web to identify how clinical incidents occur and to illustrate preventable and especially system causes of such incidents. Our work is based on a Pilot Study of Incident Monitoring in Australia general practice [Bhasale et al 1998].

From the health care perspective, an important difference between our work and other studies such as Harvard Medical Practice Study [Leape et al 1991] is that we provide detailed contextual information about specific processes and situations. Such information is then used to make specific recommendations. From the knowledge-based systems perspective, rule-based reasoning, case-based reasoning and causal reasoning are all required for solving complex real world problems. However, there has been little prior work in integrating the three [Li 1999]. In this paper, a hybrid rule base, case base and causal base approach is proposed for improving the effectiveness of the rule-based reasoning system through the case-based and causal-based reasoning. Further more, we have presented a development environment for knowledge-based medical applications on the Web, which enhances the global accessibility and useability.

There are a couple of directions in which this research can be extended. Firstly, the linking of interventions to relevant on-line medical sources can be studied. In the current system, the suggested interventions only provide strategies. It will be useful to provide some references and guidelines associated with the suggested recommendations for a better understanding of the interventions. Secondly, the retrieval of relevant cases can be based on a flexible attribute order. A fixed attribute order is currently used to specify the important order for attribute. It is desirable to allow users to specify the order for attributes used in the query.

Video on the Web: Principles of Continuity Linking and Narrative Flow

Gunnar Liestøl
Department of Media & Communication
University of Oslo
Norway
gunnar.liestol@media.uio.no

Abstract: The emergence of video on the Web finally forces hypermedia designers to solve the problems of integrating dynamic information types (audio and video) in multilinear hypermedia structures. In dynamic documents, such as film, narrative flow and coherence is ensured by the four principles of continuity editing. In hypermedia environments these principles are easily applicable to the dynamic domains, but fall short when static information types (text and still images) are included in a linked structure. The linking of dynamic and static nodes transcends textual considerations and must take into account the different activity modes of the user-subject caused by the use of multiple information types (modes). The shift and oscillation between object-action (system-dominated activity) and subject-action (user-dominated activity) enforce a fifth principle of continuity linking: activity continuity. To achieve unobtrusive activity continuity and flow in multilinear and hypermedia narratives, various means at multiple textual levels are applied, including the original four principles of continuity editing in film.

1. Video on the Web and Storytelling

Due to continued improvements of both compression algorithms and bandwidth, hypermedia in general, and the use of video in particular, is evolving rapidly on the World Wide Web. However, to date the linking of video and audio on the one side and text and graphics on the other, is discontinuous and prevents the necessary narrative flow and contiguity needed for the Web to develop as an arena for multilinear hypermedia storytelling. Narrative flow within multilinear document structures is decisive in any kind of discourse involving argument, proofs, persuasion and reasoning, all of which are core ingredients of educational discourse. In hypertext and hypermedia research and development the use of video is suspiciously absent, apart from scattered attempts. [1] Hypertext

research has traditionally been lingocentric and defined itself as non-multimedia. Another explanation might be that when video finally seemed to take off on the cd-rom platform in the early 1990s, the Web then appeared and gained popularity, with the result that the focus of hypermedia development was directed towards global hypertexts dominated by text and graphics rather than bandwidth-demanding audio and video.

In 1970, hypertext-inventor and pioneer Ted Nelson described the possible development of an all-purpose hypertext in analogy with the history of motion pictures. [2] It took 20 years, from 1895 to 1915, before filmmakers, such as Griffith, discovered the inherent and formerly unknown features of film as a medium for storytelling. Today, 10 years after the general availability of integrated digital video and 30 years after Nelson's paper, dynamic information types are hot on the agenda in Web development and design. It is time to attempt to outline some of the relevant features inherent in this still new medium. In order to ensure support for multilinear storytelling we must ask: what are the principles of linking with dynamic nodes of audio and video in hypermedia Web-environments? To answer this question it might be relevant to first look at how segments of information have been combined (linked) in film and television which are the dominant media form of dynamic information types.

2. Narrative Continuity in Film

When the novelty of watching movements on the screen faded in the early days of motion pictures, the dominant mode of film production, based on its theatrical influence, proved itself to be insufficient and dull. Film making had been organized around the *scene* as its fundamental building block. When Griffith made 'Birth of a Nation' in 1915, he switched to using the *shot* as the basic element. The shift from scene to shot marks the turn from the theatre as production model to the establishment of editing as the production technique inherent in and peculiar to film. However, when leaving the temporal and spatial continuum of the stable camera and the one-reel shot, the problem of *discontinuity* emerged. The joining together of individual shots, recorded in different positions and locations, had to be carried out according to certain principles in order to support the story which was being told. It was important – despite the fragmentation into different shots, of various length, content and visual appearance – to create a seamless experience of narrative coherence, making the fabrication of the film invisible. The way the film was actually composed and told, therefore, should not interfere with the experience of the storyline as it progressed. To achieve narrative coherence and flow, the *continuity* system of film production was discovered, invented and practised. For more than 80 years of cinematic production this has been the dominant style of film making and editing.

3. Continuity Editing and Continuity Linking

'Editing might appear to present a dilemma to the filmmaker. On one hand, the physical break between one shot and another may seem to have a disturbing effect, interrupting the viewer's flow of attention. On the other hand, editing is undeniable a primary means for constructing a film. How can one use editing and yet control its disruptive force?' [3] The strategy to balance this dilemma and to achieve narrative contiguity is known as *continuity editing* and employs four main principles of continuity: spatial, temporal, graphical and rhythmic. Spatial continuity is attained by strict adherence to the 180-degree rule which ensures a common space from shot to shot and a constant screen direction. Temporal continuity is achieved by focusing in the chronology of shots concerning action, event and cause, while at the same time supporting and sustaining the temporal manipulation of order, frequency and duration. Graphical continuity is obtained by matching the compositional display of objects, light, shade and actions between shots. Finally, rhythmic continuity relates the shot's duration to its camera perspective, information complexity, handling of distance, and display of

action. These principles of continuity editing are operational principles or conventions, which may co-exist in a given conjoining of two shots. How, then, do they relate to hypermedia?

Hypermedia linking also presents a dilemma for the author/designer. The physical break between nodes may have a disturbing effect, interrupting the user's flow of attention and interaction. Alternatively, linking is undeniably a primary means of constructing hypermedia presentations. Obviously film and hypermedia have many features in common. [4] In general, we observe that, when linking within and between audio-video dominated nodes, the principles are applicable. This is due to the fact that, in hypermedia, shots and sequences form nodes, and linking becomes equivalent to editing, but handed over from the producer to the user. The problem, however, emerges when audio-video dominated nodes are linked to nodes dominated by text and still images. The 'flow' of a story being told to us in audio-video mode – linear or multilinear – is a quality inherent in these information types, which again is strictly conditioned by their temporal dependence. Text and still images, on the other hand, do not unfold over time.

4. Static and Dynamic

Audio and video are dynamic information types; they are conditioned by temporal sequence, and use time to unfold and come into being. Text and still image are static information types; they do not change over time. Linking within the dynamic domain adheres to the principles of film editing, though conventions for presenting link anchors and handling of temporal dimension are problematic and satisfactory solutions are still to be found. Linking of nodes within the static domain is relatively unproblematic, as we know from the Web and previous hypertext systems. [5] This is due to the fact that integration of static information types have long evolved in the literary and print tradition, and integration of dynamic information types has been fully developed in the film/television tradition. A problem arises when we cross this distinction maintained by the respective analogue traditions in combining the two within the same digital environment. The linking of dynamic and static nodes transcends the textual level of the digital material and must take into consideration the opposing kinds of *user activity* which are inherent in the two different domains of information types. Video/audio and text/image, respectively, have different ways of directing the user's behaviour when interacting with given information. The dynamic domain leaves us *passive* when it comes to generating the information and also in deciding its tempo of delivery, while the static domain presupposes the user's *active* participation for its tempo of delivery and existence.

5. Subject-action and Object-action

With the consumption of dynamic information the dominant activity is located in the textual object itself, as *object-action*; with the consumption of static information, however, the dominant activity is located with the user-subject, as *subject-action*. When we follow a link from a node dominated by dynamic information (for example video) to a node dominated by static information (for example text), this includes not only a shift from one type of information to another, but also a transition from one kind of subject-behaviour to another, from 'passive' to 'active', from object-action to subject-action. The user-subject must behave according to which information type is dominating the discourse. Such obtrusive shifts create a kind of discontinuity that might interfere with the flow and progress of multimedia and multilinear narratives.

The relationship between subject-action and object-action is further complicated by the fact that all link-following – every activation of a link – also is necessarily subject-action. Thus we have two kinds of subject-actions. One is enforced by the consumption of static information types themselves (subjective) and, at a more direct level, another occurs when the user-subject interferes with, intervenes in or manipulates the materiality of the message (objective). Subject-action, at this

level, is again performed in several ways, from simple selection and activation, to more substantial and articulate input, which again influences object-action in various forms.

As a consequence, to obtain flow and continuity in hypermedia narratives, particularly devoted to include audio and video, not only must the internal qualities of the textual object itself be considered, but it is also necessary to include the extratextual relationships of both object-action and subject-action, including different forms of subject-actions.

6. A Fifth Principle of Continuity Linking

Continuity linking is a transformation of continuity editing applied as a 'technical trope' in the different but related communicational (and rhetorical) environment of hypermedia on the Web. The 'linking' of object-actions with subject-actions and vice versa, and the relationship and oscillation *between* these various kinds of activity forms a kind of *inter-activity* that is crucial to the composition and development of storytelling which exploits the potential of hypermedia. Considering this relationship, we might call the fifth principle of continuity linking *activity continuity*.

Activity continuity may be tentatively offered as a principle. As yet, there are no formal established rules which, when followed, ensure continuity between subject-action and object-action. Experiments show that *activity continuity*, despite the interplay of reciprocal actions, is basically obtained by applying the other four principles of continuity linking for this end. A main focus of attention must be given to motivate the user for the shift, and this again is achieved by exploiting semantic elements in the system itself. Any element that signals the shift is important, from the layout of the link anchor to the inventory at the story-level. [6]

7. Conclusion and Further Research

Continuity editing has been criticised for hiding the actual manufacturing of film by seamlessly masking the editing of shots. That might be a valid critique of a well-established media form. However, faced with the infancy of interactive multimedia and hypermedia, it seems more important at this stage to first put the medium together before taking it apart critically. A combination of experiments and analysis is necessary to develop this fifth principle of continuity linking into a valuable technique for improving the style and aesthetics of hypermedia and multilinear storytelling. It is rapidly becoming clear, however, that the best examples of this might not be found in attempts of the hypermedia tradition on the Web, but rather in the 3D environments of computer games. The computer medium itself contributes a unique information type to the multiple media environment of dynamic 3D. In computer games this representational form is already dominant. Further, because of the complexity and ability to include and represent all the other information types within such dynamic 3D environments, the problems of static and dynamic, subject-action and object-action, are reconfigured in challenging and interesting ways. That is another story...

Abstract : Web-based Distance Education requires skills that transcend traditional teaching methods and most faculty currently employed in higher education do not possess these required skills. An aggressive strategy of training and recruitment is required to create a professoriate which possesses the wisdom of traditional faculties and the technological skills required to effectively communicate in the future. This paper examines the need for changes in higher education staffing, identifies obstacles to those changes, and proposes strategies for overcoming those obstacles.

Introduction

As we move forward toward the new millennium, pressure for changing roles among faculty is a significant predictor of the attention that must be given to the planned preparation of those faculty. Few individuals, however, have examined faculty recruitment and training issues for Web-based distance education specifically. Yet, this topic is of intense interest to practitioners, researchers and administrators alike as higher education struggles to transform itself in a market sensitive manner. The role of Web-based distance education in this change is an important area to examine.

Faculty Recruitment

Traditionally, faculty have been hired to work on a campus or in a school building. This often required a deep financial and logistical commitment on the part of the organization and the individual to develop and sustain a relationship. Universities and colleges have historically treated faculty hiring as a decision with a significant and long term impact on the educational direction of the academic unit. Hiring a full-time faculty member was as much a philosophical decision about programmatic futures as it was a personnel action. Employment was not an action entered into lightly by either the institution or the individual. Adjunct professorial hiring added some flexibility to the activity of faculty recruitment, but the pool was usually limited to local talent. In non-metropolitan areas, finding qualified adjuncts was at least difficult, if not impossible.

Web-based distance technologies and alternative paradigms of distance learning create exciting new possibilities for staffing. Although universities have been hesitant to exploit these possibilities, a number of options are inherent in the larger pool of talent made accessible to institutions of learning.

- Distance technologies make it possible to record and/or distribute expert knowledge in ways which expand upon the use of traditional books and papers.
- Web-based text, graphics, online conferencing software, streaming audio and streaming video make dynamic expert knowledge accessible to not only appropriately equipped classrooms, but thousands of remote sites, including homes and offices.
- Courses can be conducted and managed by part-time faculty even if they live hundreds of miles away.
- Remote access benefits full-time faculty directly by offering greater flexibility when they need to be away from campus for field research, conferences, or other travel reasons.

- Additionally, these approaches can be combined in collaborative teaching models to permit faculty from multiple campuses to teach together to a group composed of representatives of each home campus and others. Even when they are hired on a very limited basis part-time content experts greatly enhance the knowledge base available to any program of study. Consequently, the demand of market forces is prodding a gentle exploration of these innovative ideas in spite of the uncertainty of university reward and recognition structures.

The new talent pool evolving from Web-based distance technologies creates opportunities for innovative recruitment strategies and options (Marquardt & Kearsley 1998). All institutions, even those that are small and remote, can advertise nationally for expert faculty to expand or complement their core faculty resources. Recruitment can be designed to attract faculty to teach entire courses or special modules, which only require modest time and effort, but special expertise. A more diverse faculty can be attracted to cover topics from a unique regional, cultural, or ideological perspective. Retired faculty can continue to participate in the life of the university as they are needed, and as they desire, from wherever they may have relocated. Large numbers of students in one class can be managed by one regular faculty who manages the course and others who contribute their special expertise and share the load for interactivity and evaluation. Some faculty can be hired exclusively for course design, while others are hired for instruction. Whether the model is individually oriented or team oriented, distance technologies mean that a more diverse, better qualified, more talented, and flexible pool of potential faculty can become available to all institutions.

The net result of more faculty and more institutions vying for their participation will be more competition. Institutional loyalty and proximity are still factors in faculty decision making, but incentives will become increasingly important especially as a professional group of free-market distance educators emerges. Institutions that wish to recruit the best and the brightest faculty will be well advised to follow traditional lessons in the context of a new reality. Faculty teaching at a distance will not be enticed by a move to a cultural center or research facilities, they are more likely to be enticed by a situation which provides them a great deal of flexibility. They may be motivated by an institutional affiliation with an institution renowned for excellence in traditional and distance programs, but they will certainly be motivated by those institutions with the most interesting curriculum options, best support services, and most enticing compensation packages. Regardless of the reputation of an institution, a recruiting strategy which attracts high quality faculty who are available, skilled, and willing to follow institutional policies is essential and must be carefully planned and executed.

Obstacles to Recruitment Success

Even a willing and capable workforce will not eradicate a bevy of serious and contentious issues which will continue to plague efforts at academic reform. Strategies such as those outlined above will conflict with traditional wisdom and practices of most higher education institutions. First among these are the dual problems of promotion and tenure. Most institutions do not have clear policies which address the decision weight for the significant efforts required for development and delivery of web based learning materials. This ambiguity will continue to be a disincentive for many non-tenured faculty to participate in web based learning activities. Experienced and tenured faculty will likewise be deterred by the threat to job security posed by a recruiting strategy which focuses on performance criteria not general institutional status. Furthermore, what is to be done if there are tenured faculty who refuse to perform web-based teaching activities or who perform poorly when asked to do so? Will faculty roles be differentiated based on ability? Will faculty work in teams?

Special work agreements with performance specifications and the necessity of course and faculty evaluations for purposes of quality assurance with part-time faculty, will also threaten some traditional notions of academic freedom. There are also concerns that a few high profile – high status faculty may dominate the instructional world of the web as an academic superstars; thus, attracting most students to their course to the detriment of other arguably superior learning opportunities. Also of interest is how intellectual property and compensation decisions will be adjudicated when intellectual wares may go to the highest bidder.

Faculty Training

Large and financially affluent institutions will have an advantage in recruiting not only the most knowledgeable faculty, but also the most skilled at Web-based distance education. Nevertheless, recruitment alone will not suffice in creating a faculty

prepared for a web based learning environment. All educational institutions will need to commit to faculty training as a core part of their academic activity. While some education and training can be delivered at a distance by even the uninitiated, normal communications skills are inadequate to achieve effective learning results across the diverse methods of distance education.

To achieve a high performance solution, it is imperative that a systematic approach be applied to the planning and development of distance learning materials, instructional methods, and communications infrastructure (Laney 1996). It is precisely because learners and faculty are physically separated in a web-based learning environment, that course structure and materials must be developed in a systematic manner that reduces the possibilities of misinterpretation and confusion. Traditional course preparation efforts range dramatically among higher education faculty. Many faculty prepare little more than a topical syllabus and allow lessons to emerge from classroom interaction coupled with the personal expertise of the faculty. Other faculty prepare learning objectives, activities, and materials, but few have training in these endeavors. These traditional approaches are not sufficient to engender high quality web based instruction.

In general, the best technique for learning to use distance education technologies is practice. Skill development evolves over time in real life situations. It is a good idea to have faculty participate as learners or observers in settings which use distance education strategies, then have them contribute information or lessons to an existing class. Finally, allow new distance faculty to design and develop a lesson without the pressure of having to deliver the actual lesson. A great deal will be learned by actually going through all the steps involved.

Generally, new faculty need to learn how to establish and maintain contact at a distance. They should attempt to create situations in which they reach out to the clients personally as though they were writing a letter. They should think about engaging the clients and communicating to them by anticipating their questions and confusion. Finally, new faculty should determine how they can best evaluate learning in a distance context. The signs are different, but the students' needs are the same. Obviously, the institution should provide as much help and support as possible to these efforts on the part of faculty, but it is the individual that must do the thinking.

Videotape for asynchronous Web-based delivery involves some kind of studio or field production of a presentation, electronic field trip, or demonstration and variations on these themes for delivery to clients to view at their convenience.

Faculty should watch several examples of high quality examples (within the production guidelines of the institutional producer) to begin conceptualizing the kind of production that can and should be accomplished. Next the faculty should work with a director to create several simple samples of on camera work, listening carefully to the director's advice. The samples should be reviewed with the director and redone for comparison purposes. Finally, some samples should be created and shared with colleagues and students for feedback. The production guidelines for each institution will dictate a good deal about what can and can't be done, but these should always be stretched in the interest of good quality instruction.

World Wide Web based text with graphics for asynchronous delivery is the distribution of HTML documents through the Internet for remote viewing and reading. Skill development with the World Wide Web is different that with video production; most important for faculty is the ability to plan and design learning resources that work well within a hypertext and hypermedia environment. This is most efficiently accomplished through the use of an instructional designer or similar support person. Faculty may also want to develop skill in HTML coding, in order to quickly update documents and add resources. HTML knowledge is not essential, but should be provided as a support resources by the institution for document creation.

Computer based conferencing for asynchronous delivery is the use of a computer based system for communicating through the use of electronic mail, newsgroups, or web based conferencing. Almost all faculty now use some form of electronic communications for sharing information. There are techniques that need to be developed to make this work effectively. Most important is the development of a careful communication style that does not inadvertently offend. It is also essential that skills in file transfer and attachment be developed as well.

Faculty are not likely to seek out assistance in learning these techniques without some motivation and encouragement by the institution. It is imperative that institutions establish a comprehensive faculty development program and require those faculty who want to participate in distance learning to participate. Faculty with well developed skills and experience will work with confidence and effectively represent the institution.

Obstacles to Training Success

Training to enhance specific job performance and skill development for a changing workplace are not easily accommodated in higher education settings. Faculty have traditionally been difficult to train for a variety of reasons; status, ego, self-confidence, and job definition are among them. Training and human development have been designated as activities best suited for staff. Attitudes are changing among faculty who see skill enhancement as a means to an end, but there are many who perceive that participation in training initiatives as the first step in changing faculty roles. Faculty roles are changing rapidly; it is imperative that training programs position themselves as opportunities for faculty survival and not vehicles for faculty demise.

Many faculty are also reluctant to be trained in the midst of their peers for fear of embarrassment. This is especially true in technical areas where foundational knowledge and prior experience are prerequisites to rapid and successful learning. Consequently, many faculty desire individualized instruction which is expensive and often impossible to provide for everyone. Screening and confidence building activities are key strategies to training success. Activities should also provide tangible and immediate benefits to the lives of faculty participants. Nothing breeds success like prior success.

Human and equipment resources are only part of the limitation in delivering successful training experiences to faculty. Faculty in higher education have a range of responsibilities which create unusual schedules; it is difficult to find a time that meet the needs of a large number of faculty, especially during the academic year. Even when scheduling can be accomplished, situations of demand that faculty set priorities on their time and training opportunities usually come last. Identifying special high profile training opportunities during non-peak times, especially summer will provide some relief, but generally planning well in advance is the best strategy.

As with any group, faculty also come to learning opportunities with a diverse set of personal and professional goals and needs. For example, some faculty may want to know 'how to' do everything necessary to design and create a website for an on-line course; others may want to provide references on-line to supplement on site instruction. These are both appropriate goals, but with radically different training experiences and time commitments attached. Trainers must be sensitive to the needs of each in structuring learning experiences. In addition to diverse goals, faculty may have different learning needs as well, some will come with a lot of prior knowledge and experience, others with very little. It is extraordinarily difficult to meet the requirements of each individual; but training that is too generic may not meet the needs of anyone. It is imperative that faculty be screened for prior knowledge; training can then be designed at an appropriate level for an individual or group of faculty.

In addition to diverse goals and learning needs, faculty members also tend to lack a common culture of pedagogy. The structure of academic disciplines, prior teaching and learning experiences, culture background, general philosophy of life and formal pedagogical training all contribute to a faculty member's view of the teaching and learning process. Distance and mediated learning in general and web-based learning specifically, compel a systematic examination of our pedagogical underpinnings, but old and successful teaching methods don't yield easily.

Many organizations find that equipment available for training is not available on faculty offices or home equipment. This is a daunting limitation. If faculty cannot practice and implement what they have learned, their interest, knowledge, and skills will soon atrophy. Efforts should be made to provide appropriate equipment to faculty who will use it, perhaps as a reward for successful training. If this is not an affordable alternative, then a facility with all appropriate equipment and staff should be provided as a central resource exclusively for faculty. Such a facility will permit faculty more resources than normally possible on the desktop and a retreat from interruptions.

Faculty Development Case Study: The Instructional Technology Laboratory

The Instructional Technology Lab was established in August of 1997 to provide the George Washington University faculty a resource to assist them in appropriate and desirable uses of instructional technologies. The ITL has evolved to offer a range of support services to the faculty that aim to effectively integrate instructional technologies into the academic program based upon a strong pedagogical foundation. Staff specialists in the ITL have instructional design, interface and graphics design, and teaching experience in traditional and mediated learning environments.

Physically, the ITL is an open environment that provides direct access to professional staff and equipment for faculty working on multimedia projects, redesigning curricula, or learning about new technologies. A complement of state of the art audio, video, and computer equipment provides faculty access to otherwise unavailable or expensive equipment. Designed for both group and individual faculty training, the physical composition of the ITL fosters cooperative project-oriented experimentation and development with a range of instructional technologies.

The earliest developmental stage of the ITL focused on development of the lab facilities. The lab supports computer, video, audio, and staff resources in a collaborative work environment. Faculty members are assisted in the creation of compelling, effective and high quality multimedia presentations and course materials.

The second stage of the ITL's development combined ITL facilities with technical workshops and presentations utilizing the computer labs, computer classrooms, and seminar rooms elsewhere on campus. Demonstrations of new technologies, emerging theories of learning and instruction, and different teaching strategies are organized and presented by ITL staff in coordination with other university units. Armed with this knowledge, faculty acquire an intellectual foundation as well as practical experiences with which they continue working with ITL staff to implement appropriate technologies into their teaching.

In responding to faculty needs, new opportunities have emerged to engage and work with faculty as they develop instructional technologies. One area of focus lies in online courseware tools. A system originally developed in the ITL and now being extended to the entire university community is *Prometheus*. This product allows faculty to easily create and manage Web based courses and course materials for both traditional and distance students. While courseware tools can facilitate and assist in Web based instruction, the ITL views its role as assisting faculty in determining why, when, and how to use this and other tools in an effective manner overcoming the relatively simple goal of 'getting my course on the Web'.

Recently, the ITL has been focusing on improving faculty development through a more systematic and proactive strategy.

In cooperation with other university departments the Summer Intensive Workshop Initiative (SIWI) was created. This project draws on staff expertise and resources to provide faculty with an intensive 3 day series of workshops and seminars on teaching and learning with instructional technologies. The initiative seeks to provide specially tailored opportunities to faculty based on their skill level. In addition to the focused and intensive workshops, the SIWI effort includes follow-up support as faculty apply their new skills. Staff from the Instructional Technology Lab work individually with faculty on problem definition and project planning in addition to instructional design and technical support. The SIWI program has at its core an ambitious series of evaluative measures and plans call for a wider evaluation of the effectiveness of faculty use of instructional technologies in the classroom. In addition to the intensive workshops and follow-up support, the ITL is working to implement a grant program that will provide faculty with fiscal resources to accomplish their course development goals.

The ITL seeks to provide the university faculty with pedagogical, as well as technological, activities and projects that support high quality learning. To this end, the ITL staff constantly seek to improve their services and respond to faculty needs. Future projects of the ITL will include a metropolitan area symposium on effective uses of instructional technologies, an electronic journal focusing on faculty projects and successes, and the addition of fee based course design, technology integration, and materials development services. These efforts and future projects will focus attention on pedagogical issues and reflect the ability of the ITL staff to think 'outside the box' while providing custom solutions and approaches to complex instructional challenges.

Conclusion

As Web-based distance education continues to rapidly grow in popularity the issues of faculty recruitment and training are moving to the forefront of items that need to be addressed. Recruitment and training of faculty to teach in Web-based distance education environments differs from recruitment and training of faculty to teach in traditional environments.

Abstract: *The World Wide Web (WWW) has considerable potential for delivering distance education programs. New software tools are being developed to facilitate the authoring, delivery and management of Web-based courses. In this paper, we perform a detailed assessment of five such Web-based educational environments, namely WebCT, TopClass, LearningSpace, Virtual-U and LearnLinc. We base our evaluation on experimentation and practice with these tools.*

1. Introduction

Tele-Education on the WWW can enhance the traditional way of teaching and offer new learning experiences to the students. However, there are many questions to be answered, for example how well a formal educational system can be delivered over the Web, will there be any human contact or communication, what are the benefits of Web-based education, etc. Recently, many Web-based educational environments have been developed. These software tools help in the development and authoring of courses, the delivery of the courses over the Web, the secure access of the course material by the students and the instructors, the automatic grading of exams, the student performance tracking and reporting, the statistical analysis of the student performance and the course material usage. Some popular software tools that facilitate the creation of sophisticated Web-based educational environments are the following: WebCT [WebCT], TopClass [TopClass], LearningSpace [LearningSpace], Virtual-U [Virtual-U] and LearnLinc [LearnLinc].

It is difficult to conclude about the best product because some are better in a particular feature area, while others in another feature area. Furthermore, every day new products and new versions of the already existing products appear. Bruce Landon [Landon 1998] compares many software tools such as WebCT, TopClass, LearningSpace, Virtual-U, Web Course in a Box, CourseInfo, FirstClass, PlaceWare. He concludes that WebCT, TopClass and LearningSpace are the best, with a slight superiority of TopClass. LearningSpace precedes the others in the synchronous collaboration features. It is important to mention that the synchronous communication abilities of LearningSpace are due to the DataBeam Learning Server, a Web-based educational product by Lotus Company. Sharon Gray [Gray 1998] surveys many software tools and concludes that LearningSpace is the best followed by WebCT and TopClass V2.0.2. Gray mainly focuses on the area of collaboration tools in which LearningSpace is a step ahead. Gray also points out the importance of WebCT for its feature of detailed student progress report and TopClass for its auto-testing feature. Herb Bethowey [Bethowey, 1997] concludes that TopClass is an easy to use software tool with extensive features for interaction between student-to-student and student-to-instructor. He also suggests LearningSpace as an excellent collaboration tool, with excellent course administration. Some other papers [Iowa 1997], [DBCC 1998], [Manitoba 1998] and [Uiterwijk & Seoane 1998] also analyze and compare Web-based educational tools, with LearningSpace, WebCT, TopClass and Virtual-U to be the most promising for Web-based education. University of Manitoba compares the three important software tools (LearningSpace, WebCT, TopClass) and the authoring tool ToolBook II. The survey concludes that WebCT has many capabilities for an integrated educational environment with TopClass and ToolBook II coming next.

In this paper, we analyze and compare WebCT, TopClass, LearningSpace, Virtual-U and LearnLinc. We evaluate the most recent versions of these products. Although LearnLinc has not many features, we evaluate it because it is a new powerful integrated program with superior characteristics for synchronous education. We provide a comprehensive table with all available features for the evaluated tools.

2. Web-Based Educational Environments Presentation

In this section, we present five popular Web-based educational environments to which we have ended up after extensive investigation: WebCT, TopClass, LearningSpace, Virtual-U and LearnLinc.

2.1 WebCT

WebCT [WebCT] is an easy to use environment for creating web-based courses without need to know programming. We have built online courses easily with the use of event-driven buttons. Only few times it was necessary to interfere with the course page's code in order to add advanced functions or modify slightly the existing features. WebCT was developed to support self-guided online courses. It supports high security as it is installed over the Apache Server. The Apache Server helps us to control the user's access and to secure the course material and framework from the hackers. We found out that the Internet Explorer is incorporated better than Netscape Navigator. WebCT also provides conferencing system, on-line chat, student progress tracking, group project organization, student self-evaluation, grade maintenance and distribution. Moreover, it provides access control, navigation tools, auto-marked quizzes, electronic mail, automatic index generation, course calendar, student homepages, course content searches and much more. WebCT gives the ability to the students to create their personal Web Pages allowing them to display their homework or any other information.

2.2 TopClass

Working in conjunction with web and media servers, TopClass ver. 3.0 [TopClass] provides scalability with sophisticated tracking and security. TopClass Server delivers courses and tests to any user connected through Intranets or the Internet. It also supports collaboration and discussion-group. It can use Oracle as a data store for training content, recording testing and tracking information. This option helps us to support more sophisticated reports and align management and backup procedures with other enterprise systems. It also supports the use of authorization information on Windows NT networks to identify users and eliminate additional login steps. It is certified to be Year 2000-compliant. Other utilities include the Player for off-line viewing and the Converter for automatic translation of MS Word documents or Web-based training content into complete TopClass courses. TopClass Player is a useful utility program, especially in remote locations where we can not afford the cost of online viewing. We only have to pay for the time being connected to the Internet in order to transfer the course content in our PCs. After finishing this transfer, we log off and continue our training in an offline viewing avoiding the connection's costs. The Creator lets us combine any web-compatible content into learning modules. The Assistants convert all documents and MS Office 97 presentations into complete courses. The Analyzer keeps track of usage, gathers feedback, and provides data for return-on-investment analysis. An advantage of TopClass Server from the other tested tools is the ability to convert instructor's material from a *.doc* or *.html* or even *.ppt* format into a customized course format to be displayed to the students. This function facilitates the instructors to build a course without the need to know programming.

2.3 LearningSpace

LearningSpace 2.5 [LearningSpace] is the latest release of Lotus solution for creating and delivering collaborative distributed education and training. LearningSpace runs on the industry-leading Domino Web Server, so it provides outstanding flexibility, advanced security and scalability. It does not require programming or technical skills. Templates help us to shape course content quickly and easily. LearningSpace transforms courses with cutting-edge video, audio and graphics, supports team learning and collaboration, manages courses and controls enrollments. It also provides private areas for discussions, assignments, grades, or confidential information. Furthermore, LearningSpace is becoming more powerful by collaborating with the DataBeam Learning Server. This results to a more integrated solution, enhancing the program's functions (Audio and VideoConference, Whiteboard and Application Sharing). An important function of this collaboration is the Application Sharing, which help us to share an application and to work in-groups effectively.

2.4 Virtual-U

Virtual-U [Virtual-U] is a server based software system that enables customized design, delivery, and enhancement of education and training courses. We can support group communication and collaboration in a secure newsgroup-style setting. Also we can easily set up collaborative groups online and define structures, tasks and objectives. A user can learn to moderate conferences and to create sub-conferences. Virtual-U enables us to organize course resources into a flexible online course syllabus without programming knowledge. These resources can include downloadable files, course texts, relevant Web links, assignments and any type of multimedia file. It automatically places the course syllabus on the Web for access by all students enrolled in that course. Virtual-U includes functions such as creating and maintaining student accounts, defining access privileges and establishing courses. Administrators can also perform batch imports of class lists from existing registration data.

2.5 LearnLinc

LearnLinc [LearnLinc] was the first live online learning classroom to support multimedia-authored courseware, allowing CBT quality synchronized content. It provides a simple user interface allowing us to configure features and presentation materials for students. It also supports full duplex audio and two-way videoconferencing with Intel ProShare 500. LearnLinc's Floor Control lists student names alphabetically, or in hand raises order allowing us to choose students easily to call on. Also it enhances our communication using videostreaming for one-way delivery of live or pre-recorded audio and video. LearnLinc's Synchronized Web Browser supports full functionality. LearnLinc supports Application Sharing for full interactivity. Moreover it contains a Question & Answer feature, to allow the instructor to write and launch questions before class or on the fly during a class and a Text Chat that allows private messages to be sent to the instructor by a student. Its Shared Whiteboard allows any file or image to be pasted-in as an object. LearnLinc is suitable for real time distance education. However, it does not include all the appropriate functions to simulate a traditional classroom.

3. Comparison Criteria

In this section, we analyze the criteria that we use in the comparison of the Web-based educational environments. The following criteria are the most important in order to make a comprehensive and extensive assessment of these educational environments. We can classify these criteria according to their related features [Mamoukaris & Economides 1999] in: technology features, administration features, student features, instructor features and communication features.

Criteria that are related to the technology of the tools include the required RAM, Platform Independence (operating system), Access from Internet or LAN, Web-Browsers, ability to refer to an Universal Resource Locator, Internal e-mail to registered users, External e-mail to non-registered users, Video, Audio and Database (internal database and external database cooperation).

Criteria that are related to students such as off-line Viewing (the ability to view a course without being connected to the Internet), Friendly User's Interface, Annotations (students keep notes near the course material), automated Index, Text-Search, Learning Goals.

Criteria related to administration features' concern the Security levels and Crash recovery tools that restore the course content and related information without loss of data from communication or server hardware failure.

Communication and Collaboration related criteria include Discussion Area to support asynchronous threaded communication, Audioconferencing, Videoconferencing (broadcasting video to users without a video input device), Bulletin Board (downloading and uploading/posting files over the Web), Chat (exchange of text in real time), Whiteboard (shared text window that may also support shared drawing), Application sharing (run an application on one machine and share the window view across the Web).

Criteria related to assist the instructor include Remote authoring & administration of courses, Customization features for Welcome Page, Customization features for the courses, Building motivation (adapting the display of the course content to the user's preferences), Syllabus (automatic creation of a page with the contents of the course), Creating Actions (provide the student with extra material depending on test's results), Language for advanced functions, Questions Pools (repositories for questions), Import/Export Courses, Import a course with a .doc format (from Word), Import a course with a .ppt format (from PowerPoint). Additional criteria concern the

Access Control to prevent unauthorized access to the courses or to the program, Restrictions for the course material or the access time, Testing, Number of question types, Submission and Auto-Correction of tests and Reports of user's progress. Also, criteria related to the friendliness and easy of use of the tool include the requirement for Knowledge of HTML, Friendly Designer's Interface, Glossary that will help the designer to automatically specify a list with keywords and their definitions.

Finally, Price comprises another critical factor to our comparison. However, there are many differences in the way every product is priced. For example, the cost of WebCT, LearningSpace and Virtual-U refers to 100 users per one course. On the other hand, TopClass and LearnLinc calculate the cost for 100 simultaneous users (there may be many more registered users than those participating at a specific moment) and for a large number of courses per user (not just one course).

4. Comparison Results

Based on our practice and experience with WebCT, TopClass, LearningSpace, Virtual-U, LearnLinc, we present the following Table:

Criteria	WebCT	TopClass	LearningSpace	Virtual-U	LearnLinc
RAM	32MB	32MB	64MB	24MB	32MB
Platform Independence	W, U	W, A, U	W, U	W, U	W
Access from Internet or LAN	Both	Both	Both	Both	Both
Web Browsers	Yes	Yes	Yes	Yes	Own Environment
Universal Resource Locator	Yes	Yes	Yes	Yes	Yes
Internal E-mail	Yes	Yes	Yes	Yes	Yes
External E-mail	*	Yes	Yes	No	Yes
Video	Yes	Yes	Yes	Yes	Yes
Audio	Yes	Yes	Yes	Yes	Yes
Database	Yes	Yes (Oracle)	Yes	Yes	Yes
Access Control	Yes	Yes	Yes	Yes	Yes
Restrictions for the courses	Yes	Yes	Yes	Yes	Yes
Testing	Yes	Yes	Yes	Yes	Yes
Number of questions types that supports	5	7	-	-	1
Submission and Correction of test	Yes	Yes	Yes	Yes	Yes
Report's of user's progress	Yes	Yes	Yes	Yes	Yes
Knowledge of HTML	No	No	No	Yes	Yes
Friendly User Interface	Yes	Yes	No	No	No
Friendly Designer's Interface	No	Yes	No	No	No
Glossary	Yes	No	No	Yes	No
Off-line Viewing	No	Yes	No	No	No
Annotations	Yes	No	Yes	Yes	Yes
Index	Yes	Yes	Yes	Yes	-
Text-Search	Yes	Yes	Yes	Yes	-
Learning Goals	Yes	No	Yes	Yes	No
Discussion Area	Yes	Yes	Yes	Yes	Yes
Audio-Conferencing	No	No	**	Yes	Yes
Video-Conferencing	No	No	**	Yes	Yes
Bulletin Board	Yes	Yes	Yes	Yes	Yes
Chat	*	No	No	No	Yes
Whiteboard	No	No	**	No	Yes
Application Sharing	No	No	**	No	Yes
Remote authoring & administration of courses	Yes	Yes	-	-	-
Customization features for Welcome Page	***	Yes	Yes	***	***
Building Motivations	No	Yes	No	No	No
Customization features for courses	Yes	Yes	Yes	No	No
Syllabus	Yes	No	Yes	Yes	Yes
Creating Actions	Yes	Yes	Yes	Yes	Yes
Language for advanced options	No	QML	No	No	No

Criteria	WebCT	TopClass	LearningSpace	Virtual-U	LearnLinc
Question Pools	No	Yes	Yes	No	No
Import/Export Courses	Yes	Yes	Yes	No	Yes
Import a course with a doc format (from Word)	No	Yes	No	No	No
Import a course with a ppt format (from PowerPoint)	No	Yes	No	No	Yes
Crash Recovery Tools	Yes	Yes	Yes	-	-
Price (see price criteria)	\$500 for 100 users	\$3,750\$ for 100 users	\$1,000 for 100 users	\$3,500 for 100 users	\$500 - \$1,000

Table 1: Comparison of the educational environments

Price example: \$500 for 100 users of WebCT, \$3,750 for 100 users of TopClass, \$1,000 for 100 users of LearningSpace, \$3,500 for 100 users of Virtual-U and \$500 - \$1,000 for users of LearnLinc. In the table W means Windows, U - Unix and A - Apple. Also the symbol "*" means *Some Problems* appeared during experimentation. The symbol "***" means that LearningSpace provides Audio and VideoConference, Whiteboard and Application Sharing by combining its features with DataBeam Learning Server's features and "****" means that these products do not offer the ability to the designer to customize the Welcome Page according to his preferences. The graphics at the Welcome Page cannot be modified. Finally the symbol "-" means *Not enough information*.

5. Conclusion

There is a huge market for Tele-education over the Internet. Many software tools have been appeared that helps the delivery of courses over the Web. We evaluate five such popular Web-based educational environments and find out that each has some special features. The right choice depends on our preferences. LearningSpace is a powerful tool for collaboration and with the support of Lotus Domino Server provides a secure environment. LearnLinc is a very powerful software tool especially for conferences. In conjunction with DataBeam Learning Server it supports Video and Audio conferences and team-based conferences, but it is weak in supporting the online courses to the students. At present, we prefer TopClass and WebCT. TopClass provides a secure environment with different security levels and cooperates with the Oracle database. Its unique feature is that someone can download the course material, disconnect from the Internet and study the course offline with the help of utilities that accompany the program. In addition we can upgrade it by using tools such as IChat, and built a synchronous environment. Moreover, by incorporating the MS NetMeeting into it, TopClass can provide an integrated environment for Web-based education. WebCT has the advantage of an internal Chat environment, enhancing its functions with real time text communication. Additionally, WebCT's Chat offers a variety of forums for different thread discussions. An advantage of WebCT is the security due to the Apache Server. Apache Server is a powerful, widespread Web Server, which controls the access to the course content and prevents unauthorized access.

Collaborative Web-Based Learning in Organizations

Peter Manhart, Johannes Bumiller
Daimler-Chrysler AG, Research Information Technology
P.O. Box 2360, 89013 Ulm, Germany
{Johannes.Bumiller, Peter.Manhart}@DaimlerChrysler.COM

Abstract: The World Wide Web is an emerging platform for learning systems; yet the interaction modes of existing approaches are often restricted to the distribution of information resulting from the underlying protocols, which were designed for the representation and distribution of hypermedia information, not to support human interaction. We present a group interaction system that generically adds human interaction support to existing web-based learning systems. Consequently, cooperative forms of distributed learning become possible and continuous knowledge creation can be implemented.

1 Introduction

Rapidly changing environments generating new requirements create the demand for life-long learning – not only for individuals but also for corporations. As a result, there is a growing need to support new methods of learning. Web technologies particularly support the platform-independent distribution of and easy access to hypermedia information. Therefore, web technologies are also emerging as a platform for computer-based learning systems. However, even if hundreds of learners, teachers-, and tutors browse a learning site, every learner works on his or her own, so that this isolated mode of learning ignores all of the advantages of collaborative learning and is a serious drawback to the effectiveness and efficiency of the learning process.

The paper begins with a description in section 2 of web-based learning scenarios which profit from enhanced human interaction. A group interaction architecture and system (GIA) is introduced in section 3. A continuous knowledge creation process using GIA is described section 4. The paper finishes with notes on related work, conclusions and references.

2 Learning Processes in Organizations

Although traditional learning forms will continue playing a significant role in a company's training portfolio, the presented approach focuses on a special subset of all of the corporate types of study and training currently deployed: computer-supported, distributed, and cooperative learning in an organizational context. In addition to the presented focus, additional requirements arise from the learning context within a company:

- The learning needs are not predefined and may change quickly and fundamentally according to the employees' actual challenges. Often, the learning process is not continuous, e.g. in a new project team a (distributed) group of people have to learn the same content within an extremely short period of time.
- The courses must be tailored to the actual needs of the learners or their specific knowledge deficits.
- Frequently the knowledge is not concentrated but scattered throughout the organization. Experts ("teachers") for a specific topic cannot always be determined. If available at all, they lack the time required for teaching.
- Learners have an acute need for learning but not enough time to learn.
- And sometimes, learners have to - but don't want to - learn something (external motivation).

In the following, we present a brief introduction of the set of learning scenarios taken under consideration. This is followed by a scenario classification and an analysis of needs for human interaction.

2.1 Learning Scenarios

The following learning scenarios can serve as an incomplete, but interesting set of organizational learning forms. They should aid in deriving useful services of a system for cooperative learning.

Asynchronous Learning Courses are a well-established method of computer-based training. Often the courses are carried out with media-based asynchronous distributed learning systems. The learning content is represented on CD-ROM or can be downloaded from a media server over a network. A number of existing learning systems support this computer-based form of study.

Video-/Audio- based Lectures enhance asynchronous learning courses by means of synchronous multimedia communication and interactive presentation techniques. This can result in heightened learning performance as learners can ask any questions on the spot. Although the required network bandwidths are high, this learning form is already established in corporate distributed training.

Individual Training and *Training on the Job* are very efficient, individual and situation-based types of learning (and, unfortunately, expensive ones, too). The interaction rate of learners and tutors is extremely high. Common CSCW systems (CSCW, Computer-Supported Cooperative Work) could be used to support these new distributed forms of individual training.

Knowledge Markets are a learning and teaching form where knowledge is based on the metaphor of supply and demand. A basic feature is rewarding experts for transferring knowledge according to their colleagues needs. The interaction of learners and teachers is basically restricted to question and answers. No specific support systems are available for this scenario.

Information Searching is meant to describe an autodidactic form of learning, where knowledge deficits are set by searching for information in a comparatively large, but possibly also crudely structured and uncertain information space, such as the World Wide Web. Generally, human interaction is absent, often even not intended. Desired communication is often initialized through existing internet services such as email and processed outside the underlying hypermedia system.

Project-oriented Learning and Distributed Task Forces focus on supporting the learner in his or her actual working situation. The interaction of learners and tutors is a key success factor and should therefore be well supported. No specific support systems are available for this case.

Content-oriented Learning Groups describes a learning situation where learners share a common interest. The interaction of learners can be supported efficiently by existing CSCW systems (e.g. NEWS).

2.2 Scenario Classification

The presented learning scenarios can be classified based on the qualities of the learning content [Fig 1]. Possible questions include the following: Can the recipient of the knowledge have faith in the truth of the information or is the information source unsure? How well does the offered knowledge fit the learning needs of the learner? Are didactical aspects considered in the representation of the learning context? How much new knowledge is created in the learning process?

In a couple of interesting scenarios, human interaction is a prerequisite for learning success, and other computer-supported learning approaches profit greatly from human interaction. Nevertheless, many existing learning systems basically support knowledge distribution through web-based hypermedia services and human interaction through electronic mail. As we do not consider this to be adequate for all of the intended organizational learning scenarios, we present an improved approach for training and study in organizations: support collaborative learning by extending existing corporate web-based learning systems by the factors of awareness and group interaction on the learning web. In the following, GIA and its functions are described.

Figure 1: Classification of Learning Scenarios and Interaction Functions

3 The Group Interaction System GIA

3.1 Requirements

A system to support cooperative learning on the web has to fulfill a number of IT-oriented constraints, which are summarized in the following. In order to enable a sufficient number of customers to use the services, the system architecture has to be as *platform independent* as possible. As most of the users are not computer experts, an *intuitive user interface* has to be implemented. Meeting the expectation of professional users necessitates a *robust and high performance* system architecture. To increase the *attractiveness* of the learning site, user interaction has to be presented effectively and in an innovative fashion. The basic GIA functions and system architecture were designed to meet these requirements. They are described in the following sections.

3.2 GIA System Architecture

The GIA system is implemented as a web-based client-server architecture. The GIA client runs as a set of coordinated Java applets on the user's computer. The GIA server consists of a set of coordinated Java and third-party servers on the computers of the learning site provider. All the components are coupled through an asynchronous event system. The architecture was designed to enhance existing web-based learning sites with a minimum of effort and minimum constraints to the site design. For a more detailed description of the system architecture, see [Manhart et al. 1998].

Figure 2: GIA Client/Server Architecture

3.3 Basic GIA Functions and Client

Currently, four basic group interaction functions are implemented in the GIA system:

1. *User Awareness*: While the learners or tutors are browsing the web site, they can recognize other users who share their location or subordinate sites [Figure 3, location map]. The web users are visualized in a room map metaphor. User awareness makes a learning site much busier and more attractive. It is also a prerequisite for meeting the people required to build learning communities, which is a comparatively efficient form of learning.
2. *Location Chat*: Users are grouped together with others who share the same location on the web. People sharing a group can communicate via chat [Figure 3, location chat]. If a customer moves to a different location, the location chat group changes to his or her current location.
3. *Cooperative Navigation*: Learners can link their browsers to other users [Figure 3, pop-up menu] who may be tutors or system administrators. In this way, individual advice can be given or interactive guided tours realized.
4. *Acquaintance Chat*: Chat groups which are independent from their users current location may be invoked. In the case of individual training, a learner can build a communication group with a member of the training staff and discuss open questions. Learners can also communicate and remain in contact via an acquaintance chat group.

These four basic functions are currently enhanced by location specific, NEWS-like discussion forums to also support asynchronous forms of communication. Just like the chat groups of the location chat, the GIA discussion forums are also coordinated with the user's navigation in the information space. Every time the user navigates in the web, the forum window automatically presents the appropriate discussion groups.

In contrast to existing web-based group interaction approaches, the GIA system coordinates its functions. The users are grouped according to their currently browsed content, and the related interaction tools are configured automatically by the system. This combination results in a generic, easy to use and powerful set of cooperation facilities.

4 Moving Towards a Continuous Process of Creating and Improving Knowledge

One objective of deploying the GIA system for cooperative learning in the described scenarios is to support a more complete set of interaction forms and awareness. Another target of our approach is to provide a continuous process chain for the acquisition, structuring, processing and distribution of knowledge.

By adding content-related discussion forums to the pure hypermedia knowledge representation, we support the interaction of learners, teachers and tutors, as well as the interaction between the learners in relation to a defined, common content. In this way, questions and comments can be exchanged between all of the users involved asynchronously. The teacher or tutor can react to the learners' inputs by responding to the comments or by improving the content. New knowledge can be generated from finalized and founded discussion threads. If sufficient users are currently logged on, the web as well as the thread messages can synchronously be discussed in the location chat groups. Hence, a broad range of knowledge, from well-defined to vague, can be discussed in an adequate form of interaction.

The result is a learning situation that not only supports processing of predefined content but also improves available knowledge as well as creating new knowledge on the fly. The ensuing process chain consists of the three phases:

1. Collecting the available knowledge or the current demands
2. Structuring and consolidating new knowledge
3. Representing new knowledge in a didactic fashion and making it available.

Cyclic Processing of this knowledge creation, evaluation, and dissemination operations should result in the rapidly growing, well-evaluated, up-to-date and demand-oriented learning contents of corporate learning systems.

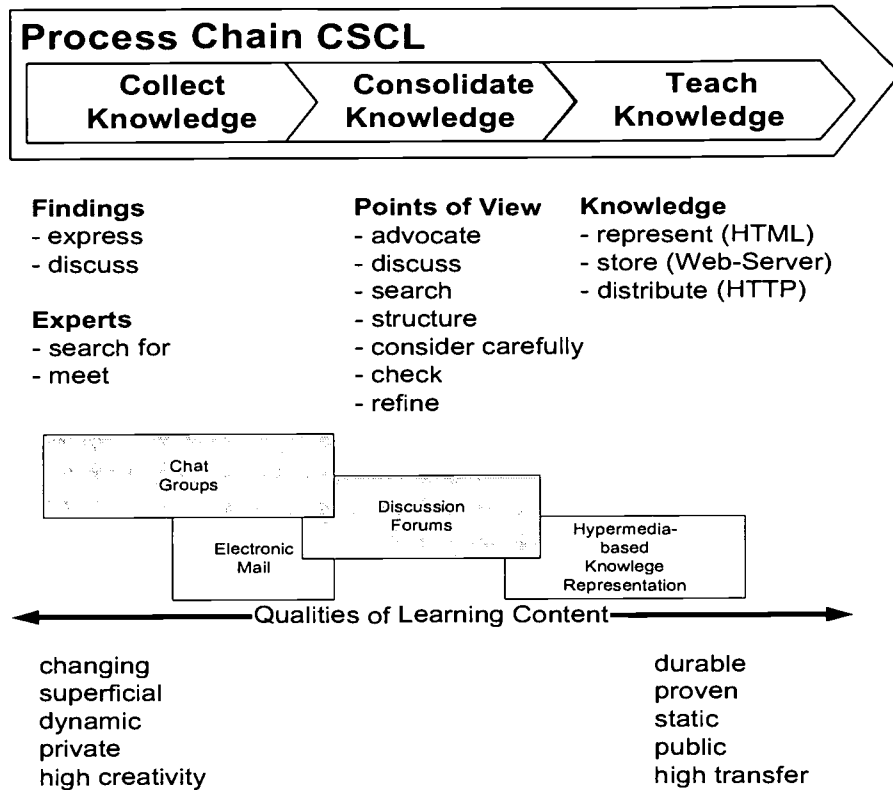

Figure 4: A knowledge Process Chain

5 Conclusions

We presented a set of new organizational learning scenarios that profit from the support of human interaction. These scenarios can be implemented through the web-based group interaction system GIA, which extends existing web-based learning sites by a coordinated set of computer-supported interaction functions. In addition to working towards a more efficient and effective learning process, we have developed the system to achieve a more continuous process of knowledge creation, discussion and distribution.

6 Related Work

User awareness is a main criterion for the support of group building and user interaction in groups [Fitzpatrick et al. 1996]. [Palfreyman & Rodden 1996] present WAP, a protocol for 'user awareness' in the web; yet they neglect to address the group aspect.

Together with the increasing amount of new knowledge and developments, a growing demand for organizations, groups and persons to augment knowledge and expertise has arisen. In the following, a few synchronous and asynchronous learning systems are mentioned:

"Answer Garden 2" [Ackerman & McDonald 1996] consists of a system architecture for asynchronous organizational memory and collaborative help support. Examples for synchronous learning are "GestureCam" [Kuzuoka et al. 1994], an approach that supports spatial workspace collaboration via a video-mediated

communication system and "CLARE" [Wan & Johnson 1994], which represents a collaborative learning system also enabling knowledge construction. In [Nakabayashi et al. 1995], several advantages of constructing an interactive educational system based on the Web are collected. [Benford et al. 1996] developed "The Internet Foyer", which provides awareness solely via the definition of a unified entry point, but which is a collaborative virtual environment not dedicated to learning.

Current commercial learning systems focus more on maximizing shared information, offer only uncoordinated group interaction support (e.g. global discussion forums, chat cafes, ...), restrict interaction structures to predefined relations (teacher-pupil), or do not provide any group support whatsoever.

A Hybrid Architecture for Filtering Information on the Web

Mauro Marinilli, Alessandro Micarelli and Filippo Sciarro
Dipartimento di Informatica e Automazione
Università di Roma Tre
Via della Vasca Navale, 79
00146 Roma, Italia
E-mail: {marinil, micarel, sciarro}@dia.uniroma3.it

Abstract: The system described in this paper has been developed with the aim of increasing the efficiency of Web Information Filtering processes and is based on a Case-Based approach. It currently acts as an intelligent interface for Web search engines. A primary characteristic of the system is its ability to adapt its filtering processes to a particular user based on the specific interests of the latter. This ability is achieved by means of a hybrid architecture, i.e., a sub-symbolic module integrated into a Case-Based reasoner. This dual component system serves to create and maintain individual user models that are stored in a library of cases for long-term reference of the system itself. The first experimental results of the system are encouraging.

1. Introduction

Nowadays, the Internet is the main route for information exchange world-wide: its growth and the World Wide Web makes it necessary for the end user to deal with the huge amount of information available on the net. Filtering information [Belkin, 1992] is a problem more and more relevant in information society. In this paper we present an Information Filtering system we have developed that selects HTML/Text documents from the World Wide Web. The system filters the documents according to the interests (and non-interests) of the user, as deduced by the system through the interaction. In order to do so, the system uses a User Modeling subsystem, particularly conceived for this task. One distinguishing feature of both components of the presented system is their hybrid architecture: a combination of a Case-Based Reasoner with a sub-symbolic module (here, an artificial neural network). In this paper we will focus on the Information Filtering Component. The system has been developed in Java on a Pentium II-based platform. The evaluation of the system is based on an empirical approach [Cohen, 1995] and makes use of a non-parametric statistics [Devore, 1995] for testing hypotheses on the system behaviour. The domain chosen for testing the system is the "computer science" domain.

This paper is structured as follows: in [The General Architecture] the general architecture of the system is presented. In [The User Modeling Component] we present briefly the user modeling component. In [The Information Filtering Component] we describe the anatomy of the Information Filtering component. In a concluding section we give some final remarks.

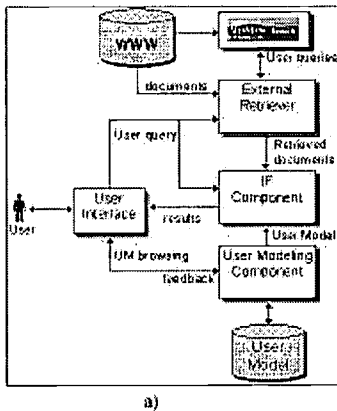

2. The General Architecture

The general architecture of the system is shown in [Fig. 1]. It is composed of the following modules:

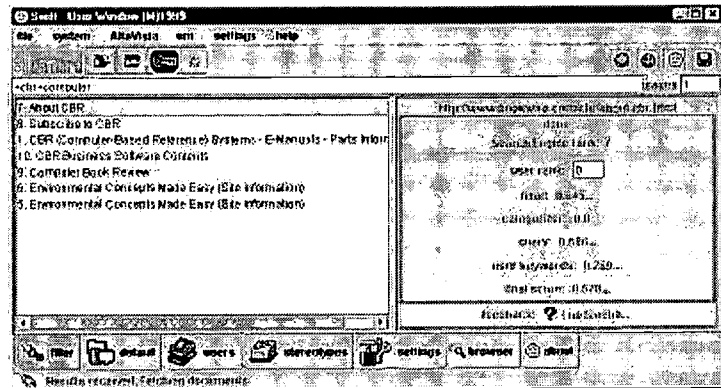

- The *User Model*, representing the characteristics and the information needs of a particular user;
- The *User Modeling component*, capable of dynamically building the user model, as deduced by the system through the interaction;
- The *External Retriever*, which interfaces with AltaVista;
- The *Information Filtering component*, which selects the relevant documents for the user, according to the content of the User Model;

- The *User Interface*, which manages the interaction.

When a user interacts with the system for the first time, her/his user model needs to be made from scratch. For quickly building a reliable model an interview is proposed to the user, expressing an interest score for each of the domain categories (throughout all the system the values used are thought ranging from -1 (dislike) to +1 (like) if not otherwise specified).

a)

b)

Figure. 1: The Architecture of the System

Figure 2: The Query Interface

The user sets a query to the system that in turn posts it to the external WWW search engine, obtaining documents that are filtered and returned to the user. In the filtering process the systems works using two different levels of refinement: a first, coarse one, and a more elaborate step that takes place only if the first stage succeeds. During the normal usage the system offers a series of panels, being the first the filtering panel shown in [Fig. 2]. Here at the left is shown the list of documents retrieved by the search engine and selected by the system, given the user query and the User Model. Each document is detailed in the right panel, where the filtering results are also reported. The user browses the needed documents by double-clicking on them, and then he can express a simple feedback (as seen in the up-right window corner) among three different values: very good, good or bad, in order to ease the burden on the user, as recommended in [Morita & Shinoda, 1996]. In this way the system can modify her/his User Model accordingly to user's preferences. Furthermore, a system objects browser has been provided in order to allow the user to inspect all the system's data structures with an effective graphical interface to shorten the semantic gap between the user and the system. As said previously, this paper focuses on the Information Filtering component of the system. In the following [The User Modeling Component] we will only describe the main data structures of the User Modeling component.

3. The User Modeling Component

This component has already been used in a previous Information Filtering system [Ambrosini et al., 1997a-b]. The reader is referred to [Micarelli et al., 1998] for more details concerning the case-based inference mechanisms used in this component. In the User Model, the following items are gathered:

- A *content vector*, i.e., an array of values that represents the information content suitable for the Vector Space model matching, as explained in [The Data Structures].
- A list of currently *active contexts*. Contexts are initialised all the same for every user with a non-zero value in her/his user model content vector, for each cluster having one or more non-null contexts. Then these contexts are copied in the User Model which evolves independently according to the single user history.
- A list of the currently *active stereotypes*.
- A set of *user keywords*, each one weighted with a value representing its actual importance for the user.

4. The Information Filtering Component

The Information Filtering task has been a major research field since the last ten years and is constantly growing thanks to the huge development of the Internet. In the following we present the main data structures and the case-based approach used in that component.

4.1 Data Structures

Information Filtering systems need sophisticated data structures to deal effectively with such an ephemeral thing as user's interests may be. On the other hand Information Retrieval research has developed fairly complex around the classical but effective Vector Space model, abstracting from single keywords to cluster of keywords and other more and more abstract objects, in order to improve discriminating performance. Our system is based on such a vector space model variant. We now introduce the two major data structures used in the system.

4.1.1. The cluster vector

The Vector Space model [see Salton, 1983] has been kept as a basis thanks to its very well known reliability and room for improvement, as constantly reported in the literature. The elements the vector is made up with are sets of <term, context> pairs, with term a word and context an object whose purpose is to disambiguate possibly ambiguous terms using words before and after the word under study [see Croft & Xu, 1995; Xu & Croft, 1996; Xu, 1997]. For instance, the term "network" can assume different meanings depending on the context where it is used. A naive Information Filtering system could assume that a document about "neural networks" is relevant for a query on computer networks. The cluster vector has been built once for all during an initial phase of knowledge extraction from a corpus of documents on a particular domain. Also in this phase all the contexts have been conceptually created examining each repetition of the same term in the corpus and measuring the distance between their contexts: if it is greater than a threshold parameter, the two instances of the same term are thought to have different meaning, and their contexts kept separated, otherwise their contexts are merged in one.

To recap:

- A Context is an object that keeps trace of words used when referring to a particular instance of the ambiguous term in a text. Its use is motivated by the assumption that terms related to different meaning of a single word tend to occur together [see Furnas et al., 1987].
- A T-C pair is a pair of <term, context> used to disambiguate the term applying its context on the input document.
- A Cluster of T-C pairs is a set of such elements clustered together for synonymy. All the T-C pairs grouped together in a cluster are all the same for the system. This mechanism allows for simplification while the use of T-C pairs instead of simple terms gives higher precision to the clustering mechanism.

4.1.2. Document Representation

Every text document in input is firstly transformed by the External Retriever in a list of words obtained selecting only those which are not present in a list of useless words (also known as a *stop-list*). Then the words are matched against the term dictionary and pointers are obtained to words known to the system. Each term is disambiguated using the known contexts for that term. For instance, if the system has three different contexts associated with a single word, the disambiguation step produces three values, representing the degree of fitness of that word occurrence in the incoming text and the given context. In the last step each pair <term,context> from the input document contributes to its belonging cluster weight with the values calculates in the third step. At the end of the process, from the initial text document (e.g. in HTML format) we have an array of values, each one for a cluster of <term,context> pairs.

4.2. Case-Based Information Filtering

Figure 3 shows the approach we have used to the selection of the most suited documents according to the *information needs* of the user represented in her/his model. In [Fig. 3] the two main steps of the case-based reasoner have been put in evidence. They are:

- The Document Categorization (retrieval phase)
- The Score Refinement (adaptation phase)

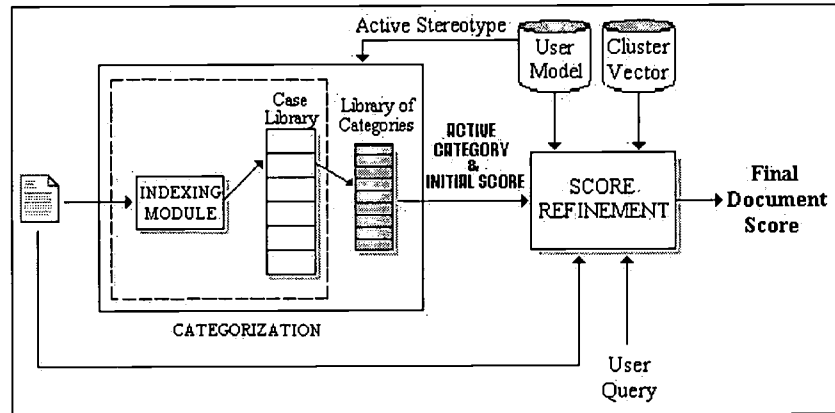

Figure 3: Case-Based Information Filtering

4.2.1. The Document Categorization

The case library contains the old cases (gathered from experts in the domain of computer science) in the form of frames, whose slots are the "document representation" and the "active category" (that can be viewed as a pointer to the Library of Categories). The categorization module takes as input the same type of weights vector of the filtering module, but with different clusters, because it needs to match different features like authors, type of documents, etc. in the incoming document. When the system is presented with a pattern of attributes relative to the particular document, the indexing module tries to find the old case that more closely matches (according to a specific metric) the new case. The selected old case contains the relevant information useful for classifying the document, i.e. the most suited category (or categories). To map the array of values - one for each category - coming as the categorization module output into stereotypes, a matrix "categories X stereotypes" (called CS-Matrix) is used, with each element representing an importance weight for that category in the given stereotype present in the User Model. Crossing the matrix columns of the currently active stereotypes with the categorization module output and summing the outcoming values we have the categorization contribution to the filtering score. The approach just described entails the definition of a metric to be used in the indexing module. The problem is that this sort of classification must often be made in presence of incomplete and contradictory information. Our proposed solution, similar to a framework which has already been experimented in the field of adaptive hypermedia [Micarelli & Sciarrone, 1996] and of User Modeling [Micarelli et al., 1998], consists in the use of a function-replacing hybrid [Fu, 1994], where an artificial neural network implements (i.e., is functionally equivalent to) the indexing functionality of the case-based reasoner. The old cases present in the library of cases have been gathered from a domain expert, and have been used as training records for training the network. The knowledge of the Case Library is therefore represented in a monolithic way into the weights of the network. As a result, the metric of the indexing module of the case-based reasoner has been replaced by the "generalisation" [Haykin, 1994] capability of the network.

BEST COPY AVAILABLE

4.2.2. The Score Refinement

The mechanism for the score refinement is described in [Fig. 4], being the first step the document transformation in a content vector:

- For the current document the categorisation module returns a score based on its output and the list of active stereotypes present in the user model.

- Only if the first stage returns a score higher than a given threshold the second step takes place. Three different modules process the document (represented differently for each module) returning three scores that combined linearly with given weights make up the final score.

The three different modules work independently each one performing the filtering based on a different perspective (Each module sharing a common mechanism for weighting words with their actual importance in the document; for instance, words appearing in the title in a HTML page are considered more important than words in a paragraph):

- The vector filter module transforms the document in an array of values that maps on the Clusters array as described in [The data Structures]. This kind of filtering is performed using the standard techniques of the Information Retrieval field.

- The query module uses a list of words representation of the document and essentially counts the occurrences of the terms in the user query.

- The user keywords module matches each document word against a list of weighted keywords in the User Model producing the total normalised sum of each occurring word's weight.

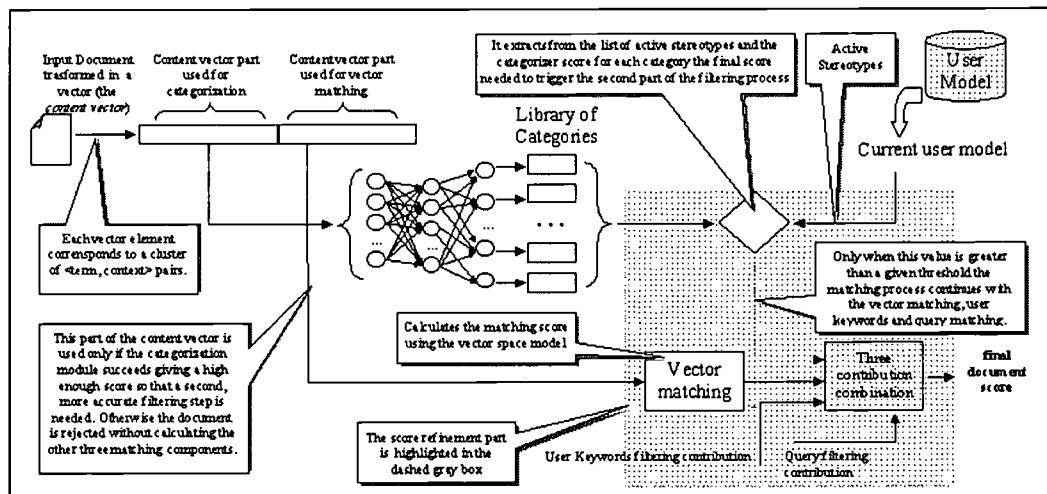

Figure 4: The Document Evaluation Process

Conclusions

In this paper we have described an Information Filtering system that uses a Case-Based approach. Such a system is able to select and to order HTML/text documents, collected from the Web, according to the "information needs" of the user, represented in a User Model. Our system is based on a hybrid architecture, where an artificial neural network is integrated into a case-based reasoner. One advantage of this architecture is the inherent fault tolerance to noise in data representing user behaviour, which allows the system to "gracefully degrade". In our work, we have turned to statistics to analyse the system behaviour, and demonstrated that the system performance "is not due to chance". A more extensive test of the system has been planned as a future work. We have also planned to develop and evaluate further features with the goal of improving the performance of both modeling and filtering processes. As for the modeling process, we are improving the modeling capabilities of the

users by using a dynamic updating process of the user model. As far as the filtering process is concerned, we are integrating the query modality with the surfing modality to obtain a system able to autonomously retrieve and filter documents. The first experimental results we have obtained using the Wilcoxon test [Wilcoxon, 1947] are encouraging and support the choice of the Case-Based approach to Information Filtering.

Virtual Laboratory for Image Processing

Nenad Marovac, San Diego State University
nenad@sdsu.edu

Norbert Harrer, Technical University, Graz
upi@sbox.tu-graz.ac.at

Abstract: The concept of Remote Education has captured considerable attention of educational organizations and the public. World wide expansion of Internet and its promulgation into every corner of our daily lives will bring a tremendous impact to the education. It will bring affordable education on every scholastic level into most areas of the world. Most education institutions in advanced countries either already offer or are experimenting with virtual classrooms. However, one area of Remote Education that has been neglected so far is the area of laboratories.

In this paper we address that issue and present a virtual laboratory for computer graphics and image processing. The laboratory can be used by individual users working on particular topics or by groups of users as peers or under the supervision of instructors. It was designed to be part of our Remote Education Platform for education in computer science.

1. Introduction

With Internet removing the distance barriers Remote Education is becoming a very important function (feature) in our society [1]. We believe that the Internet will bring important changes in the education by making it more affordable, more accessible and considerably better quality. Many educational facilities already offer virtual classrooms, education material and discussion rooms over Internet [3 through 8]. However, the issue of virtual laboratories has not been addressed yet.

In this paper we address that issue and introduce a virtual laboratory for computer graphics and image processing. The laboratory can be used concurrently by any number of students that can be anywhere in the world, provided they have access to Internet. The laboratory can be used asynchronously by individual users exploring a particular topic or an image processing technique, or synchronously by groups of users as peers or under the supervision of instructors. It is completely computer platform independent. It has been incorporated into our Remote Education Platform [8], and it can also be integrated into any other application.

2. The Organization Of The Laboratory

2.1. Working Sessions

The virtual laboratory space is organized into sessions. The system can support any number of simultaneous sessions. A session may contain a single member, or it may be a group session containing any number of world-wide distributed users. A user may start a new session or join a session in progress. A group session may be "unstructured" in which participants work as peers that together experiment with certain ideas and techniques to enhance or manipulate images. Alternatively, a session may be "structured" in which the participants are guided by an instructor who presents a topic and demonstrates the concepts by systematically applying various techniques supported by the system. The participants in a session can communicate with each other through chat windows. In the future we plan to add voice communication channels.

Each session owns a group of objects participating in the session. These objects are the users participating in the session and all artifacts that the participants have loaded or created during the session. The artifacts may be images, drawings, text of communication messages between the session participants, and text annotations of individual images. The session objects may be interconnected through relationship linkages, e.g. all artifacts loaded or created by a participant are linked to that participant; the annotations of an image are linked to that image, etc.

Each object consists of two parts:

- a data structure that holds information representing the object, e.g. the data structure for an image contains the pixmap encoding the image, and
- a set of methods that are used to access, manipulate and display the representation of the object. Furthermore, it contains a definition of a graphical user interface that enables a user to manipulate and display the object.

2.2. Session, Server and Clients

Functionally, the laboratory comprises one server and any number of clients; one client per user. Sessions are supported by the server. At any point of time the state of each session is maintained by the server, i.e. the server contains the information about all participants and the representation of all artifacts of the session. Any request by a user that affect an object within a session is sent to the server. The server performs the desired operation and updates the state of the session, e.g. a change in an image. The representation of the new state for the session is then sent to all clients corresponding to the participants in the session.

A session can be saved for a recall at a later time. The save operation will store all artifacts belonging to the session, as well as the identity of session participants. The artifacts from the session can be also stored individually. They can be saved by a user either at the server supporting the session or locally on the computer used by that user to access the laboratory.

3. The Functionality Of The Laboratory

The laboratory provides the full functionality for image processing and object recognition and some functionality for 2D graphics. It supports simultaneous display and manipulation on any number of loaded images. The operations provided by the laboratory are grouped into the following sections:

3.1. Image Handling

The operations in this section are used to load, store, scale, rotate, flip clip and convert images.

3.2. 2D Drawing

The operations in this section are used to draw 2D figures, e.g. straight lines, circles, splines, 3rd degree curves, etc. Users can draw on blank canvases or over images or already existing drawings. When drawings are made over already existing drawings or images, they are rendered as overlays. The overlay drawings can be either stored separately or together with the images. This feature makes this system a very useful tool for making engineering drawings for utilities and traffic infrastructures. Users can draw over city and county maps and design roads, utility networks and then store such designs either separately or merged with maps.

3.3. Image Processing

This section contains image enhancement and processing operations. The operations include:

- ◆ Image Averaging to remove noise spikes
- ◆ Noise Removal
- ◆ Image Sharpening
- ◆ Reduction of colors in images

- ◆ Conversion of color images to black and white or gray scale
- ◆ Adjustment of color saturation (0 - 200%).
- ◆ Display of histogram as well as histogram equalization and specification.
- ◆ Detect edges in images

3.4. Object Recognition

This section contains procedures used to perform analysis of images and recognition of patterns and objects in images. These procedures include:

- Object Separation Through Thresholding - This function separates objects from the background within an image by partition of the gray scale histogram of the image according to single or multiple thresholds.
- Region Growing by Pixel Aggregation - This function collects pixels within an image into larger regions that become candidates for individual objects. It starts from a set of seed pixels that are automatically generated or selected by the user. The result is a set of regions of neighboring (connected) pixels that have similar properties, e.g. the difference between their gray scale values is smaller than a predefined threshold.
- Region Splitting and Growing - This function identifies regions within an image, by first subdividing the image into arbitrary disjoint regions and then merging those regions that have same attributes into larger areas.
- Patter Matching by Correlation - The goal of this method is to identify an object (i.e. image) within another larger image by using the correlation between these two images.
- Pattern Matching Within Frequency Domain Using FFT - This approach is often more efficient than the previous method, i.e. Patter Matching by Correlation. This is especially the case for larger objects (sub-images).
- Hough Transform - This method is used to identify figures within an image. This method is tolerant of gaps in the figures and is relatively unaffected by the noise within the image.

4. Implementation

We implemented the laboratory in Java version 1.1.5. We did consider C++ but settled on Java as it offered a number of distinct advantages:

- Platform independence in supporting graphics and graphical user interface

Using C++ one has to deal with two very different graphical platforms, Visual C++ on PCs and MOTIF/X-windows on Unix workstations. Java offers graphical platform independence on the source as well as on the run-time levels.

- User interaction

Java allow us to relieve the server of all operations that affect only the local user and can be performed on a client machine instead on the server using CGI scripts. This allows quicker responses to certain actions, since not every user action has to be transferred to the server.

- Object serialization:

Java provides the two special streams `ObjectInputStream` and `ObjectOutputStream` that work like regular input and output streams. However, they are special in that they can read and write whole objects. We don't have to worry about the internal representation of data. That is particularly relevant as the application is used on different platforms, which run on different architectures

Of course, there are also disadvantages:

- ❑ Execution speed
- ❑ Short live time of Java versions

Conclusion

In this paper we presented a world-wide distributed virtual laboratory for image processing. The application has been tested within realm of local area networks as well as over long distance networks. The implemented concept of replicated distributed objects works stable and is reliable. Although the application was mainly designed to support remote education and distributed group studies and discussion on images, the large number of image processing functions makes the application also suitable for stand alone image processing platform.

The system was also designed to be easily extendable for other types of multimedia objects. The basic concept of the system should therefore be also usable for other distributed education platforms that are not necessarily dealing with images and image processing. In fact the plans are to expand the laboratory to include 3D modeling and rendering.

Acknowledgements

Nenad Marovac wants to acknowledge many students who participated in the development of the idea for the distributed computer graphics and image-processing platform. Finally, Norbert Harrer came over from Austria and worked on the project for a year as part of his Dipl. Ing. project. Both of us would like to thank SDSU for providing the environment for Norbert for his work and the Austrian Government for awarding Norbert with a fellowship that enabled him to stay at SDSU and complete the platform.

Abstract: This paper addresses the question of how to use Web technology to learn smarter, manage change better, continually improve learning, and offer more productive performance solutions. Offering a unique perspective about learning in the 21st century, this paper introduces (a) learner-difference profiles explaining individual learning differences, (b) reasons why some learners are more successful than others, and (c) strategies for helping learners improve Web learning ability. These insights offer simple ways to enhance and evaluate contemporary Web instructional designs so that they instill the right habits for continuous learning and performance improvement.

1.

1. Introduction

This paper is aimed at an audience wanting a new perspective on investigating and managing the impact of individual learning differences. The purpose is to offer explanations about the higher-order psychological influences on Web learning, describe when and why some learn more successfully than others, and offer practical design guidance that contributes to successful Web learning and performance. By the end of the paper, participants should have examined their own position on (a) the influence of key psychological factors (conative, affective, cognitive, and social learner-difference variables) that greatly influence Web learning, (b) recognizing critical links between Web learning environments, learning differences, and learning performance, and (c) developing supportive Web learning environments that match individual learning differences.

2. Background

For many years Russell [97] has been conducting comprehensive comparative research on using technology for distance education. After reviewing data from 355 research studies to examine what works or does not work, Russell [97, p. 1] states that research results are largely ambiguous and that "individual differences in learning dictate that technology will facilitate learning for some, but will probably inhibit learning for others, while the remainder experience no significant difference." He adds that "when lumping all the students together into a fictional 'mass' those who benefit from the technology are balanced by a like number who suffer; when combined with the 'no-significant-difference' majority, the conglomerate yields the widely reported 'no-significant-difference' results." In conclusion, Russell [97] advises that the "real challenge facing educators today is identifying the student characteristics and matching them with the appropriate technologies." Reeves [93] echoed parallel sentiments as he advocated the inclusion of stronger, more reliable theoretical foundations that explain fundamental learning differences. Similarly after his review of educational research, Bangert-Drowns and Rudner [91] concluded that no one knows what really works.

The confusing or inconsistent results arising from the research literature clearly indicates something critical is missing from our cognitive-rich learning constructs and contemporary educational technology theories. Snow and Farr [87, p. 1] suggested that sound learning theories are missing and realistically require a whole person view that

integrates cognitive, conative, and affective aspects.” These researchers advised that educators cannot ignore or overlook these key psychological aspects because they interact in important, complex ways to support learning and performance outcomes. Otherwise, explanations about learning differences will be ambiguous and *isolated* from reality [Snow & Farr, 87].

3. Intentional Learning Theory

What theories and models can help us analyze and differentiate the audience and accommodate individual learning needs for successful Web learning? Successful “whole-person” learning paradigms need to acknowledge that individuals are feeling, intentional, thinking, and social human beings. Hence, the new Web learning paradigms need to (a) recognize diverse, fundamental sources for human response, (b) differentiate the audience using higher-order psychological explanations for learning differences, and (c) offer strategies and methodology that identifies, measures, matches, and manages the impact of primary learner-difference variables.

This paper describes learning differences using *learning orientations* (learner-difference profiles) to differentiate the audience, plan “mass customized” strategies that achieve objectives and improve learning ability, and guide design of the instruction and environment. The theoretical foundation for learning orientations is the *intentional learning theory*. This theory describes higher-order psychological attributes and learner-difference variables for successful learning. It also introduces a conative-affective-cognitive-social learning model that highlights the dominance of emotions and intentions on learning. This view is in contrast to cognitive frameworks that overlook or minimize the important impact and guiding influence of conative and affective factors.

In other fields, researchers [Ledoux, 96; Goleman, 95] demonstrate that emotions and passions influence, guide, and, at times, override thinking (cognitive) processes. Child development researchers, such as Woodward [98], also describe how humans are highly goal oriented and use intentions to guide learning as early as age six months. Recognizing the power of emotions and intentions is also an important lesson for educators. Educators who can knowingly tap into a learner’s emotions and intentions have a powerful advantage. The intentional learning theory recognizes that how successfully we support learning depends on how well we support individual needs with customized solutions that foster increasingly successful learning and performance. “This transition from *one-size-fits-all* to *mass customization* is already happening. It is apparent in the growing use of templates and learning objects for multimedia” [Martinez, 99a].

To describe or represent learning orientations, there are four profiles: *intentional*, *performing*, *conforming*, and *resistant*. These profiles (Tab. 1) represent an individual’s general approach to learning—intentions, committed learning effort, and learning autonomy. The learning orientations represent how individuals, with (to some degree) varying beliefs, emotions, intentionality, and ability, plan and set goals, commit and expend effort, and then autonomously experience learning to attain goals.

Orientation	Conative/Affective Aspects	Committed Learning Effort	Learning Autonomy
INTENTIONAL LEARNER (Transformance)	Focus strong passions and intentions on learning. Be an assertive, expert, highly self-motivated learner. Use learning to transform to high, personal standards.	Set and accomplish personal short- and long-term challenging goals that may not align with goals set by others; maximize effort to reach personal goals. Commit great effort to discover, elaborate, and build new knowledge and meaning.	Assume learning responsibility and self-manage goals, learning, progress, and outcomes. Experience frustration if restricted or given little learning autonomy.
PERFORMING LEARNER (Performance)	Focus emotions/ intentions on learning selectively or situationally. Be a self-motivated learner when the content appeals. Use learning to perform to above-average group standards.	Set and achieve short-term, task-oriented goals that meet average-to-high standards; situationally minimize efforts and standards to reach assigned or negotiated standards. Selectively commit measured effort to assimilate and use relevant knowledge and meaning.	Will situationally assume learning responsibility in areas of interest but willingly give up control in areas of less interest. Prefer continual coaching and interaction for achieving goals.
CONFORMING LEARNER (Conformance)	Focus intentions and emotions cautiously and routinely as directed. Be a modestly effective, extrinsically motivated learner. Use learning to conform to easily achieved group standards.	Follow and try to accomplish simplistic task-oriented goals assigned by others – try to please and conform; maximize efforts in supportive environments with safe standards. Commit careful, measured effort to accept and reproduce knowledge to meet external requirements.	Assume little responsibility, manage learning as little as possible, be compliant, want continual guidance, and expect reinforcement for achieving short-term goals.
RESISTANT LEARNER (Resistance)	Focus on not cooperating. Be an actively or passively resistant learner. Avoid using learning to achieve academic goals assigned by others.	Consider lower standards, fewer academic goals, conflicting personal goals, or no goals; maximize or minimize efforts to resist assigned or expected goals either assertively or passively. Chronically avoid learning (apathetic, frustrated, discouraged, or disobedient).	Assume responsibility for not meeting goals set by others, and set personal goals that avoid meeting formal learning requirements or expectations.
Situational Performance or Resistance: Learners may situationally improve, perform, or resist in reaction to positive or negative learning conditions or situations			

Table 1 Learning Orientations Profiles

4. New 21st Century Learning Paradigms

In response to Russell's [97] challenge to match technology to individual differences, the authors suggest that educators need to develop learning paradigms based upon an understanding of (a) how individuals intentionally learn differently and (b) how educators can use technology to match and support the differences in learning and improve learning ability. The new paradigms should add the more dominant conative and affective factors to the traditional highly cognitive paradigms and specifically consider a learning audience with differing passions, emotions, need for structure, and willingness to set goals, plan and apply effort and manage, interact, and collaborate in Web learning environments. This unique approach to audience analysis and instructional design is in contrast to traditional perspectives that highlight cognitive processes as the universal learner-difference variable.

5. Developing Web Design Principles

Which Web design principles can accommodate learners in order to fulfil their learning objectives? A previous research study [Martinez, 99b], which investigated using learning orientations to differentiate the audience and guide analysis and design of instruction and environment, demonstrated that a learner experiences greater positive effects to the extent that the instruction and environment can appropriately match, support, and improve the individual's learning orientation. The study results also provided evidence on specific factors that impact learning differences and contributed guidelines for customizing solutions for Web learning.

As we leave the classroom, eliminate full-time instructors, and move to Web learning environments, recognizing how to match individual learning difference is becoming increasingly important. "To be effective, Web instruction and environments should emulate the instructor's experienced, intuitive ability to recognize and respond to how individual's learn differently" [Martinez, 99a]. The learning differences described in Table 2 (organized by three learning orientations) are intended as general guidance for designing Web learning environments and instruction. These descriptions consider key issues that influence Web learning and provide specific information for accommodating the differences. Their overall purpose is to match the orientation to foster self-motivation, interest, interaction and more successful, independent learning. These same descriptions are also useful for creating a set of criteria against which Web instruction may be evaluated.

Learning Issues	Intentional Learners	Performing Learners	Conforming Learners
General Environment	Prefer loosely structured, mentoring environments that promote challenging goals,	Prefer semi-complex, semi-structured, coaching environments that stimulate personal value and provide creative interaction.	Prefer simple, safe, structured environments that help learners achieve easy learning goals in a linear fashion.

	discovery, and self-managed learning.		
Goal-Setting and Standards	Set and accomplish personal short- and long-term challenging goals that may not align with goals set by others; maximize effort to reach personal goals.	Set and achieve short-term, task-oriented goals that meet average-to-high standards; situationally minimize efforts and standards to reach assigned or negotiated standards.	Follow and try to accomplish simple, task-oriented goals assigned by others – try to please and conform; maximize efforts in supportive environments with safe standards.
Learner Autonomy and Responsibility	Self-motivated to assume learning responsibility and self-direct goals, learning, progress, and outcomes. Experience frustration if restricted or given little learning autonomy.	Situationally self-motivated to assume learning responsibility in areas of interest. Will willingly give up control and extend less effort for topics of less interest or in restrictive environments.	Cautiously motivated to assume little responsibility, self-direct learning as little as possible, and like to be more compliant
Knowledge Building	Commit great effort to discover, elaborate, and build new knowledge and meaning.	Selectively commit measured effort to assimilate and use relevant knowledge and meaning.	Commit careful, measured effort to accept and reproduce knowledge to meet external requirements.
Problem Solving	Prefer case studies and complex, whole-to-part, problem solving opportunities.	Prefer competitive part-to-whole problem solving.	Prefer scaffolded support for simple problem solving.
User Interface	Open learning interface for high stimulation and processing capacity	Hands-on learning interface for medium stimulation and processing capacity	Consistent and simple interface for minimal stimulation and processing capacity
Presentation	Prefer occasional mentoring and interaction for achieving goals (MENTORING).	Prefer continual coaching and interaction for achieving goals (COACHING)	Prefer continual guidance and reinforcement for achieving short-term goals (GUIDING)
Feedback	Prefer inferential feedback.	Prefer concise feedback.	Prefer explicit feedback.
Motivational Feedback	Discovery	Interesting	Comfort
Group Interaction	Prefer open-ended, dynamic groups; balanced emphasis on social-emotional needs and high-standard task completion	Prefer semi-structured, purposeful groups; emphasis on task completion	Prefer well-structured and safe groups; emphasis on social-emotional needs
Group Collaboration	Learning-oriented; idea-seeking, encourages positive dissonance; emphasizes efficacy; numerous cycles of brainstorming, reflection, and self-critique; group prefers shared leadership; encourages intra- and inter-group interactions	Task-oriented; compromise-seeking; emphasizes efficiency; group prefers strong internal leadership; encourages intra-group interactions, avoids inter-group interactions	Completion-oriented; consensus-seeking; emphasizes compliance; group prefers strong external leadership; minimizes intra- and inter-group interactions
Learning Module Size	Short, to the point, summary linked to more detail if necessary	Medium, moderate explanations	Longer, detailed explanations, in a step wise approach
Examples	One good example and one bad example.	A few good and bad examples.	Multiple good and bad examples
Information Need	Holistic, specific information needed to solve a problem	General interests	To fill a requirement
Content Structuring	Prefer freedom to construct own content structure	Prefer a general instruction, limited ability to reorganize	Prefer to let others decide content structure
Sequencing Methods	Hypertext, sorting by meta-tags, precise access	Semi-linear, logical branching, access by subtopic	Linear, page-turner representations general access
Peer Interaction	High, belief that everyone can commit and contribute valuable insights	Moderate, easily frustrated by time required for peer interaction and superficial comments	Minimal, seldom values peer comments, wants answers from the instructor
Quality of Assignments	Usually far exceeds stated requirements	Fulfill requirements but do little more than that	Frequently don't meet the minimal requirements
Questioning Habits	Asks probing, in-depth questions about content	Asks questions to complete assignments, too busy taking notes	Asks mechanistic questions about assignments

Table 2 Learning Differences Described for Three Learning Orientations

6. Conclusions

Hopefully, these suggestions will contribute to successful learning paradigms for the 21st century and a greater understanding about fundamental learning differences. When we design a course with only a universal type of learner in mind we unintentionally set learners up for frustration and possible failure. If we are serious about providing good instruction for learners, we must provide multiple ways to provide instruction and environments so that all learners have opportunities for success. These descriptions are a first step in recognizing and accommodating individual learning differences. They are also an important step in recognizing the expanded role and impact of emotions and intentions on learning, especially as online learners need to become more self-motivating and self-directing.

A New Paradigm for Successful Learning on the Web

Dr. Margaret Martinez

Performance Dimensions, 811 E. Mountain Oaks, Orem, UT 84097 .

Tel and Fax: (801) 221-1667, E-mail: MaMartinez@compuserve.com

Abstract: How do we support successful, lifelong learners and help them competently respond to rapidly changing opportunities in the 21st century. The answer lies in how well we understand the sources for successful learning and consider audiences differentiated by individual learning differences. After years of cognitive traditions, lack of *whole-person* theoretical foundations, and imperfect *one-size-fits-all* designs, today's paradigms are still overlooking the significant, higher-order impact of affective and conative influences on learning. The investigator introduced learning orientations (learner-difference profiles) to examine learning in different environments. This is a unique perspective that considers how conative and affective factors guide, manage, and sometimes override cognitive (thinking) processes. The ANOVA results show how learning orientation, time, and environments account for significant effects and interactions. These results demonstrate useful ways to analyze and differentiate the audience before designing solutions for more successful learning and performance.

1. Introduction

If the cardinal rule for instructional designers is to know thy audience then we need greater understanding of learning audiences, especially as we move from the classroom to Web learning. After years of cognitive traditions, a review of individual learning difference research (Martinez, 99b) stills shows a heavy focus on cognitive processes and information processing mechanisms. Today's cognitive-rich paradigms need a stronger infuse of conative and affective research for a more realistic view of successful learning. To ignore or subjugate the importance of a learner's intentions and emotions is to create fuzzy, *one-size-fits-all* solutions for audiences treated as global learners with homogeneous intentions and feelings about learning. In contrast, a more realistic, comprehensive understanding of learning differences considers the complex influences and relationships between conative, affective, cognitive, social, and other relevant factors.

For many years Russell (97) has been conducting comprehensive comparative research on using technology for distance education. After compiling data from 355 research studies to examine what works or does not work, Russell (97, p. 1) states that research results are largely ambiguous and that individual differences in learning dictate that technology will facilitate learning for some, but will probably inhibit learning for others, while the remainder experience no significant difference.

He adds that when lumping all the students together into a fictional mass' those who benefit from the technology are balanced by a like number who suffer; when combined with the 'no-significant-difference' majority, the conglomerate yields the widely reported 'no-significant-difference' results. In conclusion, Russell (97) advises that the real challenge facing educators today is identifying the student characteristics and matching them with the appropriate technologies. Reeves (93) echoed parallel sentiments as he advocated the inclusion of stronger, more reliable theoretical foundations that explain individual learning differences. He suggested that much of the research in the field of computer-based instruction is pseudoscience because it fails to live up to the theoretical, definitional, methodological, and/or analytic demands of the paradigm upon which it is based, and it thus leads to ambiguous results. Similarly, after his review of educational research Bangerter-Downs and Rudner (91) concluded that no one knows what really works.

The confusing or inconsistent results arising from the research literature clearly indicates something critical is missing from our cognitive-rich learning constructs and educational technology theories. Snow and Farr (87, p. 1) suggested that sound learning theories are missing and realistically require a whole person view that integrates cognitive, conative, and affective aspects. The two researchers wrote that educators cannot ignore or overlook the key psychological aspects that interact in complex ways to support learning and performance outcomes. Otherwise, explanations about learning differences will be ambiguous and *isolated* from reality (Snow & Farr, 87).

2. Intentional Learning Theory

What theories and models can help us analyze and differentiate the audience and accommodate individual learning needs for successful Web learning? Clearly, successful learning paradigms need to acknowledge that individuals are feeling, intentional, thinking, and social human beings. Hence, the new Web learning paradigms need to (a) recognize diverse, fundamental sources for human response, (b) differentiate the audience using higher-order psychological explanations for learning differences, and (c) offer methodology that recognizes, explains, matches, and manages the impact of primary learner-difference variables. This study investigates individual differences by using *learning orientations* (unique learner-difference profiles) to differentiate the audience, guide design of the instruction and environment, and customize solutions that achieve objectives and improve learning ability. Learning orientations use the *intentional learning theory*, which describes higher-order psychological attributes and learner-difference variables for successful learning, as its theoretical foundation. There are four learning orientation categories: *intentional*, *performing*, *conforming*, and *resistant*. The learning orientations represent how individuals, with (to some degree) varying beliefs, emotions, intentionality, and ability, plan and set goals, commit and expend effort, and then autonomously experience learning to attain goals. This approach to audience analysis is possible because learning orientations encompass the higher-order, dominant influence of intentions and emotions. Researchers in other fields (Ledoux, 96; Goleman, 95) also show that emotions and passions influence, guide, and, at times, override thinking (cognitive) processes. Woodward (98), a child development researcher, also described how humans are highly goal oriented and use intentions to guide learning as early as age six months. Recognizing the power of emotions and intentions is also an important lesson for educators. Educators who can knowingly tap into a learner's emotions and intentions have a powerful advantage. This study recognizes that how successfully we support learning depends on how well we support individual needs with customized solutions that foster increasingly successful learning and performance. This transition from *one-size-fits-all* to *mass customization* is already happening. It is apparent in the growing use of templates and learning objects for multimedia (Martinez, 99a).

3. Study Purpose

The study purpose was to determine if learning orientation, time, and learning environment accounted for significant variance, effects, and interactions. For this study, the investigator developed a course, presented it in three Web learning environments, and provided adapted solutions for audiences differentiated by three learning orientations. After the analysis, significance levels would indicate how likely a result or relationship was true (that is, not due to chance). Significance would indicate the importance of analyzing learning audiences to identify learning orientations and match solutions to the major learning attributes for each learning orientation. Since individuals were not expected to learn alike, the investigator used learning orientations to hypothesize how individuals would learn more successfully in matched environments and less successfully in mismatched environments. Learning orientations helped to represent and examine human learning variability more realistically. This method for audience analysis is more discerning and robust than typical cognitive explanations (such as, learning styles and strategies) because it specifically highlights the dominant impact of emotions and intentions on cognitive and social processes. The investigator developed two research questions to examine the effects of learning orientations on the selected dependent research variables. (1) Do learners using intentional learning environments (Group EX1) benefit more than learners not using intentional learning environments (Control Groups CO1 and CO2)? (2) Do learning orientations influence group interactions?

4. Method

Before taking the *Discovering the Web* course, the learners took the Learning Orientation Questionnaire, which identified the individual's learning orientation, and were randomly assigned to a research group, that is, one of three Web learning environments, where they received different instructions (the intervention) for taking the course.

1. *Web Learning Environment 1* was the experimental group (Group EX1) and presented an intentional learning environment. It offered the treatment that matched and supported the three learning orientations and intentional learning performance. The instructions delivered the intervention, called Intentional Learning Training (ILT), at the beginning of the course to encourage intentional learning performance.
2. *Web Learning Environment 2* was the first control group (Group CO1) and presented the performing learning environment. It offered the Group EX1 instructional setting but omitted the special ILT intervention instruction.

3. *Web Learning Environment 3* was the second control group (Group CO2) and presented the conforming learning environment. It offered a menu-driven version, but not the intentional learning resources or the ILT intervention.

These Web learning environments were part of an instructional and research model called the System for Intentional Learning and Performance (SILPA). The assignment to an environment did not necessarily match the learner's learning orientation. Learners took the course on their own, stopping as necessary, until they completed the eight lessons and assessments. Learners typically took one and a half hours in one session to finish. 49 women and 22 men (mean age = 22) volunteered to take the Web course. All adult subjects had very limited or no Web experience. Most of the volunteers were undergraduate students from a local Western University. Other volunteers were from the general public, including white- and blue-collar employees in positions at all levels of business, corporate trainers, young and older housewives, university and high school faculty, retirees, and high school and university graduate students. Obtaining a broad sample was helpful in generalizing the results to the public. The course assessments were not adapted using learning orientations since preliminary research was needed to integrate conative and affective factors adequately. The investigator introduced the achievement variable to collect evidence showing how the learning orientations achieved in the three groups. In this study, achievement was not expected to show any statistical significance and was included as a basis for observation, data collection, and a beginning in the examination of how to develop instruction with assessments using a broader set of psychological factors.

4.1 Experimental Research Design

The investigator developed an experimental factorial research design and conducted multiple repeated measures univariate analyses of variance (ANOVA). This factorial design helped in the analysis of independent and interactive effects of two independent variables (learning orientation and intentional learning training) on four dependent variables (*satisfaction, learning efficacy, intentional learning performance, and achievement*). Factorial designs are useful because researchers can examine *effects* more realistically by controlling and analyzing more than one variable simultaneously. A second advantage of the factorial approach is that you can control additional variables that you know will influence the analysis. To allow for the effects of time, the investigator used repeated measures to test subjects several times (three times in this study) for a measure of each independent variable. A third advantage of this design is that the factorial approach lets the researcher manipulate, control, and analyze *interactions*, in addition to *effects*. This research design is unique because it overlays learning orientation as a separate dimension to (a) guide design and development of the research environment, content, and presentation, and (b) differentiate the audience before introducing the treatment and examining the results. This step is especially important because it distinguishes learners as individuals with predominant psychological characteristics in comparison to traditional methods that may treat learners unrealistically as a global group with homogenous influences.

Treatment	Orientations	A ₁	A ₂	A ₃
1 GROUP EX1 (with ILT & iCenter)	Cat. 1 - 3	Y Measures	Y Measures	Y Measures
2 GROUP CO1 (w/o ILT, with iCenter)	Cat. 1 - 3	Y Measures	Y Measures	Y Measures
3 GROUP CO2 (w/o ILT & iCenter)	Cat. 1 - 3	Y Measures	Y Measures	Y Measures

Note. The table shows three research groups with or without the Intentional Learning Training (independent variable 1) and *iCenter* resources: Group EX1 is the experimental group, and Groups CO1 and CO2 are the control groups. The three orientation categories appear as Cat. 1, Cat. 2, and Cat. 3 to differentiate the subjects within the three research groups by three learning orientations (independent variable 2): intentional, performing, and conforming learners, respectively. Resistant learners are not included. The repeated Y measures for the four dependent variables appear in columns A₁, A₂, and A₃.

Table 1: Repeated Measures Research Design

The repeated measures design resulted in four data sets: (1) pre-course registration and (2) three sets from the practice and assessment activities in the three time periods. To analyze the data, the investigator used an analytical model that would treat the time variable as repeated subintervals of the instructional cycle between and among the three research groups. According to Littell et al., repeated measures data need mixed models because of correlations between measurements on the same subject (Littell et al. 96). Following this advice, the investigator used a modified mixed model repeated measures

(PROC MIXED) example from Littell, Freund, and Spector (91) in the SAS system (with special parameters for learning orientation treated as a continuous subject variable).

5. Results

The study's evidence suggests that learning orientation is a rational and useful way to (a) provide theoretical foundations using a comprehensive view of learning, (b) recognize dominant psychological factors, other than just cognitive aspects, that influence learning (c) analyze and differentiate the audience an important aspect of determining what works for the audience, and (d) guide design, development, implementation, analysis, and evaluation of solutions and environments.

5.1 Multiple Repeated Measure ANOVA Results

Using *ILO* (learning orientation), *GROUP* (EX1, CO1, and CO2), and *TIME* (A₁, A₂, and A₃ for three instructional units) as variables, the ANOVA results exhibited significant main effects and interactions for three dependent variables

1. *GROUP* effects on satisfaction ($F = 5.30$, $p = .0074$) and learning efficacy ($F = 6.64$, $p = .0024$) at a significance level of .01 (99%)
2. *ILO * GROUP* interactions on satisfaction ($F = 6.48$, $p = .0027$) and learning efficacy ($F = 3.93$, $p = .0245$) at a significance level of .01 (99%) and .05 (95%), respectively
3. *TIME* effects on learning efficacy ($F = 31.82$, $p = .0001$) and intentional learning performance ($F = 14.77$, $p = .0001$) both at a significance level of .0001 (99.9%)

Significance levels exhibit whether there is a statistically significant difference between two means. Significance levels of .0001, .01, and .05 are the values commonly used to show statistical significance. In academic fields, a theory should have at least a 95% chance (.05 significance level) of being true. The first significance level, such as .01, means that the finding has a one percent (.01) chance of not being true, which is the converse of a 99% chance of being true. In contrast, the high significance level for *TIME* effects (.001) has a 99.9% chance of being true. Examining these results, the investigator concluded that *GROUP*, *TIME* and *ILO * GROUP* have significant effects and interactions on the sample population regarding satisfaction, learning efficacy, and learning performance. Specifically, these results suggested the importance of understanding *GROUP* and *TIME* effects and *ILO * GROUP* interactions as factors in supporting and improving learner attitudes, learning efficacy, and intentional learning performance. As expected, the ANOVA analyses (not shown) presented nonsignificant results for the achievement variable.

To supplement the ANOVA analyses, the investigator examined group means and standard deviations by time for the four dependent variables. These results show that Group EX1 had the highest overall group means for three of the four dependent variables. However, the overall group means for achievement are very similar between groups (Group EX1: $M = .83$, Group CO1: $M = .85$, and Group CO2: $M = .84$). As expected, each group mean averaged out to the group's majority orientation (that is, performing learners for each group). Yet, if we look closely at the achievement results (organized in the groups by learning orientation), the findings show that each of the learning orientations performed highest in the group with their matching learning environment (Group EX1: $M = 94\%$ for intentional learners, Group CO1: $M = 91\%$ for performing learners, and Group CO2: $M = 87\%$ for conforming learners).

5.2 Bivariate Plots by Learning Orientation

It was not possible to use ANOVA analyses to examine specific performance by learning orientation within the groups. However, the investigator used eight bivariate plots to exhibit how individuals, grouped by learning orientations, performed within the *GROUP* and by *TIME*. Using the SAS system's PROC REG and the unstandardized regression weights for the predicted intercept and slope by *GROUP* or *TIME*, the investigator plotted the regression lines between X and Y. One of the eight plot (shown in Figure 1) describes achievement by learning orientation within the three *GROUPS*. These results suggest that as learning orientation increased, the learners in Group EX1 exhibited the highest achievement and vice versa. In the other two learning environments the learner's achievement barely improved, regardless of the learning orientation. Interestingly, the slope of *GROUP* EX1 is steep enough (Figure 1) to suggest that refinements to the assessment models may contribute to significant effects and interactions in the future.

Figure 1. Linear Equations for Achievement (ACH) Showing the Regression of Y on X by Group

Research Question 1: Do learners using intentional learning environments (Group EX1) benefit more than learners not using intentional learning environments (Groups CO1 and CO2)? Group EX1 offered the learning environment with the highest group means for three dependent variables (satisfaction, intentional learning performance, and learning efficacy) and highest achievement means for intentional learners. As was previously mentioned, the achievement group means showed that individuals did best in the environments which best suited their learning orientation. The ANOVA results (Section 5.1) indicate the 99% probability that learning environments impacted learning satisfaction and efficacy. The group means showed that the learning environments impacted all the dependent variables. These findings suggest that learning environments influence learning outcomes depending on how successfully it matches and supports the learning orientation and individual learning differences.

Research Question 2: Do learning orientations influence group interactions? The ANOVA results (Section 5.1) indicate how interactions between learning orientation and environment seem to have impacted satisfaction (99%) and learning efficacy (95%). The evidence suggests that recognizing and being sensitive to the learning orientations is useful in guiding the design of instructional solutions and environments. Although learners achieved best in the environment which suited their learning orientation, it is important to consider that they were not in an environment that would help them experiment and improve intentional learning ability. The investigator will use these findings to focus development efforts on making the performing and conforming learning orientations more comfortable, engaged, and willing to perform in environments that subtly help them improve learning ability.

6. Conclusion and Contributions

This study investigates the importance of learning orientation and (a) using it to determine and explain key learner-difference variables, (b) integrating it into audience analysis and design methodologies to differentiate audiences and customize solutions, and (c) supporting it for more satisfying, successful learning and improved learning performance. These findings highlight how to support differentiated audiences with greater sophistication and specificity than primarily cognitive perspectives permit. Supporting the research hypothesis, the results indicate the need to provide (a) sophisticated, discovery learning situations for intentional learners when they want to be assertive, high-standard, high-effort learners, (b) non-risk, competitive, interactive settings that help performing learners overlook requirements for extra effort and difficult standards, and (c) scaffolded, structured, non-risk settings that help conforming learners learn safely and comfortably, then gradually help them internalize more intentional learning performance. The investigator hopes that these results revitalize the often-ignored, human perspective for differentiating audiences using conative and affective factors along with the more commonly explored cognitive and social learning factors. With practice, the matched solutions for differentiated audiences will be less expensive and offer better results because the individual assumes greater responsibility, sets and attains increasingly higher goals, expends greater, faster effort, and enjoys continually improving learning and performance. As a contribution to study of individual learning differences, this study

(1) Highlights the importance of considering a comprehensive set of affective, conative, cognitive, social, and other related learner-difference variables. (2) Demonstrates the need for sound theoretical foundations that incorporate the influence and relationship between higher-order psychological factors into measurable whole-person learning constructs. (3) Offers explanations on how some learners benefit from one type of solution and others do not. (4) Provides a Web learning

environment that can differentiate the audience by learning orientation, match individual and mass customized solutions, offer components that help learners internalize more intentional learning performance, and enhance use of learner-managed instructional treatments. (5) Offers analysis and design strategies for mass customization, that is, ones that identify and match differentiated-audience solutions to foster improved learning and performance.

Appendix A

Learning Orientations

Intentional Learners Deeply influenced by an awareness of the passions and intentions that motivate them, intentional learners place great importance on personal strengths, intrinsic resources, ability, committed, persistent, assertive effort, sophisticated learning, performance, planning and problem-solving skills and strategies, and positive expectations to self-manage learning successfully. These learners manage holistic to partist strategies, short- and long-term goals, and enjoy using learning to acquire expertise; they will even risk making mistakes to attain greater expertise. Intentional learners enjoy taking responsibility and control of their learning and willingly become actively involved in self-managed learning. These individuals learn best in open or discovery environments that support expertise building; risk-taking; mentoring relationships; self-directed learning; complex, problem-solving or case study situations; and high learning standards.

Performing Learners Performing learners are low-risk, skilled learners that consciously and capably use strategies, preferences, and self-regulated learning skills to achieve average-standard learning objectives. Performing learners, in contrast to intentional learners, are short-term thinkers, task-oriented, and often extrinsically motivated. They take fewer risks with mistakes and difficult goals, focus on grades, rewards, and normative achievement standards, and often rely on coaching relationships, available external resources, and social influences to accomplish a task. Performing learners will selectively work hard to learn topics and skills that they highly value and find particularly interesting. Otherwise, they clearly acknowledge that they want to limit learning effort (e.g., they do not have enough time) by only meeting stated objectives or getting the grade. These learners learn best in semi-structured learning environments that add competition, fun, interaction, and coaching for self-motivation.

Conforming Learners Conforming learners are more complying and passively accept knowledge, store it, and reproduce it to conform, complete assigned tasks if they can, and please others. The conforming learner does not typically use initiative, think critically, like to make mistakes, reflect on progress, synthesize feedback, or give knowledge new meaning to change themselves or the environment. These learners are less skilled and have difficulty solving complex problems and accepting or managing change. They have little desire to control or manage their learning or set challenging personal learning goals.

Modeling Information to Support Value-Adding: EdNA Online

Abstract: An historical and technical account of the development of EdNA Online, a website which serves the education and training community within Australia and focused on maximising the benefits of the Internet for education. The collaborative framework that is EdNA (Education Network Australia) is outlined with an emphasis upon the aggregation of value achieved through collaboration. Shortlisted for the 1998 Carl Bertelsmann prize, EdNA Online provides a range of services and functions – from a directory of information about all aspects of education and training in Australia, to quality content supporting resource discovery, to a facilitator of networking opportunities among its constituencies. A ‘data model’ is presented as an abstraction which attempts to synthesise the current foundations of the website while providing a tool for considering its ongoing development. Matching the pursuit of mutual benefit through collaboration with the data model reveals the commonality of ‘value-adding’.

1. Introduction

Originally initiated in 1995 through a cooperative arrangement between the Ministers of Education and Training of the Australian Commonwealth, State and Territory governments – and at the time primarily as an infrastructure connectivity project – Education Network Australia (EdNA) has since consolidated as an ongoing national collaboration. It is focused on maximising the benefits of the Internet for education. As well as government interests, it brings together representatives from all the education sectors – schools, vocational education and training (VET), adult and community education (ACE), and higher education. In 1997 its most visible product of this collaborative activity, the EdNA Directory Service, was formally launched as a Website. At this stage, this website was clearly positioned to act as the foremost gateway for online educational information in Australia. The potential for resource discovery which promised a stamp of quality (through careful evaluation by educators) was seen as a tremendous value-add for all involved. In late 1998 the EdNA Directory Service was renamed [EdNA Online 1999] to reflect the fact that communications, interactive services, and networking were recognised to be equally as important for education as quality online information-based content.

While it is important that as an ongoing collaboration EdNA is understood to be much more than an information gateway – and much more than a website – this paper is focused on what stakeholders began to refer to in 1998 as a data model for EdNA Online. In this discussion, we concentrate on illustrating how value-adding emerged as an important process which not only guaranteed quality content but became identified as a strategic consideration and indeed a feature of the EdNA framework. The data model presented here is not intended to be a static picture, but rather a snapshot of an ongoing evolution.

2. System Overview

During the early stages of the EdNA project a Website (as a directory service) was established as an important central focus. It was thought that such a directory system would be best served through a browsing paradigm. At that time (1995) none of the current major search engines had achieved any widespread presence

and the main global directory was the emerging *Yahoo!* which was predominantly accessed through user browsing. Technical advisers to the EdNA Task Force offered a few software solutions with Oracle being chosen, mainly because of its support for the dynamic generation of Web pages, a feature that was very much in its infancy at the time. A fundamental part of this process was the use of Oracle's PL/SQL to generate pages dynamically from information stored in a database.

The dynamic generation of Web pages was also very new at that stage and the possibilities seemed endless. Features such as personalised pages were trialled, with users being able to select different graphical themes and starting points in the category tree. These were supported through use of 'cookies', which, in Australia at least, suffered considerable misunderstanding and criticism from those concerned about privacy issues. Use of logins through user-IDs and passwords were considered to have greater privacy implications and in the end, the personalising features were dropped. With the current, and more sophisticated, implementations of 'profiles' in office-based software as well as on the Web this is now being re-visited for EdNA Online.

It was quickly recognised that the browsing facility needed to be complemented by a searching mechanism. There were several alternatives for this and a combination of the Verity Internet search engine with the Harvest freeware robot was selected. The robot was set up to gather full-text information based on the items that had been stored in the database. This information included directions for the robot as to how deep and how wide it should follow hyperlinks.

An index was also created from the information held for each item in the database. This provided a much more targeted searching capability and one which was guaranteed to return only quality information which had been evaluated and enriched with metadata by education experts.

Once the basic technical mechanisms were in place, there was a necessity to identify suitable Web resources and to build the content to a level that would be useful. At first this was done centrally but due to the widespread nature of the user and stakeholder base a concept of 'devolved (or distributed) administration' seemed to offer better leverage. There were, after all, potentially thousands of content identifiers. To do this it was necessary to provide a distributed administration system which included security control through user-IDs and passwords.

When this part of the system was developed in early 1996 there was nothing available commercially to support such a security system and so it was built into the system using the Oracle database and PL/SQL code. A system of security groups was developed and the 'state' was maintained through a code which was passed in successive URLs. This was made possible through the dynamic generation of each page which could include the appropriate code with each URL written into every page.

The distributed administration enabled the identification and inclusion of quality content to be built up to a reasonable level. This was supplemented by a form made available to users to suggest their own items for inclusion. Suggested items were stored in the database in a 'pending' state until they could be examined and either rejected or included for public access. An email address was also provided for feedback and suggestions which also assisted in building up the level of content.

Another feature included in the initial system was the hosting of Majordomo mailing lists. Registered users were able to utilise the administration system to set up and manage their own mailing lists via a forms interface. This was set up to buffer the user from the complexities of the normal mailing list administration and also to control the features that were allowable within the EdNA-hosted lists. Archival of these lists was provided as an option which was achieved through the EdNA system 'subscribing' to these lists and groups. The messages were stored and indexed for searching using the same Verity engine which was supporting the main searching facilities.

2.1 Current Implementation

These features have served EdNA well and the database of approved items has been built up to some 8,500 items. These items have spawned the full-text indexing of over 230,000 additional Web pages which can be accessed via the search facility.

Considerable work has been undertaken on the development of a comprehensive category tree which is used for browsing and allocation of items to parts of that tree. By and large, this process has been fairly disciplined resulting in a reliable, though not entirely engaging, method of resource discovery.

However, by mid 1998 the initial system architecture was showing its age. The increase in information held and the growing use of the service created additional strains. Like any large scale information technology development, this has made it increasingly more difficult to amend the system and to integrate new features.

Performance has been an issue which has largely been dealt with through increasing the power of the hardware. The mechanism of generating every page through PL/SQL code is now dated and is scheduled to be replaced so that the bulk of the processing is more closely aligned with the Web Server software rather than being executed within the database environment.

The freeware Harvest robot, used for gathering full-text searchable information, has not been supported for some time and has caused problems, probably due to the size and complexity of the tasks it was attempting to perform. The use of the Majordomo software for EdNA hosted mailing lists has also shown similar problems.

The original 'devolved administration' system has worked well, but it no longer provides the flexibility required due to the base of those who would administer particular parts of the system increasing significantly. One example of this is in the control of the mailing lists, where it is desirable for various levels of education participants (e.g., state bureaucracies, educational institutions, individual educators and even students) to be able to manage lists and possibly allocate list management rights to others.

The Noticeboard system implemented in 1997, based on NNTP, likewise hasn't provided the flexibility required in the management of notices or in the selection and presentation of notices to users.

Considerable effort has gone into the area of metadata usage as this is seen as one of the most important strategies for providing a quality and coherent set of resources that can be easily and usefully accessed by users. The 'Dublin Core' standard was chosen as a sound foundation from which to proceed.

The issues described above have now provided the opportunity to step back and examine the architecture and direction of EdNA Online and, in particular, to develop a data model which will provide a solid basis for its development and beneficial use into the future. The remainder of this paper describes the current thinking and implementation surrounding this evolving data model.

3. The Data Model (1)

Developed in 1998 the first draft of an EdNA Online data model identifies five types of information: documents; items; search indexes; categories; and, linkages. 'Documents' are Web-based resources of potential interest to users in the education community. 'Items' can be described as value-added containers which consist of all metadata that EdNA has associated with a particular document, regardless of the origin of that metadata. In this regard, EdNA has been an early adopter of Dublin Core metadata as a basis for its own standard which is implemented as a means for enriching its database of stored items (URLs enriched with metadata after evaluation). The main difference between these two information types is that documents are the raw resources that are created and maintained outside the EdNA environment (in fact anywhere on the Web) whereas items are the units on EdNA which contain the information about each document.

Searching functions of EdNA Online are, based on 'indexes' which contain detailed information about the text within each document. 'Categories' support the browse approach to information retrieval and enable navigation to useful material as an alternative to search. 'Linkage' is an architectural concept; an attempt to extend 'traditional' metadata concepts to include the relationship that documents have to additional, associated information such as review material or other documents. To date, this concept currently only has a very basic implementation. The higher education sector, in particular, sees a lot of benefit from developing this concept for providing greater flexibility and malleability into the data structures within the EdNA Online database.

These information types support the process of value-adding – an essential component of good customer service and in harmony with the value-adding brought about through collaboration

3.1 Documents

Documents have not typically been hosted by EdNA Online, although there is a move toward changing this. With its initial emphasis as a directory service and gateway, EdNA Online largely points to documents which reside on their original servers.

The issue of quality is addressed in a number of ways. With documents residing on other servers, and the Web with a characteristic disposition toward changeable content, the quality of a document is usually beyond EdNA's control. However, the overall co-ordinating body of EdNA – Education.Au Limited – enters into 'service agreements' with 'registered partners', or information providers, who in turn ensure certain quality standards are adhered to. Ultimate responsibility for the quality of a document lies, of course, with the information provider. Each sector has appointed project officers who attend to evaluating content for the service. Complementing this activity, Education.Au also engages in continued monitoring of the service as well as in a range of other activities such as maintaining overall coherence and currency of content. Such processes work to ensure that content accessed via EdNA Online is of a suitable standard.

3.2 Items

Items, the identifiers which refer to documents, are the metadata stored in the database. The bulk of items currently on EdNA Online have been input manually and are either collected by suggestions from the Website users or routinely sought out by project officers. However, there are many organisations within Australia which perform similar functions within their own localities and maintain similar information which is of interest to their particular constituents. These organisations have also been manually entering their identified items into the EdNA database, a process which has resulted in 'double handling' of the information. The potential efficiencies of an automated process have been recognised for some time and this has led to the implementation of a harvesting project, currently being tested.

Items currently have provision for holding content relating to all the 15 Dublin Core elements as well as a further nine EdNA-defined elements. Of these latter elements, the EDNA.Categories and EDNA.Indexing elements are of particular relevance to this paper. If an item contains EDNA.Categories metadata the document pointed to by the item becomes browsable 'core' item. EDNA.Indexing values are assigned by administrators as a depth guide for the EdNA robot indexer. These documents are full-text indexed and stored in a separate index to the core items. Items may identify more than one category, thereby linking the referenced document to relevant 'information zones'.

3.3 Categories

The browse directory on EdNA Online displays categories arranged as a tree structure. The linkages for this structure are held in a table in the database which is used to dynamically generate the pages which display each section of the tree as the user drills down. The category tree provides a comprehensive overview of Australian education and enables users to browse for 'core' or evaluated information.

Adding a category to an item requires a certain amount of education and training in itself and is non-trivial. Attaching categories to documents places the document in particular information zones. Familiarity with the category tree certainly assists in locating information quickly. However, at the time of writing, stakeholders are engaged in the process of examining different categories and their relationships with a view to de-coupling category functionality from the current interface constraints of a drill-down category tree.

3.4 Indexes

Indexes are used as the basis for the search facilities on EdNA Online. This task is currently performed by the Netscape Compass Server which, based on the EDNA.Indexing metadata field, gathers text and metadata from pages referenced by core items and creates a search index which is in a format that can be accessed by the

Verity search engine. There are currently two main indexes used to return the results to queries made through the search options: the full-text index for non-core items and an index for the title, keywords, and descriptions of the browsable core-items. The first is maintained through the Compass Server robot process and the second is built through a Verity gateway to the information held in the Oracle database. While this dual approach of maintaining two indexes was important in developing the Website, development work initiated in late 1998 aimed at merging the two indexes in a process which has brought search and browse into closer alignment.

3.5 Linkage

Linkages are currently implemented only through the existing constraints of the item table in the database where 'categories' are assigned. However, beyond such obvious architectural structure, the EDNA.Review element (designed to store reviews of documents provided by third parties) also relates closely to this concept. Annotations also operate as a linkage to a document. The current implementation in the form of metadata elements is limited by a uni-directional information flow. The authors believe, however, that there is potential for a new mechanism which provides a bi-directional linkages. While this may be difficult to implement it may also break new ground in enhancing a model for collaboration and community building in education.

4. The Data Model (2)

Further refinement of the model presented above has now led to another abstraction which classifies all data types into three. In this abstraction these types are named Types 1, 2, and 3 respectively.

4.1 Type 1 Data

Resources that end users are interested in and often referred to as 'content' can be described as Type 1 data. Such resources may include Web pages, software, or dynamic data (such as current stock values or the weather). In the first model, 'documents' describe Type 1 data. However, if an end user is specifically interested in Type 2 and Type 3 data then in a way their interest determines that the data they seek also has some Type 1 status.

4.2 Type 2 Data

Type 2 data is defined as data which is derived directly from Type 1 data in order to conserve computation or cognitive load in performing some function on Type 1 data. For EdNA Online, the 'items', 'categories' and 'indexes' are Type 2 data, as is metadata (information about data). These are data derived from Type 1 data (harvested metadata, or created by the search engine as an index). In other terminology, Type 2 data can be seen as an 'asset' of search sites (such as *Yahoo!* or *Alta Vista*).

4.3 Type 3 Data

Type 3 data is defined as data that describes relationship(s) between data and therefore cannot be derived from Type 1 data alone. It relates to 'linkages' described in the first model. Examples of Type 3 data include: the data that describes the hyperlinks between documents; the grouping relationships between data (the EdNA category tree is itself Type 3 data although the metadata element 'EDNA.Categories' in each resource is not); the usage logs of a proxy server about Web pages; or, the popularity rating of a Web page among similar pages. Clearly, a single datum of Type 3 is fairly useless – just like a telephone, if only one existed it would be useless. The power of Type 3 data is the collection.

For EdNA Online, Type 3 data is a key to engineering new flexibility into the information retrieval and resource discovery functions of the website through the design of user-customised pathways. Conceptually, it also acts as a useful abstraction from which to develop mechanisms to support and promote online collaboration and online educational culture. It is expected that the practical implementation of this can inform the development of appropriate specifications for the 'collaboration' module within the Instructional Management Systems (IMS) Project [IMS 1999].

From a design point of view the application of Type 3 data enables the dismantling of the rigidity of a hierarchically branched (drill-down) category structure and re-rendering it depending on user entry points. This is achieved through the development of a small master set of categories supported by a controlled vocabulary and the use of metadata. This opens the opportunity for a much tighter integration between the browse and search functions and further allows the definition of new pathways to information which can be saved, exported and shared as educational objects of value.

The model presented here using 'Types' of data bears some resemblance to Tim Berners-Lee's *Metadata Architecture* [Berners-Lee 1998]. However, we see the need for a model which extends further into interactive services, EdNA Online being very much a test-bed in distributed administration as much as it is in the sharing of aggregated educational resources. Berners-Lee's definition of 'resource' is our Type 1 data. His notion of metadata is close to our Type 2 data. An important point here is that our model is not intended to be constrained by its own attempts to be definitive – our definition is intended to be flexible enough to accommodate other forms of Type 2 data not yet revealed.

For our purposes, Berners-Lee's notion of 'link' can be seen as Type 3 data. In contemplating the possibility of innovative uses of other forms of Type 3 data our model extends beyond links as they exist in hyperlinks themselves. Hyperlinks are certainly one of the most important examples of Type 3 data and in many ways the fundamental technology of the Web. Perhaps it may be just wishful thinking but we believe that creative application of Type 3 data will be a key in propelling EdNA Online into its next stage of development.

Both the data models presented above are currently providing EdNA stakeholders involved with progressing development of services for EdNA Online with a tool for conceptualising a 'best-fit' approach to matching the requirements of human networks with available online technologies. The central commonality of the data model(s) with the collaborative framework of EdNA can be seen in the processes of pursuing 'added-value'.

5. Conclusion

Throughout the development of projects associated with EdNA Online, value-adding can be seen to be a common feature. Collaboration within the EdNA framework can be seen as the pursuit of mutual benefit. At the same time, value-adding can be viewed as an intrinsic opportunity that exists in any network, online or otherwise. In acting on this recognition through implementing a range of strategic initiatives, EdNA can be seen as developing a framework for lifelong learning support. Coupling the flexibility of multiple user pathways with concepts such as the linkages is expected to provide a very powerful means of resource discovery.

Achieving these aims will require an ongoing balance between taking advantage of the opportunities provided by an expanding range of enabling technologies and the promotion of facilities which result in the maximum benefit to EdNA users.

How to Make Discussion Forums Work on the WWW

Hermann Maurer, Graz University of Technology, Graz, Austria, hmaurer@iicm.edu

Abstract

It has often been claimed that networks like the WWW must not be seen just as huge distributed information systems, but rather also as systems that allow transactions, cooperation and communication. In this paper we discuss the technical features necessary for a good discussion forum, the fact that it should be really seen as part of a more general cooperation space, and psycho- sociological aspect that are essential for success.

1. Introduction

It has often been claimed that networks like the WWW must not be seen just as huge distributed information systems, but rather also as systems that allow transactions, cooperation and communication.

One of the most obvious tools for communication is the discussion forum. Indeed, see e.g. [Parsimony, ETI, Talkcity, Delphy], there are quite a few such discussion forums on the WWW. However, it is interesting to note that (a) a high percentage is used only quite infrequently, (b) they are often combined with other functions such as chats, see e.g. [Talkcity] and [Delphi], and that (c) the "older" type of discussions, news groups (outside WWW), are still very much alive, although more and more with cross-references to the WWW. It is worthwhile to examine why newsgroups, overall, are more successful than discussion forums, so far. We believe that there are five main reasons: (i) one is that all newsgroups are found in one place, rather than distributed over thousands of WWW servers; however, there is also a tendency today to combine many different forums in the same place: [Parsimony] is a very good example or to establish a "ring of forums" (where one forum leads to others); (ii) many desirable features that are conceivable are not available in discussion forums yet, e.g. the subscription technique (that new items are automatically shown when one has subscribed to them: this is a standard feature in news groups, yet is oddly missing in most discussion forums) (iii) access to news groups is often faster due to the extensive duplication/ propagation tools involved, (iv) discussion forums should be seen in a wider context as general cooperation tools (GCTs), and (v) many psycho- sociological phenomena one should be aware of when installing communication facilities are often blatantly ignored. It is our belief that discussion forums on the WWW will eventually replace newsgroups, due to the greater versatility of the WWW, particularly if they are used as true GCTs. In this paper we will report on some of the findings of our research on which conditions must be met to assure the success of a WWW discussion forum. This is based on the analysis of both successful and not so successful forums and techniques. Thus, this paper should be of interest to anyone intending to set up and operate a successful system for sharing and exchanging ideas:

The most important observations are that a successful discussion forum must of course be satisfactory from a technological point of view (and we mention some important parameters in [Chapter 2]). Yet at least as important are aspects of a socio- psychological nature (and we list some of them in [Chapter 3]). And that, finally, discussion forums, to be truly successful, should turn into general cooperation tools (GCTs) as explained in [Chapter 4].

2. Technological parameters

It is important to understand that discussion forums must have a solid functional (technological basis) and user-interface, yet this is not enough to make them succeed. Other often overlooked yet more important issues are on a psychological level as we will discuss in [Chapter 3] and that discussion forums must not be seen in isolation but as GCTs with features such as described in [Chapter 4].

There is also another aspect that needs careful consideration: discussion forums can serve rather different purposes, and as such may have to vary from application to application. To be more specific, consider two rather different applications: One, a discussion forum on certain medical issues, the other a discussion forum related to some Web Based Training applications in a subject area that requires much learner participation. In the first case, see e.g. [Infomed], the discussion forum very often "degenerates" in a collection of questions and answers: users tend to re-visit the same topic many times to find out if new contributions have been added or if their question has been answered. Hence in such a forum it is of paramount importance that new information can be located readily or that users are actively notified if an answer to their query is entered in the forum. In a Web Based Training environment as mentioned, see e.g. [Dietinger 98], the forum is often more a "real discussion" forum, with a thread of arguments that users have to be able to follow easily, no matter how those "threads" diverge or again converge. And in both cases more than just plain vanilla flavored communication and cooperation should be supported.

It is clear that a forum must be easy and fast to use; yet this is in direct contradiction to the demand of some users for powerful functionality: Typically, in a thread of discussion some contributors may not be of interest and the option to make their contributions invisible should exist; conversely, some contributors always make such erudite remarks that almost independent of the topic one wants to see what they have to say. It may be desirable to only see contributions that are fairly recent, or those that have received good marks from other readers (yes, such a grading system as available in some recommender systems, see below, is a very powerful function); it should be possible to highlight contributions by domain experts and also possible to collect interesting contributions in a private workspace (or one shared with others); users should be able to link contributions that they think belong together, such links being visible only to themselves or again to a well defined group of users. One of the important functions is a notification mechanism. Although some forums such as [Infomed] (using push technology) allow users to be notified of new contributions in topics of their choice (much as has been a long tradition with news groups) it would be e.g. nice if users could mark individual contributions posed (by themselves and others) so that they receive a notification as soon as someone reacts to the contributions at issue; or that users are notified if a new contribution containing a certain word or keyword is added into the forum. Of course discussion forums must be searchable by content, keywords, author, title, etc., etc. The list of functions that come up in connection with discussion forums is sheer endless. However, each new function introduced also introduces more cognitive overhead (i.e. makes the user interface and the learning of the system more difficult).

There are three main approaches to solve this problem: one is to keep the user interface and the functionality to a minimum; the second is to have various modes for, say, beginners, more advanced and expert users; and the third one is to offer a naive user interface, but a choice labeled "functions for experts" or such, that indeed yields much more functionality.

However, there is one feature that is crucial to an extent that we want to mention it right here: participants of a forum may just work with an assumed pen-name, or with a real identity. In either case it must be possible to send emails to (or chat with) other persons: and if they use pen-names their "anonymity" must not be violated by such emails! Integrated email or a private chat forum that can be started by a consenting group of participants at any point in time are crucial instruments for making a forum work, as we will see in [Chapter 3]. However, there is increasing concern with privacy issues on the WWW as such, and this extends to discussions: if someone uses a pen-name, the identity of the person behind it must be hidden for everyone, except in cases that are in violation of the law. We refer to the thorough discussion on those matters to [CACM 99] and to the fact that at least seven levels of anonymity can be identified to [Resnick 97]. However, we want to point out here that a "certification"

mechanism that permits to ask questions about some pen- name that are answered by a trusted server to an extent determined by the owner of the penname is a feature that is still missing in all systems we are aware of.

3. Non-technological parameters

As important as technological parameters like user friendliness, fast response times, a number of different access paradigms etc. may be, the best forum does not work if a number of psycho- sociological parameters are not right. The most important one of those is that there must be a "leader" or a "group of leaders". This does not mean that the forum has to be moderated (although a good moderator often helps), but it does mean that one or more persons should feel responsible for the forum to be "alive". Such persons can play this role because they explicitly started the forum with this function in mind, or such roles may emerge by themselves. It is not important that the leaders are "officially" known as having this role (although this usually is not a drawback): the only thing that counts is that they play a lead role:

Playing a lead role means carrying out at least some (and best all) of the following actions:

(i) Read all contributions in the forum and make sure that every question is answered, even if only by a temporary generic answer such as "This is an interesting question, I am also interested in an answer."

(ii) Make sure that questions are indeed answered in a meaningful way at some stage. This can often be done by someone playing the lead role in a hidden way, by e.g. sending an email to some participant who is suspected to know the answer in a way like " X has asked this question that I find interesting. I wonder if you could help find the answer?"

(iii) Point (ii) is the core of a more general issue: the combination of a forum and email (even if pen-names are allowed the email has to still work on the basis of those pen- names!) is essential. First, participants of forums sometimes want to discuss some things in private (starting a "private chat" or "private forum" may be alternatives to email); second, an important function of the lead role is to use email that is not visible in the forum to encourage participants, to solicit questions and answers, and to make sure that participants feel like they belong to a kind of electronic community. We want to explicitly acknowledge that this fact is already alluded to in (1) and was mentioned very explicitly by Lee Sproull in her keynote address at WebNet 98 in Orlando, Florida: and we can only emphasize her point: a forum without some participants that develop a minimal amount of bonding is usually doomed.

(iv) The development of a bond between participants of a forum can be fostered in many ways. The most personal ones are emails, thank you's in the forum and even common actions outside the Web (e.g. a forum on skin-cancer might support a donation campaign for research in this area, and progress of the action is reported). There are many other actions, some even automatable, that make or break a forum: if participants are asked for their birthday (not the year, please!) a "Happy Birthday" message is sent on time (preferably via a moderator who can add a personal note: nothing is worse than people believing they are treated personally and finding out that they are not!); if someone is a "frequent writer" this is gratefully acknowledged once in a while; if someone has not written for a long time, an email is sent to the effect "you have written such interesting contributions in the past; I have not heard a long time from you--- hope you are ok?". Note that those actions can be done by some "lead group" or can be automated to some extent: they must look personal and ideally they should be, the system just acting as a reminder.

(v) It is an important part of the lead role that persons are made aware of existing functionality, like "it seems you are very interested in how to deal with respiratory problems; do you know that you can subscribe to new contributions in the forum by doing such-and-such"; it is equally important that persons are brought together e.g. in the sense "I have noticed that person x is very interested in topic y; do you actually agree with the statements made?" (this could be an email or part of the forum).

(vi) A forum should have this personal touch due to an appointed or self-appointed or tacitly existing group of lead persons. However, the forum must also stay on track. It is not optimal if in a group on how to care for cats the whole forum becomes cluttered with "get well" wishes because some participant is known to have had an operation, or even worse with "Happy Easter" from everyone to everyone. Such exchanges should occur, but only to a certain level or in an isolated part in the forum, the rest by email or in chats or private forums.

The list above gives a good indication of some of the items that we have observed, and we hope they convey our message: a forum is dead if there is not at least one person constantly looking after it!

4. Discussion forums as part of a greater concept: general cooperation tools (GCTs) and general cooperation spaces (GCSs).

One important point to observe is that discussion forums can usually only be started by site administrators, are usually open to the general public or one well defined group, and are basically for writing comments (albeit possibly with some multimedia attachments). A General Cooperation Tool (GCT) does more: it permits all persons with write access to a part of the Server to define their own General Cooperation Space (GCS). Anyone creating such a cooperation space is a so-called facilitator for that particular GCS. Facilitators can make their GCS available with read and write privileges for whatever users they choose, and contributions can take any forms: notes, URLs, WinWord or PDF documents, pictures etc. Every entry comes with a short textual description, with optional attributes and an optional "grade". In conjunction with annotation and linking facilities as e.g. found in Hyperwave (see e.g. <http://www.hyperwave.com/whitepaper>, <http://www.hyperwave.de/documentation>, or http://www.hyperwave.com/hw_web_pages/delphi_opinion.pdf) such a GCS is indeed a collaborative environment to share e.g. bookmarks or other documents within the group defined by the facilitator. A push- functionality (akin to what is provided in Hyperwave as "query object") must allow automatic notification of participants of new entries at certain times, or depending on certain events and attributes. By also using various presentation strategies offered in the GCS, finding and sharing information becomes easy. By collecting information of particular interest in private areas of the Server users should be able to further personalize information according to their needs, including information residing in various GCS, or even outside such GCS. It is felt that such a GCT, by allowing the creation of arbitrarily many GCSs on the same server for different groups of persons is an ideal platform for communication and cooperation in Intranet and Internet environments.

Let us now look at GCTs and GCSs in some more detail. First, a GCT must be useable either in conjunction with ordinary Web Browsers or as separate application as a "floating window" while working with a WWW Server. It comes with different functionalities for the facilitator and for ordinary users.

A facilitator is any person that has write access to some part of the Server at issue. Typically, every identified user should have a special personal area with write privileges: in this case, every user with a personal area can become a facilitator. A facilitator can establish one or more GCS with a space capacity as determined by the administrator. (When space runs out, it is up to the facilitator to ask for more, prune manually, prune using a utility provided e.g. by date, or set limits to the size of documents that can be added by users.) When establishing a GCS, a unique name has to be chosen for the GCS at issue and a number of parameters have to be set initially (and some can be changed and set also later) by the facilitator. The most important parameter is the list of users: the facilitator can include the emails of arbitrary persons who thereby become users of the GCS. However, any new user added becomes only active after the user (who is notified by email) agrees to be active. Also, users can leave a GCS at any time they desire, i.e. no user is ever in a GCS without explicit agreeing to be in it, and is free to leave at any time. Conversely, the facilitator may exclude any person at any time. Facilitators may permit self-registration for their GCS, or may insist that they install each user (one main difference is the anonymity of users, see below, and the fact that self-registering makes permanent exclusion of "nuisance members" complicated).

The facilitator may suggest one or more main topics: nobody else can suggest main topics, but everyone can suggest subtopics that are hierarchically structured to a level determined by the facilitator with some default (like e.g. 5 levels) preset. (Note that if the depth of levels allowed is set to one, then only contributions to the main topics suggested by the facilitator can be added.) The facilitator and only the facilitator can arrange, rearrange or delete contributions created by other users. The facilitator can designate himself or other persons for each main topic as "responsible", i.e. whenever a document is added in this topic an email to that extent is sent to the facilitator either immediately, or at certain times as designated by the facilitator. It is also the facilitator who decides whether additional attributes (like one of a set of keywords) has to be added to a contribution to later ease searching or the automatic posting of contributions with just certain properties: here the need for a powerful server allowing the addition of meta-data becomes essential.

When an ordinary user enters a GCS the view is very similar to what one expects in a newsgroup, or in the discussion forum of e.g. GENTLE see [Dietinger 98] and <http://wbt.icm.edu> . A list of main topics is shown, and the contributions to the main topic can be expanded step-wise or "the whole thread at the same time" very much as in GENTLE. When a contribution is added, a short descriptive text is mandatory (and sometimes, in discussions, this is all that is required). An attachment is optional: such attachments can be a URL or list of URLs or some other document, including arbitrary multimedia files. Contributions can be given a "grade" between 0 to 10 (0 worst, 10 the best). Indeed such a grade can also be given when reading the contribution: the range of grades and their average is also shown for information. Only a single grade can be given to a document by the same person (to avoid "cheating").

When looking at contributions, users have a number of options similar to the ones mentioned in connection with discussion forums: indeed, one way to look at GCSs is to consider them very fancy discussion forums, of course: user can consult a GCS e.g. hierarchically (the usual way), but they can also sort the documents by author, by date, by date from a certain date onward, by opening the hierarchical structures only to the extent of showing branches that lead to documents that have been added after a certain date and by omitting contributions of certain authors ("blacklist"). Users can mark individual documents satisfying certain criteria (e.g. belonging to a particular topic or subtopic with an average grade higher than 6) so that information on them is sent at intervals they decide on (daily, weekly, bi- weekly or monthly).

A good GCT also supports "business cards" with information as provided by users. The business card has a pen-name chosen by the user, comes with or without picture, and whatever other information including email or phone number: clearly a "non-certified" business card without email or such may contain purely fictitious information! However, the GCT does keep track of the connection between pen-name and email (to which the password is sent): this information is treated as confidential except if opened for legal procedures. A GCS contains a messaging system that is based on the pen-names chosen, i.e. one- to- one communication is possible in a GCS, if desired. Note that the functionality of adding notes (both for private use or public with the GCS) should be supported, the same way as users should be able to create links even in material not authored by them (for their own use, or for the HCS). Such GCS- public notes and links are only visibly if the toggle "show notes of others " has been turned on by the facilitator, or is turned on by a user (in the latter case, notes and links are only visible during the current session for this user).

A GCT should also provide the "psyco- sociological" features mentioned in [Chapter 3] above. Indeed, everything that has been said so far is really an extension of "ordinary" discussion forums. However, there is one further feature that makes a GCT particularly useful: the book-marking facility. When browsing WWW sites users may find an interesting entry. Rather than making a bookmark for themselves on their PC they hit the GCT bookmark button, rather than the bookmark button of the browser. As a result, a list of groups in which they participate (potentially after identifying with name and password) is shown: they put their bookmark in the appropriate space with a short description (for themselves and others) and a "grade". Thus, the GCS is a powerful tool for bookmark sharing, an important feature for efficient WWW use.

Note that the bookmarks created can be checked for validity or changed contents by the GCT: the creators of bookmarks (and the facilitator if the toggle is set this way) can be notified if there is a potentially invalid link!

Thus, the list of shared bookmarks has a good chance to stay better up to date than any private list! When users find a bookmark that does not work, simply pressing a "bookmark does not work" button notifies the author and (see above) the facilitator.

5. Summary

Discussion forums have been around in the form of newsgroups for many years. They are also becoming more and more popular on WWW servers. None comes close to the functionalities described above, yet it is our belief that such functionalities are essential.

Note that a number of recommender systems [Resnick 97] have been around and are increasing in importance. A GCT can be seen as such a system where the recommendation (the grades, and the fact that bookmarks, i.e. URLs or other documents are added into the GCS) is coming from the fact that the group using a GCS is homogeneous and is supposed to have shared interests. Our approach is in line with the Personalized Recommender System, a prototype of which was developed by J.Horwarth and others under the guidance of Barry Fenn.

It is also conceivable that "recommendations" that come from similarities in judgement are exploited: this is increasingly done on some commercial WWW servers, and is pursued in recommender systems such as PHOAKS, ReferralWeb, GroupLens, Sitemeter, Fab, Alexa and others. Also, the density and usage of links may be used to measure the importance of contributions, as is indeed done e.g. by the search-engine Google <http://www.google.com>. It is clear that powerful GCTs will be merged with some such attempts in the future. To put it into a nut-shell: discussion forums of the news group type will be more and more replaced by sophisticated WWW discussion forums that are really General Cooperation Tools. One such tool, called Hyperwave Cooperation Tool is currently being implemented at the institute of the second author.

Idle Computing Resources as Micro-Currencies - Bartering CPU Time for Online Content

Michael May
LRR-TUM, Department of Computer Science
Technical University of Munich
Michael.May@in.tum.de

July 10, 1999

Abstract

In this paper we present a brokerage system for using idle computing resources as a micro-currency for Web services hardly quantifiable with real currencies as downloading stock charts or accessing a search engine. The Locust (LOW cost Computing Utilizing Skimmed idle Time) system acts as a Broker for micro-payable services by demanding a part of the user's idle computing resources in exchange for accessing the service. We introduce the price/market model of Locust enabling the collection, aggregation and trade of resource surpluses or lacks between coupled sub-markets and eventually leading to an electronic resource market focused on the mainstream Internet user as supplier of idle computing time. We further describe Locust's inter-operable, secure and ubiquitous Web and Java based infrastructure to make micro-paying with CPU cycles for online content literally as easy as surfing a Web page with embedded banner advertisements.

1 Introduction

Wide-area Networks as Resource Pools The exponential growth of wide area networks – especially the Internet with its currently over 70 million nodes from over 58 connected nations – has lead to a drastic increase in the pool of available resources and to the need to access these heterogeneous resources uniformly. The potential of combined global computing resources has already showed up in a number of news-breaking distributed computing efforts, e.g. the decryption of assorted cryptographic algorithms as DES [5] and RC5 [14] or the search for mersenne primes and extraterrestrial life (SETI, [9]).

The need for uniform access to distributed resources has spawned a number of meta- and web-computing and resource brokerage frameworks addressing this problem. While meta-computing systems offer access to dedicated hardware and permanent resources by means of highly efficient, low-level programming models and protocols, Web-computing infrastructures as Locust target casual users and resources of the World Wide Web which are only temporary online and available for exploitation, by means of interoperable, secure and ubiquitous Web technologies as Web Browsers, Java and HTTP. Resource brokers act as a meeting point for demand and supply and thus provide an electronic market place for idle computing resources.

Goods and Services of Resource Pools Our vision is to harness the idle computing resources of millions of anonymous World Wide Web users temporarily connected to the Internet and transform these resources from crude and heterogeneous to standardized and homogeneous marketable services similar to other services already available on the Web, but on a much larger scale. Homogeneous goods and services already marketed include disk space provided by `httpd`, email and name service provided by `sendmail` and `bind`. The universal access tool for these services is the Web browser. These standard Web services are completely homogeneous and exchangeable like electric current coming from one provider or another allowing a demander to switch service providers anytime if not content with the service offered to her. A standardized interface for a computing or processing service – the CGI interface is not suitable for serious distributed applications – has not yet emerged on the Web though. So we strive to produce the electric current that fuels the applications of next generation computational grids.

Economic Model and Brokerage Computing time is a typical representative of resources with immediate expiration if unused. So every user of an idle machine should be thinking about ways to save his otherwise unused resources from decay. Locust's economic Price/Market model enables the export or import of resource surpluses or lacks between so-called submarkets and thus enables spare resources to pay off or to build stocks for future usage. Traditional resource allocation strategies have severe drawbacks outside of closed systems. Economic strategies however concurrently allocate several resources by efficient decentral decision making. The local self regulation between supply and demand is a key point to the management of large resource pools.

Architecture We propose a brokerage infrastructure called *Locust* (LOW cost Computing Utilizing Skimmed idle Time) based on interoperable, secure and ubiquitous Web technologies, i.e. Web browsers and servers, Java applets and HTTP. The usage of Web applications and protocols extends both the ease of participation and the target audience. While other Web-computing frameworks are collecting parallel tasks and distributing them to World Wide Web users with idle computing resources, Locust treats this scenario from a different point of view. We rather are collecting idle computing resources from casual WWW users and distributing them to programmers with parallel tasks to be executed. Locust achieves this by accepting parallel tasks in form of Java applets, embedding them into attractive Web pages and dynamically scheduling them onto anonymous Web users accessing those Web pages.

Outline The rest of this paper is structured as follows. In the next section we sketch deficiencies that sparked our own work by giving an overview of related work. In section 3 we present the necessary prerequisites to use idle computing resources as a micro-payment system including a price/market model and its application to realize micro-paying and trade. In section 4 we present the technical issues, the implementation and applications of Locust. We conclude with a summary of the features we think make Locust unique both as a micro-payment system and a web-computing framework.

2 Deficiencies of Related Work

Before we present the main topic of this paper we would like to shed some light on deficiencies of related work that sparked our own efforts in the field of computing resource brokerage. Among these works are ReGTime [6], a broker system for marketing and using computing power on idle workstations, the cypher breaking metacomputer of *distributed.net* [4] and Damp [15], Jet [10] and Javelin [8] – interfaces to meta computing facilities based on Java. They all share common features as infrastructural overhead, demander orientation and volunteering.

Infrastructural overhead Current web-based distributed computing systems try to add or circumvent features lacking or featuring the Java virtual machine in order to deliver a full-grown parallel computing environment. These enhancements include applet-to-applet communication, fault-tolerance, load balance by work stealing, consistent checkpointing, high availability by redundancy and encryption. This considerably adds overhead to the already prevailing drawbacks of wide area distributed computing as poor network latency and bandwidth and slow Java byte code interpretation.

ReGTime as the only real resource brokerage system focuses the formal and legal aspects of selling and buying idle computing time. In order to enable controlling and accounting of resources additional software overhead is granted as necessary i.e. maintenance of separate logins and such. Thus the (architecture dependent) installation of ReGTime is more a matter of hours than minutes.

Demander orientation All related projects are clearly more oriented towards the sparse demanders than to the thousands or hundred thousands of potential suppliers of idle computing time. A parallel programming environment is provided from the programmer's or user's point of view neglecting the fact it takes several magnitudes more suppliers than demanders if an resource brokerage framework shall work out and propagate in practice.

Volunteering - Lack of Incentives All systems lack an effective incentive to propagate the acceptance and usage of their systems. Most environments completely lack any motivation at all for suppliers to donate idle CPU time. They set their hopes in volunteer computing and address their target group in the scientific and computer science field.

ReGTime brings together supply and demand in a resource spot market without any pre-information about a possible price – the negotiation is left to supplier and demander. So before contacting a ReGTime broker a potential supplier or demander has no hint how much resources he is going to get or supply and at which price. This situation is far from suited to successfully establish an electronic resource market.

A few others as `distributed.net` feature a kind of abstract motivation as feelings of community or feelings of doing something 'good' by joining i.e. the proof of the inefficiency of the DES algorithm for ensuring privacy ([4]). In [13] this feeling is referred to as *bayanihan*, a "community spirit of unity and cooperation that makes seemingly impossible tasks possible through the concerted effort of many people". These incentives, whose value is hard to quantify, make the success of a resource facility subject to good will or luck and – depending on the situation – may work or may not.

3 Micro-Paying with Idle Computing Resources

All of the Java based distributed computing environment described above share some common conceptual deficiencies leading to a limited acceptance among potential users and inhibiting the propagation of resource brokerage. In the following we propose new paradigms – ease of participation and supplier orientation, low overhead, working incentives and an economic market model – which heal most of those deficiencies and could give way to establishing an electronic resource market. By making joining a distributed computing brokerage system and providing cpu cycles as easy as surfing a Web page with embedded banner advertisements, idle computing resources have the potential to become a marketable Internet good similar to other goods as web space, banner placements and advertisement clicks.

Supplier Orientation As it takes several magnitudes more suppliers than demanders if a resource brokerage framework shall work out and propagate in practice, an initiative addressing anonymous Internet users – the Internet *mainstream* – should be as simple and intuitive as possible. Meta-computing systems though are more oriented towards the sparse demanders than to the thousands or hundred thousands of potential suppliers of idle computing time requiring them to visit a certain web page in order to donate resource. We think this is far from being easy enough.

Besides, a computational applet for consumption of idle cpu time will, in the mainstream user's point of view, do *nothing*. No flashing messages, no moving animations, nothing. As the surfer is not rewarded directly we cannot rely on any action of him to donate resource, instead we must make sure the applet does its work even without interaction by making it running *automatically*. In short: If we cannot make the supplier come to the worker applet, we have to bring the applet to the mainstream supplier. We will shed more light on this point in the next paragraph *Incentives*.

Incentives - Finding the right price Most computing environments cited in this paper have no incentive at all to move potential suppliers to supply computing resources. We propose a two-way approach to the problem of an effective incentive.

First, we propagate idle computing time as a replacement of money or micro-currencies on the Web, a tendency that can already be observed in some parts of the commercial Internet. In online advertisement business, banner placement, page impressions and ad clicks are sold by webmasters (to finance expensive bandwidth), bought by the industry (to reach their target groups) and – eventually but literally – paid by the average Internet user for the access of an attractive online content, be it access to an online database or up-to-date news¹.

Online advertisement is thus already used as a micro-currency in order to pay for hardly quantifiable online services as visiting a web page, downloading brand new stock charts or accessing a search engine. None of these services are *free* as it may appear to the surfer. All of them are guarded by a small animated or flashing customs stations invisibly demanding a small toll for accessing the site. We are sure that the mainstream surfer will be accepting worker applets just like he has accepted banner ads on his favourite web sites, worker applets literally doing *nothing* but skimming his idle cpu time. If we make joining a distributed computing brokerage system and

¹This phenomenon was recently backed up by an open letter of Clearway, Inc. accompanying the withdrawal of their ad blocking *Adscreen* software after only ten hours [11]. In this letter, Mark Kriegsman, President of Clearway, recommends **not** to block any ads lest starving out *free* web sites either being forced to shut down or charge memberships for access.

providing cpu cycles as easy as surfing a Web page with embedded banner ads, then (micro-) paying for online content with cpu cycles will become common practice.

Second we think that the most natural means of payment for an resource market are computational *resources* themselves. Conversion from and to real money raises transaction costs and may be superfluous if suppliers want to spare idle computing time during the night or weekends and consume accumulated resources – less a certain amount for the commission – when having increased demand for it.

Low overhead - keep it simple Most of the related work in this field, ambitious and elaborate projects with powerful features in order to deliver a full-grown parallel computing environment (so-called *infrastructure, framework, toolkit*), considerably add overhead to the already pending penalties of wide area distributed computing. In our opinion an initiative addressing the Internet mainstream should be embarassingly simple. It is questionable if the end user is going to use a distributed meta-computing environment he does not understand and that sends him encrypted worker applets of unknown origin to do encrypted computations of unknown good and kind.

Openness Security issues take up a substantial part in the efforts of distributed computing infrastructures to deliver a traditional parallel computing environment. Other systems enforce correctness, privacy and safety of the involved code, data and results by means of encrypted processing, cross and statistical checking, checksum methods, redundant computation and task splitting into parts too small to reveal useful information.

We discourage from any method for enforcement of security issues going beyond the features of the Java Virtual Machine. Distributed computing on the Internet is not (yet) for businesses with sensitive proprietary data. The reason why Internet computing projects exist is not the Internet's fundamental qualification for distributed computing but mainly because it is out there and it is dirt cheap. So idle cycle computing, once established, will be a low-cost niche market with a number of inconveniences such as latency, bandwidth, security and timeline constraints that will be made up by an unbeatable price-value-ratio. Professionals and businesses seeking for secure parallel job processing should stock up their budget for computing time in a computing center.

Model for a Resource Market Outlined in the following we present a model for the establishment and management of an electronic resource market.

Asymmetric Model

A resource market focused on casual WWW users is characterized by its asymmetric structure: there are many potential suppliers of small quantities of computing resources and only few demanders of aggregated amounts. This fact justifies a stronger orientation of a resource market to the supplier side and an enforcement of easier market participation for resource suppliers than resource sinks.

Decentral Hierarchical Management

By establishing a hierarchy of intermediary traders we can have the resource market handled efficiently and decentrally by local traders each following individual policies for accessing and aggregation of resources. These policies may be defined by individual target groups, transaction costs, administrative domains and so on. Additionally, market participation should be the easier, the lower the abstraction level is. Suppliers participate as local markets with resource surplus, demanders as submarkets with resource lack.

Incentives for Market Participation

To reduce transaction costs as much as possible we propose the usage of micro-currencies for suppliers of computing resources in low hierachical levels of the market model. Exchange to real currencies will be offered only for accumulated resource amounts in higher levels of the trader hierarchy.

4 Locust – Infrastructure and Applications

Infrastructure The current prototype of Locust [1] is collecting resources by *Content Providing*. We have written Java applet code to download, test and return tasks from a Master Java application located on the Web server. The so-called *Locii* applets implementing the worker role of embarassingly or brute-force parallel applications are embedded into the Web pages of a search engine. The so-called Locust *tasker* – responsible for determining the capabilities i.e. the hardware and software of a connected Web-terminal and scheduling an appropriate task to it –

consists of a Java servlet running on the search engine Web server. Combining the Web server and the tasker on the same machine might form a potential bottleneck but is necessary to suffice the restrictive security aspects of the Java Virtual Machine. The communication between tasker and *Locii* for job assignment and return of results is done via light-weight UDP.

By placing the *Locii* applets on frequented Web sites and skimming its visitor's idle computing resources, Locust is able to create a working distributed computing scenario on the fly delivering encouraging performance [2]. In contrast to other works on Java based distributed computing we emphasized our approach to be as simple as possible and to make up the simplicity and the performance lack of Java by the sheer number of concurrent applets. We have made yet no further efforts to support extended scalability, load balancing or further communication routing.

Suppliers and Demanders Locust currently relies on so-called *Web-Terminals* – arbitrary, temporarily connected hardware under any operating system capable of running a Java-enabled Web browser – as suppliers of idle computing resources. Their incentive to provide resources is an abstract micro-currency saving transaction costs: access to attractive Web content. Alongside it is possible for owners of computing clusters to donate spare resources by installing the *Locii* applets as Java applications.

The role of the intermediate traders in the market model is adopted by world Wide Web content suppliers collecting idle resources by embedding *Locii* applets into their Web pages. Intermediary traders are rewarded by cash for accumulated resource amounts similar to accounting for banner placements or ad clicks.

Currently we consume the accumulated cpu resources ourselves for raytracing and RC5 decryption which is described in more detail in the next section. However we anticipate SOHO offices and small businesses as enduser demanders of those resources in the future. Eventually we foresee meta-computing projects to further process our basic resources into a standard meta-computing service.

Applications Basically Locust works with every Java applet, we are even evaluating our system as a substrate for executing cooperating Java beans on the Web. But only parallel and distributed applets exhaust the full potential of web-computing with idle resources of hundred thousands of anonymous nodes. Because of the inherent latency and security constraints of the Internet and the Java sandbox model we have to confine to embarrassingly parallel or brute-force application, the prototypical problem class for every distributed meta-computing scenario. These properties are best implemented by using a master/slave computation model. The master splits the main problem into sub-problems and distributes them to the slaves that he keeps track of. Upon completion of their sub-tasks slaves return the sub-result to the master and trigger a new sub-problem being sent. In the RC5 case the RC5 key space is divided into keyblocks and distributed to the slaves which check them against the known plain text. Their return value for a completed key block is either Key found or No key found. The Master code we used was implemented by Laurence Vanhelsuwe [15].

Java Optimization One of the features of the RC5 algorithm implementation is its simplicity and independency from hardware acceleration, hence it is straight-forward to formulate the algorithm in C and with a little more effort in an object-oriented language as Java. Due to the lack of mathematical functions support in Java only moderate speeds were achieved by this naive approach with the initialization, setup and encryption methods implemented straight-forward by means of loops. In order to achieve acceptable performance compared to native implementation all loops were unrolled in above methods. Benchmarks show that the RC5 applet can achieve – under an efficient implementation or plug-in of the Java virtual machine with just-in-time compilation – up to one fifth of the keyrates of native implementations with optimized assembly core. So by just using more than five worker applets any native RC5 application can be recovered and outperformed [3].

5 Conclusion

We have investigated merits and deficiencies of current Java-based distributed computing and resource brokerage frameworks realizing that related approaches suffer from common misconcepts leading to poor acceptance and usage of idle computing resources. We disagree to related works centering around the extension of the Java sandbox model in order to supply a full-grown, user-oriented distributed computing environment for traditional parallel applications.

Instead we suggested new concepts – easy participation, working incentives and supplier orientation embedded in an economic market model – solving those deficiencies and giving way to a fuller propagation of an electronic resource market. The prototype implementing this simple and light-weight approach is *Locust*, a framework for skimming and consuming idle computing resources of WWW users in exchange for online content.

Ease of participation and a broad target audience – crucial for a framework focused on the mainstream Internet user as suppliers of idle computing resources – is achieved by means of inter-operable, secure and ubiquitous Web technologies as Browsers and Java. By placing embarrassingly parallel tasks e.g. RC5 decrypting applets on a frequented Web site and joining its visitors into an instant distributed Web-computing scenario, *Locust* is able to deliver encouraging performance. Future versions of *Locust* will address further aspects of the economic market model, such as coupling of sub-markets and trade of resources.

Ethical Considerations in Web-Site Design: Developing a Graphical Metric

WD McDaniel, EDPP and PC McGrew, EDPP

June 15, 1999

Abstract

"(we should do) good, not from inclination, but from duty." ¹ from Groundwork of the Metaphysics of Morals.

*"Act in such a way that you always treat humanity, whether in your own person or in the person of any other, never simply as a means, but always at the same time as an end."
Immanuel Kant*

Kant's belief that duty and respect should be the basis for interacting with our fellow humans forms the basis for many discussions as new technologies emerge. Each new technology that changes the type of information that is available and how it can be accessed opens up the need to review that technology in light of how the information is gathered, protected, and made presented. One technology that presents a variety of challenges worthy of this discussion is the World Wide Web and its supporting technologies. The Web has been more quickly integrated into business, academic, and personal life than any technology that has come before it, and yet it was not until long after its original deployment that discussion regarding accessibility issues began.

With the proposal and adoption of Web Accessibility initiatives around the world, it is time to carefully review the perceived ethical obligations to make websites "accessible" to the handicapped. This approach to web site design, while honorable, may not be realistic for certain types of sites and for users with certain types of handicaps. Using the Kantian view of duty and respect and Rawls' Ethics of Justice as the basis, certain criteria may be derived for evaluating the ethical responsibilities of web site designers and of web site users. These can be expressed as vectors on a planar graph, the size and direction of the vector providing information about ethical choices made by both the designer and the user.

This paper examines the accommodations both designers and users must make. In the process we develop and present a two dimensional plane of practicality vs. ethicality with our newly developed accommodation vectors as they apply to a variety of web design techniques and web deployment technologies.

Introduction

The AccessAbility initiative in Australia², the Trace Research & Development Center's "Designing a More Usable World" project at the University of Wisconsin³, and the W3C Web Accessibility Initiative⁴ offered for international acceptance are only a sampling of the projects⁵ that demonstrate that there is concern among those who work in the Web world for their fellow web-surfers who may have limitations in their access. In addition to these initiatives, more web sites devoted to web design education are including discussions of ethical considerations in the design of web spaces for universal accessibility.⁶ You can also find some discussion in the internet newsgroups with regard to the requirements for making sites more accessible to blind, physically limited, and even access-limited (slow access speed, limited band width, limited color depth on monitors) web users. There are also the discussions raised as part of classroom discussion in Ethics sources and in Academic conferences regarding the ethics of computing.⁷

With all of the discussion there is a surprising omission. The concentration has been on the side of encouraging and demanding web designers to make allowances for the potential range of limitations that a visitor to their webspace may have. What is not discussed is the obligation a webspace visitor has to meet the web designer halfway, hence meeting their ethical duty as a visitor.

We started with Kant's concepts of duty and respect in concert with the refined version of Rawls⁸ concept of Justice as political fairness.⁹ From their precepts we sought to codify a representation of ethical responsibility

versus technical and consumer practicality using a plane. Along one axis we place practicality, with ethicality along another. We then plot vectors of the behaviour within web systems in this space. This approach provides more than a simple linear sliding scale of understanding of each party's obligations. Instead it provides web designers with a tool whereby they can decide if inclusion of a feature or a function for the sake of usability is ethically necessary or impractical at any cost.

Web Technology: Usability and Accessibility

For this paper we define usability in terms of the measure of a web-application's ease of use by anyone, regardless of limitations and disabilities. This includes such features as three-dimensional controls, accelerator keys, and scroll bars. We define accessibility in terms of the features a web-application has which support use by people with disabilities. This includes features such as user-defined font sizes, alternative input and output devices, and modifications to the usual input device behaviours.

Web technology evolved very quickly and it is certainly justifiable to say that most usability factors have been ignored or forgotten in the rush to the net. HTML does not easily support keyboard interfaces for interactive documents. There are no default behaviors for images and multimedia files to make them accessible to visually impaired web surfers. There is no simple way to enable a default button in all browsers (what the W3C call user agents). Rather, these usability features are provided (or not) by each programmer coding appropriate and sometimes highly elaborate routines in a scripting language.

Accessibility missed consideration in the first web browser designs, as well. While web browsers have, since the first version of Mosaic, allowed readers to change the size of the fonts in a document in real-time, few others accessibility features appear in the commercial browsers. Accessibility requirements have recently become more of an issue, however. The move of commercial businesses, academic organizations, and consumer groups to the web for information dissemination and customer support intensifies the concerns about accessibility.

The Problem

The theory of web technology is that it allows for a variety of usability and accessibility features to be made available to the user, not the designer. Button styles, colors, font sizes, input and output devices; all of these can be exploited to make the web-site in question more accessible to disabled users. But implementing an alternative technology for the benefit of these users comes with a cost. It requires more time to design, more time to code, and possibly more money to implement.

At the same time, both usability and accessibility are certainly desirable things; web designers attempting to communicate to a world should not limit the site to only the able-bodied. This tension between accessibility and practicality provides the potential ethical dilemma.

Do web-site designers and owners have an obligation to make their sites accessible? At what cost? What level of accessibility is the minimum allowable? Are all sites obligated?

A quick survey of the initiatives cited above gives a clear indication that the onus of providing accessible web sites to the masses is solely on the website owner and designer, with a passing nod to the browser manufacturers. However, using our premise of Kant's duty and respect and Rawls' political fairness as a basis, this hardly seems correct.

Surely there must be an ethical obligation on the part of a vision-impaired reader to learn about and utilize the font sizing ability of the browsers. But, does such an obligation extend to acquiring a Braille reader? A voice I/O device?

All such accommodation by both the web site designer and the web site user must be balanced on some scale of practicality vs. ethicality. To this end, we have developed a planar approach to measuring the ethical versus practical trades designers *and* users should apply when deciding how far accommodation for accessibility

should go. The plot of such relationships could have been done as a quartile graph that plotted a subjective location of web sites on a grid as shown below:

A system in the Northeast quadrant of such a graph balances the needs of the user against the means of the designer. It employs practical techniques to satisfy the legitimate needs of the user without bankrupting the designer. It also implies a certain responsibility of the user to have acquired or learned about features which the designer has exploited to provide accessibility.

A system in the Southwest quadrant tends to represent a waste of time. The designer has implemented a site that does not provide much accessibility, but was difficult to create anyway and employs impractical and expensive techniques. For example, a system which requires a Braille output device to be attached regardless of the users situation is unfair to fully sighted users, partially sighted users, and even to unsighted users.

A Northwest quadrant system indicates the designer did not bother to incorporate much accessibility, but took practicality to the extreme. Many current web applications fall into this quadrant. Webspaces that use small fonts, large graphics with little explanatory text, and misuse tags are the primary culprits, and quite common.

Finally, a system in the Southeast quadrant is unfair to the designer. While meeting the fair needs of the handicapped user, it has done so at the expense of the designer. Highly impractical techniques have been employed to meet those needs. Such a system puts too much of the onus for accessibility on the designer and not enough on the user. An example would be a web application that implemented its own font scaling technology because the users refused to learn about how to use the engine available in the browsers.

The Accommodation Vector

Such quartile graphs are useful, but do not take into account the other dimensions of the problem. While we could have expressed the problem in a three space (and there are situations where this is appropriate) we decided that representing other dimensions of the problem as a vector quantity in the quartile space would provide more accessibility to audiences attempting to measure the accessibility of such systems.

The quartile graph shows the location of a system as a dimensionless point; a snapshot in time, but also in attitude. A system designer may have a strong desire and intent to add more accessibility to a web application but not be able to do so in a practical manner at a given moment. In addition, a system evolves and may evolve toward the Northeast quadrant or away from it.

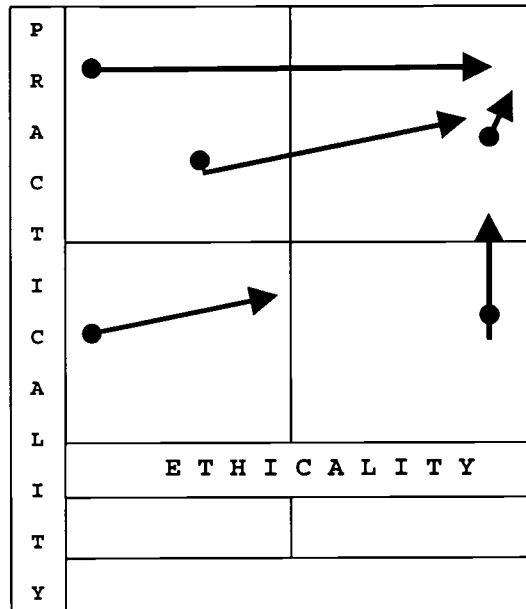

Therefore, rather than just plotting the static location of systems, we decided it made more sense to represent the ethical/practical tension as a vector. Vectors have a great many uses in the real world. They provide not only information about a location, but also about a starting point and about a direction. In addition, they

encode magnitude, which we felt we could use to indicate yet another aspect of the tension between the ethical obligations laid on web applications and the practicality of accommodating those obligations.

Typically, for designers, the more practical a design is, the less ethical it is in terms of meeting a reasonable set of needs and requirements for an impaired user. We plot the evolution of a system by a starting point for the vector and by the direction its accommodation vector takes. We use the length of the vector to indicate the intent of the designer to provide more accessibility as it becomes more practical.

All web systems evolve over time and over time the cost of any individual accommodation falls. For example, it would have been very difficult to accommodate vision impairment with scalable fonts before the invention of true-type fonts in Windows. The cost of building or acquiring such an engine would be beyond the means of almost all persons who need it before Microsoft included in the Windows operating system. Once there, however, the cost of providing the ability to browser users was almost nil.

The quartile graph then begins to take on the shape shown below. It begins to represent a plane of vectors where the starting point, the direction, and the length represent where a system is and where it is going with respect to its ethical requirements for accessibility. In addition the balance between systems that require too much commitment from the user and those which require too much commitment from the designer is encoded and shown.

Conclusion

Web applications need to be designed with more accessibility for disabled and impaired users, but such users share a responsibility for learning the techniques available to make their use of a system enjoyable and useful. Designers must balance a desire for simple, highly practical systems with the needs of disabled users for sophisticated accessibility options. All users must balance their needs for accessibility with the practicalities of current state of the art technology and costs of development.

Representing systems on a plane as a state vector can be a useful way to show the relative success of web applications at balancing this tension. Web designers can use this method to enter into discussion with site owners in discussing the merits of building in limited or extensive accessibility and usability features.

Web-based Training: A South African Experience

M.A. Mearns

Department of Information Studies, Rand Afrikaans University,
Republic of South Africa
E-mail: map@lw.rau.ac.za

Abstract: The future of the people of Africa is believed to be determined through education, organisation and energisation [Mbeki 1997]. In building Africa's information society acceleration towards development plans, stimulation of growth and new opportunities in education, trade, healthcare, job creation and food security will raise the overall African living standards. To deal with the convergence in functionality of information, the education system in South Africa is forced to deal with the rapidly developing technological field. This paper reports on a web-based diploma that address a niche market to train subject specialists so that they may be able to manage information in their specific fields of expertise. The paper also reports on the statistical profile of the students, problems and pitfalls experienced as well as success achieved.

1. Introduction

Educational institutions are eagerly utilising the potential of the Internet and more specifically the World-Wide Web as a mechanism to deliver distance education courses to students. The Internet has eliminated national and international boundaries and has reduced the cost of transmitting information tremendously. Information is the latest word that is connected to revolutions. The information and communications technologies (ICT) revolution is believed to have had an effect the past 20 years [European Commission 1996]. In November 1998 a new word, also connected to revolutions, emerged when Thabo Mbeki [Mbeki 1997] mentioned the African Renaissance in which he recognises a central aim to provide a better life so that the people of Africa may determine their future through "education, organisation and energisation". The word also implies that this renaissance should be achieved by the people of Africa, not through an historical culture of begging, but brought about by them.

The African Information Society Initiative, according to Butcher [1998] believes that "building Africa's Information Society will help Africa to accelerate its development plans, stimulate growth and provide new opportunities in education, trade, healthcare, job creation and food security, helping African countries to leapfrog stages of development and raise their standards of living". Although the term "Information Society" refer to improving living standards in African countries, the definition for Information Society in first world countries refer to the integration of information technology in "industrial production and in information dissemination in all fields, one in which technology establishes completely new premises for production, distribution and consumption of information and the creation of knowledge" [Thornhaug *et al* 1997:8]. There appears to be a marginalisation between the development of the information society to act as an improvement for living standards, whereas on the other hand, it should create knowledge. The continuing growth of the Global Information Society creates a fear in some that it will accelerate the marginalisation of Africa [Butcher 1998]. However, Mbeki [1997] recognises that the African Renaissance cannot take place without globalisation and that the possibilities represented by globalisation will ensure that both rich and poor may benefit from globalisation.

Statistics for the number of Internet users indicates that one out of every 5 000 people in Africa, excluding South Africa, utilises the Internet. Compared to the world average of one out of 45, South Africa compares well with a ratio of 1:65. South Africa's relative status as an Internet user is in the 18th position worldwide [Butcher 1998]. The education and training system in South Africa must deal with the convergence in functionality of information, due to being exposed to rapid development in especially the technological field [Butcher 1998].

Companies in South Africa have realised that information, technology and the management of both these fields are of crucial importance in delivering improved services and products. Training in these fields will address a specific niche market, especially the training of subject specialists so that they may be able to manage information in their specific fields of expertise.

Such a group of subject specialists have enrolled for a two year Diploma in Information Management at the Department of Information Studies (Rand Afrikaans University). The need for subject specialists to gain experience in finding and manipulating electronically-stored information in their fields of expertise were realised and a Web-based diploma was developed. The diploma is offered and completed via the Web only, and although access to the Internet is essential, access to the Internet, as well as individualised tutorial training, have been provided to historically disadvantaged students. All study material including study guides, instructions and references are published on a secure Web site, accessible only to registered students. Although the diploma is offered as a distance education course, full interactive activity is promoted especially by means of electronic mail and discussion groups. All assignments that are completed by students are submitted as attached documents via e-mail.

The contents of the course represent the very latest international developments regarding Information Science and Information Management. Assignments are designed to provide hands-on experience through practical projects such as case studies and represent a problem centred approach to learning. The first study year of the diploma introduces information management on a personal level, followed by an organisational level to a strategic level of information management. The second year of the diploma entails advanced research work regarding a choice of four modules out of a possible selection of eight modules:

- Information Management Strategies
- Information Management Systems
- Information Economy
- Knowledge Management
- Electronic Publishing
- World Wide Web Management
- Internet Infrastructures
- Electronic Indexing and Information Retrieval.

Currently the diploma has its second intake of students for the first study year and the first registration of students commencing with the second year.

2. Statistical profile of the students

A total of 43 students enrolled for the diploma in 1998. The representation of these students in the workforce is divided into the private sector, universities as well as research or information centres. Students working in the private sector are 42%, in universities 28% and research or information centres 30%. Interesting to note that 77% of the students that enrolled for the course were female, possibly due to the impression that research workers and traditional librarians are mostly regarded as females. Of the 1999 student intake a slight drop in the female number with 73% that are represented by females. There were some cancellations during 1998. Of these cancellations 20% were due to reasons of ill health, 65% of a private nature and 15% due to technological problems preventing students to be able to work effectively. Two students from neighbouring countries enrolled for the course in 1998, one from Zimbabwe and the other from Namibia. The student from Zimbabwe had to cancel due to technological problems that could not be solved relating to the sending and receiving of electronic mail. The student from Namibia cancelled due to personal problems, but re-enrolled for the 1999 intake. The prior highest qualifications of the students that enrolled during 1998 vary between students that have only a bachelor's degree, those with a bachelor and a post graduate diploma, honours degrees, master and doctorates. Students with a bachelor degree makes up the biggest portion (46%) followed by students with a bachelor as well as a post graduate diploma (26%), then students with a honours as highest qualification (17%), masters students (9%) and lastly doctorates (2%).

The average pass rate of the 1998 student group was 68.217%. Nine percent of the students that wrote the examination achieved an average mark between 50% and 59%, forty eight percent of the students had averages between 60% and 69%, thirty percent of the students an average between 70% and 74%, and thirteen percent of the students achieved a distinction.

A total of 51 students enrolled for the 1999 intake. Interesting to note that the prior qualifications of the 1999 students differ somewhat from those of 1998. The largest group has a bachelor degree and a post graduate diploma (39%), followed by those with only a bachelor degree (29%), then honours (22%), then by doctorates (6%) and lastly masters (4%).

3. Problems and pitfalls

Students that were inexperienced with the Internet and also computers in general, initially had difficulty in getting used to the interactive environment. Some had no experience in sending electronic mail and had to be tutored via the telephone. Inexperienced students are often those from historically disadvantaged communities. Fortunately these students were also those that accessed the Internet from the in-house computer laboratory and they received individualised tutoring. As soon as the students became familiar with the computer and Internet environment their confidence improved, resulting in the improvement of their experience level and the overall success of their studies.

The largest portion of problems that were encountered was of a technological nature. As mentioned before, 15% of cancellations were due to technological problems that could not be solved. These students experienced frustration due to outdated hardware and networks. Some had difficulty with the Web browsers and electronic mail, which is specified by company policy. Another problem that was encountered is high levels of security on the student's computer which is specified by the company at which the student is employed, resulting in the prevention of the browser to be able to access certain sites.

The content itself of the course never proved to be a reason for failure. However, it was realised that the workload of the students was too demanding. They had to submit a document of at least five typed pages every week on their opinion and discussion of provided references. Every six weeks they had to submit a research report of at least 15 typed pages on a provided topic, but from references retrieved by themselves. After realising how demanding this workload was for part-time students, a minimum submission of two opinion papers and one research report was initiated. The workload of the student was decreased, but they still had to cover all the discussed topics for examination.

Another problem that was encountered was to reply and comment on the work that the students submitted. It is less time consuming to jot down a few remarks in pencil on a written assignment than to make knowledgeable sense through individualised replied remarks via electronic mail. In many cases undelivered mail, due to technological problems again, resulted in the re-sending of the remarks on assignments.

4. Successes

The greatest success lies within the content of the coursework. The student is stimulated to work independently on the most recent developments within the Information Science field. Feedback on the course content has in the two years never been regarded in a negative light. The students remark that they have grown to such an extent that they can handle information in their specialisation field with utmost confidence. They perceive the Postgraduate Diploma in Information Management as one that answers in their needs and one that address a specific niche were a specialist in a specific field may also be an information specialist in that field, more likely turning such a person into a knowledge worker.

Another success of the course that can only be ascribed to the electronic medium, in which it is delivered, is the fact that the content may be changed to the most recent developments within minutes. The tutor of a specific topic may have finalised and published the topic, just to retrieve a reference appropriate to that topic the

following day. The reference can be added to the published topic and can be immediately available to the students.

The world economy is presently characterised by the phenomena of shrinking job opportunities and South Africa is no exception to this. The problem of poverty and unemployment in South Africa have not been conquered yet [Manual 1999]. Research by Lascaris and Hunt in 1998 indicates that 69% of young South Africans would rather work for themselves than in existing enterprises [Koenderman, 1998]. The Postgraduate Diploma in Information Management is perceived as one answering in this specific need of the South African environment. Students develop the skills of becoming entrepreneurs in the information field so that they can process information effectively for financial gain. They learn to use information technology effectively to achieve a competitive edge in a country where the information society is still in the early developing stages. They learn to create new marketing opportunities and to identify opportunities to develop new information products.

5. Conclusion

According to Margolis [1998] cost savings can be achieved through the elimination of classroom lectures. The educational and social situation in South Africa necessitates that more students be reached at a lower cost in order to develop the information society. This can be achieved by making use of the Internet, however, the technological infrastructure should be improved to try to eliminate the technology-related problems that were encountered.

Sinclair [1998:298] mentions that real teaching should be concerned with more than information and its transformation, but that it is concerned with mentoring, internalisation, identification, role modelling, guidance, socialisation, interaction and group activities. The Postgraduate Diploma in Information Management does not necessarily exclude these aspects from the learning situation. These activities can take place to a certain extent within the interactive environment that facilities such as electronic mail, chat rooms and discussion groups can provide. These facilities have not yet been implemented in the diploma, but are in future planning. With persistence, creativity and patience the Postgraduate Diploma in Information Management will reduce its problems, increase the success and turn knowledge and learning into...

"...commodities, with information being the chief currency through which participants buy, sell and trade in the educational domain" [Roberts and Peters 1998]

G. Kouroupetroglou, Ass. Professor, Department of Informatics, University of Athens, Greece,
koupe@di.uoa.gr

Abstract: In this work we present the design of an environment to construct and exploit historical events. The event can be a personality, a historical event or a time period. Various sources can be combined and presented according to their content and relevance to the selected event. The construction and the exploitation can be achieved through different paths. Those paths can broaden the event content or give a more narrow, deeper view. We avoid existing categorization and limiting factors to enhance user abilities to understand history.

Introduction

The aim of the educational procedures is to reveal a person's inborn aptitudes, give form to and activate inner potentials. Current scientific studies and practice for innovation of education emphasize the amounts of information which the students have to retain. The creation and provision of tools capable of supporting learning and knowledge acquisition can help exploit the potentials of this information [Metaxaki et al. 1996a] [Metaxaki et al. 1996b] [Tziva et al. 1993] [Collis 1996].

The presented application is an effort to use current technological advances and products to serve educational purposes. More than an information provider, the internet is supposed to promote dialogue and exchange of opinions and ideas. This could be a catalyst for the creation of mental interconnections and sequences leading to the acquisition of meta-skills.

The application refers to the European contemporary history and can be easily expanded to incorporate other countries. Our team is working on different aspects and tools for the history lesson [Metaxaki 1998]. We target to technology integration stimulating the interested parties to:

- investigate the underlying causes of historical events
- understand the general and specific consequences
- enhance abilities for information sources' selection and evaluation
- develop metacognitive skills.

In the following we present the designed environment, which is realized by widely accepted communication media and tools, of low cost. The application is interactive and easily accessible, without need of special training or equipment.

General Considerations

Studying History

Trying to enrich the usually poor content of the schoolbooks for history, we can come to the other end: the endless gathering of information sources and past events. We have to emphasize that the available information sources for contemporary history (newspapers, photographs, books, radio programs, TV and news shows etc.) are many more than for other periods. Moreover, historians and/or teachers, when selecting sources and past events very often limit them to their own views. Meanwhile, the application focuses on our century. There should be a quite serious selection of the facts to be named as historical events.

To overcome the mentioned problems we propose a process to exploit and shape a *global event*. The global event has a *virtual content* consisting of directly or indirectly connected views, opinions, beliefs, e.t.c. These are collected from a variety of sources and themes (historical sources, memories, news, arts, science e.t.c.)

This approach is actually a dynamic procedure of selections - comparisons - adoptions/rejections. The history lesson resembles an investigation/research procedure. In this way the underlying forces creating and moving history are recognized and understood, the consequences and effects are estimated.

One more problem for the realization of this approach is the existing time periods' taxonomies and categorizations, which express an already adopted view. They create difficulties for making projections and recognizing significance. We propose a categorization in short time modules-periods. These modules, without diminishing the existing ones, support the comparisons on inter-and intra country level. The modules can be accessed sequentially or randomly. The time module-period has four-year's duration and can easily be the Olympiada (the four years period between the Olympic Games). Starting from the last Olympic Games, and going back with time we reach the beginning of the nineteenth century.

The Classroom Settings

New didactic procedures and technological developments very early established an interactive mutual relationship, offering to each other means to develop and progress [Metaxaki 1997] [Metaxaki 1998] [Collis 1996] [Metaxaki 1994]. The new technological features (data transmission, animation, sound - image - text coexistence, databases etc.) can be used to solve educational problems. "Telemathisis" (greek word formed from "tele-" and "mathisis"=learning) is one of the words used to name procedures, investigations and practices for learning and teaching.

In distance learning and teaching the traditional classroom gives its place to a virtual one. The interaction between the changing or not parties can be occasional and asynchronous (access to a common database of specific content), or systematic and constructive. In this last case, one of the interconnected terminals or nodes possesses a more responsible role, like a teacher in a classroom. This role can be interchanged or transferred by a predefined sequence and usually controls or suggests or coordinates the educational procedure.

In our system, the roles are interchangeable by transfer or expressed requirement. Teleconference facilities are provided. The content of the lesson can be selected pre-didactically for discussion or constructed during the contact hour. The accessed or collected information can stay in the system uncombined for re-exploitation and re-use. The system thoroughly promotes the *stochastic navigation* to find answers or *documentate* and *formulate a hypothesis*.

System Design Approach

Main System Modules

The proposed environment for the modern history lesson is presented in the block diagram of Figure 1. The system includes virtual modules, listings, selection boxes, main pages, figurative pages e.t.c. facts [Aisher 1996] [Kobsa and Wahlster 1989]. This makes the system easily accessible and supports the linking and the navigation, which can lead to the creation of mental interconnections.

There exist two types of virtual modules according to the content presentation, shown on the lower dark shaded part of Fig. 1. There are modules for accessing the information content according to the time period (Olympiada). They are called *Time Main Period Modules* (TMPM). The other type are modules for accessing the information content according to the subject. They are called *Subject Main Category Modules* (SMCM). There are already implemented nine SMCM for: geography, nations, religion, life, political history, languages, arts, sciences, technology. The number is expandable through splitting or addition of other subjects.

All the virtual modules are implemented in hypertext form. The structure of their main pages is the same. As there are no specific modules for country information, but this is quite often needed, there is relevant provision. On each module page exist both the listing of countries and a *marked space* for each one. The facts or events are retrieved in text-, plain link - or icon link-form, depending on their importance and information amount.

Figure 1: Block diagram and Interconnections of the system

Content organization

There are two virtual access organizations for the content of the system. One is according to the main time periods and the other is according to the main subject categories. This simulates the co-existence of different encyclopaedias.

The information can be introduced or retrieved once and be clipped and transferred for accessing by the appropriate SMCM or TPCM. In this case the information looks independent of the structure of the system's modules. This does not yield always. We can have differentiations in the contained information i.e. there may be only a phrase for a piece of art in a battle description accessed by a time-period selection. The same piece of art can be presented by detailed description when accessed by the subject art selection. This differentiation provision serves the recognition of the context the global event is formed or investigated in.

System Functioning

The content retrieval and the event presentation can be adjusted in different ways. The selection of a way can be predefined for the lesson's need or/and be adapted to the dialogue evolution.

In Figure 1 we show the block diagram and the functioning capabilities of the system. The communication and the screens were designed and implemented to match the multi-path exploration and avoid sequential tracing, which is also permitted by default.

When the system is functioning, we reach the content of one SMCM or TPCM. To achieve this the user has to interact with the system and start a selection procedure. Whatever the selection, the procedure is always a two-step navigation.

The upper light shaded part of Fig.1 shows the ways we can communicate with the SMCM, TPCM. There is a central communication page which is organized in three frames. The one frame is the largest, and serves as the *Presentation Frame* (P.F.). All the information (text of main events, images e.t.c.) are shown in it. The other two frames appear on the page as *Constantly Shown Fields* (CSF) and do not change. They are placed on the two margins side-vertical and down-horizontal. The selection options provided on the CSF give us direct access to the SMCM, TPM. By one more step the events and facts contained in the module are presented.

Together with them, the country name is always present on the specially allocated marked space. In this way an exploration on a certain subject can be overviewed in parallel for two different countries. To change module the user has always to go over the CSF. In this way, the user is always aware of the context the event or fact is stored and accessed in.

As there is no content organization per country we create an intermediate *Figurative Page* (FIP) for each country. This page is not concrete. It is created by a cgi program starting by a country selection function on the CSF. During the system's trials, the users tended to start the navigation by country selection. Owing to that, another option for the FIP was added. It can be created through the bit map of Europe shown on the cover page of the system. Via the FIP page there is direct access to the marked space of the corresponding country. In case a global event is studied for only one country, inter-subject and inter-period navigation is needed.

Technological media and tools

Our aim was to create a tool which could be simple and of immediate use and appliance [Metaxaki et al 1990] [Kouroupetroglou et al. 1995] [De Diana et al. 1994] [Smith 1991] [Metaxaki et al. 1996c]. For the implementation we have chosen currently used programs and common computer configurations.

The communication media is the WWW. The programming language was HTML, javascript and the required cgi programs were written with the use of the Bourne Shell [Reynolds 1996]. The working environment is Netscape Communicator, which is a tool that is quite spread and offers elements and services that support teleteaching's principles. Those are mostly the real time communication and the real time navigation through conference services.

The conference service offered is the chat tool, a real time exchange of written messages between the participants. This is done simultaneously with guiding and use of collaborative browsing.

An Example of Use

In this chapter we present a multi-path example of use. We start by Greek history. The simplest approach would be to study a time-period. Let us choose 1940-1944. There are two paths to be followed, both requiring two steps to match the two elements of the query (period-country).

One path is via the figurative country page [Fig. 1]. This page appears either from clicking on Greece on the bitmap or by choosing Greece from the country selection box on the CSF. After the FIP of Greece has appeared, we chose the years 1940-1944, through the time period selection box. As a result, we are guided to the marked space for Greece and can further access the events presented there.

Another path could be via the CSF. Through the time periods list, we are guided to the TPM's main page. To view the events of concern, we choose Greece from the list of countries on the top of the page. The targeted link guides us to the space marked for Greece, where the events are presented.

When overviewing the content we can recognize the most important event, which is World War II. After this estimation we can proceed in a variety of ways, depending on the global event under study.

In case our global event is the selected time period, we can enrich this period by navigating through subject modules and broaden our views, comparing information on what happened between 1940-1944 in this country. The system offers opportunities to access information from other countries and make comparisons.

Another way could be to start from a small event e.g. that the opposition was using theatre shows for covert actions and start another navigation, concerning the role of arts and artists in the liberation battles. Navigating through other countries and other time periods, we could reach Picasso's "Guernica". Alternatively, moving to another country we could recognise the use of the first radar and start a navigation concerning technology (role, development, consequences). Another event is the absence of Olympic Games, which could be followed. All these different paths are actually changing the global event the users have started with. The scope of the lesson and the coordinator could select that path. We show in Fig.2 one of the working pages.

The mentioned example shows that working on broadening or overviewing a global event the users meet different sources, opinions and they have to make estimations, comparisons, adoptions/rejections.

Discussion and Results

The system we present in this paper is an environment to study history using advanced communication technologies.

The environment is user friendly and easily accessible. The constantly shown fields of the communication page help the selection procedures. At the same time, the user does not feel lost navigating through countries and events.

The system prototype is fully expandable. We think that an intranet server could be very helpful, if constructed by repeated use of the system. The global event can be estimated and become the leading factor for the exploitation, without eliminating system capabilities. The virtual modules and their crossing to combine sources, views etc are supporting the global event study.

During the system development and design we tried to intergrate the technology in a learning process by proposing structuring for accessing, combining and linking. This is quite a difficult task, as the good and fruitful didactic techniques intergrating the communication technologies in a virtual classroom are still under exploration. We tried to preserve the system's flexibility for multi-path exploration and benefit of the large amount of information sources which can be compared and merged.

Our next scope is to let users of different background and ages interact with the system. In this way, we could improve learning procedures and estimate new evaluation parameters.

Using 3D For Electronic Commerce On The Web: A Psychological Perspective

Gareth E. Miles & Andrew Howes

School of Psychology, Cardiff University, P.O. Box 901, Cardiff, UK. CF1 3YG.

Contact: milesge@cardiff.ac.uk

Abstract: We argue that the limited use of 3D technologies in e-commerce should not discourage designers from using these technologies. A review of empirical psychological work, supported by a model of consumer web behaviour, suggests that 3D environments will allow users to navigate intuitively if designers take care to provide suitable support (e.g. landmarks, maps). We describe recent work by the authors that found 3D environments led to greater retention of information, such as the location and identity of products within a store environment.

1. Introduction

The Internet is seeing the rapid development of different approaches to electronic commerce [Miles et.al., in press]. One class of approaches uses 3D-like virtual simulations of spatial real-world environments. [Richmond, 96] found subjects using a 3D VRML (Virtual Reality Markup Language) web site spent more money on average than subjects using 4 comparable hypermedia interfaces. Responses to Richmond's questionnaire found that the VRML subjects viewed the 3D interface very favourably, spent more time shopping in the VRML world, and under-estimated how much time they had spent. However, [Wickens & Baker, 95] argue that 3D environments might incur negative psychological effects, making 3D WWW sites harder to navigate than 2D sites. Our purpose here is to try and identify the qualities of 3D environments that might make them suitable for the WWW, focusing on electronic commerce (e-commerce) applications. Whilst many advantages of 3D worlds may emerge from their novelty value at present, there are more intrinsically valid reasons for using 3D. We draw on work carried out recently by the authors and our colleagues to identify advantages of using 3D on web sites. These advantages derive from the inherent psychological properties of three-dimensional environments, many of which have been explored experimentally. Our paper has three principal sections:

The first provides a basic psychological model of e-commerce user's behaviour; the second section argues that 3D environments can ease navigation problems on complex web sites; the last section suggests that 3D environments provide excellent support for general learning about a web space and its contents.

Although our conclusions are specific to e-commerce user's of the web, it is our belief that these conclusions can be generalised to other web uses, e.g. information retrieval.

To begin with we will take a brief look at an existing 3D e-commerce site. SuperCity's 3D shopping mall is primarily a collection of Internet stores presented using VRML. Most of these stores are actually conventional hypermedia stores, though the Legal and General store is an example of a store where the VRML environment is carried through into the shop itself.

VRML is the dominant 3D technology used on the web today. The technology is based on a vector graphic engine with advanced features such as texture mapping, gourard shading, mapping of movies, animation and interactive controls. A contrast is the photo-realism of Apple's QuickTime Virtual Reality (QTVR) and Livepicture (www.livepicture.com). Although this has been used to help visualise products (e.g. BMW) and as a novelty feature (e.g. Wine Cellar U.K.), the more general use of QTVR on the web has been limited, perhaps by file sizes.

In this paper we concentrate on the use of 3D in e-commerce environments, primarily business-to-consumer situations. It is anticipated that many of our observations will generalise to other applications on the WWW. Long download times have been a major reason for not using 3D environments for commercial applications. However with compression of 3D files becoming more efficient and the bandwidth of the Internet generally increasing it may now be time for Internet sellers to consider 3D. Here we explain some of the the costs and benefits of such a move from a psychological perspective. The starting point for our analysis is a model of e-commerce consumer.

2. A Model Of Consumer Behaviour On The WWW

The processes required for completing an electronic commerce transaction are complex. [Guttman et. al., 98] have articulated a model of consumer buying behaviour. In their model are six stages: Need identification (the buyer identifies the need for a product or service); product brokering (the buyer identifies a range of products to satisfy the need); merchant brokering (the buyer determines who to buy from); negotiation (the terms of the transaction are determined); purchase and delivery; and service and evaluation. These stages offer a broad scope model of the entire purchasing process, in contrast, [Miles et. al., in press] choose to focus on the early stages of product and merchant brokering. They identify three principal categories of behaviour found in a user browsing commercial web pages: Criteria management, Search and Comparison. Briefly; *criteria management* describes behaviours that determine what product a buyer will be looking for, including search for more information on a product's features and alternative options; *search* behaviours involve navigation of the web in an attempt to find products that meet these criteria; *comparison* involves the evaluation and contrasting of information about products that meet the target criteria. Three-dimensional environments serve these user behaviours in a variety of ways. Below we focus on two ways that 3D environments can provide extra value to e-commerce environments. Section 3 explores a broad range of psychological issues that emerge when designing highly navigable 3D environments that facilitate *search*. Section 4 looks at how the information richness of 3D environments can help the seller provide information to the buyer that can potentially influence *the criteria management* and *comparison* activities in our user model.

3. Navigation In 3D Worlds

The problems of navigating hypermedia environments, such as the World-Wide Web, are well known (e.g. [Conklin, 87]; [Kim & Hurtle, 95]). We argue here that 3D environments are a potential means of easing navigation problems at complex e-commerce sites (and presumably other complex sites).

3.1 Knowledge About Real World Navigation

Work from real world navigation has found evidence for three distinct types of spatial knowledge about environments: Landmark, route, and survey knowledge [Thorndyke & Hayes-Roth, 82]. Landmark knowledge is centred on salient features of a 3D world. It is known that people encode knowledge of object locations in terms of their positions relative to such landmarks. Whilst this landmark-based knowledge may contain information about routes from this location, a more task-based form of knowledge is route knowledge. This can be considered a series of directions from one location to another. The most comprehensive form of information is that provided by survey-type knowledge. This is essentially a location- and route-independent cognitive map of an environment. It is a form of mental model and should allow rapid access to the information it contains irrespective of where the person is.

3.2 Making Navigation Easier: Where Do Current Technologies Fit In?

Disorientation in hypermedia environments is a well known problem and is a likely reason why e-commerce sites might fail. Those who have suggested VR has a very limited place in e-commerce and other web applications. [Wann & MonWilliams, 96] point to increased difficulty in navigating and using VR environments as a reason. However research has demonstrated a number of methods for reducing disorientation in VR environments. [Ruddle et. al., 97]'s Experiment 1 looked at people's ability to navigate large-scale VR environments using a non-immersive interface. They found that after extended experience in an environment that users navigated the environment with ease, doing as well as subjects in [Thorndyke & Hayes-Roth's, 82] study of people navigating real buildings. More evidence for the navigability of VR environments is provided by [Howes et. al., 98] who found that in a series of product finding tasks in QTVR environments that subjects took more direct routes to target products when using a VR interface than when using a Hypermedia interface. [Howes et. al., 98] point out that one of the advantages of VR navigation is the vista provided of distant locations. The effects of seeing small images of the content of distant locations (the vista) may be similar to the effect of fish-eye views in hypermedia (e.g. [Schaffer et. al., 96]) where nearby nodes can also be seen. VR interfaces are likely to be more intuitive than fish-eye interfaces however (as the latter have no real world analogue).

There are many characteristics of VR systems that can be changed in order to increase the ease of navigation. [Ruddle, 98] lists 12. These include display type (e.g. immersive/non-immersive), size of the environment, graphic detail level, use of sound, movement constraints (e.g. walls), field of view and movement dimensions (e.g. many VR environments are based on 2D layouts). Below we focus on a number of other considerations that those designing VR-based web sites might want to consider.

3.3 The Use Of Landmarks

It seems that the shape, size and familiarity of landmarks is an important determinant of how useful they are. [Ruddle et. al., 97] found that landmarks did not help navigation in a VR world when the landmark was a rectangular block with a unique pattern on it, but did facilitate navigation when the landmark was an object familiar to the subjects on top of an unpatterned rectangular block. When these familiar objects were used subjects took more direct routes to target items, shifted their strategies to use the objects, but did not develop better survey knowledge. Whilst the Ruddle et. al. study used local landmarks only visible from the vicinity of the landmark, other VR studies have looked at the effects of global landmarks (e.g. such as a sun) that are visible from anywhere in the VR environment (although walls and other objects may potentially obscure the landmark). Studies of global landmarks by [Darken & Sibert, 93, 96] and [Tlauka & Wilson, 94] have found a strategy shifts toward using the landmarks, but have not reported better route knowledge (as evidenced by navigational efficiency) or survey-type knowledge (as evidenced by distance and direction estimates).

3.4 Orientation Aids

Whilst global landmarks might be considered a form of orientation aid (e.g. the sun in [Darken & Sibert, 93]) they can become obscured or just outside of the field of view. An orientation aid by contrast is independent of the environment and can be relied upon by the user as a constant. Although [Ruddle, 98] suggests that subjects felt more comfortable with a compass displayed as an overlay on the screen, he found no evidence for any significant route finding or survey knowledge differences when a subject had a compass, as compared to when there was no compass. An alternative to a compass that designers might consider is a map. The usefulness of a map appears more assured. [Ruddle, 98] compared five navigation conditions: without any aids, with a compass, with a local map, with a global map and with a global plus local map. They found that the map conditions all led to superior target finding than the compass and no-aids conditions. The local plus global map condition was in turn superior to the other map conditions. The global map provided by Ruddle showed a static image of the full environment with major landmark features marked but no target objects marked. The dynamic local map showed only the immediate locale but also showed any objects within that area. Orientation was indicated on both maps. The disadvantage of maps is of course the extra screen area needed to display them and the extra computational cost of updating a 2D map image as well as the main 3D screen (not a problem for static global maps however).

3.5 Adding Hyperlinks To 3D Environments

Ten attributes of hyperlinks in a 3D environment are listed by [Ruddle et. al., 98b]. They characterise the possible values on each dimension by their effect on usability, specifically the 'ease or speed of navigation'. Below we interpret these dimensions in terms of 3D environments used in commercial Internet roles.

Their first dimension is 'Integration'. This refers to the use of hyperlinks within a 3D environment. On one hand a 3D environment might have no hyperlinks at all. Alternatively there can be 3D 'islands' joined by hyperlink 'bridges', for instance in Supercity's shopping mall the 3D world of the mall is linked by a hyperlink with the 3D world of Legal and General shop, but movement is not possible using the 3D interface between the two (i.e. they are separate euclidean spaces). [Ruddle et. al., 98b] suggest a more navigable alternative is a large scale 3D 'hybrid' environment with districts that can be reached by hyperlinks or by motion through the 3D environment (i.e. the hyperlinks are between different locations in a single large 3D environment).

Other dimensions describe the '*Appearance*', '*Timing*', '*Directionality*', '*Rotational offset*' and '*Motion profile*' of a 3D hyperlink. [Ruddle et. al., 98b] argue that whilst a hyperlink can appear as a linked 3D object it is more desirable that the link appears either on a locality sensitive pop-up menu or (better still) in a constant 2D 'menu-bar' style lining to the 3D environment. They also argue that a short delay (2 or 3 seconds) associated with traversal of the

hyperlink should reduce disorientation caused by instantaneous hyperlink traversals (see [Ruddle et. al., 98a], Experiments 1 and 2). More intuitively [Ruddle et. al., 98b] argue for bi-directional 3D hyperlinks (i.e. a 'back' button equivalent) and that when a hyperlink has been traversed the user should still be facing approximately the same direction. ([Howes et. al., 98] note problems associated with changes in orientation inherent in QTVR 2.0). The 'Motion profile' dimension is used to describe animations associated with the hyperlink jump. Two of [Ruddle et. al.'s, 98b] dimensions describe the visual features of a hyperlink that help the user predict where the link goes and orient themselves once they get there. The 'Preview' provided by a link provides information about where that link goes. In its simplest form the preview might just be a node title (e.g. 'Office products'). The 'Directional affordance' of a link will also help the user in orienting themselves and constructing cognitive maps of the 3D space.

3.6 Experimental Data On Hyperlinks In 3D Environments

Discontinuity in spatial environments potential decreases the users ability to navigate [Ruddle et. al., 98a, 98b]. A hyperlink that jumps a user from one part of a 3D space to another is one sort of discontinuity. [Ruddle et. al., 98b] argue that discontinuity can be quite subtle, including slow updates to notionally continuous movement in a 3D environment. The effects of discontinuity are greater when there is no visual overlap between the screen before and after the discontinuity. For instance if the user is jumped from one side of a room to another, and remains facing the same way, then the screens before and after the jump will share common elements. However if the jump is from one room to another, with no 'window' between the rooms then there will be no elements visible in both the before and after screens. [Ruddle et. al., 98a] compared subjects jumping through hyperlinks, ghost doors and visually continuous doors. All subjects attempted to find objects in a large-scale virtual environment made of uniform square rooms. The hyperlink condition used hot-spots on a wall to allow a user to jump to the room behind that wall; the ghost door condition allowed subjects to move through the wall into the next room (importantly there was no visual continuity); the visually continuous doors subjects moved toward a door which opened as they approached allowing them to see into the next room (i.e. visual continuity is maintained). The Hyperlinks environment was found to be harder to navigate than the continuous movement environments. In Experiment 5 [Ruddle et. al., 98a] found that the visually continuous interface allowed better navigation than the ghost doors interface, even though both used the same method of movement and control.

3.7 Spatial Overlap In A 3D Web Space: Compressing Large Spaces Into A 'Tardis'

One problem that 3D environments have in presenting information is the space needed between nodes. Whilst small information structures might be easy to represent without asking the user to move too far in the 3D space, when large menu structures, typical of those found on many commercial web sites, then the distance between nodes is potentially very great. For instance a site with 10,000 products would need 10,000 different locations in the 3D space. The average Euclidian distance between any two products will be considerable. In contrast, using a menu structure, such as that on Quill's office products, catalogue only three links are needed to reach any of the thousands of products sold there. One solution to this problem is to use the same location many times. [Ruddle et. al., 98b] define this spatial overlap as a form of discontinuity in virtual environments. A classic example of such spatial overlap is the 'Tardis' telephone box in the old Doctor Who science fiction series, where the space inside the box appears much greater than the external dimensions of the box would appear to allow. Thus if you walked into the 'Tardis' and then walked a distance just greater than the external length of the box then you would be standing somewhere in the middle of the Tardis. This would be a different spot than if you had walked to the opposite-side around the external perimeter. The Euclidean co-ordinates would correspond but the physical location would not. Of course this is not possible in physical spaces, but it is in virtual spaces.

[Ruddle et. al., 98a] investigated the consequences on navigation of a 3D environment with 'severe spatial overlap' (Experiment 4). They found that participants initially made more navigation errors in the overlapping condition, but with a little practice this difference disappeared.

Imagine an overlapping 'shopping mall' with entrance doors to each store that are very close together but with large, Tardis-like interiors. The distance to any one shop is minimised. Once within a shop, the various departments are again made as close to the initial view-point as possible, using 'recursive' overlapping. As each department is entered it expands. Using an overlapping scheme, such as this, the complex three-level hierarchy at Quill's on-line catalogue can be navigated without the need to move large distances through the 3D space. The results provided by

[Ruddle et. al., 98a] suggest that with practice any decrement in a user's ability to navigate such a space may become negligible.

4. Learning About The Web Space In 3D Environments

As well as the buyers having goals that a seller should support, the seller will have a separate set of goals. These goals may sometimes conflict with the buyer's goals and an ideal e-commerce environment will allow seller's goals to be met whilst not infringing the buyer's behaviour. A principal advantage of 3D environments is the way that they allow seller's marketing goals to be met whilst not blocking buyer's navigation goals.

For example: The layout and arrangement of a large food store is a form of complex interface. Finding items is quite hard without the use of pre-existent knowledge about that store and that class of store layout. Whilst the navigational advantages of a real world store are important, perhaps their greatest advantage is their support for incidental encoding. By incidental encoding we mean learning about the environment whilst pursuing a specific goal. The goal specificity of human behaviour is well-documented [Anderson, 83] and items that are not involved in the critical path to a goal will often not be encoded. In real world environments people are able to engage in incidental browsing, noticing new items, desired items and well-priced items. Some of those who have experimented with home food shopping in the UK have reported that, as well as navigational problems, shoppers tend to buy fewer items than they would if they actually went to the shop (Sunday Times, October 98). Whilst this might empower the shopper and reduce the impact of unwanted marketing, it does seem that requiring the shopper to generate every item they need imposes a large memory load on the shopper (a large amount of cueing will occur in a typical shop environment). This may remove value from the Internet shopping experience when compared to real shopping. Of course the seller will want to bring other items they carry to the shoppers attention as well. It appears that the problem is in the flatness of the hypermedia environment and its graphical paucity. A 3D environment might be expected to allow the user to not only successfully navigate to the target item but also to learn about the environment they are in. [Thorndyke & Hayes-Roth, 82] established that people navigating real environments learn survey and landmark knowledge; by contrast those navigating menu like structures (and presumably hypertext) seem to acquire very little knowledge about the menus they use [Payne, 91].

[Howes et. al., 98] conducted a series of studies that contrasted a VR environment with a Hypertext environment. Howes et. al.'s choice for a VR environment was Apple's QTVR. The hypermedia comparison was made to text based tables containing the same product links as the VR environment, with the same number of nodes in each. The images used in all Howes et. al.'s Experiments were high resolution digital photographs. The use of photo-realistic images is a feature of QTVR, though VRML 2.0 has the potential to incorporate similarly high quality bit-maps.

Howes et. al. conducted 3 Experiments. The first used photographs of a real coffee shop, and the products it sold, as its navigable structure. There were four different locations in the VR coffee shop with 83 products, the majority of these located by category (this, of course, was true of the Hypermedia control as well). Subjects in the Experiment were asked to find 20 items from the coffee shop. The Experiment found that the VR subjects were able to generate many more novel items from this coffee shop than the Hypermedia control subjects. Novel items were those that the subject had not been asked to search for. However the VR subjects also took significantly longer to navigate the environment.

A second Experiment created a custom 'Garage sale' environment in order to control the presentation of the QTVR in more detail. There were just over 200 items in the Jumble Sale spread over 5 leaf nodes with 2 nodes used solely for navigation. Again the hypermedia control environment was a structural copy. Half the items were books, whilst the other half of the items were household objects. All these items were randomly distributed between the five leaf nodes. Again the subjects were asked to find target items (equal numbers of books and objects). In this environment VR and Hypermedia subjects showed no difference in the amount of time they spent completing the search tasks, but still the VR subjects were able to generate many more novel items than the Hypermedia subjects (markedly so, the VR group generated an average of 15 novel items, compared to 5 novel items from the Hypermedia controls). This generation data was also split by book and item with the finding that there was an interaction between item type and condition: VR subjects recalled many more objects but not book titles (though there was still a small advantage for the VR group on the latter). This is reminiscent of [Ruddle et. al.'s, 97] finding that only familiar objects rather than abstract patterns were useful as landmarks in VR navigation. This suggests that when people are looking for an item in a VR environment they learn about other useful landmarks, so long as the encoding of that landmark is easy (encoding a familiar object is easy). Hence when they navigate a 3D e-commerce environment they learn about items they are not looking for.

Howes et. al. leave open the reasons for why this is the case. The increased incidental learning in their QTVR environments may result from an evolutionary need to navigate real environments or perhaps be learnt from experience in complex modern environments. Whatever the detailed reasons, it does seem wise for designers of e-commerce sites to exploit this effect when designing sites where learning incidental information is useful.

Howes et. al.'s last Experiment used a VR analogue of a portion of the Quill on-line catalogue to look at the generality of the results from the other two Experiments. A further feature of the final Experiment was the use of a QTVR environment created using image processing software to paste product images into the 3D panorama. This effectively placed each item in a spatial location where that product had never been. Signposts helped the user find their way around Quill's flat menu structure. Again more novel objects were generated by the QTVR condition versus a Hypermedia condition (the latter was a version of the Quill on-line interface). The use of image processing software to create the environment for this final Experiment suggests that QTVR commerce sites, of the type described, might be created without the need to actually physically create a very large environment.

5. Conclusions

Here we have argued that 3D environments have a role to play in e-commerce. There is empirical evidence to support the view that 3D supports (a) navigation of complex web spaces, and (b) incidental acquisition of knowledge about the web space. Whether future technology will be sufficient to support fast 3D over an ever growing WWW is not at present clear, though recent developments in compression technology are encouraging.

The Alliance+ Project: An Innovative Partnership to Promote Teacher Training on Internet's Use in the Curriculum

Cindy L. Miles, League for Innovation in the Community College (CA), miles@league.org
Geoffrey Andrews, Polaris Career Center, Cleveland (OH), gandrews@polaris.edu
Lani Ritter, Cleveland Municipal Schools, Cleveland (OH) Ritterla@cleveland.k12.oh.us

Abstract: The background, partnerships, strategic decisions, and design features of the Alliance+ program are presented. Alliance+ brings a national community college organization, a career center, a technological university, educational research entities, community colleges from Cleveland, Miami and Phoenix, and the school systems from those cities together in a five year effort to provide technology-in-education training for 10,000 teachers.

The Challenges

Alliance+ was undertaken as a large-scale national teacher training model in the United States as a solution to two fundamental problems that confront educators worldwide, both of which must be solved with high quality programs at affordable cost:

1. The need to accomplish transfer of “best practices” from a small group of localized innovators to a larger national or global community of teachers; and
2. The task of providing ongoing support for these large numbers of teachers on the implementation of the “best practices” in a city, county or province.

These challenges are of critical importance for all educational innovations but are particularly severe for technology-based applications in pre-university settings. The vast majority of teachers are not prepared to quickly gain mastery over new artifacts and systems and to integrate those new technologies into classroom practice. Some of the hurdles that are uniquely associated with technology-based innovations include the following:

- Since technology is constantly changing, teachers are frequently challenged with mastering the intrinsic characteristics of the new technology itself. The time required for this can easily be one year.
- A teacher who masters a new technology must then explore how this technology can be used in classroom practice and as a tool to facilitate student learning. This period of exploration can take an additional year.
- Finally, a teacher who masters the new artifact or system and understands its pedagogical potential, must then create new classroom materials and strategies. In many cases the advantages inherent in the new technology are best exploited through project-oriented, student-centered activities. For most teachers, these modes of teaching are new and require acquisition of new skills and the development of new sensitivities, attitudes and methods of classroom practice. Coming to grips with these challenges and refining new approaches can require yet another year!

This three year developmental process has limitations—not all teachers have the vision and insight needed to independently create new approaches. For those who do, it is unlikely that they will be given the time and support needed for such extended curriculum development efforts. Even if they are successful, after three years there is a good chance that the technology itself will be replaced with something that is vastly superior.

Since Alliance+ is dealing with the Internet, the program must grapple with another, somewhat more subtle challenge. While most computer-based techniques can be categorized as “tools” for teachers or students, the Internet creates a new environment for learning that potentially encompasses all segments of society and all

instrumentation that can be digitized. In dealing with the Internet, teachers are not merely learning techniques, they are entering into a new culture, new ways of learning, and new ways of communicating.

The cultural transformation inherent in this process engages teachers in continuous learning and adaptation. Introduction of Internet into schools requires more than participation in a finite number of workshops, but immersion into a community of users. There is no fixed time period for this process. Rather it will be ongoing. Since there is no end in sight for the development of Internet technology, there will be no end in sight for the adaptation process. It is critical that Internet-related training be structured to engage teachers in a stable supportive infrastructure.

With this perspective, we re-examine the original questions. Given a small cadre of early innovators who have gained insight, understanding, and experience with the new capabilities of Internet technology—how can this expertise be disseminated widely and how can large numbers of teachers in a given locale be provided with appropriate training and essential continuing support?

Partners & Philosophy

Alliance+ is a model for teacher professional development that reaches teachers who are thousands of miles apart, but which provides face-to-face workshops and support as well as tools, resources, and assistance through distance communications. To achieve its mission, Alliance+ unites the efforts of more than 35 state, local, and higher education partners who have been independently concerned about workforce development in general and teacher preparation in particular for a number of years.

The core members are the Center for Improved Engineering and Science Education (CIESE) at Stevens Institute of Technology (NJ); Polaris Career Center (OH); Cuyahoga (OH), Maricopa (AZ), and Miami-Dade (FL) Community Colleges; The League for Innovation in the Community College (CA); the public school systems in Miami, Phoenix and Cleveland; Educational Testing Service (NJ), and Bank Street College of Education (NY). Coupling these partners' diverse expertise in teacher professional development, curriculum development, computers-in-education innovation, project management, workforce training, and educational assessment, this five-year project aims at preparing 10,000 classroom teachers to integrate Internet technology into the curriculum, with a direct impact on over a quarter million children.

The question of how to use Internet most appropriately in instruction has been a constant concern for many of the project partners. We have worked collaboratively with teachers on the analysis of potential classroom applications. We also visited and consulted other programs throughout the United States. What we found was that many educators were relying on Internet applications that were essentially archival in nature. While the Internet is a vast library resource, we believe that its greatest potential lies in its interactivity and its ability to bring real-time data, particularly in science, into classrooms.

We, therefore, concentrated on accessing Internet-based curriculum resources that empower students at all age levels to “do” science instead of hearing about science and to otherwise pursue constructivist learning experiences. Some of the materials can be examined at web sites at CIESE and at Polaris (www.ciese.org and www.polaris.edu/iltli). CIESE has also published articles that describe the approach (e.g., “Web Adventures in K-12 Science,” *Technos*, Vol. 6 No. 4, Winter 1997).

As we worked through some of our earlier, independent projects, we realized that we had acquired expertise that was not widespread. To gain perspective, we remind ourselves that the Netscape Company was incorporated in November of 1994. As we speak at ACE '99, Netscape has been a product for less than five years! Yet graphical user Web browsers are now used by scores of millions of people worldwide. The challenge for Alliance+ members as we approached this project was how might we share our experience with distant teachers and school systems.

Rationale for the Model's Design

In our cumulative experience, many inexperienced teachers encountering applications of new technologies profit more from face-to-face workshops than from distance learning. Many such novice users require an initial level of personal attention from an individual or a group with whom they can consult in an ongoing fashion. Once relationships have been established and technology hurdles have been crossed, the option of online instruction and support is more attractive and effective.

In designing this model, one learning option we considered was interactive video. In past years CIESE produced more than 30 hours of satellite video broadcasts on applications of software in mathematics education to teachers throughout the United States. While these programs included documentary television segments of real classroom experience as well as discussion sessions, teachers were quite clear in requesting face-to-face hands-on workshops as an essential learning experience.

Another option was online instruction. Several Alliance+ partners have significant backgrounds in online instruction. These experiences have revealed that while large numbers of teachers participate in and profit from online courses, many teachers need more direct and personal learning experiences that involve mastery of hardware and software in locations where they can interact with others and receive assistance in working directly with materials that are being presented in their courses. The efficacy of online instruction for teaching new technology applications is routinely debated within the Alliance+ group, but the consensus is that online instruction will play a larger role in the next several years of the project.

In some cases, school systems themselves will be able to provide the required instruction and support. However, many school systems in the U. S. are too small to be able to grapple effectively with challenges of technology-in-education. In addition, many large school systems are either too bureaucratic or too bogged down with social and behavioral problems to be successful in this arena. State agencies could help meet this need, but have not addressed these issues. Alliance+ partners feel that the most effective strategy is to manage the needed educational programs via the nation's strong cadre of higher education institutions and other demonstrably effective organizations.

In the Alliance+ approach, materials are produced and organized for national distribution at a technically-sophisticated research university and then implemented at regional resource centers. Project partners share a strong commitment to producing curriculum and training materials through close collaboration between higher education developers and teachers and schools. All materials are tested and proven effective through use in classrooms.

An added strength of the Alliance+ design stems from the fact that the higher education institutions involved in developing materials, especially those with engineering and computer science departments, are close to the evolution of technology itself. These institutions are optimally positioned to anticipate and respond to constantly evolving technology.

The Key Role for Community Colleges

The United States has an extraordinary opportunity to develop regional resources centers for teacher professional development in applications of technology in instruction at regionally located community colleges. Approximately 1,000 community colleges exist in the United States, with approximately one institution within commuting distance of 90 percent of the American population. These colleges provide two years of postsecondary education as well as many continuing education courses and special education programs for adults.

More than one-half of all students enrolled in post secondary education in America today are attending community colleges. Some students are enrolled in transition programs that will prepare them to enter the third year of a four-year college program, and some are enrolled in terminal one- or two-year programs for certificates or associate degrees in fields such as engineering technology, medical technology, and culinary arts, among others.

The Alliance+ approach relies on community colleges as the local nexus in a train-the-trainer model, in which the CIESE group at Stevens Institute of Technology trains faculty and staff at community colleges who, in turn, provide continuing education and follow-up support for teachers in school systems in their region. Some of the advantages of this system of using community colleges as regional training centers include the following:

- Community colleges are more teaching-oriented than four-year schools, which usually place higher priority on faculty research and publication records than on teaching.
- Community colleges are focused on supporting their immediate geographical region. They are usually funded to provide education for individuals in a particular region and are seriously committed to this pursuit.
- Because they are organized by region, with no competitor within in their own region, they are more likely to collaborate with other institutions since they are free of rivalries.
- Community colleges in the United States have many programs to help students in secondary school make the academic transition to higher education. They are familiar with the secondary school curriculum and provide remedial courses and review courses, as well as advanced placement and dual enrollment courses for secondary students. Through programs of this sort, many community colleges have established working relationships with local school systems and have become familiar with their culture and mores.
- Community colleges also engage in education that is highly focused on the workplace and have strong sensitivity to the needs of working professionals. Community colleges have vast experience with continuing education of adult learners and have also implemented extensive programs of workplace training through direct contracts with corporations and government agencies.

Given these factors, it is surprising that community colleges have not been more active in providing continuing education for teachers. Perhaps they have been standing aside from that market in deference to colleges of teacher education. But experience shows that colleges of teacher education in the U. S. are generally not eager to undertake such field-centered programs. This is especially true in the domain of technology where many of the colleges of teacher education have not yet become proficient themselves. In contrast, in many cases, community colleges are leaders in the use of technology in their academic and outreach programs and poised with potential to meet the critical ongoing teacher development need in this nation.

Alliance+ Organization

At the center of Alliance+ curriculum and project development is the Center for Improved Engineering and Science Education (CIESE) at Stevens Institute of Technology. Stevens is a small private technological university founded in New Jersey in 1870 on the left bank of the Hudson River across from mid-Manhattan in New York City. While Stevens does not have teacher education programs, for more than 20 years it has been an innovator in applications of computers and information technology in the education of scientists and engineers. For more than a decade the CIESE group has been providing training programs for teachers and outreach assistance to school systems on applications of computers and networks in teaching mathematics and science in elementary, middle and high school programs.

A crucial aspect of this model is the high level of partnership and collaboration by the League for Innovation in the Community College. The League is the premier organization in the United States devoted to creation and dissemination of new programs that strengthen the role of community colleges as centers of educational and training services to meet local needs. The three community colleges participating in the project are included among the 20 institutions that hold full membership in the League, and are considered national models for technology implementation and building relationships with local communities and schools. Not only is participation of the three community colleges in Alliance+ coordinated by the League, but the League is in a strategic position to bring knowledge of this project to the full cadre of community colleges located throughout the United States. While Alliance+ was not organized to be an international project, it is also the case that the League is actively working with educational organizations on a global scale through its members in Canada, Guam, the U.K., The Netherlands, and Australia.

Although materials development and dissemination are centered in higher education institutions, Alliance+ is fundamentally a school system project. A key school leadership role in the project is held by the Polaris Career

Center, a regional vocational-technical school district in Middleburg Heights, Ohio, which has as its mission workforce development. To this end, the Instruction, Learning and Technology Leadership Institute (ILTLI) was developed at Polaris to provide professional development to prepare teachers to more effectively use technology in schools. The ILTLI focuses on improving the technical and pedagogical skills of teachers by helping them understand not only the technology but the ramifications it has on teachers behavior, knowledge construction, deepening student understanding of concepts, and providing a more authentic means of student assessment. Polaris functions nationally in overall Alliance+ project leadership, as well as in local teacher training and project implementation in the Cleveland area.

Liaison with school districts in all three implementation sites is maintained by the community colleges in each region, and implementation is pursued jointly with the leadership of the school systems in each of the participating metropolitan areas. The level of school system commitment to Alliance+ is demonstrated in financial contributions that they have made to this program. The five year award from the U. S. Department of Education for this Technology Innovation Challenge Grant (Grant #R303A980063) is \$9.3 million. Funds allocated by the partners toward the program total \$11.8 million of which \$9.6 million is from the participating school systems. These school systems are expending resources to cover the costs for teacher participation in the program, as well as costs for their own staff who will serve as mentor teachers and program administrators. These figures demonstrate a tangible commitment to a program that is highly valued by the participating school systems in Arizona, Florida and Ohio. In each case, educational leaders in those states report that Alliance+ is providing vital training that brings applications of technology together with curriculum innovations and that such training and assistance is not available locally.

The specific implementation model establishes a team of core trainers at each community college site. The core trainers are either community college faculty or staff. These core team members are trained directly by CIESE staff. The core trainers in turn train lead teachers at school systems who are designated as mentor trainers. It is the mentor trainers who then provide workshops for the teachers in the school systems. The training sequence is summarized in the following flow chart: Stevens Institute Team → Core Trainers → Mentor Trainers → Teacher Trainees

Implementation is taking place at three Alliance+ sites simultaneously. We obtain a factor of approximately 10 in human resources in each transition. For example, Stevens trains 10 Core Trainers in an intensive face-to-face week of sessions; these 10 core trainers then train 100 mentor trainers, who in turn reach at least 1,000 teachers. The exact timing, scheduling and organization of these sessions vary from site to site. While this is a national program, the implementation is orchestrated and implemented locally.

Community college partners include Cuyahoga Community College in Cleveland, Ohio, Maricopa Community College in Phoenix, Arizona, and Miami-Dade Community College in Miami, Florida. The three locations were purposefully chosen to have partners separated by large distances as a context for a meaningful test of a model that could be applicable on a national scale. Cleveland lies 675 kilometers to the west of Stevens, while Phoenix is 3,500 kilometers to the southwest and Miami is 1125 kilometers to the south.

Another significant reason for the selection of these three locations for inclusion in Alliance+ is their level of need. Each of the three metropolitan areas is categorized as economically disadvantaged by federal criteria. In addition there are large numbers of families whose children in these schools are recent immigrants without a firm base in the United States and lacking knowledge of the English language. Phoenix has a large Mexican American population and Miami has many families from Central and South America.

The educational problems in the school systems are severe. Control of the Cleveland Municipal schools has recently been transferred to the mayor in a dramatic reorganization effort. The Miami-Dade Public Schools, the fourth largest in the United States, has an enrollment of about 350,000 students and is grappling with growth in student population of 10,000 per year. Phoenix is currently the fastest growing city in the U.S., and currently the city cannot build schools quickly enough to keep up with population expansion. In addition, all three sites are highly multicultural and rich with political histories, thus educational development programs in these cities must take place with full cognizance of and sensitivity to cultural, social and political realities. Community colleges provide a viable base for success in dealing with these issues.

Alliance+ Materials and Systems

The goal of the program is to train at least 10,000 teachers in a 30-hour course on the use of Internet in science education in a five-year period. A concomitant goal is to engage teachers in a community of educators that will sustain and develop professional practice with Internet-based education. Kindergarten through 12th grade teacher preparation is being addressed through three separate curricula: elementary, middle school and high school.

The 30 hours of hands-on workshops are divided into 10 three hour sessions with the overall instructional program known as the *Savvy Cyber Teacher*[™] (SCT) series. SCT introduces teachers to the functionality of the Internet and its use in instruction in unique and compelling applications. SCT stresses real-time interactivity, acquisition of real-time data and opportunities for students of all ages to engage in the scientific process. [The outline for SCT and examples of curriculum applications can be reviewed at the CIESE Web site: <http://www.k12science.org> by clicking on "Alliance" to examine project information and on "Curriculum" to examine Internet-based learning materials.]

SCT provides teaching techniques on using email to bring expert advice into classrooms, knowledge of systematic approaches to web search, the development of web pages and classroom management techniques for one computer or many computer facilities. In addition, SCT offers real-time data projects, such as the Stowaway Adventure (<http://k12science.stevens-tech.edu/curriculum/oceans/cyberstowaway.html>), in which middle school children track the progress of merchant ships located in any of the world's oceans. Acting as virtual "stowaways," these students use mathematics to calculate velocity and geometry to track the ship's voyage and plan their arrival at a safe haven.

In addition to engaging teachers in hands-on experience, Alliance+ provides follow up visits to the schools and discussions with mentors and trainees on their experience with these techniques. Alliance+ also brings community college and school system administrators together in joint efforts to achieve educational improvement. The CIESE group at Stevens interacts with the core trainers and mentor trainers on a regular basis using email, listservs, visits, videoconferences and periodic face-to-face meetings of the key participants from the three sites. Listservs, email, and telephone assistance from core and mentor trainers provide classroom teachers with assistance and support.

Online feedback is obtained as teachers attend each training session. The feedback details their experience in each session. Also, a comprehensive online database is maintained known as the DataFeed System. This system provides information on the identification of participants, time, and location of all workshop sessions.

During the second year of Alliance+, Bank Street College of Education in New York City will work with other partners of Alliance+ to create pre-service materials (for university students preparing to become teachers) based upon the three versions of SCT.

The progress of Alliance+ and its impact on teachers, their school systems and ultimately students is being monitored by researchers from Educational Testing Service in Princeton, New Jersey. In addition to questions of efficacy, the project is being studied to evaluate the viability of the organizational model and its potential for replicability in other locales.

As this five-year program evolves, we feel certain that it will undergo significant changes as teachers become more adept in the use of the technology and as the technology itself undergoes change. At this stage, we see great enthusiasm for introduction of these approaches into classroom practice. We have high expectations for the evolution of exciting new educational environments in the coming years and look forward to contributing to the cultural transformation taking place in education as teachers embrace new ways of teaching and learning.

Abstract: This paper examines the concept of time in multimedia, web-based courseware development. The biological concept of entrainment as extended to social psychology reveals four components of entrainment that could be valuable in accelerating courseware development: rhythm, mesh, tempo, and pace.

1. Introduction

The phrase, "I'll be *right* back," is literally translated into Chinese as, "I'll be back *on a horse*." If necessary as a face-saving gesture, a slow return may politely be attributed to a slow horse. Although "right back" and "back on a horse" are temporally ambiguous, both phrases are extremely meaningful in context. [Hall 83 p. 13] explained "...that there are as many different kinds of time as there are human beings on this earth... ." The western concept of time as even time, chronological time, or clock time has evolved over the ages [Bluedorn & Denhardt 88]. Time-keeping was originally based on events, such as planting or harvesting, but as Marx's writings on the "commodization" of labor resulted in treating labor (and laborers) as commodities, time eventually emerged as an equation, "time is money." [Bluedorn & Denhardt 88] point out that most organizations are likely to experience some natural tension between even time and event time (linear and cyclical); however, the "time is money" equation is a factor in courseware development. Some experts estimate more than 100 hours of development time to develop a single contact hour of multimedia instruction. Certainly courseware developers have been caught bringing their courses to market "on a slow horse" and are looking for ways to speed products to market.

This paper explores the application of entrainment (the alignment of rhythms within and between systems) to accelerate courseware development. Certain parallels are drawn from new product development in industry to courseware development. The discussion begins with the foundational concepts of entrainment, from biological systems and social psychology. Second, examples of entrainment in courseware development are presented and discussed, including illustrations of rhythm, mesh, tempo, and pace. Concluding remarks are then offered.

2. Entrainment

2.1 Biological Entrainment

The concept of entrainment first developed as scientists observed rhythms in physiological systems that seemed to be synchronized in terms of period, amplitude, and phase [Brown 82]. Both physiological and behavioral events, or systems of events, were found to be *entrained*, or synchronized internally to each other, as well as entrained to pacers in the external environment.

A system is not modified when entrained, but its phase and periodicity is captured by a pacer or *zeitgeber* (German: time + giver). The biological cycles exist at multiple levels (molecule, cell, system, and organism) and within various temporal orders, ranging from months and years to milliseconds [Rose 88].

Cardiorespiratory rhythmicity is an example of the complexity of mutual entrainment of the rhythms manifest by both the respiratory and cardiovascular systems to each other and to external pacers [Koepchen 90]. The two systems are coupled to each other peripherally as well as centrally to transport oxygen to cells and carbon dioxide from cells. Since the transport demand can change by a factor of more than twenty to meet metabolic needs, the systems must adapt to actual behavioral activity from moment to moment—even though the system rhythms have different drivers. The circulation driver originates in the periphery, whereas the respiration driver originates in the central nervous system. Adding to the complexity of entrainment is the evidence that the heart's pacemaker is modified by central nervous influences which interfere with the central respiratory rhythm generator. [Koepchen p. 16] concludes that the rhythms present in every function interact with each other in a variable manner without a fixed relation of cause and effect: "One rhythm can lead, entrain, or influence the other in a more or less strong way." Self-organization results in a rhythmic order that "enslaves"

the individual elements.

In addition to mutual, internal entrainment, biologists have identified strong external pacers to which systems become entrained. Probably the single most commonly observed entrainment phenomenon is human entrainment of *circadian* (Latin: about + a day) cycles to the light-dark cycle resulting from the earth's solar orbit. For example, humans have an elaborate temperature regulatory system to regulate body temperature regardless of ambient temperature, but it also fluctuates cyclically in a circadian rhythm (low temperatures at night from 3 to 5 a.m.), synchronized with overall activity levels which are also circadian in nature [Wilkinson 82]. *Ultradian* (Latin: within + a day) rhythms also appear in activities such as eating, respiration, metabolism, work-rest cycles, etc. When the external pacer (the 24-hour light-dark cycle) shifts, as may be the case after transmeridian flights, the entrained rhythms become desynchronized to the external zeitgeber as well as losing their mutual entrainment with individual systems. The result is "jet lag" (transmeridian desynchronization) manifested in a variety of psychophysiological maladies, including gastrointestinal distress, loss of appetite, insomnia, headaches, irritability, dizziness, and a general feeling of weakness and fatigue [Graeber 82]. It is hypothesized that circadian rhythms are allowed "free run" during flight and spontaneously deviate from an exacting 24-hour clock. When again exposed to naturally occurring geophysical and social time cues, the circadian rhythms regain their 24-hour periodicity. The discomfort and behavioral impairment from jet lag is a direct result of a series of events: first, the systems become decoupled from the external pacer, resulting in external desynchronization (*i.e.*, lag if going east); second, the systems become decoupled from each other, destroying mutual entrainment and resulting in internal desynchronization; and third, the systems readjust at different rates [Aschoff *et al.* 75].

As can be seen from the foregoing examples, biological and behavioral entrainment is a central concept for human well-being. Both mutual entrainment of individual systems and entrainment to environmental zeitgebers are essential for sustaining life.

2.2 Social Entrainment

Extension of the concept of biological entrainment to social entrainment has taken place over the last twenty five-years. It has been identified at the individual, group, and societal levels [Condon 78] [McGrath & Kelly 86] [Hall 83].

[McGrath & Kelly 86] used entrainment concepts to develop a model explaining the social psychology of time and to explore entrainment of behavior in social and organizational settings. They observed that, similar to the biological model, systems or patterns of behavior can be mutually entrained, as well as entrained to external pacers or entraining cycles (zeitgebers).

[McGrath, *et al.* 84] found human behavior at the social psychological level to be mutually entrained to arbitrary, but powerful, external cycles such as work schedules, the standard cultural definitions of the seasons, social definitions of day and night, etc. Assigning groups different time periods to complete the same problem-solving tasks, McGrath *et al.* found that the work expanded to fit the available time [Parkinson 57], as well as the converse, work contracts to fill the time available. Interestingly, when observing work in temporally altered subsequent time periods, they found that groups continued to work at the initial pace. McGrath *et al.* concluded that the groups entrained to the initial pace (whether fast or slow) and had difficulty changing their pace.

Other patterns involving social entrainment have been observed, but with slightly different group dynamics. Gersick [1988] observed a pattern of punctuated equilibrium in group work: at the approximate mid-point of the time constraint, groups appeared to go through some type of crisis, changed their problem-solving strategy, and paced themselves for the second half of the time period. In entrainment terms, it appears that the group became desynchronized at midpoint after evaluating its progress, after which the group re-entrained to a new pace (only half of the time left).

Although much research is needed in this area, it appears that individuals in groups experienced mutual entrainment, as well as the group being entrained to an initial external pacer. [McGrath & Kelly 86] constructed a model of social entrainment consisting of the following four components.

- RHYTHM: multiple endogenous temporal or rhythmic processes or patterns
- MESH: mutual entrainment or synchronization of rhythms
- TEMPO: temporal patterns expressed in actual behavior resulting from synchronization of rhythms
- PACE: external pacer events or entraining cycles affecting rhythm, mesh, and tempo

Differing slightly from the biological model, which emphasizes the "capture" of rhythms by external pacers, the social model of entrainment seems to allow a little more participant discretion.

3. Entrainment in courseware development

Similar to the rhythms of various functional systems studied by biologists and social interaction patterns studied by social psychologists, different rhythms in courseware development exist, including those manifest by the assorted functional groups engaged in new product development such as engineering, manufacturing, marketing, and executives. The various rhythms or patterns of the groups have the potential to be mutually entrained (meshed). For example, in multi-functional development teams, the team members mesh their individual functional rhythms; or the team meshes its own rhythm and patterns with consumer patterns and cycles. Internal and external pacers also play a role in examples of entrainment observed in courseware development. Internal project phase review cycles and external regulatory agency cycles tend to capture the courseware development cycle, resulting in a distinctive tempo associated with development. With an eye to better understanding the principles that determine the tempo of courseware development, this section discusses manifestations of entrainment in development in terms of rhythm, mesh, and tempo.

3.1 Rhythms in Courseware Development

There are a number of rhythms (multiple, endogenous, temporal, or rhythmic patterns or cycles) observable in new product development in general, both internal and external to the organization. Examples of rhythms within the organization are presented first, followed by examples of rhythms external to the organization, concluding with formal propositions.

The assertion made by [Berger & Luckman 66] that time is a social construction varying between and within societies can be extended to the sub-societies involved in courseware development. For example, [Gurvitch 64] concluded that different classes or groups within cultures move with different rhythms and with different temporal perspectives. Within the organization, different rhythms or patterns (systematic differences in goal orientations, time frames, norms, and shared coding or language schemes) have been associated with organizational differentiation [Lawrence & Lorsch 67] [Thompson 67]. Furthermore, individuals establish unique organizational role identities through socialization into organizations [Katz 88]. The socialization process also includes learning how to deal with one's boss and co-workers, as well as deciphering reward systems and situational norms. Newcomers are taught, "This is how we do it here," whether it be a company such as Microsoft or General Electric, or a functional group such as engineering, manufacturing, or marketing.

Functional groups operate with certain natural or man-made rhythms, patterns, or cycles. For example, in manufacturing, progressive companies are now tracking inventory turns, quality metrics, slashes in set-up time, and throughput time reductions, rather than labor efficiency and machine utilization [Schmenner 88]. Resulting manufacturing cell (group technology) concepts, u-shaped lines, and multi-model lines yield greatly improved productivity, flexibility, space utilization, and quality. This type of rhythm within manufacturing requires cooperation from the natural rhythms of traditional factory departments or kingdoms, such as: equipment, layout, quality, materials handling, production planning, inventory control, and cost accounting.

Certain rhythms or patterns have been observed in R&D work. Examples include the S-curve phenomenon observed in comparing technical performance with research effort over time [Foster 86]; learning and unlearning [Imai *et al.* 85]; patterns of communication [Katz 82]; fluid, transitional, and specific patterns of innovation [Abernathy & Utterback 88]; and the rhythm of product introduction and retirement [Von Braun 90]. Certain patterns have been identified in groups that accelerate new product development that probably apply to courseware development, namely those patterns associated with critical roles played by group members such as product champion, gatekeeper, and technical experts [Smith & Reinertsen 91].

The external environment of the organization manifests certain rhythms or patterns. [Tushman & Romanelli 85] identified patterns of alternating periods of inertia and revolution experienced by organizations. Technological, legal, regulatory, and/or market discontinuities occur to disrupt periods of inertia, requiring adaptation. These external rhythms play out in the web arena in terms of technological discontinuities and uncertain regulation.

Examples of patterns or rhythms internal and external to the organization such as those mentioned above appear to play a role in the speed of courseware development. To understand the implications of their existence, particularly in connection with accelerating new courseware development, it is necessary to examine how these patterns or rhythms mutually entrain or are entrained to other pacers.

3.2 Mesh in Courseware Development

Mesh is the synchronizing or mutual entrainment of different rhythms or patterns involved in courseware development. One of the most frequent techniques for accelerating product development that applies to courseware development is to employ cross-functional teams [Rosenau 92]. Cooperation and coordination of these teams (graphics,

audio, video, instructional design, programming, user-interface, etc.) is critical to success. Specific findings in industry studies have led to counsel such as the following: secure early involvement of functional groups [Gupta & Wilemon 90]; use small, self-managing, multi-functional project teams [Takeuchi & Nonaka 86]; allow "sign-up" for teams rather than edict [Gupta & Wilemon 90].

In addition to functional diversity requirements, satisfying other team criteria has also been recommended to accelerate courseware development. Suggestions include limiting teams to ten or fewer members, having members serve on the team from conception to production, making full-time assignments to a team, having members report directly to the team leader, and physically locating the team within conversational distance of each other [Smith & Reinertsen 91].

Although there seems to be agreement on the effectiveness of multi-functional teams in accelerating new product development, some dissension exists. A recent empirical study examining new product development teams concluded that the overall effect of diversity (functional and tenure) on teams actually impeded performance [Ancona & Caldwell 92]. Even though diversity brought more creativity to problem solving and product development, the diverse team was less capable of teamwork than a homogenous team. Functional diversity was found to facilitate increased communication outside the team's boundaries--to the possible detriment of internal communication. Based on field interviews and a mail survey of managers and technologists involved in development, [Gupta & Wilemon 90] identified four ways functional groups delay the product development process: failure to give product development program priority, continually changing requirements, poor intergroup relations, and slow response time. [Stalk & Hout 90] also found that functional support groups could delay or "gate" the key sequence of activities for product development by forcing key activities to wait in queues for execution, delaying other key resources.

From the above, it appears that multi-functional groups can accelerate courseware development, but researchers are beginning to identify some contingencies. [Bower & Hout 88] argue that the concept of accelerating development through multi-functional teamwork must be extended to the entire organization or company, building a strategic "fast-cycle capability." Otherwise, the teams become special task forces or "skunk works," which cannot provide a sustainable, competitive advantage in the long run. Fast-cycle capability requires mutual entrainment of functions. Only when multi-functional team members synchronize their functional rhythms to a new, appropriate "team rhythm" can time be reduced in new product development. From a broader perspective, Jack Welch, the CEO of General Electric, insists that best practices of any of his businesses (going beyond functional groups) be transferred "across all the businesses, with lightning speed" [Tichy & Charan 89:115].

Besides the mutual entrainment or mesh of internal functions and cycles, entraining to external rhythms and patterns, such as students, teachers, development tools, technological advances made in the web environment, is also critical. [Clark & Fujimoto 90] assert that the single most important task for product development is external integration: "matching the philosophy and details of product design to the expectations of target customers (p. 112)." Courseware developers could benefit from strategies employed by companies who have been forced to integrate customers and suppliers into the new product development process. Courseware developers face similar external challenges with a shift to a less stable market, shorter course life cycles, and teacher/student preoccupation with technical performance. Even though structural mechanisms (such as multi-functional teams) speed problem solving and improve the quality of solutions and create fresh, technologically advanced products, they fall short if the product concept fails to anticipate future needs and wants.

Timing is also a key factor when considering meshing mutually entrained functions to technological rhythms. For example, the timing or release of certain development tools or compression techniques certainly influence courseware development.

Another thread in a mesh designed for decreasing product development time is to connect with external sources for product innovations. Courseware developers could license or buy advances achieved by others, buy courses that have achieved the desired advances, and use independent contractors with specific R&D skills needed. Courseware developers must be able to recognize patterns and advances in the environment and determine the fit with new course development.

As discussed above, the types of meshing, or synchronizing of rhythms and patterns manifest in courseware development include mutual entrainment within the institution or company, such as multi-functional groups or roles as well as mutual entrainment with external rhythms such as consumer patterns or external technological advances. Recognizing the existence of mesh, or mutual entrainment, pushes researchers to identify the determinants in which mutual entrainment of courseware development rhythms would decrease development time.

3.3 Tempo in Courseware Development

Mutual entrainment alone may not accelerate courseware development unless the courseware development rhythms are entrained or re-entrained to an appropriate pace or cycle. This section discusses tempo or tempo entrainment, the pacing of meshed rhythms or patterns such as those considered above, and its effects on courseware time. There are a number of internal and external pacers manifested throughout the development process. For better or worse, the pacers tend to capture

the process and force it to proceed at a certain tempo. The following discussion first addresses internal pacers and their effects on the tempo of courseware development, then considers external pacers, and finally appraises the issues surrounding the decoupling and re-entraining to appropriate pacers.

Internal pacers or entraining cycles include budget and funding cycles, strategic planning cycles, project or phase review cycles, and projected milestone completion dates. The tempo that these pacers impose may not be the most appropriate for courseware development.

Certain external pacers also have a marked effect on the courseware development tempo. [Stalk & Hout 90] conclude that the pace of innovation varies from industry to industry, depending on the specific development cycles and what specifically drives those cycles. At one extreme is the eight-to-ten year tempo of the pharmaceutical industry, with the pace of government and nature itself capturing the industry's tempo; the pace of the FDA can be viewed as an uncontrollable zeitgeber in this case. At the other extreme, [Stalk & Hout 90] refer to the television news industry, in which product development cycles are measured in hours or minutes. The consumers' desire to know what is news as soon as it is news drives the cycle. Courseware development for the web faces both the fast pace of technological advances and the more stodgy pace of traditional instructional design.

On the other hand, some rhythms naturally resist entrainment to pacers. In the biological examples of entrainment, a rhythm naturally occurring as nearly a 24-hour rhythm was easily entrained to an exact 24-hour cycle. But in terms of courseware development, changing to a new tempo may not be that easy. For example, [Rosenau 92] lists forcing scientists to "invent on schedule" as a classic development delay.

Another possible source of resistance to entrainment springs from the varying difficulties encountered with the type or extent of innovation involved in courseware development. Courseware projects can range from mere production tasks to full-scale research and development of technology and pedagogy. Although different types of innovation project paces might not be as obvious as the circadian cycle, different types of projects seem to require or capture different rhythms or patterns--which in turn are related to speeding the development timeframe.

The linking of courseware development rhythms and patterns to each other and to appropriate pacers or entraining cycles is critical to increasing the tempo of new product development.

4. Conclusion

This paper began with a discussion of the entrainment concept manifest in biological and social systems. Possible applications of rhythm, mesh, tempo, and pace in courseware development were explored, along with possible links to accelerating courseware development. Application of entrainment to courseware development has the potential to provide researchers with an underpinning theory of courseware development acceleration to move research from a better understanding or co-variations to discovering important causal elements. The fulfillment of these aspirations will likely help the delivery of new courses "on a horse" that is quick and sure-footed.

A New Role for the University in the Information Age

Thomas Monaghan
Web Administration, University of Notre Dame, USA
monaghan.l@nd.edu

Abstract: This paper will propose an emerging role for the University in light of the technological tidal wave that has occurred in the recent decade. It will scan the changing landscape facing higher education, re-evaluate who the learner is, highlight the expanded learning community opportunities, and underlying the entire paper, introduce a new philosophy for Universities to follow: teaching and learning, from cradle to grave.

1. Introduction

What is the role of the University? Traditionally, it has a few major components: a place for the high school graduate to expand his/her higher learning processes, a center for worldwide research, and a place for those seeking expanded specialized education, particularly in the professional fields, such as law and medicine. In the past decade, this role is coming under increased pressure and may need to be redefined if the University is to grow, much less continue, in the next century.

This paper recognizes the value in the traditional University model. The experiences of the residential campus, students away from home for the first time, living with other students from different religions, ideologies, and geographies is integral to the maturity process that should complement any academic achievements. With the emergence of technology, these benefits can be enhanced with new resources, experiences and environments that were never before possible.

The University is uniquely positioned to be the focal point for learning in the information age. To be this learning hub, it needs to foster the coming together of both young and old who are on the path of knowledge. While specific learning opportunities are important, the main point of this paper is to introduce that the University should be positioning itself to expand its identity and role to cater to the expanding learning community.

2. The Changing Landscape

Higher education institutions of all sizes are coming under increased pressure to provide a learning community to traditional and non-traditional learners. This is happening in the midst of additional education providers aggressively moving into the teaching and learning enterprise. Some of these players didn't even exist several years ago! With the ability to provide content via the Internet, now educational opportunities are available from corporations, textbook publishers [see Mendels 1999a], and even colleges that only exist in the virtual sense.

Many established Universities are beginning to recognize the changing educational landscape as well. Stanford is one of the most aggressive institutions in exploring online academic offerings. The Stanford Online web site states the following premise:

The virtual classroom could not have become a possibility at a more opportune time. Three educational trends are currently on a collision course. Firstly, education has become and will continue to become increasingly important for occupational and personal success. Second, increasing demographic and occupational diversity is rendering many long-held assumptions about the education process obsolete. This in turn is creating increasing pressure for alternatives. And lastly, education has become increasingly expensive, with cost increases leading inflation by a significant margin. There is now increasing pressure to re-engineer the educational process to be significantly more cost effective [Stanford 1999].

In addition to established Universities who are exploring this changing landscape, some institutions now exist in only the virtual world, with an Internet presence representing the core of the school. While some may think that these don't pose much of an alternative to the established Universities with real campuses, these virtual colleges are beginning to gain in stature. For example, Jones International University, one of the few virtual Universities, has recently received accreditation from the same body that accredits institutions such as Northwestern University, the University of Notre Dame, and the University of Michigan [Macavinta 1999].

Another player in the educational arena is the private corporation. Historically, they have always been involved in post-graduate training as it relates to a specific need of the employer. Now they are beginning to cross over into many traditional teaching areas. This paper will highlight some examples of this involvement by the private sector. These examples should not be taken, necessarily, as threats to the University, but as opportunities for both to work together to enhance the learning experience.

3. The Expanded Learning Community

Like never before, the University has the ability to extend its reach to new communities of learners. These communities span all ages - from high school students to those well past the traditional college age, looking for life lessons. There are three main communities that the information age presents to Universities, each with important needs and priorities. These communities are outlined in the graphic below:

Before introducing each area, it should again be noted that the importance is not just in highlighting each learning group, but that the strength of the University would be to create an environment where all three groups coexist within the context of a single learning community.

3.1 Pre-College Learners

The traditional model states that the undergraduate admissions area of a college or University is focused on attracting the brightest high school students and that the academic departments focus on teaching those same students once they've enrolled. Many institutions try to find ways to market the academy through campus workshops for high school students, faculty involvement either via email or in person, and campus visits, just to name a few admission strategies.

Attracting these prospective students, especially for the more selective institutions, is tough. In a recent article that deals with the current job market and how the dynamics have changed dramatically in the recent decade, there are strong parallels to the change in how high school students may be courted by the academic institutions:

For companies, the rules of recruiting have changed dramatically. What's out is the notion that an employer can simply show up at interviews and collect the talent. What's in is pitching to hot prospects early and often. You don't start with the senior class at the top Universities - you introduce your company to the freshman class. You sponsor research in the labs. You build relationships. Soon the top performers are using your software. You've given them free Internet access for four years. So when other companies show up

on campus and host another cattle call, you've established your brand among the people who can take your company where it needs to go [Breen 1998].

Today, the opportunity exists to involve these students unlike ever before. It is now possible to allow high school students to experience – directly – the academic strengths of the institution, by welcoming them into the University learning community well before they ever step foot on campus.

A typical high school student, while taking all of the proper standardized tests and working towards graduating from high school, might also be looking forward enough to take Advanced Placement tests. With the advent of technology, that high school student could take classes online (through the University) specifically designed to prepare for these placement tests.

Private industry is already offering these tutorials online. From a recent article in the New York Times:

Like 54,000 other high school students, Elizabeth J. Hanson plans to test her grasp of everything from the Federalist Papers to theories of bureaucracy when she takes the Advanced Placement examination in U.S. government and politics May 18.

Unlike most of them, however, she will have prepared for the rigorous test, which can help high-scorers get college credit, largely by sitting in front of a computer connected to the Internet.

Hanson, a senior at Charlotte Catholic High School in North Carolina, is one of a pioneer group of 150 students who enrolled this semester in an Advanced Placement course offered on the Web by APEX Online Learning Inc., a new company whose executives are convinced there is a market for Advanced Placement classes online [Mendels 1999b].

In addition to offering online tutorials for placement tests, the University could explore the offering of an actual introductory-level course to high school students who don't have access to college-prep curriculum in their local high school. In partnership with high schools, this would allow many students the chance to explore the educational academy by taking part directly in the University curriculum. These classes could be offered in the summer, thus not impeding on the high school students' standard workload.

What's exciting about this opportunity is that the high school student is not just limited to the college-level courses in their geographic area, but if qualified, any University across the country would be possible options.

As part of the University learning community, the high school student would also have access to college students who have taken the same course. This allows for mentoring to take place and possibly the ability for the college student to earn academic credit for tutoring these high school students online.

Another benefit of offering introductory-level courses online to high school students is that in some institutional environments, this strategy is less threatening to traditional academic leadership because it doesn't necessarily disrupt the on-campus fabric of education.

3.2 Traditional Campus Community

Some interesting milestones have occurred in recent years that are profoundly affecting the education process. The ability to provide academic courses online is one such milestone. As already noted, Stanford University is an example of a leading academic institution that currently offers not only individual courses online, but also an entire academic degree that can be earned through the Internet. Now schools are joining together to provide a bank of courses available that are accepted for credit in any of the partner schools. For example, the Indiana College Network offers almost 500 online academic courses. These courses are offered through the largest institutions (Indiana University and Purdue University) as well as smaller private colleges throughout the state [ICN 1999].

What happens when and if on-campus traditional students want to enroll in an online course offered by another school as part of their normal semester load? This is a question that traditional college students could soon be asking their institution. It is an accepted practice to allow this option outside of the

traditional semester (summer for example). Now, however, nothing is technically stopping this class from being offered during the semester as part of a student's normal workload. Like many examples in this paper, this possibility should be considered an opportunity for the academic institution. Each University or college could provide students courses in a variety of subjects that were not economically possible in the past. This could help to promote expanded collaboration between Universities and colleges around the world.

For an institution to explore this issue, understandably, there would be many issues to work through. Some of these issues include the sharing of finances, academic standards, transferal of credits, and the logistics of class scheduling. The point is that the current student now could have the opportunity to blend the local academic experience with remote learning as an enhancement to the entire learning process.

Another recent milestone has been the exploding availability of digital information on the Internet. As highlighted later in this paper [see Digital Resources], the University needs to find ways to give the traditional campus student direct and appropriate access to this new wealth of information. When it all comes together, campus students could have access to outside experts, alumni, faculty from other institutions, libraries of information, and resources in the private sector. As an enhancement to the traditional classroom time, the student could consult with other content experts, view the actual data, and discuss the topic with other students throughout the world, without ever leaving the dorm room!

The reality is that a local or regional college could provide world-class resources by enlisting technology to welcome these outside partners into their learning community. Historically, only those who could afford to hire the experts and build the libraries were able to expose their students to these types of resources.

3.3 Alumni and Extended Learning Community

Learning has continued to be a life-long journey. The University has the opportunity unlike ever before to be an integral part of this process. In addition to the on-campus classes, what if the University offered graduate, certificate, and enrichment courses to adult professionals across the country? Through the Internet and complimentary technologies, the learning community could receive convenient local access to world-class education. In fact, some Universities are providing these courses today.

What's important here is finding ways to expand the crucial underlying aspect, maintaining the relationship between the University and the learner. The University has a tremendous opportunity to provide a plethora of resources to alumni, business professionals, and those seeking information about life choices. The goal is for the University to mold the learning community in a such a way that it responds to the changing needs of this group - very much like it maintains a learning environment designed for its on-campus students. These diverse learners can use the University to discuss topics, attend a virtual lecture, provide mentoring, conduct research, and so much more.

An added benefit of expanding the learning community is the resources made available may not have to be standard academic courses. Many learners who have graduated from college often seek guidance and information about important life choices. Universities across the country are a perfect place for offering these resources online to those who are looking for this type of guidance. The University of Notre Dame, for example, offers campus workshops and videos that explore different topics ranging from the changing American family, death of a spouse, and medical ethics [Notre Dame 1999]. The next step is to offer these workshops online so that someone can experience these resources without having the luxury of being in South Bend.

Partnership opportunities in this area are also on the rise. Corporations, who are in desperate need of skilled workers, are spending tremendous resources to find ways to train existing employees as well as plant the seeds of the importance of education to those still too young to be considering higher learning. As an example, Joint Venture: Silicon Valley is spending millions of dollars on a partnership with Silicon Valley elementary, middle, and high schools [Joint Venture 1999]. The goal is to promote the importance of preparing youth for the world of today and tomorrow, one that places supreme importance on the information worker. Although that particular partnership does not involve any colleges or Universities, the time is ripe for higher education to join with the private sector in these expanding educational opportunities. In fact, it is already happening in some very public arenas. Unext.com is one such effort. Formed as a separate company, Unext.com is partnering with Universities to provide educational opportunities to the business world. Their goal is "to create powerful learning communities that marry the

world's most respected academic scholars and institutions with the global reach and interactive capabilities of the Internet" [Unext 1999].

So whether it's a professional looking for a career change, a remote scholar conducting research, someone looking to expand their knowledge in a certain discipline, or an adult looking for guidance in a life situation, the University has the tremendous opportunity to be an important resource for guidance and information. With the expansion of the Internet, this relationship has the potential to last a lifetime!

4. Digital Resources

A critical element in building and maintaining this expanding role is the availability of online resources. These are online resources that could relate directly or indirectly to the University curriculum. The University should be viewed as the keeper of these valuable resources, making them available to the worldwide learning community. An example of providing these resources online can be found in a joint effort between the private sector and University publishers called netLibrary. With 8,000 volumes currently available, users can search for scholarly, professional, or reference books, and then view the entire contents online. NetLibrary is partnering with over 40 publishers that include Harvard Business School Press, Macmillan Reference, McGraw-Hill Companies, MIT Press, and University of California Press [netLibrary 1999]. While the readability of online books is still in question, one has to ask if it is better than not having access to this information at all. Beyond simply providing books online, Universities should also be finding ways to provide content that enriches all senses, thus allowing for a deeper understanding of the subject matter, including images, sounds and video.

The value in making these resources available to a wider audience through the Internet is reaching the agenda of government as well. President Clinton has asked for \$30 million for the creation of a digital library for education. If the money is approved, it could eventually mean that images of items like the pages of Thomas Edison's lab notebooks and the hat worn by Abraham Lincoln the night of his assassination would be online, and freely available to students and the public at large [Mendels 1999c].

Higher education should be aggressively exploring these opportunities so that the University is properly positioned as an important part of these learning resources. Unlike corporations and even governments, the University can blend these resources into the learning community providing the proper context and instruction that truly make these digital resources valuable to the learning process.

5. Interesting Possibilities

Some of the following possibilities highlight the potential of the lifelong learning model. In fact, some may already be happening across the country:

- A senior in a small Midwest college is earning credit for assisting a faculty member who is teaching an introductory-level course. The difference is that the faculty member is teaching this class in a large state school in Florida. The student teaching assistant is earning credit by making herself available twice a week on the Internet for tutorial sessions and as a resource for student questions.
- A college junior studying overseas for the semester is able to finish a required class, thus staying on track for graduation. The required class is only offered back in the student's American campus, but he is able to take and complete the entire course online during his semester abroad.
- During the summer, an introductory Philosophy course in this southwestern University not only has the typical number of college students, but also two high school students who have been accepted into the class. They are taking it because their high school doesn't offer any college prep classes and if they pass, they will earn credits transferable to any partnering college or University.
- A high school teacher is working on expanding her knowledge in an emerging field. With that goal in mind, she is taking a couple of courses during the summer from two different Universities – both online.

- An alumnus who lives overseas is auditing an online Biology seminar. This alumnus has always been extremely interested in the subject but never had the chance to learn more about field.
- A college senior is offered a position based partly on knowing an alumnus online through the University learning community.

6. Conclusion

With technology, the University has the ability to market itself more effectively to prospective students (young and old), create a far-reaching learning community for all its members, and retain relationships with those who come and go from the academic landscape. Thus, the new philosophy for higher education involves learning from cradle to grave!

Abstract: The SAGRES system is an environment built on the Web, that facilitates the presentation of information bases of the museum, in a way which is adapted to the individual characteristics of each visitor. The interaction with the system may occur individually or in groups of students. The system offers also resources to support some forms of cooperative learning, allowing visitors to interact both synchronously and asynchronously, and both, locally, inside the museum, and non-locally, in places geographically distant from the museum. This cooperative learning is stimulated and monitored by software agents that use the human-computer interaction paradigm called directed improvisation to interact with the user. The agents improvise, while helping the user, a group of behaviors similar to human behaviors (happyness, satisfaction and vibration), making the interaction more friendly.

1 Introduction

Most of the virtual museums on the Web are sites that offer on-line learning resources, inviting the visitor to investigate and to explore the information available. The SAGRES system is a virtual museum that seeks a cooperation between museum and schools, in order to create a new educational environment that provides continuous education, allowing access to information of the museum to the community in general. It aims to help cooperative learning processes of visitors, both local and remote. Due to the possibility of using the system as a distance teaching tool, and to the diversity of the school population to be reached, SAGRES was conceived as a flexible and adaptive system, able to pay attention to the different needs and situations of its various visitors.

The hypermedia systems on the Web are among the many systems that facilitate the adaptation of information. These systems are an efficient form to manage data collections too, as well as to bring into effect education and learning in museums. However, Yamada et al. [1995] state that hypermedia systems for education in museums present some limitations, such as: the lack of initial training from the part of the user; the time of limited use of the system (just during the visits); the different ages and the different levels of the users' background. To overcome these limitations, Nielsen [1990] emphasized the need to facilitate the use of such systems. They should be simple, so that the visitors can navigate without needing a training period, their simplicity, being related to the reduction of the navigation options in the interfaces.

Complementing Nielsen's proposal, we are using software agents to assist users in SAGRES. According to Genesereth [1994] software agents are very useful to analyze information and to monitorate the user's actions, helping them in the performance of tasks. In this way, the agents are able to facilitate the system's operation, to

construct a user's history, with topics visited and activities performed, and to generate reports based on the user's history.

People are social beings and need to interact with each others. In fact, we enjoy and thrive on affective relationships with other social beings at home, at work and at play [Hayes-Roth 1998]. In this way, our agents are animated characters that resemble real and fictional characters. They do this, improvising a set of behaviors while executing the user's request.

We can visualize the organization of the whole system through figure 1. It shows that the SAGRES is built on the Web and the agents are running on SAGRES. The integration of the agents into the SAGRES was made through agents procedures calls inside SAGRES. At present, SAGRES can be reached at the URL <http://sagres.mct.pucrs.br/>.

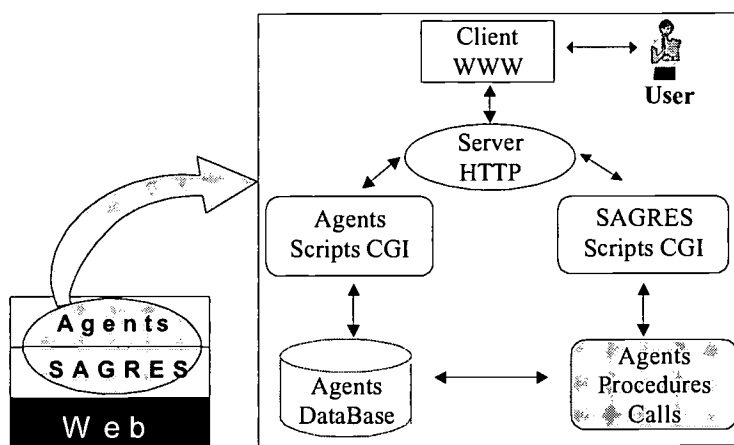

Figure 1: System Organization

2 SAGRES

The SAGRES system [Bertoletti 1999] is an educational environment, that facilitates the organization of visits to museums, presenting museums information bases in a way adapted to the user's characteristics (capacities and preferences). The system determines the group of links appropriate to the user(s) and showing them in a resultant HTML page. In addition, SAGRES carries cooperative learning by supporting the interaction among visitors and also among members of groups of visitors.

SAGRES allows visitors to plan visits to the museum in advance. Thus, when arriving at the museum the visitor already knows from where to find the specific experiments. Later on, already at home, the visitors can read other information related to the visited experiments, as support material available in the system.

For teachers SAGRES is a powerful tool to support education, because it works as a repository of information from which the teacher can elaborate a library of activities (for example: questionnaires for tests) and share them with other teachers.

- Basically, the system is handled by different groups of users:
- *System Administrator*: responsible for the maintenance of the system, having a deep knowledge about its
 - *Information Manager*: responsible for the information bases of the museum, generating them and establishing the degree of difficulty of each piece of information.
 - *Teacher*: is generally identified as a school teacher whose student groups visit the museum, being responsible for the definition of the profile of the group. By a profile we understand the set of characteristics of the

group, that is, the students' background and preferences, any particular subject being focused in the visit, and the activities. The teacher is also responsible to register the students, as well as to accompany and evaluate their performance during the visit, through reports delivered by the system.

- *Visitor*: any individual visitor of the museum. A visitor can interact with the system as both is:
 - An Individual Visitor: he accomplishes the interaction with the system individually. He is included in the system by a process of self-registering, in which he is responsible for defining his profile, informing his characteristics, capacities and preferences, in order to facilitate the construction of his model.
 - A Student: he is allowed to change ideas with his group colleagues and to work in the activities and subjects determined by the teacher.

2.2 Adaptation of Information

In the adaptation process of SAGRES two main factors are considered: its use in the educational atmosphere (museum and school) and the different types of visitors that use the system. In this sense, the system uses an *adaptive presentation of information*, so that the user just receives, as a result of his consultation, the information that is in agreement with his level of understanding, stored in his visitor model.

The modeling module receives the information about the visitor, processes it and generates the visitor model, storing it in the database of models. The acquisition of knowledge about the visitor is done in an explicit way: information is directly extracted, through the filling of forms, with direct answers to questionnaires. SAGRES works with two kinds of models: individual model and group model. The individual model stores all the characteristics of the individual visitors. The group model is built by the teacher and used by students. The teacher is responsible for the definition of the students characteristics, by the definition of the group stereotype (subject, knowledge level and language of the consultation), the activities stereotypes and the classes (name of the students presented in the group). The activities stereotypes can contain: "n" questions (true or false; multiple choice; to relate columns and dissertation); "n" orders (that specify the teacher's desire before the students' course in the system); "n" editions of documents (where the teacher requests the students the report writing, for example) and "n" discussions (where the students change messages in order to discuss certain themes established by the teacher).

Once defined, the group and activities stereotypes can be used for the construction of several models, which store codes for the identification of them. The control of the use of the stereotypes fits to the teacher, that can also share them with other teachers.

The adaptation process accomplishes the mapping of the information (documents about the experiments in exhibition and works published by the staff of the museum) contained in the information bases for a presentation page, in accordance to the visitor's model. Such mapping results in a dynamically created HTML page, with links pointing to information selected. This page is created dynamically in each interaction and presents links to the documents, besides presenting connections to the communication mural (where visitors can interact with each other), to the document edition, and to the activities the visitor should perform (in case of a group visit). The visitor can use this page as a visitation guide to the museum.

2

The cooperation process in the SAGRES happens in two ways:

- **Communication Mural**: allows the students of a group to send messages to each other, facilitating local and remote communication among them, very important to the learning process. In this mural the students place their ideas, questions, comments and help messages. When the group model is created, the system automatically generates an HTML page, which works as a communication mural. The mural can only be used by the students of the group. The teacher also has access to this mural, facilitating the coordination of the cooperative process.
- **Document Edition**: The cooperation process in the SAGRES system also facilitates the edition of HTML documents on the part of the students. These documents, unlike the communication mural, are available to all users of the system. In such documents the students state their ideas on the consulted subjects, they add new information associated to that already presented and, also, arrange the related works.

3 Agents

In order to develop a system that can be more friendly, assisting the users in SAGRES, through the communication between the users and animated characters, our agents use the human-computer interaction paradigm called directed improvisation [Hayes-Roth 1997]. Based on the metaphor of the virtual theater, it was developed a multi-agent architecture formed by four kinds of agents: director, guide, presentation and assistant. Figure 2 shows the way these agents are organized. The innovative and peculiar feature of this architecture is the existence of the director agent, responsible to connect the behavior to the actors, in an improvised way. Therefore, the actors have different personalities and different ways to interact with users. We call this director's behavior "improvised direction", in order to distinguish it from directed improvisation.

Figure 2: Global architecture of the agents

Hayes-Roth [1994] defined directed improvisation as a paradigm for human-computer interaction, where users give character abstract directions either interactively or in preconceived scripts. The characters improvise a course of behavior that follows the directions, expresses their individual styles and reflects social principles. The directed improvisation is incorporated in the architecture in the following way: each one of the agents has a script that contains the actions to be executed by the agent and a behavior related to these actions. Two kinds of behaviors have been defined: interaction, which occurs when the agent interacts with the user, and processing, which occurs when the agent processes a request from the user. The interaction behaviors incorporate the verbal behaviors (word choices) and physical (movement behaviors) of the agents. It has associated instances for each of the interaction behaviors of the agents. As the verbal behaviors define the personality of the agent, we defined different "personality instances" for the guide agents, presentation and assistant, providing varied personalities to them. The director agent is responsible to choose, in an improvised way, which behaviors will be related to the agents actions. Figure 3 shows the director's script, with some of its functionalities. The guide agent is responsible to assist users and build their history. A reduced format of the guide agent script is presented in the figure 4; the text in italic is representing the behavior that the agent can improvise at that moment. The assistant agent helps teachers to construct visits and to monitorate a students' group and the presentation agent presents the contents requested by the users.

We may notice in the figure 4 that an action can have more than one associated behavior. In this way, the agent has to choose which behavior will be improvised. Beyond these scripts each agent has a data structure, the same for all, that is: `id_agent` (contains the name of the agent), `state_agent` (contains the current internal state of the agent), `list_neighbours` (contains the name of the agents that it will be able to communicate to) and `who_is_communicating` (contains the name of the agent that is communicating at the moment). The agents have common knowledge about the world, which is implicitly incorporated in the program structure.

1. To construct the agents' scripts, connecting, in an improvised way, behaviors to the agents' actions.
2. To inform these scripts to the agents.
3. To manage the execution of the agents.
4. To create a solution when it doesn't exist a guide agent to guide a user or it doesn't exist a presentation agent to present some specific topic requested by the user.

Figure 3: Example of Director agent's script

1. To present to the visitor (*to greet, to wave*)
2. To invite the visitor to make a visit to the museum (*to invite, to dance*)
3. To wait reply of the visitor (*to wait*)
 - 3.1 If visitor selects a consultation
 - Looks to presentation agent for content (*researcher*)
 - Demonstrates satisfaction (*satisfaction, vibration*)
 - 3.2 Else demonstrates reprovation (*to refuse, to disapprove*)
 - Stimulates visitor to make visit (*to stimulate, to move*)
 - 3.3 If visitor requests mural's monitoring
 - Monitorate communication mural (*investigating, artist*)
 - 3.4 If visitor requests the monitoring of document edition
 - Carries through edition of document (*researcher, artist*)

Figure 4: Sample of Guide agent's script

The communication between agents is carried out through sending and receiving messages. A set of messages was created to use in the interaction between agents; some of these messages can be seen in figure 5.

Figure 5: Sample of Communication in an individual visit

Running on SAGRES, the agent carries through the assistance of users, constructing the users' history, that is the topics visited and activities performed. The agents are constantly looking for new messages in the communication mural and informing the user who writes the message and what is its content. The agents execute also the procedure of looking for documents edited by other users, suppling access to these documents. The system also supports some facilities to the teacher, when a group visit is occurring. Based on the user's history, the agents generate reports to the teacher. There are three kinds of reports: group's report, that lists all activities made by the group, including communication mural and document edition, student's report (lists activities partialy or completly performed by the student, with his grade) and activities' report (lists percentage of activities finished by the group and degree of correct and incorrect answers).

4 Conclusion

A virtual museum, in the pattern proposed by SAGRES, is shown viable, performing among other functions, the support for cooperative learning. SAGRES is being developed to offer to the visitors of museums (local or remote visitors) the chance to learn cooperatively, exploring information adapted to their personal characteristics. The style of SAGRES system demands that the student takes part in the decisions concerning the activities he will perform, and not only to repeat preset routes mechanically.

This way, SAGRES will make remotely available to the public visitor the interactive museum of PUCRS, as well as it will contribute to the improvement of teaching, facilitating cooperative work among students, and promoting the exchange of information among schools geographically distant.

The agents in SAGRES are built in order to offer a friendly interface and to facilitate the management of groups' visits. They do this through the assistance of users, helping them during the exploration of information and system operation. Furthermore, they stimulate communication among students and among visitors, because they are constantly looking for new messages in the communication mural and informing the user the author and contents of the message. Besides, they provide facilities to monitorate group of students.

Privacy is a Right and not a Privilege: Why Legislation is Necessary to Protect Privacy

Noreen Mac Morrow

Department of Information Science, University of Strathclyde, 26 Richmond Street, Glasgow G1 1XH, UK
noreen@dis.strath.ac.uk

Abstract This paper discusses the concept of privacy and looks at threats to this right stemming from the electronic age. Legislation, in the form of data protection law is discussed as a means to protect individuals' privacy and the example of the UK Data Protection Act is given to illustrate the scope of legislation in this domain. The reasons as to why the European Union has chosen legislation as the means of protection rather than relying on self regulation are considered. The paper concludes by highlighting the importance of such legislation to counter threats to privacy and outlines its implications for organisations.

1. The concept of privacy

The privacy concept traces back to the famous American jurists Samuel Warren and Louis Brandeis who described it as "the right to be left alone". Although subject to various interpretations privacy concerns the right for individuals to determine to what extent and in what circumstances information about themselves is communicated to others. The right to privacy is enshrined in the Universal Declaration of Human Rights and the European Convention for the Protection of Human Rights. According to Foran privacy means: "that individuals have a right to control the flow of information about themselves, the right to fair, reasonable and confidential information practices. This claim of information privacy assumes that all information about an individual is fundamentally his or her property to communicate or withhold as desired - it is the democratic notion of self-determination or autonomy which, in the case of information, dictates that no one should have more control over a person's information than the person. But the more that can be known about a person, the less the person's autonomy. And these days, in an information society, our individual autonomy and our sense of control are on the line. This is the heart of the privacy problem and that is why privacy has become such an emotionally charged issue" (Foran 1995).

The growth in the amount of information gathered on individuals, the creation of large databases, not least by government, combined with the ability to link information across such databases have brought the issue of privacy to the attention of the public. Growth in database marketing and the activities of credit reference agencies who utilise such large databases have raised public awareness about how much personal information is held in electronic form and the negative consequences which can ensue should such information be found to be erroneous. There is a growing concern over civil liberties and personal privacy especially in respect of personal data contained in for example, medical, financial and employment records.

Another issue with privacy lies in the fact that people's actions and behaviours over electronic networks can be observed and used to draw conclusions about a person's beliefs and interests. These so called transactional data are one of the most controversial items in the privacy discussion.

2. Privacy concerns and the internet

Rapid development of the internet has led to growing concerns among individuals about their personal data and the use to which it is put. For example a survey of net users by GVO states "Privacy now overshadows censorship as the number one most important issue facing the Internet". (GVO 1997) Fears about misuse of personal information are an issue for Net users and there is evident support for privacy laws to be enacted. In particular the use of "cookie" technology which can potentially disclose personal information of unsuspecting Web users is subject to criticism. (Mayer-Schonberger 1997, EPIC 1997)

In the US in particular there have been calls for stronger safeguards to protect personal privacy. The testimony of the Director of the Electronic Privacy Center to the US House of representatives committee on International Relations in May 1998 (EPIC 1998) succinctly states the reasons why to date legislative measures, self regulation and industry codes in the US have failed to give adequate protection to the individual in respect of their privacy.

Technological solutions such as the Open Profiling Standard, the Platform for Privacy Preferences and Truste have not yet met with success. However it is recognised that privacy and related issues such as anonymous payment systems will be important in the establishment and development of electronic commerce. Thus it can be seen that the issue of privacy has come to the fore especially in recent years. In Europe a 1995 Directive on Data Protection (European Union 1995), has firmly established the importance of the issue. Privacy and its protection are seen as inextricably linked with the development of trust in electronic commerce.

3. Generic principles underlying data protection laws

The need to protect privacy in regard to the use of computer systems has been recognised for some time. The OECD Guidelines (OECD 1980) were the first international policy for the protection of privacy in computerised data processing systems. These guidelines were designed in a technology neutral way to accommodate future developments. Much national legislation in this area including the European Directive are based on these principles which apply to all types of personal data whether traffic data or content data. They outline the rights and obligations of individuals in the context of automated processing of personal data and the rights and obligations of those who engage in such processing. These eight principles comprise the following:

Collection Limitation Principle

There should be limits to the collection of personal data and any such data should be obtained by lawful and fair means, and where appropriate with the knowledge or consent of the data subject.

Data Quality Principle

Personal data should be relevant to the purposes for which they are to be used and, to the extent necessary for those purposes should be accurate, complete and kept up to date.

Purpose Specification Principle

The purposes for which personal data are collected should be specified not later than at the time of data collection and the subsequent use limited to the fulfilment of those purposes or such others as are not incompatible with those purposes and as are specified on each occasion of change of purpose.

Use limitation Principle

Personal data should not be disclosed, made available or otherwise used for purposes other than those specified in accordance with the purpose specification principle except: a) with the consent of the data subject; or b) by the authority of law

Security Safeguards principle

Personal data should be protected by reasonable security safeguards against such risks as loss or unauthorised access, destruction, use, modification or disclosure of data.

Openness principle

There should be a general policy of openness about developments, practices and policies with respect to personal data. Means should be readily available of establishing the existence and nature of personal data and the main purposes of their use, as well as the identity and usual residence of the data controller.

Individual Participation principle

An individual should have the right:

- a) to obtain from a data controller confirmation of whether or not the data controller has data relating to him;
- b) to have communicated to him, data relating to him within a reasonable time; at a charge, if any, that is not excessive; in a reasonable manner; and in a form that is readily intelligible to him;
- c) to be given reasons if a request made under paragraphs a) and b) is denied, and to be able to challenge such denial;
- d) to challenge data relating to him and, if successful, to have the data erased, rectified, completed or amended.

Accountability principle

A data controller should be accountable for complying with measures which give effect to the principles stated above

4. European Union Directive on Data Protection 1995: Main objectives

The Directive is seen as an essential part of a clear and stable legal framework which is necessary for the development of an information society in Europe. It is designed to ensure that personal data can move freely throughout the Community by ensuring that a high level of protection for individuals in all Member States with regard to processing of such data. This is achieved on the one hand by imposing obligations on those who process data and by establishing rights for the individuals whose data is being processed. The directive is applicable to all files within the public and private sector thus files whether computerised or not fall under the Directive so long as they relate to living individuals and are structured files. Information relating to living individuals gathered over the Internet will therefore have to comply with the principles of the Directive.

5. European Union Directive on Data Protection 1995: Key provisions

The key provisions of the Directive are as follows.

- It applies to automatically processed and certain types of manually processed data.
- It contains a wide definition of "processing" (i.e. everything from collection to destruction).
- It establishes data protection principles with which processing must comply.
- It sets conditions which must be met before personal data may be processed with stringent conditions for the processing of "sensitive" data e.g. data about racial or ethnic origin.
- It provides for certain exemptions for e.g. journalism, national security, crime investigation
- It requires individuals whose data are processed to be provided with certain information (e.g. about purpose of processing).
- It gives individuals the right of access to their personal data, and the right to have inaccurate data amended etc.
- It gives individuals the right to object to their data being used for direct marketing purposes.
- It places restrictions on fully automated decision-making.
- It sets specific requirements for ensuring the security of processing operations and it requires information about processing operations to be publicly available.
- Finally it gives detailed conditions for transfer of personal data to countries outside the European Economic Area.

In the United Kingdom the legislation enacted to bring the Directive into force is the 1998 Data Protection Act (HMSO 1998). It is important to understand the overall significance of this legislation for the protection of personal privacy. It makes more stringent demands of data controllers than previous legislation and strengthens individual rights.

6. Implications of the legislation

As the UK legislation is, at the time of writing, so recent the full implications of the new Act are not yet clear but it is useful to highlight two of the most important provisions and explain their significance.

The first Data Protection Principle requires that "Personal data shall be processed fairly and lawfully". The advice of the Data Protection Commissioner is that all data controllers should ask themselves "Do I have legitimate grounds for my processing operations?" One of the conditions for processing is that the processing is carried on with the consent of the data subject. Consent is not defined in the Act but the original Directive on which it is based defines it as:- "... any freely given specific and informed indication of his wishes by which the data subject signifies his agreement to personal data relating to him being processed."

The fact that the data subject must "signify" their agreement means that there must be some active communication between the parties. Data controllers cannot infer consent from e.g. non-response to a communication. In the case of sensitive data this consent must be "explicit". Part of this first principle also requires that data controllers comply with what is known as the "Fair Processing Code". This code set out requirements as to the fair obtaining of personal data and the information that must be provided to the data subject. Compliance with

"the fair processing code" should in most cases ensure that consent is both "specific" and "informed" and that the data subject is informed of the purpose for which the data is intended to be processed. With this legislation the use of "cookie" technology which gathers information about the data subject without their knowledge would not be permissible. Organisations would have to ensure that where personal information is gathered over the Internet that data subjects were aware of this and understood the purposes for which that data would be used. Furthermore individuals now have an explicit right to object to their data being used for the purposes of direct marketing - one of the most common uses of information gathered over the internet.

Secondly the eighth Data Protection principle states that "Personal data shall not be transferred to a country or territory outside the European Economic Area, unless that country or territory ensures an adequate level of protection for the rights and freedoms of data subjects in relation to the processing of personal data." European countries are not allowed to send personal information to countries that do not maintain adequate standards of privacy. The European Union does not consider the US to have adequate privacy laws and in December 1998 declared that the proposals for voluntary-based privacy policies as set out in "Safe Harbour" were unacceptable. As a result a huge amount of business between Europe and the US may potentially be blocked in areas such as banking, credit card transactions, ecommerce and travel (Banisar 1998, Davies 1998). Data gathered by US companies on European citizens over the Internet could be considered as breaching this principle and such companies may find themselves challenged in the courts as a result. Privacy International for example has stated that it intends to challenge any "illegal" processing by US companies to protect European citizen's rights.

In contrast the US claim that it has equivalent privacy protection but that it is different, than that existing in Europe. Specifically it relies on self regulation and technological solutions rather than legislation to ensure privacy. This is not seen as being sufficient by Europe and it remains to be seen the extent to which the new privacy laws will be invoked in terms of the transfer of data between the two trading blocks.

7. Conclusions

To date voluntary self regulation has not proven to be adequate in ensuring the individual privacy is protected. Legislation brings the force of law to the issue of privacy. The Internet transcends national boundaries hence national legislation is insufficient. International agreement as to the importance of privacy and commitment to legislating for its protection is necessary. Legislation though is not enough, effective enforcement is also essential. In the case of the UK the previous Data Protection Act of 1984 was poorly enforced not least because of the limited resources of the Data Protection Registrar to investigate breaches of the law. An informed and educated populace is necessary to ensure that individuals understand their rights and wish to see them enforced. A major task for the new Data Protection Commissioner will be to ensure that such education is given a high priority.

There is some evidence to suggest that the public are becoming more concerned about the extent to which information is routinely collected about them and the uses to which it is put. On October 11th 1998 the Sunday Times published an article "Privacy row as firms draw up list of customers' politics". In it the extent to which companies as diverse as Eagle Star, Mothercare and Bupa Care Services collect information on their customers for marketing purposes is revealed. Some of this information is in categories such as race, mental health, political party membership. Under the new data protection act such sensitive information will require the "explicit" consent of the data subject and indeed under the legislation the data subject has the explicit right to object to the processing of any of their personal data for direct marketing purposes regardless of whether such data is in the "sensitive" category. This will require many organisations to reconsider their information management practices with respect to the collection, processing and use of personal data. The same article stated that up to 4m people have taken part in surveys distributed by direct mail often lured into participation by the prospect of a prize. Yet often how this information is used is not known or well understood. The same situation pertains in cyberspace - on a regular basis millions of people give away personal information about themselves often without their knowledge and frequently with little understanding of how it is subsequently used. This situation is likely to change according to John Hagel and Jeffrey Rayport.

In their article in Harvard Business Review "The coming battle for customer information" (Hagel & Rayport 1997) they argue that as consumers take control of information about themselves companies will have to pay for it. Further they anticipate that consumers will not bargain with vendors on their own but rather that companies which they call "infomediaries" will seize the opportunity to act as custodians, agents and brokers of customer information

marketing it to businesses on the consumer's behalf which protect their privacy at the same time. They point out that only a few companies will be able to undertake this role - those who have ongoing relationships with customers in a variety of commercial activities and who can earn their trust but this handful of elite service companies could work on behalf of their customers to force a shift toward the ownership of information by consumers. They further argue that this shift in ownership will require businesses in a variety of industries to refocus their information strategies. Once the collection of information is no longer "free" then companies will have to become more selective about the information they collect focusing on what they must know in order to understand and fulfil customers' needs, have to develop skills to use the information to create value for the customer and also how to manage partnership with their customers to ensure continuing access to information.

It can be argued that every business needs to develop appropriate policies and practices to address these issues, regarding both employees and customers. Don Tapscott (Tapscott 1996) suggests that effective privacy strategies will become a requirement for effective business strategies as business shifts to the new information infrastructure. Proactive strategies to address privacy problems can make good business sense but reliance on voluntary measures to introduce such strategies has not been successful. Robust and effective legislation is the only means to ensure that the right to privacy is taken seriously. Legislation can ensure that organisations, both public and private, consciously adopt privacy policies. Accompanied by effective education legislation enables individuals to know exactly what their rights are and how they can be enforced. The growth of the internet increases the threats to privacy. Only through legislation can these threats be countered and can privacy become a right that is adequately protected and guaranteed rather than a privilege.

Techniques to Implement High Speed Scalable Dynamic On-line Systems

Michael Müldner and Duane Currie
Institute for Teaching and Technology, Acadia University
Wolfville, NS, Canada B0P 1X0
email:mmuldner@sandbox.acadiau.ca
email:dcurrie@sandbox.acadiau.ca

Abstract: This paper describes the techniques involved in the implementation of high-speed online systems that are efficient, scalable and robust. The Acadia Institute for Teaching and Technology (AITT) at Acadia University has been involved in a software project, called the Automated Courseware Management Environment (ACME) over the past three years. This environment is the backbone for students and faculty at the university, providing a WWW based online system that allows centralization of online testing, discussion groups, course information as well as other features. Although other such systems exist (WebCT, Web Course In a Box), these systems for the most part are not scalable or robust to the point that many institutions require.

Introduction

Many considerations must be taken into account when designing an online interactive system. With the growth of the World Wide Web (WWW), many places are involved in building online dynamic systems to do things such as text searches, making and taking of various tests and surveys, carrying on textual discussions as well as many other tasks. These types of online systems are mostly deployed by writing programs that reside on a server and communicate with users of the Internet by using Central Gateway Interface (CGI). Although other ways exist to deploy online Internet systems it was found that CGI along with the Perl programming language was the most efficient, secure and robust way of implementing the current course management system used at Acadia University (ACME).

This paper focuses on the decisions that were made and the techniques used over the course of the last three years while designing ACME as well as lessons that were learned from the deployment of the system. ACME currently allows the online taking and marking of multiple choice and short answer tests, collaborative discussion groups, organization of uploaded notes, calendar tracking, course information storage and statistics as well as other features. With an online system of this nature much work went into optimization due to the lack of ability to distribute the processing load among clients when using CGI to communicate between the system and it's users.

To present a better understanding of the amount of processing that an online system of this nature may be expected to handle (as well as the benefits for deploying such a system) the following statistics were gathered at Acadia University with a student population of approximately 4000 (of which not all were active on the system). Between the time of September 1 1998 and March 4 1999 (a period of 185 days) the system processed 7,851,578 total requests. These requests were further broken down as follows: Creation of 1,905,086 dynamic web pages, marking of 58,851 online tests, displaying of 45,583 discussion groups, and uploading of 6,855 files. To further amount to what these statistics meant the following scenario was considered: Since ACME marked an average of approximately 318 tests per day for 185 days, if it took five minutes of *manual* marking time to mark each test and a student was paid eight dollars an hour to mark these tests, then the total cost that the system saved on the testing alone over the 185 day span was approximately \$39,234.00.

The high demand and overall savings of online systems continue to fuel their growth. Unfortunately with the *success* of a large system come many repercussions. Mistakes that go unnoticed in small systems and lack of optimization are not tolerable in larger highly used systems. For these reasons the main issues that are addressed in this paper are: the programming language used for the system, the operating system support on the server, robustness, optimizations of the system, and scalability.

Choice of Programming Language

In the implementation of web-based systems, three languages are prevalent: C, Java, and PERL. In the development of ACME each language was considered based on the advantages and disadvantages it would provide to the development of the system.

The C language is the most low-level from the three considered because it is less abstract and offers more low-level functionality. It has the ability to directly support any services provided by an operating system, and has the largest user base for general purpose programming of any of the three languages. .

PERL (Practical Extraction and Report Language) is a high-level language similar to C, but with specialized support for efficient text processing and data manipulation. PERL has been the programming language of most CGI applications for years because of its text processing capabilities and ease of use. PERL is platform-independent due to its interpreted nature. (In actuality, it interprets PERL code into a byte-code form, which is then run on a virtual machine). PERL also has support for modern programming methods including object-oriented programming, common database access, and Remote Procedure Calls (RPC).

Java is another high-level language with growing popularity in the WWW market, recently developed by Sun Microsystems to be a platform independent, network-aware programming language. It is fully object-oriented, and at the time of ACME's initial development had support for socket-level programming, and simple database access.

The advantages and disadvantages of each language are outlined below:

[The C Language]

Advantages:

- Best potential runtime efficiency
- Commonly known language
- Most flexible language
- Established language

Disadvantages

- Longest development time
- Longer testing time
- Poorly suited to processing text
- Difficult network programming (no standard interface)
- Difficult database programming (as above)

[The Java Language]

Advantages

- Shorter development time than C
- Shorter testing time than C
- Platform independent
- Simple network programming (standard API)
- Simple database programming (through JDBC)

Disadvantages

- Still a growing and changing language
- No built-in text processing
- Less runtime-efficient than the C language

[The Perl Language]

Advantages

- Shorter development time than C and Java
- Shorter testing time than C and Java
- Mostly platform independent
- Excellent text processing
- Very flexible language
- Large variety of interfaces supported (DBI, RPC, Agents)

Disadvantages

- C is more runtime-efficient
- Not as established as C

As can be seen above, the PERL language possesses the most advantages for the development of our application (an online system). It has most of the flexibility of C and has Java's advantage of platform independence through the use of

virtual machine technology. It is a high-level language with a large library of easy-to-use existing code, including network and database access libraries rivaling and sometimes surpassing the other two languages. The PERL language is not going through the changes that the Java language is now completing through development. It also has the advantage of excellent text processing capabilities, which suits PERL to the purpose of web-based applications very well.

Operating System Considerations

CGI scripts can be executed with various Web servers running under operating systems such as Windows 95/98/NT, SCO UNIX, Solaris, Linux, and many more. Current large online web based systems are mainly written in Unix environments because of their stability, fast multi-programming support and good synchronization layer. A comparison done between two web server systems running dynamic pages on the same hardware; one running Windows NT and the other running Linux kernel 2.0.35, showed that Linux outperforms NT at least 10-1 on complete response time.

The operating system platform that seems to be the most popular among web developers is the Linux Operating System, mainly because it has exceptional support for multi-programming and because it is distributed under the GNU license free of charge. In addition, the file system used under Linux (EXT2) provides extremely fast access for small files typically used with CGI systems and provides a permission layer like all other UNIX operating systems. Linux is a very portable version of UNIX operating systems, and it will run on Sparc, Alpha, Intel as well as many other hardware architectures.

For users that are very concerned with stability and support, Sun Microsystems offers the Solaris Operating System, which will run on both the Sparc and less expensive Intel platforms. Solaris has basically the same native support as Linux although its file system access on small files has been found to be considerably slower.

Finally, Microsoft offers the Windows NT/95/98 operating systems which tend to be significantly easier to administer and more popular for inexperienced users. These platforms are excellent for learning and performing low-end development; however, only at the cost of speed, efficiency and functionality. All the Windows operating systems suffer from poor multi-processing and inter process communication (IPC) support.

System Robustness

When designing large online systems, it is important to consider robustness at five levels:

- 1) The hardware being used
- 2) The operating system on the server
- 3) The web server
- 4) The CGI programming language
- 5) Storage used (typically database driven or file system)

One issue that is typically overlooked when deploying large online systems is the server that the online CGI system will be running on. If the hardware on the system (such as the disk subsystem) is not stable, then the system itself cannot be stable. In many places an expensive high end server is not an option. However, a multi-processor Intel based system with SCSI disks and a RAID subsystem can be bought for several thousand dollars as opposed to tens of thousands and yields similar robustness to many high end servers.

There are more questions to ask in relation to robustness. What happens when the system uses up all the memory and how does the operating system deal with this lack of resources? What happens when the CPU load is very high? Some operating systems deal with this problem very well (for example, Linux, Solaris, SCO) while others (Windows 95/NT) tend to crash when resources are used up without hope of recovery.

The web server allows a level of control over client connections, optimizations on connections, and sometimes even program caching. One web server that is very fast, highly configurable and freely distributed under a free license for most operating systems is the Apache Web Server. The server has support for Fast CGI, MOD_PERL, SSL (for secure transactions), keep-alive connections, and many others. Apache can be configured to control the number of clients that connect to control the load on the server as well as do various other optimizations that prove to be very useful in large systems.

The languages mentioned earlier in this paper (Perl, Java and C) all offer methods of fault tolerance and exception handling. One of the largest problems with online systems written in Perl is that it is very easy to write short simple

code to attain a goal without making it robust. Perl, unlike other languages, does not enforce strictness. All the languages mentioned offer excellent support for robustness, though it is left to the programmer to enforce these rules. The storage used by the CGI has a great implication on the continued success and growth of the system. Regular file system storage can be slow, hard to maintain and to synchronize. Databases solve these problems by allowing access to data storage from virtually any language through the use of Standard Query Language (SQL). The most popular databases in the UNIX environments are MySQL, PostgreSQL, and Oracle. These databases as well as others can be accessed from virtually any programming language and offer many benefits. MySQL and PostgreSQL are both under free licenses and can be used free of charge while Oracle must be purchased but it provides more functionality, robustness and support.

The most important thing in an enterprise/campus-wide information system is its information. Without attention to details of inter-process synchronization, it is easily possible to have situations where some editing changes submitted appear to have been lost, or worse yet, data becomes totally corrupted or deleted. The majority of web applications tend not to consider the full effects of multiple processes accessing data simultaneously.

The first step towards preserving your data integrity is to lock files while they are in use. In Perl and C, this requires using an operating system call, specifically advisory locking (`flock/fcntl`). This allows multiple processes to read the same file simultaneously, and only one process to access a file while the file is being written.

This type of approach can still be flawed. Consider the following abstract description of a routine:

1. `x = Read data from file (while using a shared lock)`
2. A large series of changes occur to `x`.
3. Write `x` back to the same file (while using an exclusive lock)

An error can occur here when more than one process is simultaneously executing the same piece of code. Assume that two processes, A and B, are both executing the above algorithm, and the order of execution due to process switching occurs as follows:

A executes 1, B executes 1, A executes 2, B executes 2, A executes 3, B executes 3

Only the changes performed by process B take effect, and those changes attempted by process A are lost. For an information system to be reliable, such errors must not be allowed to occur.

The solution to this problem is to allow some form of locking of critical sections. In Java, you can easily use the synchronized keyword. In PERL and C, the best option is IPC. Almost all Unix systems implement System V semaphores. Windows has its own similar synchronization objects, which are accessible from C and PERL.

Now, if the algorithm used above is encapsulated within a critical section block, any process wishing to execute the code will first wait for any other processes executing the same code to finish. This prevents the error discussed above, and if used carefully for any code that can modify a file, will prevent loss of information due to synchronization errors.

Optimization through Memory Caching

Caching is a common method for boosting performance by reading data from internal memory as opposed to always reading it from a much slower hard disk. In complex CGI programs, this can increase performance by up to 10 times by removing the majority of the access to the slow disk device. The negative side effect of using caching is an increase in the amount of memory required to run the CGI application. With the current low costs of high-speed SDRAM, this expense is almost negligible considering the benefit of the speed increase that can be attained.

Another benefit of caching is rarely considered; namely it also tends to reduce code complexity in an application. In applications which do not use a proper caching system, the method often taken is to use conditional code to determine if a piece of data has already been read during the execution of the program. With a proper caching system, these decisions are performed entirely within the I/O subsystem, and the programmer needs know nothing about the cache.

Effectively, application code changes from this (represented in a flattened fashion):

```
If (!defined($data)) {
    $data = &Read($datafile);
}
... # more code here
If (!defined($data)) {
    $data = &Read($datafile);
}
...
If (!defined($data)) {
    $data = &Read($datafile);
```

```

}
...
to this:
$data = &Read($datafile);
...
$data = &Read($datafile);
...
$data = &Read($datafile);
...

```

Though a trivial example, this code does demonstrate a decrease in the size and complexity of the application code which, in effect, reduces maintenance costs. However, when using caching in a set of concurrent, co-operative processes, synchronization becomes an issue. What happens when one CGI program caches a file, another CGI program loads the same file and changes it, and then afterwards, the first CGI program performs another read on the file? Should the first CGI program read the file from the cache, or from the disk?

A simple approach is to always check the file on the disk on a read operation. If the last modified time of the file is more recent than the copy in the cache, reload it. As well, all writes must be done in a write-through fashion, forcing the caches of all programs to be synchronized through the disk as well as eliminating the possibility of data loss. While this method still does access the disk on all read operations (to check the file modification time), it hides all cache control within the I/O subroutines, and still performs significantly better than using no cache.

Another, slightly faster implementation for CGI programs is to always read from cache if it exists, and not bother checking the file system. To force a reload of a file into cache, a cache item deletion function is called before calling the read operation. This is slightly faster, but tends to be more error-prone and more intrusive on the application's code.

Optimization through Mod_Perl and Apache

On every request, a pure CGI approach typically requires the following steps:

1. Identification of the URL address requested
2. Loading the CGI program
3. Executing the CGI program
4. Unloading the CGI program

In Perl CGI processes, the most time-expensive parts of the request are the loading and unloading of the interpreter and required libraries. Another implication of this process is that any caching performed by the CGI script is lost from one execution to the next even with the same client. There are several solutions proposed to solve this problem. Among the most popular are FastCGI, Servlets and Mod_Perl.

FastCGI is a method whereby the first time a CGI is loaded, it remains resident. Subsequent requests for the CGI only execute the program, and do not have to load or unload the interpreter. This increases the efficiency of the application by orders of magnitude. Various groups benchmark the performance increase as being anywhere from 400% to 2000%, depending on the application.

A similar concept is Java Servlets. Essentially, the same action is performed. The Servlet is loaded the first time its URL address is requested. Thereafter, it is not loaded or unloaded from memory; it is only executed. The observed performance difference is similar.

Mod_Perl is a pluggin to the Apache web server, which is similar to the above two approaches except that it is limited to CGI's developed using the Perl programming language. It has a similar performance improvement, but has two additional advantages:

1. It can over-ride any phase of the web server process. Effectively, you can use Mod_Perl to write customized authentication routines, URI-to-function mapping, and other useful functionality.
2. It embeds the Perl interpreter directly inside the Apache web server executable. This is beneficial for scalability on multi-processor machines because context switches are not required between phases of the web server. As well, actual Perl library and CGI script code caching is done so that code can be executed directly in internal memory without the need to load it from disk.

Because of its many advantages, Mod_Perl was used in the implementation of newer versions of the ACME system and is growing in popularity for large online systems.

With the use of Mod_Perl, cache items loaded from disk in one script can still be in the cache when the next script executes in the same web server process. This increases the effectiveness of caching, because files can be cached for an even longer period of time. This on its own increases the performance of a Mod_Perl application greatly.

System Scalability

Many online CGI systems are designed for a limited number of people; and are certainly not scalable to hundreds or even to thousands of users. The main problem with scalability is the lack of centralized data storage. When the load on a system becomes too high, it is often necessary to introduce multiple servers to split the load of the online system. The two most common ways to deal with multiple servers having to use shared data is to use databases or Remote Procedure Calls (RPC).

Databases offer the best way to implement shared data across multiple servers. They take care of all the synchronization and data can be accessed by standard SQL statements. The problem with databases is that often developers do not want to take the time to learn database specifics on top of the operating system and programming language. An alternative is to use the abstract concept of RPC on top of the operating TCP/IP layer. This approach allows creating a single RPC based data server on a dedicated server that all other CGI based systems can communicate with. The Data Server can compensate for speed lost due to network transfers by gaining performance from efficient caching of data structures. The disadvantage to this approach is the lack of standards to communicate with the data server and the efficiency lost due to data marshalling that is done internally by the RPC client and server. The data server can easily handle synchronization because of its unified nature. It also provides additional optimization by using threading without the need of forking "heavy-weight" processes to deal with each data request as servers typically do.

Conclusions

Because of many of the factors discussed in this paper, our own current choice of implementation is on a Unix system (production systems exist both on the Solaris and Linux operating systems), using the Apache web server with the Mod_Perl module, and RPC for distributed processing, though we are moving to a traditional Relational Database Management System (RDBMS) storage scheme.

To answer the requirements of a web-based enterprise solution, the methods discussed above, while not exhaustive, have been found to be very effective. Not surprisingly, many of the techniques for developing enterprise-wide WWW systems are very much the same as those used in traditional client/server application programming which tend to be ignored in WWW development: choice of language; choice of platform; design for performance; design for robustness; and design for scalability.

1 Introduction

With the increased availability of the Internet, personal computers and fast networks, there are many research efforts directed at teamwork, interactions, and in general, asynchronous and synchronous collaboration. The main focus of these efforts is to explore the possibility of fully integrating computers into the classroom, and not just on a single computer-per-classroom basis. Another reason for the interest in this research is the growing number of universities, which have built fully computerized campuses. For example, Acadia University, see [MacDougall et al. 1998, and Tomek et al. 1999] has been involved in building such a campus; it provides fast network connections for all students living on the campus as well as electronic classrooms (a setting in which every student and the teacher have access to a personal computer, and all the computers are networked see [Shneiderman et al 1995]), allowing for various types of computer-supported interaction. Computerization of a campus is a very expensive operation and it has to be proven to be cost effective. While hardware for the above initiative is readily available, there seems to be a lack of software that takes advantage of these hardware facilities and at the same time is known to be useful in learning and teaching. Groupware or computer-supported cooperative work (CSCW) refers to computer-based systems that provide an interface to a shared environment in order to support groups of people working towards a common goal, see [Grudin 1994, Norman 1996]. A related area, Collaborative Virtual Environments, CVEs is also getting a lot of interest, see for example [West et al 1998]. However, most CSCW systems do not support the creativity of a *group*, in particular they do not support procedures to achieve a goal or create a common plan. There is a significant difference between *cooperation* and *collaboration*. In a cooperative process, members of the group interact and exchange their individual ideas, and as a result, they come to understand each other. In a collaborative process, members of the group work together to *create* something new. The group can switch back and forth from one mode to the other. For more details of a group-thinking model, see [Nishimoto et al 1998].

This paper describes the design and implementation of a prototype environment, called a Shared Workspace in which information can be shared and acted on in collaboration with other users in an electronic classroom – a shared workspace as described in [Müldner & Nicholl 1996]. The system is built around a client-server architecture with the environment, called a workspace, supported by a server to which the client connects and with which the client interacts. Users can share files by making them available on their server for download by other users. Additionally, users may participate in multi-user editing sessions on files, where several users interact and negotiate with each other as they collaboratively edit a document. Each student in the electronic classroom is expected to have a computer on which a workspace resides; the instructor is also expected to maintain a workspace. Students can connect to other students' workspaces in order to share data and interact with each other. The file transfer facilities could be used in and out of the class to distribute course-related material from the instructor to the student, or to send assignments or solutions from the students to the instructor. Shared editing is useful in certain classroom interactions, particularly in situations where a piece of text, such as a block of program source code, is being discussed by the class. Here, we do not limit the scope of our discussion to "physical" classrooms in which the teacher and students share the same room; i.e. we consider both synchronous, face-to-face systems, and distributed asynchronous, virtual classrooms as used for example in distance education. In addition, we assume that each user can work on-line (connected to the network), or off-line.

This paper is organized as follows. Section 2 gives a general description of a distributed information system and introduces the basic terminology; and Section 3 discusses the Shared Workspace, and provides a brief description of the implementation. Finally, in Section 4, we describe our experience using SW.

2 Distributed Information Systems

A survey of the available literature for the term distributed information system (DIS) will likely turn up definitions ranging from distributed computation to distributed databases. On one end of the spectrum is distributed computation, where processing is distributed across multiple processors. Data is either distributed to optimise processing time, or is accessible as a shared resource [Booth 1981]. On the other end of the spectrum are distributed databases, in which the system consists of distributed data, with various services offered, which may or may not be distributed in nature. Both of these definitions require that the machines that do the processing or store the data are all connected by some kind of network.

A definition that seems to strike a middle ground is that a *distributed information system* is a system where information and functionality are distributed across multiple machines connected by a network. These systems are useful to us for various reasons. The most obvious one is that by summing the collective storage and computational power of multiple computers, we obtain a potentially more powerful system that can do the job of multiple computers. Additionally, with the duplication of resources the redundancy could mean that the failure of one component would not imply the failure of the system as a whole. Thus, distributed systems provide parallelism and fault tolerance, making them potentially much more powerful than their individual components [Mullender 1989].

2.1 Information Sharing

The most basic thing we want to be able to do is to exchange and share information. The system described above is similar to a Cooperative Information System, CIS, see [Papazoglou 1992]; but we do not assume any “intelligence” of the system; for example that it can actively reason about the information it contains and search for these pieces of information by connecting to other systems. Instead, we assume that the user takes this role. In addition, we consider only *homogenous* data sources; i.e. two information systems are assumed to be “similar”. In order to describe the above task (exchanging and sharing information), we consider two kinds of applications, here called respectively providers and fetchers. A *provider* application gives access to available information for authorized users; a *fetcher* application is designed to fetch or browse information from one or more providers. Typically, a provider is implemented as a server, and a fetcher as a client; for more information about clients and servers, see [Mullender 1989]. However, they can also be implemented using software agents, see [Huhns 1998]. Note that a single application may be both a provider (server) and a fetcher (client) at the same time, and that it can change its role, for example by switching from a providing mode to a fetching mode. The two modes described above; i.e. those of providing information and of fetching information may not be enough to provide satisfactory functionality; sometimes one would like to be notified when a certain event occurs. Thus, we add a *notification system*. A fetcher can request information in the event that it finds the required information is not available or it just wants to have up-to-date knowledge of the information system; for example when new information becomes available (addition notification) or is changed (change notification). This model is based on the concepts of “information pull”, where users are constantly trying to pull some information, and “information push”, where the system tries to push information. Note that information push systems may be profile-based, or context- and situation-based; see [Van de Velde et al. 1997]. Our model assumes that the users are active; i.e. they use the fetcher applications to obtain the required information. An alternative would be to consider active, autonomous providers, such as software agents, using planning to search for the required information; see [Huhns 1998].

It is not realistic to expect that the provider would like to make all its information available to all other users. Therefore, for each piece of information there is an associated list of users and their passwords, and the fetcher has to go through an authentication process before it can fetch information from the provider. A particular fetcher may have various permissions with regards to a piece of information; such as view, traverse, copy, or permissions related to notifications. To accommodate this process, groups of users can be created and specific permissions may be assigned to an entire group.

Probably the largest DIS in existence today, the World Wide Web (WWW) is a global network of servers, which distribute heterogeneous data to various clients. The Hyper-G system and its commercial successor,

Hyperwave, see [Maurer 1996] solve the structural problems of the WWW by using bi-directional links, and improve on coherence with a more structured method of composing information structures.

Is sharing data between users enough? Consider as an example a specific class for teaching programming in the C programming language, taking place in an electronic classroom. At the beginning of the class, the instructor (provider) makes available an example (a file) of a program in C to all students in the classroom. (As an alternative, the instructor may prepare several examples and divide students into groups by giving each group a different example.) Now, the students can download this file to their computers. They can view and modify this file, they can make new versions of this file and make these versions available to all students, or specific students. However, there is little real-time interaction in this activity; for example the instructor may wish to make a file available for viewing only (no downloading) and share the *execution* of a specific program (for example, an editor) with all students. Thus, the next section describes execution sharing.

2.2 Execution Sharing

Execution sharing is not the same as “distributed execution”, where various actions involved in the execution take place on different host computers. What we mean by *execution sharing* is a set of users (of networked computers) which simultaneously execute a single application (are involved in a session). Users can join and leave the session. Non-interactive applications are not very interesting; we are more interested in applications that interact with the user and require some form of input. Since a typical application accepts input from a single user, we will say a *controller* is the user who currently provides this input; and a *ghost* is any non-controller user that has a read-only view of the running application. Collaborative environments use a *floor control mechanism* in order to prevent contradictory events [Hilt and Geyer 1997]; hence a controller has control of the floor. When we consider a shared (in the sense of the above definition) editor, then we can easily convince ourselves that it is useful to have exactly one controller; otherwise simultaneous events may lead to confusion. However, for other applications it makes sense to consider multiple controllers; for example in a typical chat room every user is a controller. Now, who is the controller? To answer this question, let’s concentrate for a moment on the example of a shared editor. One may assume that the owner of a file is the controller; he or she would start an editing session while other users would be viewing the modifications on the edited file. There are two problems with the above definition. The first problem arises when the controller wants to pass the floor to another user (thereby giving up control of the floor); for example the instructor showing a C program may want to designate a student to remove syntax errors from the program. For this reason, we distinguish between the owner of resources involved in the execution (for example, files) and the controller of the session. The session is started by the owner, who at that time is also the controller of the session. Next, with each session we associate a token, which originally belongs to the owner and is always held by the controller. Note that the controller can pass the token to another user who then becomes the controller. Actually, one may consider different types of *token policies*; one type of a policy would force the user who gets it to later on return it to the provider; another type of a policy would allow the controller to pass the token on to another user. In any case, the owner of a token will have the right to revoke a token from the controller. Here, the owner of the token is the owner of the session. The second problem with the above definition is that while it may be satisfactory for synchronous sessions, it doesn’t provide the required functionality for asynchronous sessions. For example, consider a moderated discussion group and a moderator who is not currently available. The moderator may then wish to give all held privileges (including that of revoking) to another user. To solve both these problems, we assume that a token has various attributes, such as “permission to forward”. Now, let’s consider in more detail what passing a token to another user means. Logically speaking, another user starts controlling the application. One possible implementation would involve saving the state of the execution (data), and passing the entire application with this state to a new controller. This technique is used to implement software agents, see [Huhns 1998]. For applications such as editors, it is easy to save the state of the execution, because it does not involve saving the execution stack, and so can be accomplished even if the underlying language, such as Java, does not give access to the run time information. Finally, let’s describe how the controller makes a decision as to who gets a token. In a virtual world, there is a need for some type of communication associated with a shared session. For example, to allow the controller to ask: “Who is ready to correct a syntax error in this program?” and then make a decision based on a request list; i.e. a list of users who “raised their hands” (applied for control of the floor) to indicate their readiness.

Small DIS’s span only a few machines and perform more specialized functions. One such system is NetMeeting, see [Microsoft 1998], that attempts to support group activities by providing various forms of computer-aided communication, collaboration and data sharing functions. A simple file transfer facility also allows users to

share files. Unfortunately, NetMeeting provides a very rudimentary floor control and therefore is not useful for most CSCW applications. The shared workspace, described in more detail in the following chapters, contains a few elements from DIS's described above, but, like NetMeeting, is designed for smaller group interactions.

3 Shared Workspace

3.1 System Functionality

Shared Workspace (SW) is a centralized (residing on a single machine) information system, providing file transfers and shared editing services. Each user of SW is both a provider (server) and a fetcher (client); no notification system has been implemented. To the system, each user is identified by a username, with an associated password, used for authentication when a user attempts to fetch files from other users' workspaces. Each SW maintains its own list of (username, password) pairs. Users in SW move between file areas (described below) and interact with files and possibly other users as a result of file interactions.

For each file there is an access list of users that have permission to perform some operation on that file. By default, the owner of a file is a member of its access list. These access lists are an extra attribute imposed on the files already in the file system, and it is not presumed that all files on a file system will have an access list. Accordingly, when a file with no access list is accessed, it will be assigned the default list with the file's owner as its only member, meaning that only the owner of that file will have access to it. In order to make the file accessible to others, the owner will have to explicitly alter its access list. In order to facilitate provision of files that can be downloaded (fetched), we introduce a file area; a functional unordered collection of files. They are *functional* because file areas define the actions, which may be performed on a file area's contents. A file's access list is identical across file areas, implying that the same set of users will be able to perform the same set of actions on a file spanning multiple file areas. Actually, SW maintains two file areas: the 'download' area and the 'editable' area, and users are only allowed to directly transfer files from the download area, while only files in the editable area can be opened for editing. If a file is in the download area and the editable area at the same time, then it is downloadable and editable by the same set of users.

Each entity in a shared workspace is subject to restrictions on the actions which users may perform on it. Access restrictions are defined by ownership and access lists. The owner of an entity can alter its properties, e.g. access lists. By default, the creator of an entity is also its owner, but ownership may be passed to another user, or relinquished, meaning the entity would have no owner (in that case it is accessible at all levels to all users on the system). A user on an access list is not allowed to alter the entity's access list. The accessibility of an entity on the system can be defined in terms of ownership and access lists at three levels:

Accessibility	Owner	Access list
1. Full public	None	Empty
2. Restricted public	User	Empty
3. Restricted	User	Non-empty

If an entity's accessibility is full public, all users in the system may access the entity with no restrictions whatsoever. Once an entity has an owner, however, its accessibility is reduced to "restricted public", meaning that only the owner may alter the entity's properties, while other users may perform less sensitive operations on it, such as editing the entity if it is a file. Specifying an access list for an entity completely restricts the entity's accessibility, explicitly specifying the set of users that may perform non-sensitive operations on the entity.

3.2 Editing Sessions

SW provides asynchronous write access to a document through the use of a token-passing scheme. An editing session may be created by any user who is a member of the access list of a file in an editable area. Subsequent users who enter that file area may join a running editing session, provided they are also members of the relevant file's access list. The controller role is defined in a session, and the role is filled by a user, who is, by default, the creator of the session. The role of the controller is not restricted to the creator of the session, and the current controller may pass the role to other users. A controller is responsible for the following operations in the session: closing the session, choosing a token-passing policy, revoking the token, and passing the role of controller to another user. A token is associated with an editing session in order to control access to the document being edited. A user must possess the token in order to make changes to the document. After the desired changes have been made, the user

may relinquish the token under the rules of the current token-passing policy. The following policies are currently available:

- Return-on-completion: The user returns the token to the controller upon completion
- User-choice: The user passes the token to another user (of their choice) upon completion
- Open-choice: Upon completion, the token is open for any user to take.

Additionally, the controller may revoke the token at any time during the session. The file being edited may be saved locally on a user's machine during the course of an editing session. Only the owner of the file may permanently alter the original file being edited. This is accomplished by locally saving the file over the original file; essentially replacing the original with the newly edited version. It is difficult to perform any collaborative activity without communication, so a chat area is created as part of the editing session. This chat area functions much like channels in the Internet Relay Chart (IRC); members of the editing session post messages to the chat area, which is seen by all members of the session. Additionally, users may 'whisper' to each other, i.e. send a message directly from one user to another.

A screen dump shown below demonstrates an editing session in which the root is the controller, the current token policy is "return-to-controller". Mary is the user presented with the edit window with the text area disabled (gray), as she does not have the edit token:

The implementation is based on Java Remote Method Invocation (RMI), see [Sun Microsystems 1997], which provides a semi-transparent means for clients to access remote objects. The use of the Common Object Request Broker Architecture (CORBA), see [Object Management Group 1998] was considered as an alternative to RMI during design, but Java's built-in support for RMI provided an easier implementation. In an environment such as Acadia University, where the majority of students use laptop computers, special problems occur. A laptop computer is assigned a dynamic IP address on the network, which changes as the computer is moved from one network subnet to another. The solution implemented was to mimic a domain naming service, by providing a simplified Java RMI based naming service that maps user-defined names to dynamic IP addresses. A workspace, when first created, registers a user-defined name with the naming service, which is run on a computer with a static IP address. Subsequently, when the workspace server is activated, it must inform the naming service of its current dynamic IP address. When a server goes off-line, it informs the naming service as well. The shared editor described is implemented using the Java Shared Data Toolkit (JSDT), see [Sun Microsystems 1998] which defines a simple collaborative toolkit providing support for session-based collaboration.

4 Conclusions and Future Work

An evaluation of the usefulness of SW in electronic classrooms (its target audience) reveals deficiencies and issues at several levels, including the file system, shared editor, and distribution strategy. While the shared editor in general

is useful in a classroom setting, its chat function, if used, could hinder interaction. Imagine an entire room of students sitting in a room staring at their screens, and not paying any attention to the instructor, since all communication is handled through software! The problem arises, of course, of trying to attract the instructor's attention while he or she is busy typing into the editor. Using a chat function in such a situation might seem justified (particularly for a virtual classroom), but this problem is no different from that of an instructor writing on a blackboard with his or her back turned to the class. Hence, the chat function is only useful in the context of a virtual classroom.

The distribution strategy used in SW requires that all users be clients and/or servers. In order for a file to be transferred from one user to another, the sender must be a server, while the recipient must be a client. A totally connected system is thus impractical, since it would require n^2 connections, where n is the number of users. The simplest scheme that might be of use in a classroom would be that of the instructor's computer acting as the only server for all the students in the classroom during the duration of a class, but this lacks flexibility in the event that students need to transfer files amongst one another, which may be required in group work. The setup and possible teardown of client-server connections between students in a group at the start of each meeting would be tedious at best.

1 Introduction

Maintenance of student assignments is an important part of everyday routine of all instructors. Traditionally, assignments are prepared by an instructor in paper form, and then given to students. When student solutions are collected, they are given to markers who upon marking update student mark files and return marked assignments to students. With the advent of computerized campuses, there have been various attempts to use computers to automate some of the tasks described above. In this paper we describe a general, integrated, and Distributed Marking System, DMS which can be used to post assignment descriptions and submit solutions, mark solutions using specialized marker tools, and maintain student marks using a file system or database. Our main goal was to design a system which is user friendly, distributed, and extensible. For a system to be user friendly, our design uses specialized graphical user interfaces, GUIs. These GUIs are custom made for various kinds of users; and will appear different for students, markers and instructors. DMS consists of a server and a number of clients, and is fully distributed so that users can connect from networked computers. However, DMS supports not only pulling information such as an assignment outline, and online access such as displaying marks or outlines but also pushing information on to a client's machine so that she or he can work off-line (for example, to mark an assignment, the marker does not have to be connected to the network). Off-line work is particularly useful if the system is flexible and extensible; for example a marker should be able to use various specialized marking tools, implemented in different programming languages. We do not wish to limit ourselves to specific hardware or an operating system; for example we want to be able to accommodate a student who uses Unix on a PC, and a marker using a Macintosh. For this reason, we are using Common Object Request Broker Architecture, CORBA that extends the reach of our applications across networks, languages, component boundaries, and operating systems, (see [Object Management Group 1998]). While the current version has been written in Java (see [Sun Microsystems 1998]), any client or even the entire server could be written in any programming language, for example C++ or Smalltalk, and run under any operating system on various hardware platforms.

Why have we chosen Java rather than another language? A standard web browser is extended with a Java runtime, and it can automatically download an applet to the user's host computer and execute it there. This feature provides a simple and flexible mechanism for transferring executable software to users when it is actually needed, instead of installing it at their host or site ahead of time. Therefore WWW infrastructure and Java applets can simplify the job of deploying the user client components of a distributed application; something hardly possible with other languages; see: <http://www.arlut.utexas.edu/~itgwww/ird/JavaCORBA.html>.

Since maintenance of student files is an important part of any marking system, we designed a flexible interface that can be used to store marks, users, courses and assignment information in a file system, or through Java Data Base Connection, JDBC in practically any available data base. Therefore, DMS is designed as a 3-tier application where we have a thin-client, middleware and a database.

Clearly, only authenticated users should be allowed to use a marking system. Therefore, a "super-user", who creates student, marker and instructor password-protected accounts, administers DMS.

Other available marking systems, for example the one described in [Pillaipakkamatt, Wilkins 1998], do not provide the same functionality, flexibility and extendibility. For example, the latter system does not support off-line activities, or use of arbitrary implementation programming languages.

The rest of this paper is organized as follows. Section 2 describes assignment maintenance; Section 3 shows interfaces for various users, and Section 4 briefly describes the design and the implementation. Finally, Section 5 discusses future extensions.

2 Assignment Maintenance

DMS provides one central server, and a number of clients (see below). Let's first identify the basic activities in the assignment maintenance process, as well as actors involved in this process:

Hand-out: Assignment outline is provided by the *instructor*

Hand-in: Assignment solution is provided by every *student*

Marking: Assignment solutions are marked by the *marker*

Return: Marked solutions are returned by the marker to students.

Since every user involved must be properly authenticated by the system, she or he has a password-protected account, and therefore we provide one more type of an actor; a *super-user* who is the only user allowed to create, modify and remove accounts. Since there are four types of actors, we have four types of client applications. For a hand-out activity, the assignment outline is uploaded to the DMS server, and it is downloaded from the server to the student's machine. For a hand-in activity, an assignment solution is uploaded by the student to the server, and downloaded by the marker from the server. For a return activity, marked assignments are uploaded by the marker to the server, and then they can be downloaded by the student. (See below for detailed descriptions of different actor interfaces.) Note that the network connections are minimized, and used only when necessary. As soon as the process of uploading or downloading is completed, the user can work off-line.; in particular, the marking activity requires no network connection.

Every actor can communicate with DMS through what we call here a dms-let, which can appear in one of two ways; as a Java applet (dms-applet) or as a Java application (dms-application). Therefore, there are four types of dms-lets, one for each type of an actor; and every dms-let can be an applet or an application. Using an applet the actor merely requires a web browser and does not have to go through the installation process. However, in some cases this applet has to be able to access the user's file system. For example, the student's dms-applet has to write to the student's machine when an assignment outline is to be downloaded; and it has to read from the file system when an assignment solution is to be uploaded. Therefore, we use digitally signed applets, see [Java Applet Security 1998], which provide a secure way of giving applets access to the local machine file system. Unfortunately, with signed applets client start-up is slow, since every time all of the client applet classes need to be downloaded from the WWW server, and so the user may choose instead to use a dms-application; see [Fig. 1]. DMS provides a convenient way of deploying dms-applications; which requires a single step using any browser to point to the DMS home page, download this application and install it on her or his machine. In addition, the design described above allows for easy updates of any dms-application; update is transparent for dms-applets, and the dms-application user connecting to the DMS server can be informed that she or he should download the newer version of this application.

3 Interfaces

3.1 Super-User

The super user can carry out the following activities; see [Fig. 2]:

- create, delete and modify user (instructor, marker or student) accounts
- create, delete and modify course accounts
- register and drop courses to and from user accounts.
- set client connection time to limit server overload
- purge or archive old submissions and limit file sizes for submissions.

Courses may be taught by more than one instructor or marker. The super user assigns instructors to courses. Markers are initially assigned by the super user but instructors can modify them at any time.

Figure 1: Deploying a Marker dms-application.

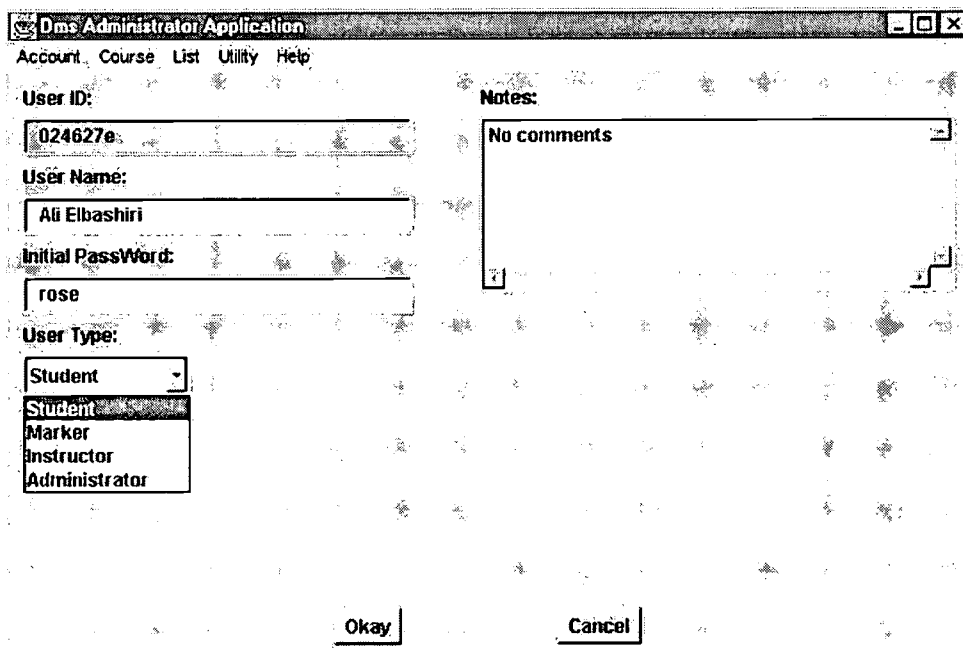

Figure 2: Super user maintains user accounts.

3.2 Instructor

The instructor can prepare an assignment description off-line or on-line; see [Fig. 3]. Assignment descriptions must be loaded in a text format so that it can be viewed on-line on the user GUI text area. To prevent instructors from

uploading files that are not in text format, we limited their off-line option, and only a cut/paste technique for uploading assignment descriptions can be used.

Figure 3: Instructor submits the assignment description.

3.3 Marker

Marker downloading assignment solutions is shown in [Fig. 4]. The left-hand side column is generated based on courses currently marked by this marker. Once a specific course is selected (MATH 1423 X1), the description of this course appears in the center column, and those assignments for this course appear in the right-hand column. A specific assignment can be chosen by selecting it (Assignment 02 above); a brief information about this assignment is appended to the central column. The Download menu provides two items, used respectively to download assignment outlines, and some or all assignment solutions.

Marker can not download solutions that have already been downloaded. Courses may have more than one marker so it is left to the markers to divide the solutions among them. Solutions will be saved in the marker drive as a tree-like structure, starting with root directory (the course name), student name and the assignment name.

Once the assignment solutions are downloaded, the marker can disconnect from the network and at her or his convenience, and mark assignments off-line. For this sake, specialized marking software can be used (not available as a part of the current version of DMS). For example, a single programming assignment in C may consist of many files, but is submitted as a single jar file. This file will include the "packing information"; for example, under Unix it may be required that the assignment source files come with the make program. This packing information and other specifications can be specified for each assignment by the instructor and be available for the marker to download as a text file. Therefore, we need a *preprocessor* that retrieves and accordingly unpacks the assignment (for the above Unix scenario, it will use make to create executable code). The preprocessor may also run the executable code against test input data, if provided, and inform the marker about the results of these runs. Then, an editor would allow the marker to choose a course to mark, and then move from one solution to another by simply selecting a menu item. Marks are automatically maintained and stored in a form suitable for upload to the DMS server. A menu item provides standard deductions that can be customized for each assignment (for example, -10% for wrong indentation). The marker can annotate the student's solution using appropriate comments.

Figure 4: Marker's GUI.

When marking is completed, the marker moves to the next solution, and the editor saves the annotated solution along with the mark. Then, when the marker uploads the assignments to the DMS server, the annotated solution and the mark become available to the students, and additionally the mark is saved in a central repository on the server. Markers can upload marked solutions the same way as they download solutions; and specify the location of the root directory. The system will automatically upload all marked solutions and show them in a separate window for submission.

3.4 Student

The student's GUI shown in [Fig. 5] looks somewhat similar to the marker's GUI, but provides slightly different functionality. Specifically, the student can download assignment outlines, marked assignments or marks. Student also can view marks or outlines on-line; and she or he can submit an assignment solution. Note that the student is allowed to submit late assignments (it is left to the marker and the instructor to deal with this problem), but is not allowed to submit the same assignment more than once.

4 System Architecture and Implementation

DMS consists of the server and four client types. It has been implemented using CORBA, specifically OrbixWeb, see [Iona Technologies 1998]. The server maintains various persistent data, such as account information, assignment descriptions, marked assignments, and student marks. In order to allow different storage mechanisms, DMS provides clearly defined interfaces, which can be used to configure it with a file system or through JDBC with any database. Note that because of this approach all back-up and clean-up operations can be performed by this DMS and are transparent to the user. Currently, the server and each client is implemented in Java; both as an applet and as an application.

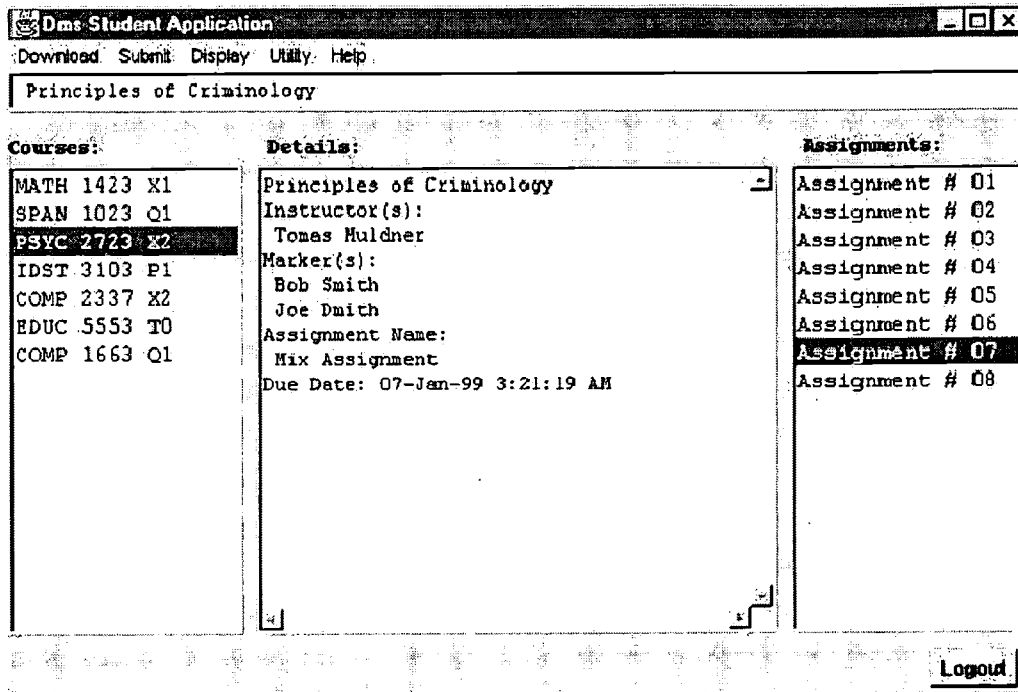

Figure 5: Student GUI

5 Future Extensions

Currently the server generates a transient object for each client connection. These objects stay alive as long as the server is alive, but in the future version they could be used to keep track of client connections and to send notifications to users. For example, students could be notified when their assignments are marked. Additionally, these objects could also be used to manipulate the server dynamically, and allow super users to monitor the server and disconnect or limit client connections.

Acknowledgements

Most of the work described in this paper has been done as a part of the Masters thesis written by the second author of this paper. JDBC connection has been implemented by William Wightman.

Periodic Polling for Web Cache Consistency

Abstract: As the size of proxy cache increases, the lifetime of objects in the cache would increase. If the objects in the cache were to be stored for a long time without checking its validity, the number of stale documents would also increase. The idle network bandwidth can be used for proxy cache consistency maintenance. We propose the selection algorithm that can be used in periodic polling mechanism for the consistency maintenance of proxy cache server.

1. Introduction

As the World-Wide-Web continues its remarkable exponential growth, proxy cache size must increase to store more objects. If the size of proxy cache increases, the hit ratio of the proxy would be higher and the lifetime of the object in the cache would increase. The longer documents stay in the cache without checking their consistency, the higher is the probability that they are stale. The current HTTP protocol provides two mechanisms for cache consistency. One is a 'time-to-live(TTL)' field, which is the a priori estimate of how long a document would remain unchanged. However, in most cases, the web servers do not provide the time-to-live field. The other is a mechanism which adapts the fact that each client can send an 'If-Modified-Since(IMS)' request to the Web server. Upon receiving this request, the server checks whether the document has been modified posterior to the timestamp. If it was modified, the server returns the new object.

2. Related Work

There are several mechanisms to maintain cache consistency: time-to-live (TTL), adaptive TTL, invalidation protocols and client-polling mechanism. TTL is an expiration-based protocol. TTL mechanism is only useful when server sends TTL fields with attached document headers to the proxy server, but this is a rare case. Adaptive TTL mechanism is also a derivative of client-polling mechanism. Adaptive TTL mechanism uses an update threshold to determine how frequently polling to the server should be performed.[Gwertzman & Seltzer 1996] Both TTL and adaptive TTL does not guarantee strong consistency. Invalidation protocol supports strong consistency, but it is too expensive because the server must keep track of the data and it should notify the copy is stale when it changes the document.[Cao & Liu 1997][Gwertzman & Seltzer 1996] Polling-every-time is another derivative of the client polling mechanism. When a client requests a document that is in proxy cache, polling-every-time mechanism sends If-Modified-Since (IMS) requests to the server. This mechanism is also expensive. Invalidation protocol and polling-every-time mechanism does not seem to be adequate for general purpose. Gwertzman and Seltzer's paper concluded that a weak-consistency approach such as adaptive TTL, would be best for Web caching.[Gwertzman & Seltzer 1996]

3. Periodic polling

By observing the log-file of the proxy server, the existence of some periods at which only the half of

network bandwidth is used could be found. [Fig. 1] shows the network traffic of the KREN¹ proxy server.

Figure 1: Network traffic of the KREN proxy server (1998.9)

At its peak time, the traffic is four times heavier than at night. We can utilize this idle network bandwidth for the consistency of proxy cache. Periodic update policy is a technique that periodically updates all documents using idle network bandwidth. Periodic polling can cooperate with adaptive TTL policy without much modification. Periodic update policy guarantees 'no more stale than the predetermined time interval' and better consistency than the adaptive TTL alone. Two decisions for periodic update policy should be made - When to update, and what to update [Kim & Chon 1998]

[Fig. 1] implies that early morning is a great time to replace stale documents for new ones. At day, idle network bandwidth does not seem to be available. If we update all documents stored in the cache every morning, this policy guarantees 'no more stale than 1 day'. We have no choice but to set the period to 24 hours for updating stale documents

3.1 Least Recently Used algorithm

Squid proxy server saves the following meta information of the documents in the cache. - validated_time, used_time and modified_time. Validated_time is the time when a proxy server confirms that the document is valid, sending an If-Modified-Since request to Web server. Used_time is the time when a client requests the document. Modified_time is the time when the document is created or modified in the Web server.

The old documents may be stale, so we would rather prefetch older documents than newer ones. [Abrams et al. 1995] LRU algorithm selects the document with the least validated_time, so we check the validness of document as following priority.

$$prefetch_priority = \frac{1}{validated_time}$$

3.2 Last-Modified-Factor algorithm

The consistency mechanism of the squid proxy is an adaptive TTL policy that uses the LMF algorithm. If the age of a document is greater than the max threshold time value, squid proxy considers it invalid, but if the age of a document is younger than the min threshold time value, squid proxy considers it fresh. If the age is between the min and max threshold, the squid proxy uses the LMF algorithm. Last-modified-factor is defined as:

$$LMF = \frac{current_time - validated_time}{validated_time - modified_time}$$

Figure 2: Last-Modified-Factor algorithm

[1] Korean Education Network

[Fig. 2] shows how this algorithm works. If the LMF is high, a document had been modified and soon it was fetched and stored in the proxy cache and its validity has not been checked for a long time. That document's validity is more doubtful than the one of which LMF is low. In the LMF algorithm, we define the prefetch priority as :

$$prefetch_priority = LMF$$

3.3 Weighted-Last-Modified-Factor algorithm

Squid proxy checks the validness of a document using the LMF algorithm only when a client requests it. It does not consider the probability that a document will be requested again by a client. If a document is stale and it is not to be used again, prefetching that document is of no use, and loads useless network overhead. WLMF algorithm considers that the probability that a document will be requested again and whether it is stale or valid.

LRU algorithm is used in the replacement mechanism because probably old documents won't be requested again. High validated_time of a document in the cache means that it will be requested again.

A document that has high LMF value and low validated_time may be stale but won't be used in the future. Periodic update policy doesn't need to prefetch this kind of documents. We should select candidates that is stale, but will be requested in the near future. In the WLMF algorithm, a document that has high LMF value and high validated_time also has high prefetch priority. Weighted-last-modified-factor is defined as:

$$WLMF = validated_time \times \frac{current_time - validated_time}{validated_time - modified_time}$$

4. Simulation Environment

We use the KREN squid proxy access log and store log to simulate the content of a proxy cache. The size of KREN proxy is 12G bytes and it stores roughly 500,000 objects in the cache. With the meta information of squid proxy, we can simulate which documents are to be requested and stored in the cache at a specific time.

Figure 3: Distribution of validated_times in KREN proxy on 1998.9.15

[Fig. 3] shows the distribution of validated_times in KREN proxy on 1998.9.15. [Fig. 3] implies that the lifetime of a document in KREN proxy cache is only 15 days. Therefore, 15 days store log is enough to simulate the content of proxy cache. We simulate with 5 days huge store log of KREN proxy from 1998.11.1 to 1998.11.5. [Fig. 3] shows that recent 5 day store log can simulate 50% of the content of the proxy cache.

Periodic update policy selects documents and sends If-Modified-Since requests to servers at night. The more a proxy receives TCP_REFRESH_MISS reply codes, the more it selects the stale documents, because the TCP_REFRESH_MISS means that a requested document is modified. The reply code is recorded in an access log file. We selected doubtful documents from simulated proxy cache using LRU, LMF, WLMF and random selection. With the access log file of the next day, we counted the number of TCP_REFRESH_MISS events, of which URLs are same with the candidates' one.

5. Simulation Result

[Fig. 4] shows the results of the simulation. WLMF algorithm shows the best performance. WLMF algorithm was better than the LMF algorithm. This result tells us that not only the staleness, but also recentness plays an important role in periodic update policy. Two factors of WLMF algorithm are in opposition, but they cooperate so well for the maintenance of cache consistency.

Figure 4: Simulation results

When we selected documents using the WLMF algorithm, about 5% of candidates had been modified and referenced after the day when we chose the doubtful documents. Among the documents selected by WLMF algorithm, about 13% documents were referenced on the next day. When we checked these 13% documents, about 20% of checked ones got the reply code - TCP_REFRESH_MISS and other 80% got the reply code - TCP_REFRESH_HIT.

LRU algorithm shows worse performance than random selection. The documents that we selected using LRU algorithm were in request not so much as random selection, so the total number of TCP_REFRESH_MISS is the lowest.

We simulated with only 5 days log. If we simulated using the 15 days log, LMF algorithm would select candidates that have high LMF but low validated_time. In the worst case, validated_time of selected candidates would be 15 days earlier. They would not be requested and WLMF wouldn't select those documents and the difference of performance between LMF and WLMF would be larger.

6. Conclusion

Many proxy cache consistency mechanisms were discussed in this research, But the World Wide Web is already used universally, so it is very hard to modify the structure to maintain strong cache consistency. In this paper, we propose to combine adaptive TTL policy with the periodic polling mechanism. Periodic polling mechanism brings acceptable degree of cache consistency. We can use the periodic polling mechanism without much modification of the original structure, and it does not load much overhead to network bandwidth. We showed that periodic polling using the 24 hours period is reasonable and the new mechanism to select stale documents is necessary.

Implementation Of School-Based Web Pages In California: Challenges for School Administrators

Maria Natera-Riles, Maria Medrano, and Walt Hale, School of Education, National University, Sacramento, California. Tel: 916-855-4314, mnatera@nunic.nu.edu

Abstract: Global cooperative on-line communication manifests itself in international exchanges, electronic pen pals and other collaborative projects in California K-12 schools. Contacts by students with countries such as England, Israel, Sweden and others enriched students' experiences especially in the areas of social studies and science. This paper highlights the impact of the use of school web pages. The results of the study reveal the potential power of school web pages when appropriately managed. Two major challenges cited by administrators were concerned with the management and supervision issues revolving around student safety and the severe financial impact of the technology commitment.

Introduction

In recent times, much has been written about the use of the internet and the need for schools to be connected. This interest was underscored in the President's Educational Technology Initiative which emphasizes that American classrooms should be connected to one another and to the outside world. [President's Technology Initiative 99] The idea that all school children could be put on the internet sounds intriguing but some educators have wondered if it is just another fad. A recent study indicates that 81.8 percent of K-12 schools are connected to the Internet. The study, which was conducted by the research firm Quality Education Data [QED 98], projects that 95.9 percent of public schools will be linked to the Internet by the end of the 1998-1999 school year. According to the survey, 34.2 percent of the nation's classrooms have direct Internet access. (QED 99) While connectivity to individual classrooms is yet at a developing stage, a recent study conducted by Dr. Maria Natera-Riles, National University, found that concerns and caveats have surfaced which school administrators need to address. [Natera-Riles, 97] This paper presents implications, challenges and recommendations on the implementation of school-based web pages for K-12 schools.

According to a recent survey (1998) commissioned by AT&T Capital Corp., respondents from school districts throughout the country believe technology is a critical factor in equipping students with the skills and knowledge necessary to succeed in the 21st century. Seventy-five percent of survey respondents (school administrators, technology planners, and funding decision-makers) rank technology needs as a top priority in the years ahead. The survey also revealed that a whopping 97% of school districts have a technology plan. However, four out of ten schools indicated a lack of financial resources to implement these plans. Schools in the Upper Midwest and South demonstrated a higher than average technology funding, while schools in the East lagged behind. It is estimated that schools will require approximately \$335 per student for the next three years to keep up with technology changes. The survey drew from a national sample of large, medium, and small K-12 school districts. [ATT 98]

With the introduction of the WWW the power and simplicity of the notion that a document could contain within it the name of another document and that you could go get it changed everything. [Natera-Riles 97] The most common use of internet heretofore had been the researching of materials and investigating informational sites. More and more schools are now developing web pages and publishing student work and information that can be shared throughout the world. The exchange of ideas, curriculum and collaborative research opportunities speaks to the interest of students and school personnel to encompass global information into the life of the classroom. Unlike so many previous educational "innovation" and fads promoted by educational "experts," regular teachers who have tested these waters are becoming convinced that the Web will indeed be one of those rare technologies that will have a true transformational impact on learning both in and out of school. [GSN 97]

The Web66 Registry of Educational Sites at the University of Minnesota maintains the most comprehensive list of K12 school sites on the internet. At the end of May, 1997 it listed over 8000 sites in 35 countries. The growth has

been explosive since January of 1995 growing from a handful to over 8000. [Gass 97] Given the current trends to connect our nations' schools, it is expected that this phenomenon will accelerate.

Importance of the Study

The study has implications for educational leadership at the preservice and inservice levels regarding implementation strategies and effectiveness of the use of the World Wide Web in the school communities. While there may be barriers in accessing information, these barriers will begin to crumble as schools continue to join the WWW as information providers and users. This growth and expansion of web pages for individual school districts will expand the information and factual data available to students and professionals in education. This new knowledge base has resulted in new instructional units being added to university courses. The results should encourage continued investigation of implementation challenges for school administrators in order to ensure safe and academically appropriate usage of the WWW.

Purpose

The purpose of the study was to identify schools that utilize web pages, and survey administrators on their implementation strategies. The survey results identified such areas as: a. the variety of strategies used by schools to design and evaluate web-based projects b. cooperative global student activities c. administrative concerns d. academic achievement of diverse populations, e. selected demographics.

A further purpose of this investigation was to find answers to such questions as: 1. Do school administrators report concerns regarding safety issues? 2. How does an administrator help learners design and evaluate Web-based projects? 3. What risks have administrators taken and/or are willing to take to help students and teachers use this Web information to master academic tasks? 4. Do administrators encourage school-based Web pages to share tools for developing better communication with parents? 5. How do administrators help web learners to participate in cooperative on-line projects with other schools globally? 6. Do administrators see evidence that technology is changing the way teachers think and students learn? 7. Do school administrators report that the web facilitates academic achievement of students from diverse racial, ethnic, and social class groups?

Review of Literature

School-based web sites are so new for most schools, yet there are plenty of resources to identify the schools, and in some instances to help them with the development of their home pages. Several locations that identify school-based web pages were studied. These locations included Web 66, Global School Net Foundation, California Department of Education, and California County Offices of Education. In California there are 920 schools, comprised of 429 elementary schools and 491 secondary schools on the Web. The registered schools in California went from 376 to 920 in one year.[Web 66 97]

School administrators and teachers are looking at the WWW implementation strategies and its impact on students. "Examples of good practice in classrooms linked to "cyberspace" can be found: students joining astronauts as they circle the globe, piloting robotic submarines or photographing the Sahara without ever leaving the classroom. [NCES13 96] To go on even further, students can now communicate through their own publications.

Classrooms linked to cyberspace have also produced concerns of various sorts for administrators from emailed obscene writings to the horrendous expense of technology as budgetary constraints continue to plague schools. In this age of accountability, school administrators find themselves thinking twice about large expenditures in this era of raising test scores, and funding programs that may or may not succeed. Administrators face close scrutiny at every step.[Keller 96] Adding to this pressure is the issue of student safety and the use of the internet. Educational leaders must find creative and practical ways to address concerns with student emotional, physical and academic safety at school and in cyberspace.

The increasing number of schools with home pages, has encouraged the collaboration, communication, and exchanging of information. Educators and students can and do design successful collaborative projects involving hundreds of classrooms and thousands of students. Creative usage of the WWW is a pervasive and consequential instructional force to be mastered and studied critically in this global transformation process.

Students can explore the cultural diversity of their own community and extend it to include the global community. When teachers and their students are connected to the world, there begins to be an understanding, appreciation and respect for cultural, political, environmental, geographic and linguistic similarities and differences. [NCES13 96] On-line chatting sessions can be made available for bilingual/translated exchanges. As students learn more about themselves and others they are more prolific and exact in their writings and more interested in researching and exchanging ideas.[Andres 98]

Transformation change appears to be occurring as teachers and students become involved in the creation of cyber communities. Teachers report that this is not just one more fad.

Research Methodology

The research methods consisted of surveying selected administrators and/or webmasters of K-12 schools with web pages. The procedure involved researching registry sites such as Web 66, Global House and county offices of education. Followed by a random selection of 120 sites. The next step was to identify the administrator or designee email addresses for the survey. The National University MIS Department(Management Information Service) provided assistance at the server level by programming CGI(Common Gateway Interface) capabilities for data gathering and tabulation. The lead researcher, received a small university presidential award to conduct this study.

The study was limited to California K-12 schools. The schools selected were comprised of elementary, middle schools, and high schools. Fourteen surveys were completed and returned. While the district response expanded the number of schools surveyed to more schools, site administrators from the districts did not participate. This study replicates an investigation expanding the geographical area in California and the number of school.[Natera-Riles 97]

Results of the Study

The most important findings of this research regarding the implementation of school-based web pages is the enthusiasm of principals and other webmasters for cooperative on-line projects with other schools, administrators see evidence that technology is changing the way teachers think and students learn, and that 13 of 14 schools responding reported a believe that on-line experiences facilitate academic achievement of students from racial, ethnic, and social class groups. Schools identified sharing papers and historical research topics with a school in England and may be doing one with a school in Thailand; electronic pen pals; e-mail collaborations with schools in other countries such as Israel and Sweden; maintenance of listservs and ensure that network connectivity is provided Wild Ones through Columbia University; weather observations and cultural exchanges. All but one respondent indicated an interest in using the web for cooperative and on-going research.

Implications, Challenges and Recommendations

The purpose of the study was to identify schools that utilized web pages, and survey administrators on their implementation strategies. The survey results identified such areas as: a. the variety of strategies used by schools to design and evaluate web-based projects, b. cooperative global student activities, c. administrative concerns, d. academic achievement of diverse populations, e. selected demographics.

The administrators were surveyed by e-mail. The survey responses, however limited, produced some information and concerns about the implementation of school-based web pages. As districts and individual schools become more proficient in the use of school web pages, the resulting web page design and information included become more sophisticated. Of significant note is the finding that although increasing numbers of schools are utilizing web pages, no evaluation of the implementation strategies was reported. However, a variety of activities including administrative leadership and support such as familiarizing teachers with: the web, content, eye catching subject areas, templates, latest research, and professional help with web design as they start to feel comfortable. Administrative support at the site level is more evident at the elementary level. Elementary principals appear to be more actively involved in the implementation of technology and on-line curricular activities, but evaluative strategies are lacking.

Of the individual schools responding to the survey only one did not report participation in cooperative on-line projects with other schools and agencies. Examples of cooperative on-line participation included: international exchanges, electronic pen pals, weather observations, historical research topics with England and Thailand, collaborative projects with countries such as Israel and Sweden in the areas of social studies and science, maintenance of listservs, NASA, and projects with universities such as the "Wild Ones". Schools are finding that the curriculum can be enhanced by the use of the web in cooperative projects. There is evidence that through cooperative global exchanges the students are becoming more aware of geography and the scientific process of research.

Concerns involving administrative risks for student safety and tech budgets were also significant. Schools shared some ideas on the handling of administrative risks that included the following: not publishing pictures of students, warning teachers about some of the unsavory or misinformation on the web, developing a "fail-safe" grouped, annotated list of resource sites that the administrators have personally visited. Other risks reported included the severe expense of the technological commitment.

However, it is important to note a large majority of the schools reported a belief that on-line experiences facilitate academic achievement of students from diverse racial, ethnic, and social class groups. This view is underscored by the reported numbers of schools that have fully translated web pages in Spanish. Reported implications indicate that: fair technology deployment has the potential for leveling equity.

Demographics reported of significance included: Thirteen of the respondents were males and there was one female. The respondents included 6 Principals, 5 teachers, and 3 web masters. It appears that more males are involved in the leadership role in the utilization of web pages. It is recommended that: 1. Follow-up studies be conducted to include a larger sample of schools throughout the nation. 2. Increase federal, state and local funding be appropriated for encouraged participation in the following areas: a. cooperative on-line projects, promote interchange with diverse population within the country and globally. 3. Continue to improve communications with local parents and communities with translations of the school-based web page to significant language or languages at the local community. 4. Provide guidelines for those that are implementing web page strategies to insure student safety. 5. Develop evaluation procedures for web page strategies. 6. Female faculty be encouraged to participate in technology. 7. School administrators at all levels be pre-serviced and inserviced to become proficient in the development of school-based web pages and to provide faculty support for web site usage.

A Guide to Moving Language-Learning Curriculum onto the Internet

Brian Nelson

University of Aizu, Tsuruga, Ikki-machi, Aizuwakamatsu, Japan 965-80
Tel: 81-242-37-2587, Fax: 81-242-37-2599, E-mail: brian@u-aizu.ac.jp

Abstract: Moving traditional, paper-based language curriculum to the World Wide Web requires more than a simple transfer from the physical to the electronic. This paper explores the steps to consider taking before creating web-based language learning activities, using the task of teaching new English vocabulary to Japanese students as an example. It begins with an examination of the pedagogical shape of the sample task, identifying the components that make it up. Next, the paper examines the symbolic fit of the task into the functional shape of the Internet. Then, it explains how to sculpt the activity, adding functionality drawn from the capabilities of the WWW. Finally, the paper describes a web-based vocabulary activity that has been built based on the steps explored.

1. Introduction: Square pegs in round holes

Teachers used to shy away from bringing new technology into the classroom. From 'the school of the air' radio programs in the 40's and 50's to educational television, new technologies have not been welcomed whole-heartedly by educators. [Oppenheimer, 1997] Now, along comes the Internet, or more specifically, the World Wide Web, and attitudes seem to be changing. Teachers are embracing the Web as an educational tool. [Oppenheimer, 1997; Fidelman, 1998] The last few years have seen an explosion of interest in using web-based curriculum to enhance education. However, as with those earlier technologies, the move to the web has been somewhat disappointing. Aside from the technical problems (slow connection speed, buggy applications, crashing machines), web-based education experiments have leaned toward the cute, the colorful, and the pedagogically weak.

The problem may lay in the direction from which use of the Internet is approached. I recently spent an enjoyable evening watching my 18-month-old nephew play with wooden blocks of various shapes. The idea was to put the blocks into holes of matching shape, the star-shaped block into the star-shaped hole, the square with the square. But he didn't care much for the rules of the game, preferring to try and jam any given block into any hole on the board. The insertion of curriculum into the WWW has taken a similar tack. Many teachers, myself included, have been trying to force traditional courseware onto the Internet, regardless of how well it fits. It is time to stop for a minute, step back, and examine the shape of both our own curriculum and the WWW. How does the shape of what we want to do fit?

In this paper, I will start with a basic task, teaching new English vocabulary to Japanese students. I will examine the pedagogical shape of the task, and see how it fits into the WWW "hole." Next, I will look at the shape of the Web, examining what capabilities the WWW has that might be used to add to the effectiveness of the vocabulary activity. Finally, I will describe a web-based activity that has been built based on the steps explored in the paper.

2. Defining the shape of the learning task

There are two ways to learn new vocabulary: implicitly or explicitly. With implicit learning, students pick up new words as a by-product of doing something else, like reading or watching TV. In explicit learning, students' attention is drawn to new vocabulary, and they are asked to memorize it [Hatch and Brown, 1995; Nation, 1990]. This is the kind of learning that forms the basic shape of the learning task to be dealt with here. To bring the shape into finer focus requires an examination of how to go about presenting new vocabulary to second language students, and how best to help them remember it.

Fortunately, there aren't too many options when it comes to presenting new words. By far the most common is the basic list of words and their definitions [Lehr, 1984; cited in Hatch and Brown, 1995]. There is some question as to whether such word glosses should be mono- or bilingual. Nation [1990] reports that first-language translations of definitions hold several benefits, including quickness, relative ease in defining all types of words, the ability of students to respond quickly to demonstrate their understanding of a word. Also, it has been shown that students using bilingual

lists score higher on vocabulary tests than students using monolingual lists [Oskarsson, 1975; cited in Hatch and Brown, 1995].

How best to remember a new word is less straightforward. Nation [1990] reports that decontextualized, rote memorization can be an effective way to quickly learn new words. However, this style of vocabulary learning may not lead to long-term retention, or promote productive word use. Presenting words in some context may help, once students have reached a certain level of second language competency [Nation, 1990; Nagy, 1997].

Oxford [1990] suggests that activating as many senses as possible can strengthen word-definition memory connections. For example, students can view pictures representing the new word (visual), hear the word pronounced or hear it used in a sentence (aural), or hold the object in their hands while learning the word for it (tactile).

Repetition may also play a part in new word memorization. Studies have found that by presenting a new word repeatedly over time, students can better retain new words [Kachroo, 1962; cited in Nation, 1990; Stevik, 1996].

So let's examine the language task at hand: learning new vocabulary. The words can be presented as a list of words and definitions. The definitions can be either in English or in Japanese, or both. Showing how the words are used in context might be useful, as would allow the students to hear the new words pronounced. Finally, presenting the words repeatedly over time seems to be a good idea.

3. Examining the fit

Now that we have a fairly well defined shape to work with, let us see how that shape fits into the WWW. Certainly, web pages can be used to present lists of words and definitions. Also, most recent web browsers can show text in both English and Japanese. Similarly, web pages can just as easily display words used in sentences to give the students contextual examples. And words can be presented repeatedly on the web, through various pages and activities for the duration of a class. Recording the words for playback on the web is a simple task, so students could easily listen to the words being pronounced.

At first glance, it seems a perfect fit. Every piece of the pedagogical puzzle fits. So why is there an underlying feeling of unease, a nagging sense of "so what?" It might be because, while the web can do all of these things, so can pencil, paper, and a tape recorder. So why use the Web at all? It would be like using a jumbo jet to go to the local supermarket. It is time to look a little more closely at our task.

4. Sculpting the task

If my young nephew had access to a good wood chisel and the manual dexterity for the job, he could shape the star block to fit into the square hole. So it is when teachers move traditional activities onto the Internet. They often rework a perfectly good classroom activity in unnatural ways to make it fit in cyberspace. But in the case of our task, teaching new vocabulary, the activity already fits. The problem is that it doesn't completely fill the Internet space. It doesn't make much use of the functionality built in to the Web. Instead, our task resembles a circular peg, sliding easily into the large, star-shaped hole of the Internet functional space. [Fig. 1]

Figure 1: Functional Activity and Internet Space

Let us examine the points of that star to see what capabilities the Internet has that could be added to our task. In doing this, however, we must walk a fine line between adding features that improve the task, and adding flashy fluff just because it is possible to do so.

4.1 Instant feedback

One capability available to WWW-based activities is instant feedback. When students complete paper-based vocabulary activities, they must turn in the activities, wait for them to be corrected, and then (hopefully) review the words they missed. This process can take a long time, and the delayed feedback is of dubious effectiveness. Contrast that with the same activities on the Web. Using web-centric programming languages, such as Java or JavaScript, web activities can be created with a level of interactivity comparable to stand-alone computer-based activities. One thing computer-based activities have to their advantage is the ability to provide interactive, individualized instruction and feedback [Kang and Dennis, 1995; Ariew and Frommer, 1987; Cobb and Stevens, 1996]. With computer-based activities, students can receive feedback continuously, as they work through them. The feedback can take many forms, from simple "right" and "wrong" messages, to suggestions and guidance to help understand why a given answer is incorrect, and how the correct answer can be found [Kulhavy and Wager, 1993; Robinson, 1991].

4.2 Data-tracking

Think for a moment about how you might go about memorizing new words in a second language. Maybe you have a stack of flashcards with words on one side and first-language translations on the other. You move quickly through the stack, putting the mastered cards in one pile, and the troublesome ones in another. As time goes by, you continue to study new words, mixing in the missed words from earlier study sessions. Once a given word has been internalized, you put that card away, focusing only on the new and difficult words. Using CGI (Common Gateway Interface) scripts, Web-based vocabulary activities can do this and more.

CGI is the standard method used to communicate between web-based programs and forms and server-based programs or databases [Zhang, T. and Till, D.; 1997]. Using web forms or Java applets that communicate with CGI scripts residing on the server, web-based vocabulary activities can track a wide variety of data about each student's work. As a student works through an activity, it can store his or her answers to each question. When the student reaches the end of an activity, he or she can be presented with a list of missed words. These words can then be instantly reviewed. As the student continues through a course, previously missed vocabulary words will pop up in the activities from time to time, until the student has mastered them.

In addition to tracking individual data, web activities can be designed to watch trends in a group of students. Say that a group of students is asked to memorize 20 new words. By having them use web-based activities to study the new words, teachers can track which words are most difficult overall. This can be done by having the activities send a list of the most frequently missed words to a file on the server. These words can then be reviewed in class. Through the same method, teachers can discover which words are rarely missed by any student. These words could become candidates for elimination from the pool of vocabulary to be studied by future classes.

Another kind of data that can be tracked is time. Web activities can register the amount of time that a student spends on each question, or on the activity as a whole. This kind of data can be very useful for the teacher. For example, if a student correctly matches a word with its definition in less than a few seconds, it may be assumed that that word has been mastered (or at least the receptive recognition of the word). In fact, an activity could be designed that would require a student to match words and definitions in less than a specified number of seconds. If it takes a student more than that time to answer a question, it is stored and presented again later, until the student can recognize it instantly.

4.3 Help systems

With traditional vocabulary activities, students can get help in a couple of ways: they can ask their teacher, or they can ask their friends. A well-designed web activity can dramatically improve on these methods. Envision the same simple activity in which students match words to their definitions. A student is presented with a word, but cannot remember its meaning. The web activity can offer a wide assortment of assistance. For example, students might be able to click on a word, calling up a help window that shows the word used in a sentence. They could click a button and hear a digital recording of the word. Perhaps the definition of the word can be given in Japanese. A streaming video of the teacher explaining the meaning of the word can be offered.

As previously discussed, all of these things can be done using more traditional methods. The advantage of the web medium is that the help can be offered at the right time, in the form most beneficial to a given student. Instead of getting a list of explanations, translations, or a cassette tape to search through, the student is shown help only for the word being studied at that moment. This idea dovetails nicely into Vygotsky's notion of language education, called "the zone of

proximal development." As described by Oxford and Scarcella [1992], this idea states that students can master material high above their current language level, if they receive individualized help of just the right type, at just the right moment. Carefully designed web activities can do just this.

5. Designing the web activities

We are finally ready to begin creating the web activity. We have a good idea of the kind of pedagogy that should guide development, along with a sense of the capabilities web activities have that are not available with traditional paper-based activities. In effect, we have a recipe to work from to create a web activity that will help students learn new vocabulary. This section will examine an actual activity, based on the "recipe" described above, and currently being used by Japanese students at the University of Aizu. At the same time, the missing ingredients, possible future improvements, will be discussed.

5.1 Web-authoring software

The activity described here was created using Macromedia Director, a software authoring system that allows one to create interactive web applications. Director applications saved in the "Shockwave" format can be run on most web browsers. Both Windows 98 and Macintosh OS 8.5 come with the Shockwave plug-in pre-installed.

All the pedagogical components discussed thus far can be realized without such an authoring system, through a combination of HTML documents and CGI scripting. Director is useful in that allows for seamless integration of text, sound, and images into a self-contained activity. In addition, with Director, the data being tracked can more transparently be passed between the web activity and a server database.

5.2 Words and definitions

The most basic ingredient is a list of words and their definitions. To help students memorize the list, our activity presents them with a definition, and then asks them to match it with a word from a list of new vocabulary. [Fig. 2] Another possible method would be to present a word, and have the student select the matching definition from among four choices. There is one major advantage to doing it the first way. Selecting a word to match a given definition eliminates the need to come up with effective distracter definitions.

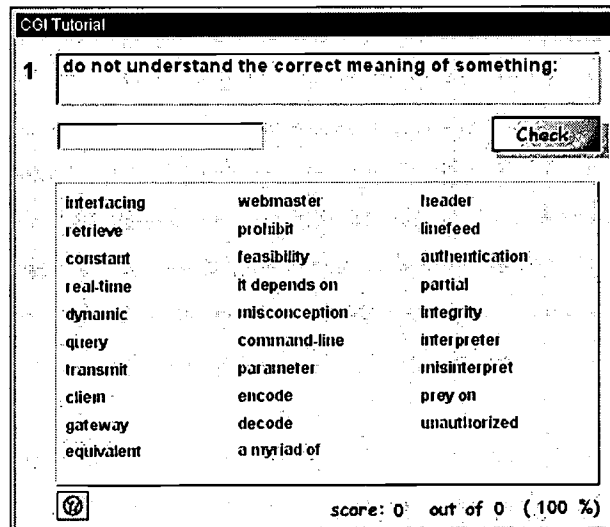

Figure 2: Vocabulary Activity

BEST COPY AVAILABLE

5.3 Help system

The activity includes a help system, combining several of the aforementioned ingredients. While in the help section, students can click on any word in the list, and view its Japanese equivalent, see it used in an English sentence, and hear it pronounced. [Fig. 3]

Figure 3: Help system

The help system in web-based activities should supplement, rather than replace other forms of help. With this in mind, pages with activities include an e-mail link to the teacher, allowing students to ask for individual help.

Future activities could link into an online corpus, allowing a student to see a word used in any number of sentences. For words referring to physical, concrete objects, a picture or line drawing of the object could be shown.

5.4 Feedback

The feedback messages have been kept simple. When students attempt to match a word to a definition, they are told immediately whether it is correct or incorrect [Fig. 4]. By keeping feedback messages simple, students are able to move quickly through the list of definitions, working toward the goal of quick recognition. If students want a more detailed response, they can find it in the help section.

Figure 4: Feedback

5.5 Data-tracking

The activities track several pieces of data about each student. First, incorrect choices are recorded, and recycled for review. Incorrect choice tracking takes two forms: short- and long-term. In short-term tracking, the missed questions are repeated within an exercise, until the student is able to correctly identify them. In long-term tracking, the missed words and definitions are stored in a server database. In proceeding unit activities, previously missed words are occasionally inserted until a student is able to match them quickly and consistently with their definitions.

At the University of Aizu, the activities are given as graded homework. Consequently, student scores are automatically sent to a server-based database for later importation into a grading program. In addition, each student receives an e-mail message upon completion of an activity, confirming that his or her score has been successfully recorded.

Future activities could record the time taken to answer each question, along with information about help system usage. A list of those words for which students most often seek help could then be kept, as well as a list of which words took the longest to recognize. This information could be used to guide in-class review sessions.

5.6 Randomization

The order in which the definitions are presented is randomized for each student, and changed each time the student tries the activity. This helps avoid "pattern memorization", in which students simply remember the order of the answers. As a side issue, randomization also helps prevent sharing of answers among students doing the activities outside of class.

6. Conclusion

Moving from traditional, paper-based language practice to web-based work requires more than a simple transfer from the physical to the electronic. Teachers need first to examine the specific task they want to move online, listing the components that make up that task as it is usually performed. Next, teachers should investigate how well those components can be transferred to the WWW. Finally, the task itself can be sculpted to make it more effective, pedagogically, using capabilities built in to the WWW.

By following through these steps before the actual creation of web-based activities begins, it is possible to develop activities that have a solid foundation of theory, coupled with dynamic functionality difficult to achieve through more traditional methodology. Put simply, define the shape of the task first, and compare that shape to the functional "hole" of the WWW. Then add functionality where appropriate to create a better fit, and a better learning tool.

PIE - Problem Based Learning, Interactive Multimedia and Experiential Learning

Urban Nulden

Viktoria Institute and Department of Informatics, Goteborg University, Sweden
E-mail: nulden@informatics.gu.se

Abstract: This paper discusses design of web-based interactive multimedia for collaborative learning. Experiential learning combined with interactive multimedia has received a great deal of attention in both educational practice and research. Advancement of multimedia technology also provide an opportunity to extend problem based learning and combine it with experiential learning. A prototype application was designed and evaluated in two different settings: university and industry. The conclusion is that the prototype works as a tool to integrate experiential learning and problem based learning.

1. Introduction and Background

A great deal of attention has been focused on interactive multimedia, especially within the educational domain. Many educational institutions have produced different types of educational interactive multimedia courseware to replace or enhance educational activities. In this paper we discuss how interactive multimedia can be used to combine experiential learning (EL) and problem based learning (PBL).

EL and PBL are alternative pedagogical models that are gaining popularity in all levels of the education system. Computing education such as software engineering, management information systems, computer information systems and informatics are no exceptions. The context for this research is computing education and training in a broader sense. In this paper we use *project failure* as an example of a phenomenon that occurs frequently in different types of projects to exemplify our ideas.

IT project failures are well known to researchers and practitioners in both industry and academia. See for instance [Nulden and Scheepers 1998] for a discussion. Project failure is of course strongly related to project management, a practical task educators often find difficult to teach realistically with traditional and conventional methods. Courses covering project management often simulate real world project like situations. The early project management simulations were built on very rational ideals, while current simulations include more complex dimensions. Today, educators design cases and simulations where students are requested to perform in realistic situations and under business pressure. Common ways to enhance the realism is communication and interaction with simulated project staff, users and consultants. Another way is pin pointing typical project problems such as absenteeism, staff diverted to higher priorities, design problems, technical problems, changed requirements, personality conflicts, overstaffing and resignations. Educators try to make sure the students experience the situations as real as possible.

With problem based learning, interactive multimedia, experiential learning and computing education, more specifically project management and project failure, as a theoretical and contextual background we formulate the following three research questions to be further elaborated in this paper: First, how can interactive multimedia enhance problem based learning? Second, how can experiential learning and problem based learning be integrated in a methodology? And third, can interactive multimedia vignettes be used outside a formal education system to train and educate in project management related issues in corporate training programs?

2. Learning and Facilitating Learning

In this section I briefly discuss problem based learning and experiential learning. It is assumed that the reader have some basic knowledge about these two pedagogical approaches. PBL is a way of designing and conducting educational activities using problems as stimulus and focus for learner activity. In experiential learning the educator is providing some form of stimulus to help students have an concrete experience.

2.1 Problem Based Learning

Problem based learning is: "... a way of constructing and teaching courses using problems as the stimulus and focus for student activity. It is not simply the addition of problem-solving activities to otherwise discipline centered curricula, but a way of conceiving of the curriculum which is centered around key problems in professional practice" [Boud and Feletti 1991 p.14]. Hence, the starting point of learning in PBL is a real world phenomenon or problem the learner wishes to learn more about. That is, a problem that is relevant from the perspective of the learner's future profession. The problem, or rather the problematic situation, is identified, designed and presented to the students, who then themselves define what the actual problem is.

The responsibility of the teacher is to present or introduce the phenomenon or problem in a stimulating way. In PBL terminology, this starting point is called a 'vignette' and is mainly understood as a starting point for self-directed learning. In many ways, PBL is an implementation of the constructivistic model of learning. This means that people can only understand what they have constructed themselves [Leidner and Jarvenpaa 1995]. Since the group is an important resource for the learning process in PBL we have a cooperative model of learning or collaborativism [Slavin 1990].

The practical implementation of PBL does of course vary. This paper discuss only one possible model. See for instance [Boud and Feletti 1991] for a more lengthy discussion about PBL in practice. The experience of actually working with the vignette is less emphasized in discussions about PBL in practice. Therefore this research look into the notion of experiential learning.

2.2 Experiential Learning

Experiential learning refers to small group work, were what is learned is directly related to what happens in the group and how it happens. Various terms have been used to label the process of learning from experience. Dewey used learning by doing, and others have discussed this process in terms of *learning-in-doing* [Kolb 1976].

Experiential learning is participative, interactive, and applied. It involves the whole person; learning takes place on the cognitive, affective and behavioral dimension [Gentry 1990]. Already 1916, Dewey noted that schools continued to tell students what to learn despite research clearly showing that teaching by telling does not work, and that learning by doing does work. It is claimed "learning is best facilitated in an environment where there is dialectic tension and conflict between immediate, concrete experience and analytical attachment" [Kolb 1984].

Experiential learning in various forms has been practiced since the early 1950's. Examples of experiential learning are internships, live case, case studies, role-play, games and simulations. Different types of simulations are probably the most common and has long been a feasible way for educators to present complex matters such as visualization of mathematical, production and logistic processes.

3. Interactive Multimedia

Innovations in technology, such as multimedia, hypertext, video, the Internet and virtual reality, are now having an impact on teaching and learning. The design of interactive multimedia (IMM) has undergone a revolution in the last ten years. Trivial HyperCard stacks and behaviorally oriented drill and practice applications common in the 80's have given way to richer interactive applications where the learner is relatively free to explore at her own pace. However, much of the multimedia training is no better than the old — it just looks sexier. We can also see a shift from CD-rom towards the 'web', as a dominating technology, but also a shift from multimedia for individual learners towards multimedia application for teams or groups of learners.

The use of hypertext and hypermedia permits links among pieces of information such as text, sound and graphics, that permit the user to "explore ideas and pursue thought in a free and 'non-linear' fashion" [Bieber and Kimbrough 1992]. Kendall et. al. compare a hypertext based (IMM) systems analysis case with a conventional case and role playing [Kendall, Kendall et al. 1996]. They found that use of hypertext allows students to navigate through the organization, interviewing and examining documents in the order they prefer rather than in the pre-described linear fashion. Their conclusion is that hypertext was an important departure

from the traditional activities conducted. The interactivity and non-linearity of hypertext means that the students learn systems analysis and design by exploring an organization, rather than reading a case study of one.

In a systems development education context, Farrimond et. al. are applying current multimedia techniques to transform current paper based case studies into interactive multimedia simulations [Farrimond 1997]. They have developed a mouse driven virtual world. The goal of the interactive case study is not to lead or guide the students towards a specific goal but to provide a context in which to explore the 'real' world. The world in the simulation is a set of interconnected rooms that are populated by people, documents and other objects. The students construct own meaning by interacting with the material rather than being taught something explicitly.

These are just two examples, but they and other simulations we have studied are quite similar to what we suggest in this paper. However, none of the simulations is explicitly building on the model of problem based learning. In the following section these ideas further are further elaborated.

4. Design

We surveyed twenty one master level students, ten men and eleven women, average age of 28 and all with at least six months experience of PBL, about their experience with PBL. The survey was analyzed by coding of keywords in their responses. The keywords were then categorized in the following three groups. First, working with PBL quickly became routine and the groups developed a standard behavior to work with the problem. Second, the vignettes were perceived as lacking relevance and not dealing with timely issues. And third, the lack of variation of the format of the vignettes.

Our major conclusion from the survey is that a great number of vignettes seem to have very low quality when it comes to stimulating and challenging the students. Supported by the literature, the result of the survey, and our own experience as facilitators we started to elaborate our ideas about multimedia vignettes. [Fig. 1] below summarizes the conceptual ideas of integrating problem based learning and experiential learning.

Figure 1: Design Framework

From here we started the design of a vignette about IT project management and failure as discussed in the introduction. The objective with this vignette was to direct the attention of the students to the complexity of IT project management. The students should act as project members and navigate through a project over time and make decisions about the project. [Fig. 2] below is an outline of a whole vignette.

The students get some background information to make decisions. The intention is to make the students, not only read about the problem, but actively be part in the creation of it. They experience the sense of time and how they have been part of the project during this time. Decisions are actually made by the students and they have thereby invested themselves in the decisions.

In the vignette, time passes in the project and the group faces additional information, and has to make other decisions. Finally, as [Fig. 2] about the whole case shows, the group will end up in the single last scene of the vignette. This is how the educator responsible for the vignette makes sure the students meet the learning objectives of the PBL session. Let us give an example of a possible end scene. After the group has worked with the vignette for one hour and been confronted with various project problems, they have been making a number of decisions about database managers, upgrading of software, hiring and firing of people etc. They are becoming more and more aware that the project is probably about to fail. The last scene is from the board-room were the president of the company and the CIO question your (the group's) ability to manage the project.

To generalize the ideas, an important aspect of this research is to develop and establish a terminology for designing cases as described in this paper. The *scene* serves as building blocks for the vignette. New information about the scenario is presented in each scene and the group is required to make decisions about matters such as technology, personnel and dates. Each scene in the vignette consists of a series of web-pages with one or a number of objects embedded. Examples are graphics, sounds, movies or database interfaces. The

purpose of a scene is to present information to the base-group and in some of the scenes the group is then required to make a decision.

Figure 2: Outline of the whole vignette

To evaluate the ideas, as described above, a simple prototype of a sequence of scenes was implemented in Microsoft Power Point (PP). The scenario contained a number of scenes setting the stage and providing the group with the background information about the problematic situation. This information was presented in smaller blocks of text on several PP slides. The purpose of this was, as discussed above, to allow the group to reflect and discuss issues raised in the scenario while it was presented. After the group had received this information, scenes, where the students were required to make decisions before continuing, were presented.

5. Evaluation

In the evaluation phase we decided to include people from the industry. Therefore, two groups, one at the Business School of a Swedish university, and one at a large manufacturing industry in Sweden, were selected to participate in the evaluation. We decided to evaluate the vignette with the student group first as approaching the students first would minimize the possible errors we otherwise would bother the professionals with.

5.1 Observing the Student Group

The student group participating in the evaluation consisted of a subset of the group surveyed about their opinions about PBL. The setting for the evaluation was a conference room with a table, a portable computer, a projector and a large screen to project on. The students were given a short description of our analysis of the survey, our ideas in general and the purpose of the vignette they were about to work with.

The group worked quietly with the first eight scenes containing the background information. They nodded their heads when they were ready and waited for the next scene. No discussion or comments were made. However, when the first interactive scene appeared the discussion started. The discussion followed a pattern we had expected, but they also raised issues concerning the actual ideas about the prototype. The group constantly made connections to their own experience of PBL. Short comments were made during the information scenes and more extensive discussions took place in the interactive or decision scenes. The group worked and discussed in an efficient and goal oriented way. It was obvious that their experience of PBL helped them in structuring the group work in this phase of the PBL model.

All members of the group found the prototype and the scenario to be of value. According to them it was easy to understand, although some found it to be too much text in some of the scenes. None of the students found the design to be too simple. A richer multimedia form with more embedded objects would not automatically raise the quality of the vignette, probably the opposite. However, the interaction was found limited due to the interactive case implementation with sequential scenes. Observing the students, it was very interesting to see how they altered their discussion from the actual problematic situation presented in the scenario, to a discussion about their own relation to PBL.

That the scenario ended with a fairly concrete task for the group to work on was not a problem, this despite the fact that this is a conflict with the PBL methodology. Summing up the students' comments during the evaluation session we find that this type of scenario should work as a good way to introduce and engage students to work with different problematic situations. They emphasized that this was certainly a promising alternative to the traditional paper based vignettes they had worked with so far.

5.2 Observing the Industry Group

The setting for the second evaluation was a team room at an industrial plant. The team room had a large conference table, some smaller tables and a table with a computer equipped with a large screen. Only four people from different teams were able to participate. The facilitator for the group belonged to a different department of the company. She received some instructions in advance about the role and purpose of the team leading she was about to enter. The team received a more extensive introduction to the task than the student group. The basics of PBL were explained as a background. They started out quietly, much like the first group. They hummed after they had read through the text in the information scenes and the person with the mouse clicked on to the next. The work was methodological and gave the impression of being very efficient. When they reached the first interactive scene about whether work practice really had changed the group started a quiet discussion. The discussion escalated after a little while and they penetrated the alternatives, and agreed on one alternative. The facilitator was successful in trying to get everyone's opinions. The group felt a bit more at ease and started to use the supplied drawing and writing material to articulate and explain their standpoints. When the group reached the actual task about suggesting an introduction program for new project members an extensive discussion was taking place. They finished their work and presented a draft of an introduction program for new project team members.

The team had no problem in moving through the interactive case. They recognized the issues raised in the scenario. Smiles and laughter were frequent as they moved through the scenario. The group agreed that the format was good in that they were introduced to a problematic situation in a stimulating way, and the team was presented with a task to complete. They found that the embedding of the instruction in the scenario was helpful. Similarly to the student group, they were not sure that additional multimedia content would automatically add to this type of scenario.

6. Discussion

Observing the students work with the scenario it is obvious that this type of alternative vignette add to the process of PBL. The student group focused on the intended issues before they reached the end of the scenario. The group stopped at the interaction scenes and discussed the situation, they reflected and analyzed the situation to understand and problematize. We did not get the feeling that they were rushing to move on in the scenario. A very important observation is that they clearly spent more high quality time with this vignette than when working with a traditional paper based one.

The industry team found a lack of structure in the scenario. This is a very delicate problem to approach. On the one hand, the scenario must not be too superficial and put words in the participants mouths. The scenario should guide the group, but not control them. On the other hand, and from the company's perspective, the aim or the expected outcome must be very clear. PBL was seen as a somewhat 'unstructured' approach, as the group, according to PBL, defines their own problem.

7. Conclusion

An interactive prototype about project management was designed. The prototype was evaluated in two different settings. The three research questions below guided the research and serve to summarize the findings.

- *How can interactive multimedia enhance problem based learning?*

The evaluation suggests that interactive multimedia have large potential in enhancing the first phase of PBL.

- *How can experiential learning and problem based learning be integrated in a methodology?*

We propose a tentative methodology, PIE (Problem based learning, Interactive multimedia and Experiential learning), which is outlined in [Tab. 1] below. PIE is a three phase methodology for structuring educational activities in modules, using interactive multimedia as an important part.

Phase 1.	Experience. The group experience the interactive case facilitated by an instructor. The instructor ensures that the group reaches the end of the scenario and leave the session with the problem on their mind. Duration two hours.
Phase 2.	Reflection. Duration one week
Phase 3.	Feedback and discussion. The group meets together with the instructor and discusses the problem presented in the interactive case. Duration two hours.

Table 1: PIE Framework and Methodology

- *Can interactive multimedia vignettes be used outside a formal education system to train and educate in project management related issues in corporate training programs?*

PIE is an approach that is useful in organized corporate training about for instance project and project management related issues.

While the findings so far are tentative, we argue that the evaluation showed us some important things about the design of vignettes, both traditional and multimedia. The main limitations of this research, as we see it, are two. First, the very simple prototype designed to implement our idea about interactive multimedia vignettes. The vignette used as example in this research is currently being transferred to a web-based interactive multimedia application. Second, the limited evaluation conducted. However, as our aim with this paper is to discuss the problem of challenging learners in a PBL setting, and suggest how these problems can be handled, we do not find these limitations to be problematic for our purposes in this paper.

Abstract: The exploration of social networks is essential to find capable collaborators who can help problem-solving and to augment cooperation between users. This paper describes PeCo-Mediator-II for seeking for a collaborator with the chain of personal connections (PeCo) in distributed organizations. Moreover, this system helps gathering, exploring, and visualizing social networks. The experimental results show that the system facilitates that learners encounter collaborators and develop a new helpful relationship beyond the classroom.

1. Introduction

Recently, opportunities for communication and collaboration via computer networks have immensely been increased in networked organizations (Sproull and Kiesler, 1991). A fundamental problem is how to encounter people who can help problem-solving. We are focusing on the problem of discovering such people through social networks. Social networks are at least as important as the official organizational structures for tasks ranging from immediate, local problem solving (e.g., fixing a piece of equipment), to primary work functions, such as creating collaborative groups (Kautz et al., 1997).

In CSCW (Computer Supported Cooperative Work), researchers are interested in the role of social networks between organizational members. Clement stated that users developed informal collaborative networks to know how to use a new software (Clement, 1990). Then, private networks are important for workers to solve problems by providing helpful information. A number of studies have shown that one of the most effective channels for gathering information and expertise within an organization is its informal networks of collaborators, colleagues and friends. The networks of helping relationships are called "Help Network" (Eveland et al., 1994). However, the networks are not collected and generally follow work group alignments rather than technical specialization. Therefore, it is significant to use members' interpersonal connections effectively in their activities.

In CSCL (Computer Supported Collaborative Learning), one common component of collaborative learning is the "informal peer-help networks". This notion is compatible with Wenger's communities of learners (Wenger, 1996), where people who share learning goals within an authentic learning environment can develop ties that reinforce learning outcomes. From this viewpoint, Greer et al. (1998) proposed PHelpS (Peer Help System) that supports workers as they perform their tasks, offers assistance in finding peer helpers when required, and mediates communication on task-related topics. On the other hand, our approach focuses on how a system can support both storing and exploring "Personal Connection" (PeCo) in a collaborative learning environment.

A concept of organizational memory is proposed as organizational knowledge with persistence (Conclin, 1992). Answer Garden (Ackerman and McDonald, 1996), and COMES (Ogata et al., 1996b) have been proposed to record and use organizational memory. In an organization, however, information seeking is not straightforward information transfer. Colleagues chose not to go to the channel of the highest quality for information, but rather to go to the channel of heights accessibility (Allen, 1977). Accessibility is concerned with psychological cost that is in the potential lack of reciprocity between giving and obtaining information and so on. PeCo makes it easy to agree to the cooperation and to access information.

We propose PeCo-Mediator-II (Ogata et al., 1996a) for gathering, seeking, and visualizing social networks in a networked organization. PeCo-Mediator-II is a distributed system with a personal database (PeCo-Collector) and a software agent (PeCo-Agent). Every user has the two softwares on the respective site. PeCo-Collector incrementally gathers information on its user's acquaintances and the relationships through watching the exchanges of e-mail. PeCo-Agent moves to colleagues' sites and negotiates with other agents and users to find collaborators. Although the users of both NetNews and e-mail lists are passive to find answers, our system can actively discover collaborators with the chain of personal connection from the user and the collaborators.

2. Overview of PeCo-Mediator-II

Our initial system called PeCo-Mediator (Ogata et al., 1995) is a groupware that allows sharing of PeCo in a group and to search for connections between the user and targets. The users need to share PeCo with the common database of PeCo-Mediator. Although the system was very available in some small groups, it was reluctant in terms of users offering their private information like PeCo into the common database. Also, it is hard for the users to entry personal data of their friends.

When a computer network connects people or organizations, it is a social network. Just as a computer network is a set of machines connected by a set of cables, a social network is a set of people connected by a set of social relationships, such as friendship, co-working, or information exchange (Garton et al., 1997). Computer Mediated Communication (CMC) systems also reduce the transaction costs of initiating and maintaining interpersonal ties (Pickering and King, 1992). Weak ties created by CMC expand the channels of information sources for the individual and have potential for strong ties.

Figure 1. Overview of PeCo-Mediator-II.

PeCo-Mediator-II is combined PeCo-Mediator and on-line social networks. It consists of the two systems; PeCo-Collector and PeCo-Agent (see Figure 1). Every organizational member has the two softwares on the respective site. PeCo-Collector gathers information on its user's acquaintances and the relationships through watching the exchanges of e-mail. PeCo-Agent moves between members' sites to find a partner in the community. The user's PeCo is a starting point for the exploration. The user's acquaintance acts as a liaison between the user and the partner in this situation. In this figure, user X requests user Y to help the problem solving, and user Y introduces user Z. After that, user Z can help user X by request.

3. Gathering Organizational Memory Based on Social Networks

We have proposed a data diagram of PeCo exploration (Ogata et al, 1998). To support the exploration of social networks, it is very important to store the history of PeCo exploration when the user has sent or receive messages. Based on PeCo exploration diagrams, the attribute includes the following user's actions: request, accept, reject, forward, receive-request, receive-forward, receive-accept, receive-reject. The topic of the request is represented with keywords that are extracted from e-mail.

Table 1. Taxonomy of users with the exploration history.

User type	Condition
Collaborator	<i>accept</i> > α and <i>accept</i> > <i>reject</i> and <i>accept</i> > <i>forward</i> and <i>accept</i> > <i>request</i>
Mediator	<i>forward</i> > α and <i>forward</i> > <i>reject</i> and <i>forward</i> > <i>accept</i>
Requestor	<i>request</i> > α and <i>request</i> > <i>accept</i> and <i>request</i> > <i>forward</i>
Non-collaborator	<i>reject</i> > α and <i>reject</i> > <i>accept</i> and <i>reject</i> > <i>forward</i>
Semi-collaborator	<i>receive_accept</i> > α and <i>receive_accept</i> > <i>accept</i>

(Italic word shows the number of the action. α is a constant given by the user.)

3.3. Taxonomy of Users

Based on the above history, we divide users into the five types (see table 1):

- 1) Collaborator: The collaborator is a user who usually accepts the request during this system use. The collaborator is often an expert about the request.
- 2) Semi-collaborator: The semi-collaborator is a user who potentially has the capability for cooperation about the request. We assume that a semi-collaborator receives the answer from others rather than accepting requests.

- 3) Mediator: The Mediator is the user who usually forwards the request to his/her friends.
- 4) Requestor: The requestor is a user who asks a question and s/he becomes a starting point of exploration of social networks.
- 5) Non-collaborator: The non-collaborator is a user who almost rejects the request.
- 6) Unknown user: If a user has never received or sent a request, the user is unknown for the system.

PeCo-Agent understands the users' capability through watching the exchanges of questions and answers. We represent the capability of the user and his/her acquaintances with the keywords in the e-mail. For example, a friend is a collaborator about C programming language although the friend is a non-collaborator about Tcl/Tk.

3.5. Collecting Organizational Memory

Organizational memory has been proposed as a concept for sharing organizational members' knowledge (Conclin, 1992). We also apply that concept into our situation. If a collaborator permits sharing of an answer, it is entered into a shared repository. Because the requesters can refer to the answers in the database before sending the requests, collaborators need not write down the same answer repeatedly. Moreover, when a collaborator permits propagation of the answer, the system sends the answer to the mediators between the collaborator and the requester as well as the requester. By this facility, mediators can also know the answer.

4. Implementation

4.1 System Configuration

We developed a prototype system on a workstation with Tcl/Tk (Ousterhout, 1994). The system consists of PeCo-Collector and PeCo-Agent. Every group user has the two systems on the respective site.

(1) PeCo-Collector: This system has two components: data management and E-mail handler. All the data is managed by TRIAS (Yamamoto et al., 1989) and the e-mail tool is TkMH based on MH (Mail Handler) (Peek, 1994). PeCo-Collector links an e-mail object and its sender's or receiver's object automatically and the user can make hypertext links among e-mails.

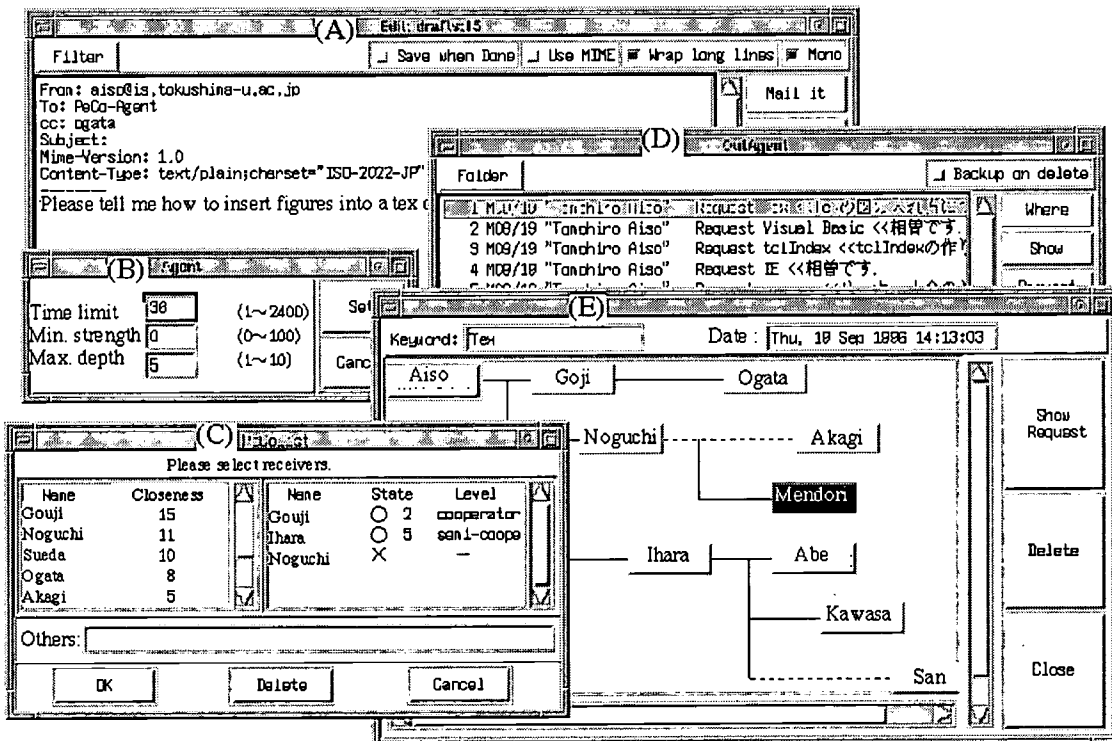

Figure 2: Screen shot of PeCo exploration with PeCo-Mediator-II.

(2) PeCo-Agent: The characteristics of PeCo-Agent are:

- 1) To represent capability of users with keywords about e-mails;
- 2) To obtain the capability of users from the user and other agent;
- 3) To move around the Internet and communicate with other users and agents;
- 4) To find the candidates of partners concurrently.

In PeCo-Mediator-II, a user communicates and negotiates with others through e-mail. In the same way, PeCo-Agent communicates with other agents with structured e-mail (Malone, 1986). Keywords are extracted with Chasen (Matsumoto, 1997) that is a Japanese morphological analysis tool. PeCo-Agent calculates the similarity between the given question and the stored questions by matching nouns elicited from Chasen filter.

4.2. Interface

Figure 2 shows the interaction after user "aiso" ask a question to his PeCo-Agent. In the window (A) "aiso" writes the request message. In the window (B), the user sets time out for seeking social networks, the minimum strength of PeCo and the maximum steps between "aiso" and the receiver. PeCo-Agent finishes the exploration according to this setting. In the window (C), PeCo-Agent assists "aiso" to decide who is the better receiver of his acquaintances and the user agent provides information about the candidates of the receivers. The window (D) displays the list of the requests that the user has sent.

The window (E) shows the flow of the exploration from he user graphically. This tree is the result of traveling with the connections of "aiso". The icons except "aiso" denote the candidates of partners. The shorter the distance between two icons, the stronger the relationship they have. While the dotted line denotes the receiver has not read the message yet, the solid line shows the receiver has already read it. The black icon means the user has rejected the request. The node icon shows the user has forwarded the message to his/her friends. The leaf and white icon means the user has accepted the cooperation. In this figure, "mendori" refused aiso's request, and "ogata", "abe", and "kawasaki" agreed to his request. "akagi" has not read the message yet. If the user reminds the reply to the request from this window, PeCo-Agent of "akagi" tells him to read the message. From this result, "aiso" is the most familiar to "goji" and can easily access the collaborator "ogata" through the mediation of "goji".

5. Experimental Use

5.1. Users and Tasks

We experimentally tested and evaluated PeCo-Mediator-II in small communities. In this experiment, we arranged 13 master course students (group A) and 94 undergraduate students (group B) who had no relationship with the members of group A at the first stage of the experiment. Only one person, teacher VI, knows all the members of group A and B. They used the prototype system during nine weeks in a class of programming language C. We divided nine weeks into three terms. Teacher VI gave group B some homework every week, for example, making a program of data sorting.

Term 1: In the first three weeks, the system gathered their usual ties. Each group member communicated among the internal group members without the contact of the other group.

Term 2: We allowed group A and B to communicate and collaborate with each other to solve problems. The users solved the given problems through this system without supporting PeCo exploration with history.

Term 3: In this period, we evaluated the function for supporting PeCo exploration with the history that was stored in the term 2.

5.2. Experimental Results

Figure 3 shows the social networks between the users after six weeks from the beginning of this experiment. While the user of group A is indicated by a circle, the user of group B is shown by a square. The thick arrows denote the requested messages from the sender to the receiver. The thin arrows represent the forwarded messages over one time. The weight of the arrow shows how many times e-mail was exchanged from the sender to the receiver. The user VI was a central person and acted as a liaison between group A and B. As shown in this figure, group A and B learned to communicate with each other through the introduction of user VI, although they did not have connections beyond the group. Moreover, most of the requests from group B concentrated on user VI and III, and the collaborators were almost fixed at six persons of group A. In this case, there was no collaborator in group B.

Figure 3. Network forming in the term 2.

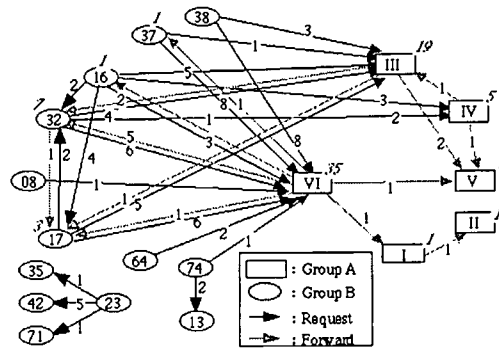

Figure 4. Network forming in the term 3.

In the previous experiment (Ogata et al., 1998), we compared this system with e-mail, mailing list and NetNews during four weeks. This experiment was executed in the same class. Both mailing list and NetNews were not often used for getting answer, because the student hesitated to ask a question. On the other hand, both this system and e-mail were frequently used. In this case, social networks were stable because direct and explicit relationships were used to get collaborative help. Likewise, (Yamakami, 1995) describes the interaction patterns of e-mail and bulletin board are stable from the long-term usage observation.

Figure 4 depicts the message flow in the term 3. Some of group B became collaborators because our system lead the users to reduce the incipient collaborators' load. For example, the system recommended user VI to forward the request from user 32 to user 17 who was a semi-collaborator. After that, user 32 directly requested user 17 to cooperate with problem solving.

In the term 3, the users provide their knowledge into the shared repository. Figure 5 shows the bar chart of its usage every week. The times of reference were 200, and the times of entry were 21. The number of knowledge in the repository was small, but the knowledge was basic. Therefore, the users often made use of it. As a result, the overload of collaborators was reduced.

Figure 5: The usage of the shared knowledge repository in term 3.

6. Related Works

There are many possible sources for determining direct relationships. The initial version of our system imposed the entry of relationship lists upon organizational members (Ogata et al., 1995). The provision of individual ties makes the burden heavy for the users. Schwartz and Wood (Schwartz and Wood, 1993) proposed a way to obtain relationships by analyzing e-mail logs. However, the use of such information raises concerns of privacy and security that are hard to allay. ReferralWeb (Kautz et al., 1997) system uses the co-occurrence of names in close proximity in any documents publicly available on the Web as evidence of a direct relationship. Although this system is readily available to discover public relationships, it may be difficult to find real private networks. Our system focuses on current and personal ties based on the exchange of e-mail.

Foner (Foner, 1995) proposes Yenta that is a matchmaker agent to bring people together. In this approach, a broker agent automatically introduces other agents and people. On the other hand, our work pays much attention to human-centered approach for enhancing cooperation between organizational members. Therefore, the agency of PeCo-Agent is weak.

7. Conclusion

This paper proposed PeCo-Mediator-II as a support to find capable collaborators with the chain of personal connections (PeCo) in a collaborative learning environment. This system helps gathering, seeking, and visualizing social networks of organizational members. PeCo-Mediator-II is an agent-based system to deal with e-mail. This system consists of PeCo-Collector as a personal database and PeCo-Agent as a user's assistant. PeCo-Mediator-II was experimentally tested and evaluated in a C programming language course. The results showed the system could help the user to encounter a collaborator and developed the new relationship with the collaborator.

SmartSearch: Built-in Algorithms Derived from Experiments

Shirabe Ogino and Masao Sakauchi
Institute of Industrial Science (IIS), University of Tokyo, Japan
ogino@sak.iis.u-tokyo.ac.jp and sakauchi@sak.iis.u-tokyo.ac.jp

Abstract: Search Engines work very powerfully these days. From the viewpoint of developing/improving meta-search engines, we conducted experiments on available search engines over two years. This paper reports the results of our experiments, and discusses the built-in algorithms and future features of SmartSearch. The University of Tokyo and the United Nations University jointly developed the "Virtual University (VU)" project, whose purpose is to research the effective educational methods in distant learning. SmartSearch is a core search engine in the project and will be served in most of the components of the VU.

1. Introduction

The Internet is growing at the speed of light. Just a decade ago, only a small percentage of the population was trying the BBS system using very slow modems. Thanks to the reduction in price of the computers whose average prices are under \$1000 now, the latest figure shows that one out of every two families in the US have computers. They use it for word-processing, spreadsheet, games, finances, etc. However, the main reason of this rapid permeation must be the popularity of the Internet.

E-mails are very popular among people because of their convenience and fast delivery. The sender does not need to worry about the availability of the receiver unlike phones, even though the letter will arrive in a minute unlike postal letters. Web pages are also convenient because of their abundant information. No encyclopedia has 100 million pages of information. The only problem with this information source is its unorganized structure, rather we should say it does not have any structure at all. If the information is scattered around, we cannot reach the desired one.

To solve this problem, search engines were invented. The first one was called Web-Directory-Service Search Engine, which listed all web pages that the users registered. This process was done by people, not programs, and took a lot of time. This method ended up falling behind the growth of the Internet. The second method was called Robot-Driven Search Engine, which sent robots/spiders to all web servers to retrieve all HTML files available. This is processed by only programs, assuring speed, but not relevancy. Both types basically match keywords with their databases. Some of them have more effective methods to improve the accuracy of the results. Still, we are not satisfied with the results of these search engines due to their inaccuracy and bothersome dead-links.

2. Meta-Search Engine

Here, the Meta-Search Engine came up. Meta-search engine is a new kind of search engine that uses both previous conventional search engines in the background. It sends the keyword to them, and retrieves the results. After re-ordering the links, it shows the result to the user.

The key point of the meta-search engine is this re-ordering technique. The technique is different in each meta-search engines, and of course, SmartSearch that we programmed has its own algorithms. Although some kinds of meta-search engines just output the results without processing much in depth, SmartSearch's algorithms are based on the results of our experiments on conventional search engines two years ago. The reason for conducting the experiment is to increase our knowledge of the factors to the accuracy. Needless to say, the connection of the results of conventional search engines with the results of the meta-search engines was unknown.

3. Past Experiment

As seen in the reference section, people have experimented and publicized the evaluation of the search engines. Here, the purpose of this experiment was not to rank conventional search engines, but to find an effective way to utilize the conventional search engines. Two years ago, not many search engines were powerful enough to output the results in a short amount of time, nor did they have a large enough database to hold all HTML documents in the Internet. Due to these restrictions, we limited the experiment to six search engines: four robot-driven search engines, one directory-service search engine and one meta-search engine. We keyed in keywords, took basically ten result links, went over to the pages, viewed and evaluated whether the pages were relevant to the topic. This evaluation process was conducted by three members, two of which should have agreed that the page has a strong connection to the topic for the results to be considered as *relevant*. *Total* means the total number of links, *Dead* means dead-links, and *repeats* means repeated links, whose information is exactly the same but resides in a different web server (mirror servers) in most cases. We excluded any page written in other than English as *non-English*, since the keyword is English and we conducted the experiment for the search engines that locate in the US.

We tried to spread the topics into as many areas as possible. Some of them are from the academic area while others are from a recreational area; Some are for business while some are for private. We decided to conduct this experiment using the following topics:

- Dilbert
- health care
- IPV6
- TWA (Trans World Airline)
- Vijak Sethaput (private name)
- Wall Street Journal
- "1996 presidential election" & Clinton & Dole
- "Fermat's Last Theorem" & proof
- Macarena & dance
- Mars & rock & (life | creature) & NASA
- Atlanta & "olympic games"
- Ransom & "Mel Gibson"
- "United Nations" & "Peace Keeping Force"

The results of the experiment are summarized in [Tab. 1]. The raw data of the experiment are available at http://www.smartsearch.org/se_experiment.html

Table 1: Dec, 1996

SEs	Total	dead	relevant	repeats	non-English	Score for people	Score for M SE
AltaVista	954	123	485	000	023	051	056
Excite	977	062	646	008	023	063	070
HotBot	1000	038	669	038	038	059	065
Lycos	846	085	454	000	023	056	061
Yahoo	754	038	415	023	008	047	051
MetaCrawler	962	054	569	008	015	058	062
avg	915	067	540	013	022	056	061

In the above, *Score for people* are calculated as:

$$\frac{\text{relevant} - \text{repeats} - \text{nonEnglish}}{\text{Total}}$$

The reason for using this equation is that we do not want repeated information or non-English information even if they are relevant. Therefore, this score is what the user would feel about the results from each search engine.

First, we would like to analyze this result from the viewpoint of human user. We specified the search engines to output the Top 10 links. We believe these ten links are the maximum for most users to check since this task is very time-consuming. There is a great possibility that the relevant links may have appeared in the next 100 links since some search engines show that they have more than a thousand of links relevant. However, it is impossible for us to check all of these returned links, nor any user would do when they search. From this special character of the abundant information on the Internet, we did not (could not) calculate the

generally known figures: precision rate and recall rate.

The figures of the dead-links show that 5-10% of the returned links are unavailable. Also, the figures of repeated links consist a few percentage of the total figure. If these figures are too large as shown here, users will feel "Search Engines are useless!" Information in particular language can be useful for people who speak that language, but not for everyone, considering the fact that most information on the Internet is written in English and resides on the US-based web servers.

The *Score for Meta-Search Engines* are calculated from different perspective.

$$\frac{\text{relevant} - \frac{1}{2} \text{repeats} - \text{nonEnglish}}{\text{Total} - \text{dead} - \frac{1}{2} \text{repeats}}$$

This score is calculated based on the algorithms used by SmartSearch. When SmartSearch receives the results from conventional search engines, it checks whether the links are active or not, deletes repeated links if mirror servers are found. However, when titles and/or contents are slightly different, SmartSearch cannot delete repeated link even when it looks almost similar to the human users. We put this rate of able/unable to delete repeated links to be 50% each, which is a experimental figure we got. As a result, the number of links to be analyzed further will be decreased from *Total*.

The number of relevant links is also decreased by a half of the repeated links, because of the process above. Looking at [Tab.1], the relevancy score has increased by 4-7% compare to the one for people. This means, the above simple algorithm can increase the relevancy rate very easily. Based on this result, SmartSearch decided to use Excite and HotBot as the background search engines for a time being.

4. Experiment on Current Search Engines

We conducted the experiment again two years later. Generally speaking, search engines have improved its relevancy rate dramatically in the past two years, which is shown in [Tab. 2]. Another change is the purpose of search engines. Today, search engines do not exist as it used to be. They try to change its style to be "portal site" which is the starting point to any kind of information for the user. In this changing process, a lot of search engines begin to hold their own listing of business/news information to encourage users to set their homepage as the default for web browsers. Interestingly, not all of them are searchable, nor they list a lot of information.

We used ten search engines for evaluation at this time: six robot-driven search engines, one directory-service search engine and three meta-search engines. We conducted this experiment with the same policy and methods, but changed some of the topics to the following:

- Dilbert
- health care
- IPV6
- TWA (Trans World Airline)
- Vijak Sethaput
- Wall Street Journal
- "1996 presidential election" & Clinton & Dole
- "Fermat's Last Theorem" & proof
- Macarena & dance
- IOC & bribe & investigation
- Titanic & movie
- "United Nations" & "Peace Keeping Force"

The analysis of the change of these topics will follow in the next chapter.

The results of this experiment are summarized in [Tab. 2]. The raw data of the experiment are available at http://www.smartsearch.org/se_experiment.html

Table 2: Feb. 1999

SEs	Total	dead	relevant	repeats	non-English	Score for people	Score for M SE
AltaVista	10.00	1.17	6.75	0.58	0.25	0.59	0.72
Excite	10.00	0.42	8.67	0.33	0.17	0.62	0.68
HotBot	9.92	0.25	8.75	1.08	0.33	0.74	0.67
Lycos	10.00	1.50	6.83	0.58	0.33	0.59	0.76
Infoseek	10.00	0.58	8.50	0.83	0.25	0.74	0.67
WebCrawler	9.33	0.25	7.92	0.17	0.25	0.78	0.62
Yahoo	8.83	0.83	6.75	1.08	0.17	0.62	0.62
MetaCrawler	10.00	0.92	7.83	0.33	0.17	0.73	0.64
Sherlock	10.00	0.83	8.00	0.58	0.17	0.73	0.65
SmartSearch	9.33	0.00	8.58	0.33	0.17	0.66	0.69
avg.	9.74	0.68	7.86	0.59	0.23	0.72	0.63

This new figure shows interesting phenomena. The number of dead-links and the number of non-English pages have not changed a lot, while the number of repeated links have increased tremendously. The scores for people and meta-search engines have both increased.

Analyzing the results, we can conclude the following facts:

The search engines are still slow to update all their databases that resulted in the number of dead links. The dead-links are usually considered as the time-rug between the time user accessed and the time when robot-driven search engines collected the information.

The rate of non-English pages stayed the same. It implies that a low percentage of non-English speaking people have bought and got used to use computers to access to the Internet. This result is quite interesting, since newspapers say more and more computers are sold in the world, but it seems to be that the computers are basically for business use in non-English speaking countries.

The increase of repeated links tells that people begin to put their pages on several servers to assure the publicity of the information. If more pages with the same contents are on the Internet, it is more likely that other people will come up and view the pages. Although this expectation is not exactly correct as most readers already know, this figure shows that at least more people try to broadcast their information than they did two years ago.

In all search engines, the score for people/meta-search engine have increased. We found this figure and felt happy since SmartSearch is dependent on the relevancy rate of the conventional search engines. As we have observed two years ago, the use of search engines that do not perform well will limit the capability of the meta-search engines. However, comparing to the situation from two years ago, all conventional search engines have become useful.

5. The Changes Over Two Years

It is very interesting to see the change of the quality and quantity of the results returned from conventional search engines. An information about a certain topics from two years ago still remains, while the other topics have become extinct. Generally, we consider that the news topics will die out quicker since most articles from newspaper companies' web sites will be updated or deleted. This is an understandable relationship.

How about academic findings? We expected that people have publicized deeper analysis of the information, for example "the rock found on Mars which contains a trace of life." However, it turned out that the most of the past information about this topic has just died out, and that is why we did not use this topic for conducting a new experiment. On the contrary, in the case of "the proof of Fermat's Last Theorem," the quantity of the information has increased. It looks like the topic about the rock was just news materials not academic.

The latest news like "the bribe suspects of IOC members" are easily found by robot-driven search engines today. This result also fortifies our hypothesis about the previous relationship.

Recreational and company information stayed over time. This fact implies that people's interests have not changed as quickly as news issues. From the point of view of meta-search engines, it is very difficult to often modify internal algorithms to catch up with the changing news-related matters, and therefore, meta-search engines should concentrate on improving matters of common interest.

6. Algorithms of SmartSearch

Unfortunately, MetaCrawler did not achieve a good record unlike what we expected. When we observed the results of MetaCrawler, we noticed most of the non-relevant links were originally from the search engines that did not perform well. The Sherlock, dramatically introduced with MacOS8.5, also depends on one search engine even though it uses several search engines. It is easily concluded that if meta-search engines are smart enough to exclude irrelevant links, the output will improve tremendously.

From this observation, SmartSearch limits its use of the conventional search engines, and only focuses on the high-relevancy rate search engines. We believe that this policy will increase the result scores, coupled by the following algorithms. SmartSearch downloads actual HTML documents and analyzes the relevancy for the user.

- *The number of keywords appearing in the title*
- *The number of keywords appearing in the main text*
- *The number of keywords appearing in the URL*
- *The relevancy information returned from conventional search engines*
- *The number of URLs which share the same web server*
- *Whether or not the keywords have jargon which can specify the area the user is looking for*
- *The host type (e.g. edu, com, net, etc.)*
- *The type of search engine which returned the link*
- *The length of the URL*

The result of [Tab. 2] shows that SmartSearch performs best in the *Score for people*, which we believe to be the best method to evaluate the results. The process to delete dead-links and repeated links decreased their numbers, which brought the total score to this point.

One of the algorithms to be implemented in the future, derived from the new experiment, is to deal with the common interest of the human being, which does not change easily over time. The jargon keywords will specify the area to be searched, and more precise analysis of the common interest will enable us to specially tune SmartSearch for that area.

7. Application on Virtual University

SmartSearch prohibits its commercial use by only allowing its use to the people who would like to facilitate our efforts to improve the engine; this results in supporting the Virtual University project. The Virtual University project is held by The United Nations University, jointly supported by the University of Tokyo. The purpose of the project is to develop the study environment for all students in the world (e.g. the Virtual Classroom and the Digital Library).

SmartSearch is a core component of the Virtual University to enhance its ability to accumulate and search information. Although digitized books are limited in quantity, SmartSearch can offer more information from the abundant information source of the Internet. Also, SmartSearch will be specially modified for its use in the Virtual Classroom, where students can refer to other students' notes or explanations by teachers.

We are implementing the sub-SmartSearch program in several areas of use. The Virtual Classroom and the Digital Library should have different models of search engines specially designed for their use. In the future, we are going to develop sub-SmartSearches for every single academic area, and call the total system "SmartSearch."

8. Conclusion & Future Work

In this paper, we conducted the experiments of search engines twice over two years, and summarized the analysis of the results from the point-of-view of developing meta-search engines. Fortunately, our SmartSearch achieved high scores in several areas. The ideas derived from the new experiment suggest a need for more precise analyses of the common human interest, which should improve the relevancy of the SmartSearch program's output.

To be used as a core component at the Virtual University, SmartSearch also needs to be specially designed for academic-specific use. The current model of meta-search engines on the Internet should help us spot the unknown problems easier, and enhance SmartSearch's ability as a search engine for any use.

Abstract. Characteristics and attributes grouping them in a hierarchy. The primary goal is to classify the elements (regarding standards) that might be part of a quantitative evaluation and comparison process. In order to effectively select quality characteristics we should consider different users' needs and behaviors. Hence, we outline more than sixty directly measurable attributes regarding the visitor standpoint and site domains that could range from museums and academic sites to electronic commerce domain. Also, we discuss some metrics and we show the big picture of the Web-site Quality Evaluation Method. The results should be useful to understand, assess, control, and improve the quality of Web-based software artifacts.

1. Introduction

The sudden irruption of the Web around the world has marked a quick growth in the developments of Web-based artifacts. However, as elsewhere stressed [Olsina 98a, Rossi 96], much defined models that leverage the development and the evaluation activities, mainly in medium and large-scale projects, have not been accompanied by that sites growth. Thus, the need of having an engineering approach to help in the understanding, evaluation, and improvement of Web-based software products should be considered a mandatory requirement. One objective for Web-site evaluation is to find out the extent which a given artifact characteristic or set of characteristics fulfills a selected set of requirements regarding a specific user view. Therefore, in this way, evaluation implies a logical decision-making process.

Evaluation methods and techniques fall in two categories: qualitative or quantitative. Even if software evaluation has more than three decades as discipline, the systematic and quantitative quality evaluation of hypermedia application and particularly of the Web sites is rather a recent and often neglected issue. The authors in [Garzotto et al 97] have introduced some evaluation criteria like richness, consistency, among others, to evaluate in a qualitative way hypermedia application. However, this approach is only well suited when the evaluation problem is rather simple and intuitive. In cases with many elementary attributes, it is difficult to evaluate accordingly and it is hard to identify minor differences between similar comparative systems.

Moreover, in the last three years Web-site style guides and design principles have emerged to assist developers in the process [IEEE 99, Nielsen 99, Rosenfeld et al 98], and also, list of guidelines that author should follow in order to make sites more accessible [W3C 99]. These guidelines and techniques have brought insight about essential characteristics and attributes and might improve the Web-site designing process but, obviously, do not constitute evaluation methods by themselves. In addition, quantitative surveys [Nielsen 99] and domain-specific evaluations for electronic commerce have recently emerged [Lohse et al 98]. Specifically, Lohse & Spiller identified and measured over 30 attributes that influence store traffic and sales. However, we need a broad and engineering-based method to assess complex quality requirements.

The aim of this work is to classify, in a standard-compliant way [IEEE 92, ISO 91], characteristics and attributes that might be part of a quantitative evaluation process. In order to effectively select quality characteristics we should consider different kind of users. We represent many characteristics and sub-characteristics, and more than sixty measurable attributes regarding the visitor standpoint and domains that could range from presentation and academic sites to electronic commerce domains. In addition, we explain some elementary evaluation criteria. The results of applying the proposed method (Web-site Quality

Evaluation Method) might contribute to understand, and potentially improve the sites' quality.

Therefore, in the following section, we present the main activities that evaluators should perform by applying the Web-site QEM. Next, we represent characteristics and attributes regarding the general visitor viewpoint and we show some metrics. Finally, we consider concluding remarks and future directions.

2. Overview Of The Web-Site QEM

In order to effectively select quality characteristics and attributes we should first consider the site domain, evaluation goals, and different stakeholders' requirements. After considering these steps, the primary objective is to group characteristics and attributes that might be part of the evaluation and comparison process. So, to get insight of the overall process we outline and describe the main steps that the evaluators should follow by applying the Web-site QEM, namely:

- *Selection of the Site Domain to Evaluate or Compare*
- *Specification of Goals and User Standpoint*
- *Definition of Quality Characteristics and Attributes*
- *Definition of Attribute Evaluation Criteria, and determination of Elementary Preferences*
- *Aggregation of Elementary Preferences to yield the Global Quality Preference*
- *Analysis and Comparison of Partial and Global Quality Outcomes*

Step one. *Selection of the Web Information System domain*: first, the evaluators should know what would be the software domain to evaluate or compare. For instance, regarding WIS or sub-systems we should emphasize more usability than security characteristic or both, depending on the specific situation. In electronic commerce, security is an essential characteristic, but in an academic site is less important. Besides, if the goal is to perform a case study to compare the quality of sites, we should select the typical ones in order to be successful throughout the process.

Step two. *Specification of Goals and User Standpoint*: in this activity, the decision-makers should define the goals and scope of the evaluation process. The results might be useful to understand, control, or improve the quality of Web artifacts. The evaluators could evaluate a new running or an operational project, the quality of a subsystem, a whole system, or compare global preferences of competitive systems. On the other hand, the relative importance of quality characteristics varies depending on the different users. Therefore, we define user views (as we will see in the next section).

Step three. *Definition of Web-site Quality Characteristics and Attributes*: in this step, the evaluators should define, categorize, and specify the quality characteristics and attributes, grouping them into a requirement tree. In order to follow well-known standards, the same conceptual characteristics or factors as in [IEEE 92, ISO 91] are used; i.e., Usability, Functionality, Reliability, Efficiency, Portability, and Maintainability characteristics. From these, sub-characteristics are derived, and, in turn, measurable attributes can be specified. For each attribute A_i , a variable X_i is associated taking a real value, i.e., the measured value. That hierarchical decomposition from characteristics in sub-characteristics and measurable attributes could be considered in the software quality metric framework depicted in the IEEE Standard.

Step four. *Definition of the Evaluation Criterion for each Quantifiable Attribute, and perform Elementary Measurement*: in this task, the evaluators should define the basis for elementary evaluation criteria and perform the measurement process. Elementary evaluation criteria say how to evaluate quantifiable attributes. The result is a rating, which can be interpreted as the degree of satisfied requirement. For each variable X_i , $i = 1, \dots, n$ it is necessary to establish an acceptable range of values and define a function, called the elementary criterion. This function is a mapping of the variable value (obtained from the empirical domain [Fenton et al 97]) into the new numerical domain and called the elementary quality preference, EQ_i . The elementary quality preference EQ_i can be assumed as the percentage of requirement satisfied by the value of X_i . In this sense, $EQ_i = 0\%$ denotes a totally unsatisfactory situation while $EQ_i = 100\%$ represents a fully satisfactory situation. For each quantifiable attribute, the measurement activity should be carried out.

Step five. *Aggregation of Elementary Preferences to yield the Global Quality Preference*: in this task, the evaluators obtain an indicator of global preference for each competitive system or for a single evaluated system. For n attributes the corresponding function, produce n elementary quality preferences. Applying a stepwise aggregation mechanism, the elementary quality preference can be grouped accordingly, allowing computing the global quality preference. The global quality preference represents the global degree of satisfaction of all involved requirements. (In two case studies we performed, the Logic Scoring of Preference model was used [Dujmovic 96]. The strength of LSP resides in the power to model simultaneity, replaceability,

and other attribute relationships using logic aggregation operators).

Step six. *Analysis and Comparison of Partial and Global Quality Outcomes*: in this final step, the evaluators assess the partial and total quantitative quality preferences regarding the stated goals and user standpoint. Thus, specific recommendations can be given to the requester.

3. Representation Of Characteristics And Attributes

3.1 Web-site Quality Characteristics and Attributes Tree

In this section, we focus on defining and categorizing a wide set of Web-site quality characteristics and attributes. Specifically, by applying the third process step the evaluators group characteristics and attributes in a requirement hierarchy. As previously said, we use the same conceptual high-level quality characteristics like *Usability*, *Functionality*, *Reliability*, *Efficiency*, *Portability*, and *Maintainability* to follow well-known standards. These characteristics give a conceptual and general description of software quality and provide a baseline for further decomposition. From these characteristics, we could derive sub-characteristics, and from these, we could specify measurable attributes.

Furthermore, the relative importance of characteristics varies depending on the different users and application domains. According to this, three views of quality are defined, namely: visitor view, developer view, and manager view [ISO 91]. The visitor category can be decomposed, in turn, in two sub-categories: *general visitors* and *expert visitors*. The former represents casual or intentional audience maybe having a general interest and/or minimum domain knowledge; the later represents, a specialist or expert in the domain. In addition, from the visitor viewpoint, quality characteristics such as *Maintainability* and *Portability* are not relevant. They are mainly interested in the site ease of use and communicativeness, in its browsing and search mechanisms, in its coherent navigation mechanisms and dependent-domain expected functionality, and also, in the site reliability and efficiency. Thus, in order to assess the Web-site quality, it should be clearly stated the desired combination of characteristics and attributes regarding the intended audience. [Figure 1] outline characteristics, sub-characteristics, and more than sixty measurable attributes regarding the general visitor standpoint and Web domains that could range from museums and academic sites to electronic commerce. Next, we discuss some characteristics and attributes.

The *Usability* characteristic is decomposed in sub-factors such as *Global Site Understandability*, *Feedback and Help*, *Interface and Aesthetic*, and *Miscellaneous Features*. The *Functionality* characteristic is split ups in *Searching and Retrieving*, *Navigability*, and *Specific Domain* issues, and so on. With regard to *Site Understandability*, in turn, we have decomposed it in *Global Organization Scheme*, *Labeling*, and *Guided Tour* sub-characteristics; i.e., features mainly available in a home page and that could remain during sub-site navigation. They contribute to a quick and overall Web-site understanding of both the structure and the content. However, for instance, the *Global Organization Scheme* factor is still too general to be quantifiable; many attributes could be grouped in this sub-characteristic. Hence, we decompose it in attributes like *Table of Content*, *Site Map*, etc. so that, finally, are measurable.

By considering a specific domain we easily might see that no necessarily all attributes should exist simultaneously; it can be necessary a *Site Map*, or a *Table of Content*, or an *Index*. Moreover, for example an index type could be replaceable according the domain. Subject-oriented indexes can be better in some circumstances than chronological-oriented indexes; besides, more than one index type could stay at any moment. (Web-site QEM allows to model simultaneity and replaceability relationships taking into account weights and levels of and/or polarization). Likewise, we can model simultaneity relationship in the *Web-site Search Mechanism*. For a given visitor view, it can often be better counting with both scoped and global search; i.e., it can be necessary a customized *Scoped Search* to search a (museum) collection by author and school as long as a *Global Search* can also be necessary to search general issues. Sometimes, specific areas of a site are highly coherent and distinct from the rest of the site that makes sense to give a scoped (restricted) search to users [Nielsen 99]. However, a basic and advanced global search feature could generally be enough.

In addition, regarding *Reliability* factor, the *Nondeficiency* sub-factor is discussed. That is, the degree to which artifacts do not contain undetected errors [IEEE 92]. In this category and considering *Link Errors*, attributes like *Broken*, *Invalid*, and *Unimplemented Links* were selected. The *Broken Links* attribute counts dangling links out of the total site links leading to absent destination nodes. Similarly, the *Invalid Links* attribute counts the founded links that drive into wrong or unrelated nodes; and the *Unimplemented Links* attribute counts links that unexpectedly drive to the same origin node. The higher the detected number of links errors, the lower the site *Reliability*. Consequently, the quality is debased.

- 1. Usability**
 - 1.1 Global Site Understandability
 - 1.1.1 Global Organization Scheme
 - 1.1.1.1 *Site Map*
 - 1.1.1.2 *Table of Content*
 - 1.1.1.3 Global Indexes
 - 1.1.1.3.1 *Subject Index*
 - 1.1.1.3.2 *Alphabetical Index*
 - 1.1.1.3.3 *Chronological Index*
 - 1.1.1.3.4 *Geographical Index*
 - 1.1.1.3.5 *Other Indexes (by audience, by format, hybrid, etc.)*
 - 1.1.2 Quality of Labeling System
 - 1.1.2.1 *Textual Labeling*
 - 1.1.2.2 *Iconic Labeling*
 - 1.1.3 Audience-oriented Guided Tour
 - 1.1.3.1 *Conventional Tour*
 - 1.1.3.2 *Virtual Tour*
 - 1.1.4 *Image Map (Metaphorical, Building, Campus, Floor and Room Imagemaps, etc.)*
 - 1.2 Feedback and Help Features
 - 1.2.1 Quality of Help Features
 - 1.2.1.1 *Web-site Explanatory Help*
 - 1.2.1.2 *Search Help*
 - 1.2.2 Web-site Last Update Indicator
 - 1.2.2.1 *Global*
 - 1.2.2.2 *Scoped (per sub-site or page)*
 - 1.2.3 Addresses Directory
 - 1.2.3.1 *E-mail Directory*
 - 1.2.3.2 *Phone-Fax Directory*
 - 1.2.3.3 *Post mail Directory*
 - 1.2.4 *FAQ Feature*
 - 1.2.5 On-line Feedback
 - 1.2.5.1 *Survey/Questionnaire Feature*
 - 1.2.5.2 *Guest book*
 - 1.2.5.3 *Comments*
 - 1.3 Interface and Aesthetic Features
 - 1.3.1 *Cohesiveness by Grouping Main Control Objects*
 - 1.3.2 Presentation Permanence and Stability of Main Controls
 - 1.3.2.1 *Direct Controls Permanence*
 - 1.3.2.2 *Indirect Controls Permanence*
 - 1.3.2.3 *Stability*
 - 1.3.3 *Style Uniformity*
 - 1.3.4 *Aesthetic Preference*
 - 1.4 Miscellaneous Features
 - 1.4.1 *Foreign Language Support*
 - 1.4.2 *What's New Feature*
 - 1.4.3 *User Profile Detection*
 - 1.4.4 *Download Feature*
 - 1.4.5 *Screen Resolution Indicator*
- 2. Functionality**
 - 2.1 Searching and Retrieving Issues
 - 2.1.1 Web-site Search Mechanisms
 - 2.1.1.1 *Scoped Search (e.g. Collections, Books, Academic Personnel, etc.)*
 - 2.1.1.2 *Global Search*
 - 2.1.2 Retrieve Mechanisms
 - 2.1.2.1 *Level of Retrieving Customization*
 - 2.1.2.2 *Level of Retrieving Feedback*
 - 2.2 Navigation (and Browsing) Issues
 - 2.2.1 Navigability
 - 2.2.1.1 Orientation
 - 2.2.1.1.1 *Indicator of Path*
 - 2.2.1.1.2 *Label of Current Position*
 - 2.2.1.2 *Average of Links per Page*
 - 2.2.2 Navigational Control Objects
 - 2.2.2.1 Presentation Permanence and Stability of Contextual (sub-site) Controls
 - 2.2.2.1.1 *Contextual Controls Permanence*
 - 2.2.2.1.2 *Contextual Controls Stability*
 - 2.2.2.2 Level of Scrolling
 - 2.2.2.2.1 *Vertical Scrolling*
 - 2.2.2.2.2 *Horizontal Scrolling*
 - 2.2.3 Navigational Prediction
 - 2.2.3.1 *Link Title (link with explanatory help)*
 - 2.2.3.2 *Quality of Link Phrase*
 - 2.3 Domain Specific and Miscellaneous Functions
 - 2.3.1 Content Relevancy (depending on the domain we should decompose it accordingly)
 - 2.3.2 *Link Relevancy*
 - 2.3.3 Electronic Commerce (valid for some domains. Besides, it can widely be decomposed)
 - 2.3.3.1 Purchase Features
 - 2.3.3.1.1 *Shopping Basket Facility*
 - 2.3.3.1.2 *1-Click Setting*
 - 2.3.3.1.3 *Quality of Product Catalog*
 - 2.3.3.2 *Secure Transaction*
 - 2.3.3.3 *Account Facility*
 - 2.3.4 Image Features
 - 2.3.4.1 *Size Indicator*
 - 2.3.4.2 *Zooming (for museums, campus, etc.)*
- 3. Site Reliability**
 - 3.1 Nondeficiency
 - 3.1.1 Link Errors
 - 3.1.1.1 *Broken Links*
 - 3.1.1.2 *Invalid Links*
 - 3.1.1.3 *Unimplemented Links*
 - 3.1.2 Miscellaneous Errors or Drawbacks
 - 3.1.2.1 *Deficiencies or absent features due to different browsers*
 - 3.1.2.2 *Deficiencies or unexpected results (e.g. non-trapped search errors, frame problems, etc.) independent of browsers*
 - 3.1.2.3 *Dead-end Web Nodes*
 - 3.1.2.4 *Destination Nodes (unexpectedly) under Construction*
- 4. Efficiency**
 - 4.1 Performance behavior
 - 4.1.1 *Page Size*
 - 4.2 Accessibility
 - 4.2.1 Information Accessibility
 - 4.2.1.1 *Support for text-only version*
 - 4.2.1.2 Readability by deactivating Browser Image Feature
 - 4.2.1.2.1 *Image Title*
 - 4.2.1.2.2 *Global Readability*
 - 4.2.2 Window Accessibility
 - 4.2.2.1 *Number of panes regarding frames*
 - 4.2.2.2 *Non-frame Version*

Figure 1

3.2 Some Web-site Attributes And Its Metrics

As said above, for each measurable attribute A_i evaluators can associate a variable X_i , which can take a real value. In addition, for each variable it is necessary to establish an acceptable range of values and define a function, called the elementary criterion function. The result of this mapping is the elementary quality preference, EQ_i . In turn, preferences can be rated in three acceptability levels: satisfactory, marginal, and unsatisfactory.

[Figure 2], shows a set of 4 elementary quality criteria represented by a preference scale. For instance, the evaluation criterion for a *Site Map* attribute is a simple discrete binary criterion: we only ask if it is available (completely satisfactory) or not (completely unsatisfactory). Instead, the evaluation criterion for a *Foreign Language Support* attribute is according to the formula, shown in the right upper side of the figure. The variables considered are the number of foreign languages supported by the Web-site (e.g., for museums), and the level of support (total, partial, or minimum). The resulting value could be between 0 (completely unsatisfactory) and X_{max} (completely satisfactory). If the measured value of X is above X_{max} , the corresponding elementary preference EQ will be equal to X_{max} . (Also, the reader can see the equation in order to obtain the elementary preference for the broken link attribute).

Figure 2

On the other hand, the evaluation criterion for a *Scoped Search* attribute is a multi-level discrete absolute criterion defined as a subset, where 0 implies no search mechanism available; 1 implies a basic search mechanism (accomplishing 70% of the requirement); and 2 implies the basic and advanced (expanded) search mechanism (accomplishing 100% of the requirement).

Once all elementary criteria are agreed and data collected, we can obtain the quality preference for each attribute of a system or competitive systems (the fourth step of Web-site QEM). The global quality degree of satisfaction of all involved characteristics is obtained by logic aggregation of elementary preferences. In the fifth step, we use the Logic Scoring of Preference which compute the global site preference from elementary ones applying logic operators based on weighted power means [Dujmovic 96].

4. Concluding Remarks And Future Directions

Web developments are continuous and rapidly growing due to the wide acceptance of Web-based systems for very different audiences. However, this rises issues like how to design for quality and cost-effectiveness taking into account the satisfaction of different users' needs and behaviors, or how to assess, interpret outcomes, and, ultimately, improve the quality of Web artifacts, among other issues. One effective strategy to face these, is product (and process) modeling using prescriptive and/or descriptive approaches [Olsina 98b]. Process and product modeling potentially allows us, the understanding and communication; the evaluation and improvement; the control and forecasting.

In this direction, this work proposes a quantitative evaluation method to assess and compare the current Web-site quality regarding a user viewpoint. The primary goal was to classify, in a standard-compliant way, quality

characteristics and attributes for general visitors. This activity (as part of the third process step), implies a hierarchical decomposition from the higher level of the tree –at the characteristic level-, to the lower level of the tree, the quantifiable attribute. Hence, the attribute is at the elementary metric level. This requirement decomposition framework is easy to understand, powerful, and flexible. It allows deletions, additions, and modification of its components. Moreover, we are arranging characteristics and sub-characteristics to be as useful for most Web-site domains as possible regarding specific users. (In fact, the highest level like Usability, Functionality, Reliability, etc. are thought to be domain-independent characteristics). Also, as previously said, the relative importance of characteristics varies depending on users and domains. Therefore, we have defined three views of quality: visitors view, developers view, and managers view. Thus, from the point of view of general visitors, artifacts characteristics such as Maintainability and Portability will not be taken into account; though, from the point of view of developers might not be excluded. On the other hand, managers not only will be concerned with quality but also with cost-effectiveness issues.

Besides, we have discussed quantitative evaluation criteria for some elementary attributes, and we have shown the main method activities. One strength of Web-site QEM resides in the modeling of great amount of attributes using the LSP approach. We can model simultaneity, replaceability, neutrality, symmetric and asymmetric attribute relationships using logical aggregation operators. At the end of the evaluation and comparison process, we obtain for each selected Web system a global indicator using the scale from 0 to 100%. Such cardinal rating will fall in three acceptability levels, namely: *unsatisfactory* (from 0 to 40%), *marginal* (from 40 to 60%), and *satisfactory* (from 60 to 100%). Ultimately, the rational utilization of our method should help reduce subjectivity in the process by providing a quantitative basis for quality assessment. Furthermore, it provides a powerful tool and concepts to understand and improve the quality of Web sites.

Finally, we have run a case study on typical, well-known museums [Olsina 99], and other on typical academic sites [Olsina et al 99]. Currently, we are running two evaluation projects in the arena of e-commerce. On the other hand, the Web-site QEM include a step for the quality metric validation, both theoretically and empirically. Ultimately, this research aim is strengthening the evaluation methodology.

Abstract: The administration of the University of Central Florida has found a top-down formula that is successful at encouraging the faculty to design, develop, and deliver Web-based academic courses. This paper describes the history of the development of the program and reviews one faculty member's experiences in designing, developing, and delivering a Web-based graduate level course.

1. Growth of UCF

UCF has grown from an initial enrollment of just under 2,000 in 1968 to just under 30,000 during the 1998-1999 academic year. During recent times, a new academic building has been added almost every year, and parking garages are now taking the place of parking lots. Growth of the campus, the adjacent research park, and area business and industries have pushed the regional transportation infrastructures to the limits. As a result, the administration of the University of Central Florida has become very interested in nontraditional methods of course delivery, and travel-weary students have shown surprising support for some of the alternatives that have been offered.

UCF Student Profiles

Student Classification	Part-Time	Full-Time	Avg. Age
Freshman	347	4,782	18
Sophomore	1,092	3,428	22
Junior	1,701	3,691	24
Senior	3,993	5,209	27
Total Undergraduate	7,133	17,110	24
Beginning Graduate	2,481	1,002	32
Advanced Graduate	428	192	35
Total Graduate	2,909	1,194	32
Post-Baccalaureate	1,358	117	34
Total UCF	11,400	18,421	26

Figure 1: 1998-1999 UCF Student Profile

The statistics illustrated in Figure 1 show a significant part-time student body with average ages above what is commonly found in resident university settings. The higher than normal number of part-time students, and the higher than average ages of the students are typical of a modern metropolitan university. These are the students supporting the increasing demand for non-traditional course delivery strategies. Additional statistics can be accessed online at two locations:

University of Central Florida Public Relations (<http://www.oir.ucf.edu/pubrel/facts/index.htm>)

University of Central Florida Institutional Research and Planning Support (<http://pegasus.cc.ucf.edu/~irps/>)

2. UCF Budget Model

The budget at UCF is similar to the budgets at many universities. It has objective, formula based components and subjective "special initiative" components. Some portions are based upon historic funding models that are older than UCF itself. What follows is a simplified and not completely accurate discussion of one of the more controversial aspects of the funding model

Perhaps the most divisive component of the budget is a formula that determines the base level of funding for the individual colleges. It is tied to productivity as measured by student credit hours and produces an output of administrative, faculty, and staff positions that can either be filled with real people or left unfilled, releasing the salary dollars for other purposes. Figure 2 is a greatly simplified illustration of this issue. For the sake of simplification, a number of additional factors such as advising loads and off-campus course activities have been excluded, although they also enter into the determination of the final number of faculty lines per college. The real-world results are similar to the simplified illustration though; it is very possible for the same initial level of student productivity to produce twice the funds in one college compared to another.

College	Sample SCH	Productivity Factor	Faculty Lines	Line Salaries	Dollars Generated	
A	10000		1283	7.79	\$55,000.00	\$428,682.77
B	10000		1300	7.69	\$90,000.00	\$692,307.69
C	10000		987	10.13	\$53,000.00	\$536,980.75
D	10000		819	12.21	\$68,000.00	\$830,280.83
E	10000		1250	8.00	\$58,000.00	\$464,000.00

Figure 2: Sample of formula-based funding inequities

It can reasonably be argued that historically, some colleges have had to pay much higher faculty salaries than others in order to attract equally qualified people. However, the model intentionally produces more faculty lines than are normally filled by the colleges. The funding from the unfilled lines is converted into operating funds, and this is where it is possible for colleges to end up with major differences. For example, it can be argued that productivity-based funds that are not used to fill faculty lines in a "have" college can be used to purchase almost twice as many computers as similar funds in a "have not" college.

To counter some of the apparent inequities that are created by the formula-based funding model, significant funds are held in reserve to be awarded as special projects, or "specials" as they are commonly called. Although specials are awarded to all colleges, there is little evidence that they balance the apparent inequities in funding.

3. Development of a Distributed Learning Plan

Although many administrators at UCF acknowledge that the base model of funding is not perfect, there is no consensus upon how to improve it. Any changes that improve funding to colleges that appear to be under-funded will naturally reduce the proportion of funding to the other colleges. It is almost certain that no dean will build popularity within his or her college by willingly giving funds to other colleges. It is in this financial environment that the need to expand our distributed learning initiatives arose. The solution was to take the needed funds "off the top" of the budget.

3.1 Center for Distributed Learning (<http://distrib.ucf.edu/cdl/home.html>)

By the summer of 1997 a decision was made to provide a new service to the colleges and faculty of UCF. The Center for Distributed Learning was created under the office of the Vice Provost of Academic Programs. Funding for the center is taken off the top of the University budget, and its resources were made available to all faculty. The Center coordinates all distributed learning activities, including delivery technologies such as videotape, interactive television, electronic mail, and web-based instruction for the distant learner as well as traditional on-campus courses delivered in part through electronic media. For this paper, we focus upon the course development and delivery that uses the World Wide Web in whole or in part.

To "kick start" the Center, funds were set aside for internal grants that were given to faculty through a competitive grant program. The funds were sufficient to supply faculty with a state of the art desktop or laptop

computer, an adjunct to cover one course during the development semester, and a graduate assistant to help during the first time the course was taught during the next semester. The Center is now starting its third year, and it continues to fund at least 12 new course development projects each semester.

3.2 Course Development and Web Services (<http://reach.ucf.edu/~coursdev/>)

A second new office, Course Development and Web Services, was created under the Vice Provost of Information Technologies to provide direct faculty support in the design and development of new Web courses. This office, too, is funded off the top of the university budget. This office is available to all faculty, whether they have a course development grant or not, and whether they are working on their first or sixth Web-based course. A number of services are provided, including faculty training, assistance with course design, course coding, and trouble shooting. A faculty member can choose to design, develop, and code the course with a minimum of assistance, or the faculty member can supply the basic curricular content to the Course Development staff and let them do most of the work of getting the course online.

4. Growth and Current Operations (<http://distrib.ucf.edu/dlucf/home.html>)

There are two types of courses that are of particular interest when we discuss Web courses at the University of Central Florida. They are designated by specific section codes.

M Sections. Courses that contain an M in their section number have at least half of their content offered through the Web. They are structured in such a way that a single classroom time slot can be used to support the in-class time of two or more M courses by alternating the course meeting dates. This allows more efficient use of on campus classroom space

W Sections. Courses that contain a W in their section number are offered through the World Wide Web. They require only minimal visits to a campus. For example, the only visit might be for an in-person final exam.

The offices of the Center for Distributed Learning and Course Development and Web Services are just two years old now, so it is difficult to determine any clear patterns at this point. However, the Figure 3 summarizes the number of students who have taken courses that have significant Web components. Web courses are now offered by all five colleges. This represents a very solid argument for providing open access to campus-wide offices that are funded off the top of the university budget.

	Fall 1997	Spring 1998	Summer 1998	Total 97 - 98	Fall 1998	Spring 1999	Summer 1999	Total 98 - 99
Students in "M" Sections	3700	2250	749	6699	5758	4293	1324	11375
Students in "W" Sections	392	691	667	1750	968	1407	1585	3960

Figure 3: Students enrolled in "M" and "W" course sections over the first two years

5. Web Courses from the Faculty Perspective

The paper up to this point has provided a background to the driving forces and current state of Web course development at the University of Central Florida. What follows are the experiences and opinions of this faculty member as he went through the processes of initial training, development, coding, and delivery of a Web course. It is said that trying to get faculty to do anything new will be futile unless three conditions are present: incentives, resources, and rewards.

5.1 Incentives

The perceived incentives are certain to vary from one faculty member to another. However, the UCF Web course development program has made it likely that many faculty will find some form of incentives. For many, the incentive of the grant – recognition, released time from teaching, graduate student assistance, and funding – serves as sufficient motivation to get going. My case is a bit different. I was on a sabbatical and did not need released

time. I'm a full professor and don't really need much more recognition, and I have an adequate computer system at my desk. However, there were still incentives.

I teach courses in a graduate Instructional Technology program. In fact, a number of my current and former students are now employees of Course Development and Web Services. With a number of faculty around me getting involved in Web courses, I was starting to feel a bit outdated. It occurred to me that a sabbatical was the perfect time to get caught up.

I work a great deal with multimedia technologies, and I'm uncomfortable talking about technologies in my classes unless I've actually worked with them. I was being asked more and more questions about Web-based training by my industry and military students, and I was having trouble finding answers. What better way to speak with authority than to use your own Web course as an example?

5.2 Resources

The UCF Web course development program provides outstanding resources. In fact, first exposure to the number of resources can be overwhelming. As previously mentioned, a faculty member with an internal development grant gets an adjunct to cover a course to provide released time, funding for computer equipment, and graduate assistant support. Beyond that however, any faculty member has numerous resources available.

IDL 6543 (<http://reach.ucf.edu/~idl6543/>) is an intensive, almost formal course that is taught by the Course Development staff. Portions are lecture / discussion, laboratory, and Web-based. It is open to any faculty member, but it is required for those who are awarded the internal grants for Web course development. The course covers a wide range of topics relating to Web course attributes, course design, course coding, and implementation. Projects during IDL 6543 result in the actual development of significant portions of a Web course.

WebCT Academy (<http://reach.ucf.edu/~webct411/>) is a series of Course Development workshops that provide a range of experiences with WebCT (<http://www.webct.com/webct/>), the course development, delivery, and management tool used at UCF. The workshops range from introductory overviews of WebCT through intensive authoring and management tasks.

Pegasus Connections CDROM (<http://reach.ucf.edu/~coursdev/cdrom>) is a modern faculty and student resource that contains almost every document or link that you can imagine. It also contains basic Web course training for students and faculty, and it has a number of licensed programs and plug-ins that are commonly used with Web browsers. It is given to faculty who are teaching Web courses, and it is sold to students for a minimal \$5.00 charge.

Finally, the Office of Course Development and Web Services supplies a wealth of resources in the form of talented people. There are instructional designers, graphic artists, course programmers, technical problem solvers, and others. Faculty who are new at developing Web courses are linked to a primary contact who serves as the facilitator throughout course design, development, and delivery.

5.3 Rewards

Standards have evolved over the last few years at UCF. While in the past there was a very clear "technology penalty" for working with or producing anything that was not ink on paper, that is not the case now. Successful innovation in course development and delivery is now viewed as an important component in the tenure and promotion processes at both the college and university levels. A successful implementation of a technology mediated course is often considered the equal of a refereed research journal article.

At the end of each course development cycle, the new courses are demonstrated at a luncheon ceremony. Deans, department chairs, and faculty attend, and faculty give short presentations that highlight key aspects of their courses. Deans and chairs have frequently commented that the presentations have really made them aware of the outstanding efforts that have gone into the course production activities.

6. EME 6062 – Course Design, Development and Delivery

The remainder of this paper provides documentation into the amount of time required to develop and deliver a Web course. Figure 4 provides a summary chart of the time spent on various tasks. I am a "typical" faculty member in most ways. I know my course content very well. I know how students react to various parts of my courses. I have a number of courses to teach. I advise students, and I work on many different types of committees. However, I am probably not a typical faculty member when it comes to technology-based course

development. I teach the process of instructional design, and I teach computer-based authoring systems. I chose to do much of the Web course development on my own so that I could better understand what is involved.

**EME 6062 Web Development and Delivery
Hours on Tasks**

	Faculty Training	Course Development	Course Coding	Forums Email	Grading	Totals
Spring '99	68	75	75	43	45	306
Summer '99	4	2	2	*	*	*

* Incomplete data

Figure 4: Hours required to perform specific tasks in course development

6.1 Faculty Training - IDL 6543

This is the quasi-formal course for faculty who are developing Web-based content. It has lecture, lab, and online components. There are assigned activities, and products that must be turned in. During this course the faculty member learns to use the prescribed tools and techniques that are supported at UCF for Web course development and delivery. This was a very interesting course for me, in that I was a student of some of my former students. I found that they had no problem treating me as “one of the faculty,” and I found that I was soon interacting with them as a peer.

Probably the most rewarding aspect of this course was the interaction with a variety of faculty from across the campus. While I knew technology very well, I quickly learned that some of the faculty from Arts and Science had far better ideas about successful communication and presentation strategies than I did. The “cross fertilization” of academic disciplines was most rewarding. The total time required to complete the course was approximately 72 hours, divided almost equally between lecture sessions, lab sessions, and online time. There were also a few minor training components relating to WebCT advanced features and course recycling that are included in this figure.

6.2 Instructional Design and Coding

I selected a graduate research literature course (<http://reach.ucf.edu/~eme6062/>) for development into a Web delivery format. To address accreditation issues, the course has two “in person” meetings. One is at the start of the course to meet the students and provide a basic course indoctrination, and the other is for an “in person” final exam. For students who are distant, the final exam can be proctored by a faculty member at a local university or community college. The Web section of the course is now finishing its second cycle. During the spring semester, 1999 the first Web section was offered concurrently with a traditional section and students were given their choice of taking either. There were 24 students in the Web section and a similar number in the traditional section. During summer session, enrollments are typically lower. Only the Web section of the course is being offered, and there are 16 students enrolled.

Probably the greatest surprise for me was the amount of “new” course material that was required in order for the traditional course to become a Web-based course. Although I had heard the warning a number of times, I was not initially prepared for the effort it took to create a Web course that provided experiences similar to the traditional course. Web course design is not simply a process of converting your course notes to electronic format! The time spent on course design was approximately 75 hours. However, the second time the Web course was taught, only 2 hours were required to correct some minor flaws.

Getting the course into the WebCT format was time consuming, but it was no different than learning a new authoring system. The content of the course is stored in HTML format. Although WebCT provides basic tools that convert text to HTML, I found in many cases it was faster and easier to edit directly in HTML code. Unless you are already familiar with authoring systems and HTML code, this is the one area that I would advise faculty to turn over to the technical programmers. Course coding took approximately 75 hours. However, with proper materials at hand, one of the course programmers probably could have completed the task in less than half the time. The second time the course was taught, only an additional 2 hours of coding were required to make some minor corrections, update some Web links, and reset the course for the new students.

6.3 Web Course Delivery

There are two face-to-face meetings with the students. The first is a course orientation at the beginning of the semester. This orientation covers general University procedures for Web courses, and specific procedures for this course. Since this course relies very heavily upon electronic library resources, there is an electronic library orientation. At the end of the course, there is a standard "in person" final exam. Student ID's are checked to confirm their identity, and they then take a comprehensive course final exam. The face-to-face components take a total of about 8 hours each time the course is taught.

The primary methods of communication with the students are through email, forums, and online interactive chat sessions. The total time spent during the first time the course was offered is 35 hours, with 3 of those being online chats. At this time, the second session of the course is not complete, but it appears that the "communication" time will be slightly lower. This is almost certainly due to the lower summer enrollment in the course. The level of communication time seems closely related to the number of students in the course.

6.4 Grading

This is a graduate research literature course, so the students produce quite a bit of literature. The first quiz is graded by WebCT because it is completely objective, but all remaining work requires some level of "hand" grading. By far the most time consuming is the process of grading the final projects, which are literature reviews or annotated bibliographies. Grading for the spring semester course took approximately 45 hours, but it is expected that this number will be lower for summer term due to the reduced enrollment.

7. Student Perceptions

Since this course has run through completion only one time so far, insufficient data have been collected to provide a clear picture of student attitudes and performance. From the information collected, students considered the course to be about the same amount of work as similar traditional graduate courses that they have completed. They had a few frustrations dealing with technical details of getting everything started, but once they were underway they liked being able to work at home on their own terms. The final grade distribution appears to be very similar to those of the traditional sections of this course.

Faculty and staff are conducting research regarding student attitudes and over-all effectiveness of our online courses. Much of this research can be viewed online at (<http://reach.ucf.edu/~research/>). In general, students like Web courses. They have had frustrations with slow connections to campus, but recent campus Internet connection improvements seem to have reduced those problems. Preliminary research is indicating that there do appear to be differences in attitudes among the students based upon personality and learning style measures.

8. Things to Improve Upon

Perhaps the greatest problem is the limited physical space that is available to the Course Development and Web Services office. The rapid growth in staffing has resulted in three or four employees working in what would normally be considered a single office. There is little room for people or equipment, and the ventilation system is not capable of handling the load. Efforts are underway to locate additional space.

Rapid growth has also created confusing logistics. While many faculty do build and revise their own Web courses now, there are barriers to the process. The Web server that delivers the courses is also the Web server upon which courses are developed. Testing and debugging courses and associated programs have been known to bring down the entire server – something that can be very frustrating to students in the middle of other courses. A separate server is needed for course development and debugging. This would make it possible to implement the server side of Web page development software, something that is not now permitted.

The Center for Distributed Learning and the office of Course Development and Web Services are both very new. They have been positioned into an otherwise very traditional academic structure. There are confusing overlaps and contradictions in the missions of the two new offices and several older offices, including Faculty Training and Development, Instructional Resources, and Computer Services. Additional efforts should go into more clearly defining the roles of these offices, and improving information flow and cooperation among them.

Developing a Science Inquiry-Based Web Site: The Science Junction

Abstract: NC State University provided funds for a project called The Science Junction. The primary purpose of The Science Junction is to promote the “doing” of science by students of grades 4-12 through Web-based activities and resources. Other purposes of the site include assisting teachers and parents to locate good science learning resources, promoting communication among teachers for collaboration and for the development of a science teacher learning community, and assisting teachers in the learning of new technologies and the practicing of new methodologies. This paper describes the development of the activities included in the Science Junction, <http://www.ncsu.edu/sciencejunction/>

I. Introduction

In recent years, Internet connectivity in U.S. schools has advanced substantially as a result of increased attention from national policy making leaders and community leaders. The President's Educational Technology Initiative [Gore 1996] calls for classrooms to be connected to one another and to the outside world and for teachers to be ready to use and teach using technology. In just three years, the percentage of U.S. public schools with Internet access increased from 35 percent in fall 1994 to 78 percent in fall 1997 [Bare & Meek 1998]. More instructional classrooms are becoming connected to online telecommunications. Bare and Meek also reported that the percentage of schools with Internet access in five or more instructional rooms per school increased from 25 percent in 1996 to 43 percent in 1997. A 1997 report from the National Center of Education Statistics [Heavside, Riggins, & Farris 1997] indicated that 87 percent of the schools that lacked Internet capabilities reported planning to obtain Internet access by the year 2000. If these schools are able to acquire access, 95 percent of all American schools will have Internet access in the year 2000.

There has been a significant increase in the number of educators who use telecommunications networks, as well as growth in the number and quality of networked educational resources [Anderson & Harris 1997]. There are many common rationales for using advanced telecommunications to meet pedagogical goals. Frequently cited in current research are: Bringing real-world relevance into the classroom; helping students perceive knowledge as constructed rather than delivered from a book or teacher; providing students with an effective model for lifelong learning; strengthening social, communication, and critical thinking skills; meeting standards for inquiry-based learning; increasing the authenticity of the learning environment; changing the definition of the learning community

to extend beyond classroom walls; finding role models for students; and promoting equity by providing all schools access to the same resources [Schrum & Berenfeld 1997; SRI International 1997].

Web-based networks use can help educators stay current with best practices in their field and help them to overcome problems such as teacher isolation. As with any profession, teachers need opportunities to expand their knowledge, keep pace with developments in their field, try out new innovative teaching methods, exchange ideas with peers and experts, and refine their skills. Network exchanges present a prime opportunity for collaboration among teachers [Merseeth 1991]. Teachers with access to telecommunications networks can contact other educators to discuss issues relating to their teaching practice, developments in their field, and classroom experiences.

Text-dominated pages with few graphics and photographs characterized the advent of web page authoring. As the media has developed, more sophisticated techniques can be used to promote more interactivity. This includes the use of cgi, java programming, and various formats of video displays. The development of the Net Forum enables users to interact with other users using a Web-based format. The use of these cutting edge developments along with more advanced Web browsers allows creative authors to generate Interactive Web-based, hands-on science activities.

NC State University provided funds for a project called The Science Junction. The primary purpose of The Science Junction is to promote the “doing” of science by students of grades 4-12 through Web-based activities and resources. Other purposes of the site include assisting teachers and parents to locate good science learning resources, promoting communication among teachers for collaboration and for the development of a science teacher learning community, and assisting teachers in the learning of new technologies and the practicing of new methodologies.

2. Description of the Site

The Science Junction is indexed into six interconnected areas: The Data Depot, the Teacher Terminal, NC State Frontiers, Student Station, Communications Bridge, and Upgrade Route. Half of these areas are dedicated to student use and half for teacher and parent use. The Web site can be found at www.ncsu.edu/sciencejunction/.

2.1 The Data Depot

The Data Depot contains three sections: Collaborative Experiments, Collected Data, and Simulated Data. The focus of this area is to provide a means for students to post and share data they have collected on various experiments, to extract and evaluate other data previously posted, or to manipulate data generated by mathematical models. The Simulated Data section uses data generated from mathematical models. One good use of such generated data is shown in the Solar Eclipse Data Set '98. The data from the solar eclipse of February 26, 1998 was originally generated by NASA. This site includes the data in a modified data set which is useful for pattern finding and analysis. All data sets include a visualization of the data. The solar eclipse data allows the user to select two locations from where the eclipse was visible. The browser allows the user to view the eclipse at the two locations. By looking at various locations, times when the eclipse occurs, and the eclipsed part of the sun, students can discover relationships between location and the parameters of the viewed eclipse. Even though the students did not directly collect the data, they are able to sift through the information using scientific processes.

An example of an activity from Collaborative Experiments is Water What-If's. This site enables teachers to learn how to make water quality measurements and to provide a way for schools around the world to share their water quality data. Instructional modules and lesson plans can be downloaded from the site in copy-ready forms.

2.2 The Teacher Terminal

The Teacher Terminal area is a resource for science teachers, which includes IMSEnet and Science Lesson Plans. IMSEnet (Instructional Materials for Science Teachers network) is a large Web site which lists science Web sites that have been determined to be useful for science teachers. The Web sites are categorized by content areas and topics of interest to teachers. When a category is selected, annotations of various web sites are delivered to the user. This resource is a time saver for science teachers who do not have the time or the expertise to search and evaluate the expanding number of science related web sites.

The Lesson Plans section contains original lessons developed by science educators at NC State to promote inquiry activities in the science classroom and laboratory. One such lesson plan, Carolina Coastal Science, uses

photographs to prompt students to reflect upon environmental science issues. Within this site resides a classroom simulation/debate called The Shell Island Dilemma. The scenario of the dilemma is that the Shell Island Resort is in danger of being destroyed by a migrating inlet. Mason's Inlet is moving south rapidly. The Shell Island Resort is currently situated in an Inlet Hazard Zone and is in dire straits. The objective is to investigate the issues concerning the fate of the Shell Island Resort and then to debate the future of this and other oceanfront structures threatened by coastal erosion. As students engage in the investigation, they must identify the social, political and scientific issues with which different stakeholders must deal. The students are placed into the role of one of the stakeholders. Web-based materials are provided for student research.

We have been exploring ways to use virtual reality in our science investigations. Examples of this can be found in this lesson plans area. "Which Way Is North?" is an activity that allows students to develop skills in understanding location by exploring a variety of unique geological formations using Quicktime Virtual Reality (QTVR) panoramas and topographic maps. "Dino Inquiry" allows you to explore a variety of dinosaur fossil bones from the Dinosaur National Monument quarry using panoramas and digital still imagery. "Geologic Explorations" allows you to explore a variety of unique geological formations through the use of QTVR.

2.3 NC State Frontiers

To promote the reading of cutting edge research in the sciences, we have included a section in the Science Junction that enables users to review the research done at NC State. This area serves as a pointer to departmental, research group, and individual researcher web pages at the university. These web pages are written in non-technical terms so middle school students should be able to understand the content.

2.4 The Student Station

The Student Station is a place for students to interact with science outside of a school environment. This area contains two sections: Game Room and Home Experiments. Again, the focus of this area is to promote the "doing" of science. The Game Room allows students to explore with science simulations, and Home Experiments is an area for sources of ideas for hands-on experiments that students can do at home.

The Game Room is a place where students can interact with computer games that teach concepts in the various sciences. For example, Space Trak is a game where the students must move a spaceship around a prescribed path by applying an impulse in a given direction. If the students move outside the path, the spaceship explodes. By interacting with this game, students learn aspects of Newton's first and second laws of motion. Through trial and error, or through analysis of mistakes, students realize that net forces in the opposite direction to motion will cause the spacecraft to slow down, which is required to successfully navigate the turns. Another simulation located in the Game Room is called REACT! The students control the collision of two molecules by changing the orientation and speed of the molecules before the collision. By exploring the simulation, students discover that for reactions to occur, the molecules must collide, collide with the appropriate amount of energy, and collide in proper orientation.

A new site being developed for the Student Station is the North Carolina EarthKam website. This site allows visitors to explore the NASA EarthKam project work being done by middle school students in North Carolina. This site also includes science simulations of concepts to be learned by students who are involved in the Science House Student Mission Operations Center (SMOC).

2.5 The Communications Bridge

The Communications Bridge is an area that allows science teachers to interact with one another using a variety of tools. The site is for both novice and veteran science teachers. The SciTeach Forum is a web forum where teachers can easily send messages and read what others have to say. Messages are sorted by topic headings, making it easy to find items of interest. North Carolina State University student teachers of science use this web forum extensively during their professional semester.

Science Teachers who are interested in collaboration projects can register in the "Join the Database" section. They may also search the database to see if there are any other teachers who have similar interests for collaborative experiments.

2.6 The Upgrade Route

Not all science teachers have the ability to attend professional workshops to learn new teaching methodologies and to practice using new technology tools due to the remoteness of their locations or to their hectic schedule. This area provides a mechanism for those teachers to learn about such topics. The Upgrade Route consists of two areas: Professional Development and Technology Skills. Professional Development provides resources to upgrade the teacher's knowledge of such topics as National Science Education Standards, gender equity, cooperative learning, and multicultural education. This area is textual in nature and provides little interactivity. Technology Skills provides information on how to use the latest instructional technology advances for science teaching. The Upgrade Route provides step-by-step worksheets, video, and instruction manuals for a variety of tools for the science classroom.

3. Conclusions

The SERVIT Group (Science Education Research on Visual Instructional Technology) at North Carolina State University has been brainstorming and developing activities for the Science Junction for the past two years. We are now in the evaluation phase of the project, testing to see what students are learning by exploring this interactive environment. It is our intent to increase the motivation for students to pursue science and science related careers, as well as to provide the environment for learning science concepts.

The presentation of the paper will include demonstrations of the activities developed for the Science Junction. Participants are invited to preview the site before attending the conference to provide input to the developers of the Science Junction.

Abstract: This paper proposes an effective personalization method, especially on rule-based matching technique and feedback profiling systems. This technique is able to support various personalized content by using rule-based matching system : rule statement was designed to describe or present various personalization technique. Customer reflects personalized content to feedback system for adaptive customer profiling information. Rule-based matching of one-to-one marketing is extremely useful for the ever-growing number of personalized electronic commerce systems.

1. Introduction

The rapid growth of the World Wide Web(WWW) has made it possible for a large amount of information resources on the Internet to be accessed easily, but most web sites don't communicate with customers because they don't deliver the information customer actually want. Most of time it is because web sites present the same information that companies use in their catalogs. In light of these trends, companies creating web sites to supply their customers, employees, and business partners with products, services, and information must evaluate their web strategies to provide personally relevant content and create one-to-one relationships [Peppers and Rogers 1996] with their customers.

we are approaching this goal from two directions that are closely related to each other: rule based matching technique, and feed back profiling system for adaptive personalized services. Personalization technology helps the customer get useful information easily. On most personalized WWW pages, the selection of information is customized according to each customer's preference or interest. The personalized Internet merchant server that we have developed is one of the systems using automatic personalization and feedback system. It creates personalized shopping malls or catalogs for each customer on the fly using customer profile and purchase history, and customer action to evaluate the customer's expected interest in each web page.(The rule based matching engine and the template process engine used in this evaluation process were developed by our lab) The customer profile is created automatically and is automatically updated according to the customer's operations on the web pages. We planned to get the advantages of both personalization by developing a personalized rule based matching system and adaptive feedback profiling. That is, the information would be filtered using personalization technology and would then be delivered automatically using the push mechanism and template process. This paper gives a high-level explanation of what one-to-one relationships are and how they are achieved with personalization techniques. Personalization is the third stage of web evolution.(the first stage is static site and the second stage is dynamic site with database connectivity), also builds on dynamic web technology to deliver dynamically generated content. In addition, it provides the capability to present personally relevant content. Each customer gets a customized view of the web site. Personalization is the only way to create customer loyalty and generate repeat visits to cyber shopping malls.

2. Personalized shopping mall for One-to-One marketing

Today many businesses approach the new technique of electronic commerce by usually placing their product catalogs on the cyber shopping mall and combining them with an interactive order processing function to capture payment and process the order. To these businesses, selling their products via the cyber shopping mall is simply another business channel. This approach is not suitable, as it does not differentiate them from their competitors and fails to attract and sustain the attention of their target customers. Businesses that strive to be successful in selling their merchandise through the Internet will have to take advantage of its inherent strengths.

The sequential solution to solve the problem is that attract and sustain consumers by pushing personalized and customized services related with a sense of community relevant to them, and that engage consumers in personalized dialogue, learning more about their needs to better anticipate their future needs and requirements. The next procedure is that motivate consumers by providing personalized incentives (coupons, advertisements) for them to move from dialogue to action such as ordering a product or completing a survey ,that fulfill transactions by reliably and securely supporting the full process of electronic commerce from promotional pricing to secure payment handling and that manage the process by monitoring results and allowing dynamic changes to business rules and content to ensure the system is achieving business goals.[Cliff Allen 1998]

3. Rule-based matching technique

The merchant server classifies its customers in categories based on their purchase history, customer relation with shopping mall. It recommends new products and services based on your customer category. The server also shows the customer targeted incentives and advertisement based on the customer profile. This is called rule-based matching because business managers can define business rules to match content with customer. The rule-based matching system has client-server architecture. The client side has two program modules, rule maker and profile maker that make or operate rule statement and the customer profile. The server side has three program modules, rule based matching engine, template process module, and feedback profiling system, and it matches input rule and generate personalized templates. The client side is in charge of rule and profile generation and the server side is in charge of evaluation of the rule and generation of personalized services.

	Return	condition function	Operator	Variable	Conj.	
IF		Customer(profile name)	== + - / * % in != < <= > >=	numeric string	and or	
	date	BoughtDate(product)				
	int	BoughtCount(product)				
	double	BoughtAmount(product)				
	double	BoughtAmountSince(product, date)				
	int	BoughtCountSince(product, date)				
	int	BasketCount(product)				
	double	BasketAmount(product)				
	date	BoughtCatalogDate(catalog)				
	int	BoughtCatalogCount(catalog)				
	double	BoughtCatalogAmount(catalog)				
	double	BoughtCatalogAmountSince(catalog, date)				
	int	BoughtCatalogCountSince(catalog, date)				
	int	BasketCatalogCount(catalog)				
	double	BasketCatalogAmount(catalog)				
		View(product), ViewCatalog(catalog)				
	Buy(product), BuyCatalog(catalog)					
	Register()					
Action function	Target kind	Target	Apply count		Apply filter	
Push	Catalog Product	catalogno	Integer		times anytime notbought tillbought	
PushInBasket		productno				
Mail	Adbanner	adbannerno				
AddBasket	Product	productno				
Action function	Discount Amount	Discount Method	Target kind	Target	Apply count	Apply filter
Discount	double	% amount	Catalog Product	Catalogno Productno	integer	times anytime notbought tillbought
			Basket			
Customer(profilename)	=	Customer(profilename)	+	Customer(profilename)		
		string, number	- * %	string, number		

Table 1. Syntax of rule statement.

Rule-based matching technology needs rule statement for evaluate customer's condition that enable to receive personalized services. Thus, we have designed syntax of rule statement like that shown [Table 1]. These rule syntax almost cover or describe the personalization technique (that is cross-selling, up-selling, target mailing, target discount, profile updating, coupon and advertisement) for one-to-one marketing on cyber shopping mall. It is easy for web developers to provide personalized services because rule maker at client side help us to make the

rule easily and conveniently. Rule statement is composed of “IF~THEN“ mood syntax. The “IF“ clause is composed of condition function for evaluation of the customer profile, purchase history, etc., operator for comparing with relevant value, actual comparison value, and conjunction for combination of various customer’s condition. The “Then“ clause is composed of action function for activating push process, target, target kind for object to push, apply filter for filtering candidate of rule, apply count for push count, discount amount, discount method for targeting discount. Defining the multiple conditions and one action does creating one rule for pushing personalized content with the rule maker. The rule will be generated by a relevant combination of rule component.

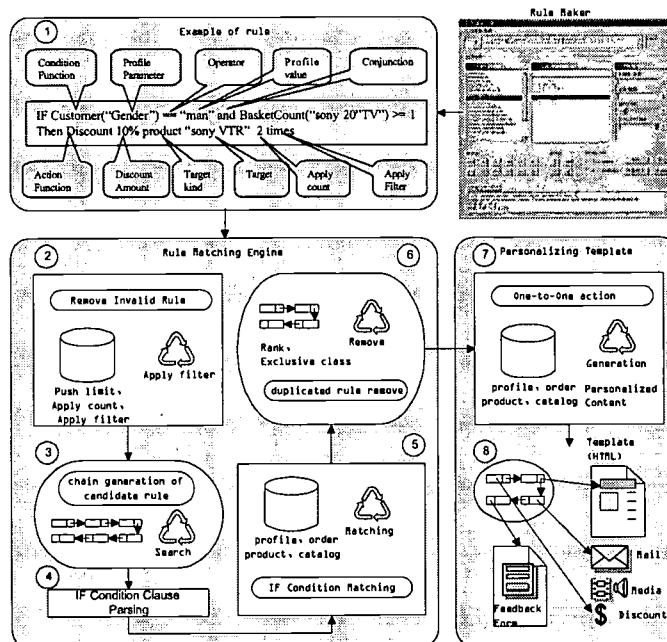

Figure 1. Rule-based matching technique

[Fig 1]. shows the rule maker window at the client side, example of rule statement by rule maker and rule-based matching process. The “IF“ condition clause can compose complex sentence, but “Then“ clause can only simple sentence. If condition clause is true by matching process, action clause is processed. Of course, not every personalization rule is as simple as the example of rule. Complex personalization rules are supported with minor variations in this example. The Basic information of matching process is the purchase history of each customer that a set of words extracted from customer’s order list . And the customer profile is a set of words and value. Then template tags are used to specify those rules. Template is pseudo HTML files to be composed of pure HTML tags and special tags. Template files is stored in database. The special tags represents the substitution value of actual database information that is catalog and product information and personalized contents. We explain rule-based matching technique by process flow shown in [Fig 1].

1. When customer navigated shopping mall, then rule matching process start. This rule in advance was generated by the rulemaker at client side, and rules maker store the rule to database at server side. Also basic profile information is generated by profile maker at client side, and profile maker store the profile in database at server side.
2. Fetch the rule from database. Then remove invalid rules using evaluation of apply filter and pick up the relevant rule.
3. Search matching rule using criterions of apply count. Then make a linked list for candidate rules.
4. Using yacc/lex parser, the “IF“ condition clause is interpreted, and is divided into tokens.
5. Based of each token, relevant SQL statement was generated, and query is sent to database. Result of query is compared with token value, and output of matching process is true or false. Needed information of matching is customer profile, customer’s purchase history, order information, catalog and product information of cyber shopping mall database.
6. Rule matching process can match duplicated rule. The push rule has the priority of rank, and this rank was interpreted. According to priority, remove the rule of low priority. The discount rule has exclusive class that is 0 or 1. If exclusive class is 0 , then unconditionally sum all discount’s amount of matched rules. If exclusive class is 1, then select discount’s amount of all.
7. Action process represents all personalized services: push(target-marketing, cross-selling, up-selling, target-advertisement), discount(shopping cart or basket discount, product discount, coupon), profile updating, and target-mail, etc. The function

BEST COPY AVAILABLE

of these services included inside action process. Action processes start from interpreting “Then” clause, and then determine a kind of action function using results of interpretation. According to action type, content to be required will be fetched from database. For example, push services require catalog or product information, discount services requires customer’s purchase history, and advertisement services require the customer profile.

8. Finally, template process generated a personalized content as HTML file, E-mail, or various media. For feedback profile updating, when type of action function in “Then” clause is “customer”, template process generated a personalized HTML Form to get customer’s response or preference. The merchant selects appropriate content that will appeal to customer based on rules stored in HTML template files. The template files also determine how content will be formatted, which means that the design of shopping mall can be separated from the content creation - making it easier to develop and maintain a personalized shopping mall.

4. Feedback profiling system

Rule-based matching technique must need the customer profile. The reason is that personalized services depend on customer profile as customer’s interest, preferences, and taste. The purchase history of each customer is a set of words extracted from customer’s order list. The customer profile is a set of words and value. Because of these characteristics of profile, basic information to be required to service will be acquired from customer by personalized HTML form type. Then additional profile updating, deleting, inserting is performed by feedback profiling system. Thus, immediately it can serve customer better.

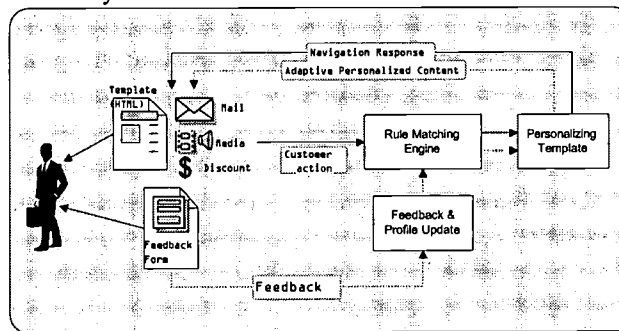

Figure 2. Adaptive feedback profiling system.

[Fig 2]. shows feedback profiling system that include feedback process. The feedback process builds and modifies a customer profile according to the customer’s behaviors. When a customer does such operations as searching and viewing product on catalog, the system regards that the customer is interested in the catalog and modifies the customer profile or submit the HTML form related with the customer’s preference so that it reflects the customer’s interest more precisely. The dashed line flow is feedback process in [Fig 2]. The merchant server first sends a general content when customer entered into shopping mall as anonymous. If customer log in shopping mall as registered customer, it sends personalized content to be matched for customer. Without feedback process, profile operation was not occurred, and the enhanced one-to-one service will not be provided to the customer.

5. Conclusion

We developed the rule-based matching technique and feedback profiling for personalized cyber shopping mall by using information of the customer’s profile, purchase history, the immediate customer’ action, and we have applied the technique to personalized merchant server systems. There are various types of information on the cyber shopping mall. Some pages are updated very often, and some pages are updated only a few times a month or less. Conventional personalized services consider only the personal interest when filtering or sorting information, but our experience in a personalized web page service showed that the feedback system needed to be considered in order to help customers to get relevant information. The integration of the service supply needed to also be considered, especially in push-type services. Using the rule statement to represent the various one-to-one service enables separated services to be handled as one method of rule-based matching technique efficiently. By deploying the rule-based matching technique, web marketer will be capable of targeting single individuals and their unique needs. This will enable web marketers to extend the highest levels of personalized attention and service to all of their customers and to realize new opportunities to serve customers and generate profits.

the electronic charrette:

Internet Tools for Participatory Planning

william george paul - archtype // design research wpaul@vt.edu
www.lar.arch.vt.edu/program/CDT/ARCHTYPE.HTML

the electronic charrette (Paul, 1996) is a short-term, interdisciplinary and collaborative online workshop that incorporates traditional communication tools and processes to generate real time planning and design data and a web site archive.

Introduction

As an electronic decision tool, the Internet is often championed by e-business and big government as the new 21st Century agora, or meeting place. But even with the rise and success of community networks like the Blacksburg (VA) Electronic Village, the Web as a community building and design place for community interaction lags behind the bucks and hype of the "where do you want to go today" set. At Virginia Tech and other places in the world, a focus on assisting people with their community visions both on and offline continues. MIT's Design Studio of the Future [1] and the UK's Online Planning Journal [2] are seeking ways to shift our focus from the high budget / high tech exclusive approach to a more equitable framework so that a citizen can educate, share and build vision into reality online—using asynchronous and synchronous tools and processes.

Bells and whistles do not a 21st Century village make!

As a test of our ability to work the Internet for the citizenry, a traditional - electronic decision making prototype, the electronic charrette (ec) is now under development at Virginia Tech. Our overall goal to strengthen grassroots community building and education through a smarter information technology tool kit for anyone interested in participatory planning and implementation.

The electronic charrette (ec) is both an extension and a hybrid of the traditional landscape or urban design charrette that became popular with groups like the AIA / UDAT [3] and the Minnesota Design Team [4] back in the 1970's and 80's. The ec combines online and traditional community building and design tools for the Internet. The electronic charrette was created and tested twice at the Urban and Regional Studies Institute at the University of Minnesota – Mankato [5] in 1996-97.

The third ec test event ran from October 5th – November 20th 1998 at Virginia Tech and incorporated a series of archived forums (i.e., bulletin board), e-mail and a live, one-to-one design event. While this ec test was modeling a community participation and design process, it became clear early on that the planners and computer scientists who volunteered to participate were not tied to any real issues. Clearly their overall involvement was deemed to be less than realistic than had they been stakeholders in a real issue –pushed community process. The test was a test of the ec process and tools; it was not about using these tools for a real community problem such as a pocket park or a strategic planning report.

This paper concludes with a brief discussion of the ec model can be deployed in additional ways.

Identifying participatory planning & design theory

While the ec technologies and process are still undergoing testing, companion investigation is moving parallel into identifying key participatory planning & design theories from academia. On the planning side, John Friedmann pointed out in 1973 that "the growing technocracy of our society demands a decision-making method based on mutual learning. It is necessary to join scientific and technical intelligence with personal knowledge at the critical points of social intervention in order to avoid decision-making at the exclusive hands of the technocrat. **Transactive Planning** (TP), he maintains, is the most appropriate method for achieving this linkage." [6] Current research targets include: communication pathways between planner and citizenry; the context of social and physical landscape; and public participation processes

Two theories from Computer Science research also play a guiding role in this research. The first, **Participatory Design** (PD), gained prominence in the late 1970's when several Scandinavian countries introduced legislation requiring organizations to involve employees in decisions affecting their future conditions of work. PD is a philosophy, which encompasses the system lifecycle, incorporating the user not only as an experimental subject but also as a key member of the actual design team. Users are viewed as active collaborators in the design process rather than just 'passengers' whose involvement is defined by the system's developers. Tools and Techniques are similar to traditional (non-mediated) charrettes and can include: Storyboarding; pencil and paper exercises; workshops; and brainstorming session(s). Current research targets include competition, participation, corporate control, membership, and product lifecycle [7]

A second interrelated theory from computer science is **Computer Supported Collaborative Work** (CSCW). This research is machine-dependent and includes computer-based systems that support groups of people engaged in a common task that provides an interface to a shared environment. Coordination in CSCW is a key principle— that is, how actors can work together harmoniously. Current research targets include user activeness, openness, awareness, control, and conflict. [8]

Is a new (hybrid) theory possible? It could be promising to propose and test a participatory planning and design theory that incorporates the traditional planning and design charrette with its Internet-process of the ec.

Project Goals:

The goals for the electronic charrette test #3 were follows:

1. Test concurrent use of real-time communication tools that include shareware.
2. Test and suggest possible extensions of the ec process model for other disciplines.
3. Better understand how the traditional process works online. How can we combine the two?

The process

Over a period of approximately six weeks, 5-6 participants used the ec participation guide (pdf - online) and web site instructions to test and critique the ec process model (described previously). Communication was channeled through e-mail, regular phone, fax, web sites, the ec forum and archive, and the ec mail archive. The live group collaboration event was later changed to a one-to-one live collaboration for simplicity and convenience. The process ended with a fully archived project web site and an evaluation. Please see the *ec news link* on the site for the accumulated data from the test.

Test #3 participants:

Anne Giffen, Comprehensive Planner - Town of Blacksburg, Virginia.
Shiv Pal Singh, Computer Science M.S. Student - Virginia Tech.
Edward Davis, Planner - Montgomery County, Virginia.
Supawadee Ingsriwang, Computer Science M.S. Student - Virginia Tech.
John Paul Foulger, EDP Student - Virginia Tech.
Selden Richardson, Architectural Archivist - Library of Virginia.

The tools

Both synchronous and asynchronous communications were employed during the ec test #3. They are listed below:

- **project web sites** – two Mac servers were used for the test: one for the main pages and a second machine for the ec forum tool.
- **ec participation guide** – published as an Adobe pdf document, this includes all of the beginning web material and technical data to help the participants install the required software and to participate in the event.
- **pre-test survey** – placed and returned in e-mail, the survey attempted to lay a baseline for the subsequent discussions and evaluation.
- **ec forum** – an archived bulletin board tool that facilitated discussions on three (3) topics during the test.
- **Jackson Ward Data Archive** – A database with multiple image and text formats was designed and deployed for the test that required plug-ins. This site was the "community" or issue set for the test. It included a panoramic image (VR), a gallery tour, an aerial photo, original building plans, and text documents concerning the historic Jackson Wad Armory in Richmond, VA.
- **DataBeam + NetMeeting** – shareware collaboration software for the live collaboration work. DataBeam supported the test. NetMeeting was used as a chat tool and DataBeam provided an enhanced whiteboard tool and workbook system for organizing and saving a document series.
- **ec mail archive** – the storage vehicle for miscellaneous communication during the test.
- **project archive and evaluation** – since the process was documented and archived at each stage, the test is considered "self-documenting." See the *ec news* site for event data. [9]
- **The ec process model** (see below) - while some would argue that the process model is a "timeline", it is clearly more than a time based "scheduler." A series of distinct charrette events are coordinated that include face-to-face sessions, various electronic communication channels, real-time design events and a project archive. Because specific total times for each ec project will vary, the ec process model is flexible by design.

electronic charrette process model

test results from ec test #3:

summary data from the pre-test survey and event

<u>Tool, Stage or Process:</u>	<u>Pre-Event Survey Responses:</u>	<u>Feedback from Overall Event:</u>
1. project web site:	<ul style="list-style-type: none"> - expectations of participants unclear - index not needed - scrolling too much! - hit counter needed for sub-links 	<ul style="list-style-type: none"> - ec model graphic is too small - site is easy to navigate - model needs to be image map / more explanation - more generalized?
2. pre-test survey:	(n/a)	<ul style="list-style-type: none"> - easy to use as an e-mail tool - design(s) for different user levels? - paper / fax option also desired
3. ec forum tool:	<ul style="list-style-type: none"> - easy to use - somewhat helpful for guided dialogue - good for introductions and instructions 	
i. pre-forum session ("getting ready")	(n/a)	<ul style="list-style-type: none"> - useful for distance collaboration - good for archiving discussion/data - need more than one forum at a time - thread each participant and topic for record - good: responses are time / location independent
ii. Data Archive forum	<ul style="list-style-type: none"> - helpful site - usefulness of data based on each user's background and professional tract 	<ul style="list-style-type: none"> - needs to be topic driven - download restrictions at VT-CS lab! for plug-ins - broad and inclusive data set - panoramic is Java-based and requires Java browser - need for more technical support: installation - how to fully realize "fabric" of building / site? - base level planning data needed (i.e.- zoning map)

BEST COPY AVAILABLE

		<ul style="list-style-type: none"> - building plans are extremely important - create a hard copy version of the Data Archive - create linked floor plans for photo gallery tour - more aerials; less writing on the web site image - dead link to MSNBC piece on JW Armory
iii. ec participation guide forum	<ul style="list-style-type: none"> - somewhat helpful - more needed on overall ec process and goals - good as a broad explanation of event 	<ul style="list-style-type: none"> - more tech help for practice session <ul style="list-style-type: none"> - more tech help: installation of plug-ins - glossary not used much – eliminate it? - good to print it as a companion to online site - add more screen shots of DataBeam + NetMeeting - create a web version of the guide - create "splashier graphics"
4. DataBeam + NetMeeting Tools:	(n/a)	<ul style="list-style-type: none"> - good combination for ec - need to test with more than two participants - use with audio + video for next test - decision to work one-to-one right move - more training and support needed for two tools - tip: practice with (MS) Paint program - prior knowledge / input on images selected - an integrated tool is needed to streamline process - collaboration moderator needed - chat helped to enlarge / extend collaboration context - use telephone when technical trouble hits - message to "take your time" - welcomed feedback - some were quick to take-off and try additional tasks - data bank needs to be designed for a "real problem" (i.e.- the test archive were not "reality centered!") - need a mouse to use these two tools! - overall, graphic design tools are good
5. ec mail archive:	(n/a)	<ul style="list-style-type: none"> - good tool for archiving secondary communication - source of outside event happenings and context - more useful to researcher than to participants
6. project archive and evaluation:	(n/a)	<ul style="list-style-type: none"> - project archive is the sum total of the completed ec event site; see ec news site for data from participant interaction. - this evaluation is designed to be published as a stand alone document (summary)

conclusions and future considerations

The electronic charrette process will undergo more tests with different problem types and participants in the coming months as new interactive tools and variations of the process model are tested. It is worth restating that this collaborative vision is more about proactive user training and less so on high-end software design. Additional corporate support, like DataBeam's contribution, will be sought! Overall, test #3 was successful in training and testing concurrent, real-time communication tools including shareware. By designing a variety of formats for the same information, participants had a choice in their preparation and could read the results of their interactions in the ec forum or through in the archives. The ec participation guide, while filled with useful information, and designed to be a hard copy tool, was both too complex and too little data for some members. More research is needed here. Finally, while member training was largely self-driven, more face-to-face / group sessions are required to support the ec process. In the future participants can use DataBeam workbooks / images off-line and better prepare for real-time collaborations. Audio and video should be incorporated in the next test to evaluate how participants respond to these added technologies.

extending ec process model:

It is possible to look toward future variations of the ec process model for other disciplines. If needed, times for each stage of the process are flexible. The ec process model is a time-flexible tool and can be adjusted with participant input at any time during the event. Instructions and other plans or images can be delivered on demand. Possible uses include:

- * distant learning courses
- * emergency project web sites
- * just in time training
- * software design (iteration)
- * cyber-medicine

The author was project manager / designer for the summer 98' Jackson Ward Electronic Community Project (JWEC). [10] While the JWEC project utilized many of the test #3 tools and web design standards, it suffered from a lack of an online participant pool and from a proprietary-bent client who placed profit over assistance to the larger community. If the ec process model is to take on other disciplines and wider use, it is just these lessons from Jackson Ward that will need to be addressed.

Universidade de Vigo
jrodeiro@uvigo.es

Abstract

In this article we will approach the topic of security in Web Servers, specifying the different applicable methods and its corresponding obtained levels of security. Besides a generic description, the information is extended with a real example of a Virtual Library for a better understanding of the concepts. The system has been developed in the Department of Languages and Computer Systems of the University of Vigo. Our purpose was to find a simple way to join two technologies: Web servers and database managers, and apply that to an easy-to-use school library service, both for students and library staff, while, at the same time, strengthening the concept of security, so that foreign people can't manipulate the stored information.

Keywords

Secure Web Servers, SSL, databases.

1 Introduction

Day after day, the most modern and well-known system of world communication, is not only monopolizing those fields for which it was considered good, but even changing the typical customs in human life, slowly relegating them to a completely virtual system.

Internet, the great net of nets, has not only suffered the biggest expansion ever in telematic nets, but it has also succeeded in taking advantage of the large technological base over which it was created, and in fulfilling the high-priority objective in any society: communication. The communication, together with the advantages that telematic services provide, allows us to offer the final user something that few people dare to reject: comfort. The big problem is that, along with this global communication, there appear new dangers related with the privacy of the information that circulates through the net, in our particular case, the one exchanged between clients and web servers. All this, and the hope of making clearer the concepts of security in web servers, and to eliminate part of the existent fear among the users when it comes to information running through Internet, is what has taken us to write this article and to develop a Virtual Library, together with the hope of being useful for the current scientific and educational society.

2 Description of the system

The system is based on a Web server that implements a series of security levels that are not available by default. The server, apart from controlling the graphic interface that is presented to clients, has the task of interacting with the database.

Security levels are added as server modules or as web page implementations. For the client-server connection, the http protocol is used, over the service offered by the SSL specification (secure sockets layer),

using the POST and GET methods for sending information, which means that clients send character strings with the data to the server. The server receives these data and interacts with the database through sockets (tcp).

We have used as server a PC with Linux as operating system, specifically Debian 1.3.1. This server runs version 1.3.4. of the Apache Web Server, with patches for securetransactions, and the database engine PostgreSQL 6.3.2. Both the operating system, the web server, and the database manager are free-distributed. As for the development languages, we used html and PHP for the creation of dynamic pages.

3 Public and Private key

There exist two main ways to send encrypted data and their later processing. Those known as algorithms of private key, or symmetrical encrypting, use only one key that must be known by the two entities that communicate. When applied to Web servers, a big problem arises: the high number of users, that implies the same number of keys. This problem is solved with the algorithms of public key or asymmetric encrypting. Each user has two keys, a public and a private one, the former available at the so-called public-key servers, while the later is only known by him. These two keys are inverse, which means that what one encrypts the other one unencrypts, and viceversa.

When an user wants to send something to another one, he sends the information encrypted with the later's public key (known by all). Only someone who knows the private key can unencrypt the information, and the only one who does is the destination user. This method is very useful for the generation of so-called digital signatures that make possible to certify the authenticity of a message. An user, to certify that he is the source of a message and before he encrypts it with the public key of the receiving user, encrypts it (or at least a part) with his private key. Then he does it again with the public key of the destination user, whounencrypts the message with his private key, which results in an encrypted part, that he unencrypts with the public key of the former user. If the process is successful, two goals have been completed: nobody has been able to obtain the information since he should know the private key of the destination user, and he makes sure that the information has been sent by the source user, since nobody else can encrypt the signature with his private key.

4 Apache+SSL

SSL (Secure Sockets Layer) is a proprietary specification of Netscape, made public-domain for the definition of secure channels over TCP, Internet's point to point protocol. Its former goal was the establishing of secure connections to Web Servers, to send credit card numbers or access passwords, placing the HTTP protocol over the SSL [Fig. 1].

Figure 1. Description of the Secure Sockets Layer Protocol

When a client wants to begin a secure connection, it sends a message to the server along with a random number (a challenge). The server responds with its public key credited by a certification authority. Next, the client generates a key denominated session key (symmetrical) and sends it to the server encrypted with its public key. Now the server proves that it knows the private key associated to the public one by returning the challenge, encrypted with the session key that it would not have been able to obtain otherwise. Starting from this moment, a secure connection has been established, using the session key for the encrypting. To implement this, a Web server that allows secure transactions is needed. In the example, we have used a patch for the Apache server that is known as `apache+ssl`. This patch modifies the source code of the Apache so that, if the `SSL` function library is installed in the system, transforms the Apache into a secure server or secure transaction server. A client that wants to connect to a secure server just substitutes the protocol `http://` for `https://` in the url.

We can have different parts of the web with secure transactions or not in a single system running a web server, which makes sense as every encrypting operation slows down the system. Depending on the information to be encrypted, the slowing down effect may be worth or not. Secure servers prevent the stealing of access passwords or credit card numbers, through the use of sniffers.

5. PHP Language

What is PHP?. PHP[8] is a tool that lets you create dynamic web pages. PHP-enabled web pages are treated just like regular HTML pages and you can create and edit them the same way you normally create regular HTML pages. (PHP Page www.php.net) .PHP is a language specially focused in text file processing and access to databases.

It is a scripting language that the very web server can process if it is installed as a module or, otherwise, it can use an interpreter and run it through the CGI gateway[1]. It features a great simplicity in the processing of form variables and in accessing databases, providing functions for diverse database managers: Oracle, Informix, PostgreSQL[2][3][4][5][6][7], ODBC interface,... It works in the following way: when the client requests the server to send a pagewith the `.php3` extension, the server preprocesses the file, executing the different commands as it finds them.

6. Security levels.

All UNIX systems have been designed with net-connectivity in mind, and thus they include many security tools[8]. We have used and taken advantage of several of these tools in our model, while we had to implement others. We can distinguish several levels:

- User Authentication.
- Ip Authentication.
- Access to certain directories.
- Access to the database.

6.1. User Authentication.

One of the essential ways to control a system's security is knowledge of who is using it, because with this information one can make a registration of use and carried out actions, grant a series of privileges or other, etc. The degree of security provided by authentication when accessing a webpage is totally similar to the one that an operating system offers. This level is implemented at the first connection to the server. When connecting to the library server through a web client, a dialog window pops requesting a login and a password.

6.2. Ip Authentication.

This level of security is completely transparent to the user. Access is restricted to a subset of ip addresses, for example, those within a Department, an University, etc. At this level of security, the system will have to deal with ip spoofing or ip falsification attacks.

6.3. Access to certain directories.

Built within the own server there is an authentication module for users or groups, and for accesses, reading and/or execution. We can include in these directories all those files that we want to protect. This level forces the client to provide a user's name and password that will grant him a certain access level. Once successful, the server no longer requests again. The authentication can be basic, challenge/answer-like as in NT, and even encrypting as in Kerberos. To implement this level, we have to deal with the access control files of the web server.

We can work with the access.conf file, from where we can control the access to any directory, but with the disadvantage that if it is modified, we must stop and run the server again, for it to update the modifications. On the other hand, we can use a file, usually denominated .htaccess that, placed in each directory, it allows us to set the same specifications as access.conf, but without having to stop and execute again the server when they are modified, as the server reads them everytime it accesses the directory. It is very used in Web servers where you want each user to be able to control the access to his web directories without having to warn the administrator. You can specify the annulment of the guidelines specified in this file or make those in .htaccess prevail on the ones indicated by the administrator in the access.conf.

6.4. Access to the database.

In principle, every access to the database uses the privileges given to the user nobody. If necessary, you could include in this level of security the own database manager, but we should not forget that one of the most important factors in the development of this project is comfort for users.

7 Other dangers

Another important problem that Web Servers have to deal with are the attacks that try to block it (Deny Of Service) like nukes, teardrop, ping flood, etc. To avoid all this we recommend to have the last stable version of the LINUX kernel installed, as well as to often revise the security lists to know new bugs in browsers or servers as soon as possible. Many are the elements needed for a system of this type to work correctly. All of them, hardware, software and the telematic net supporting it, bring about a higher degree of complexity in the system, due to the strong relationship that must exist among them.

This system has been designed to be used in TCP-IP, client-server communication nets, taking advantage of World Wide Web services[8]. All kind of nets are suitable: LANs (Local Area Networks), as far as they incorporate tcp/ip; any Extranets and Intranets; and, of course, its main application environment for which it has been developed, Internet.

Any WEB browser will do as client, since the application is based on the http service and it is the server that supplies the requested information in html format through the net. But as server, we need a system connected to the net, so that it can answer the incoming requests, be it a computer linked to a local net or a system in an ISP (Internet Service Provider). Maybe the most important thing to stand out is the absolute transparency to the user with regard to security levels, because we have sought to obtain a secure but at the same time usable system, always looking for a balance between both parts.

8. Conclusions and future

As implementation example of that explained in the article a virtual library has been developed for an university center, in the one that besides consultation of the existent titles in the database is allowed the reservation and on-line consultation of some of them. For the reservations and to restrict the access levels to certain areas (administration area, internal documents to the university community) the protection methods explained in the article have been used, from the encryption of the communications to some administration protocols, generation and exchanges of keys of superior level.

As hardware server a Pentium 200 has been used with 64 Mb and hard disk of 4Gb, maybe some enlargeable characteristics in future versions if the access statistics and the size of the database require it.

The results have been very good and it has been proved that the use of a hardware not too high it is replaced with the use of an operating system one that takes advantage of the maximum the resources of the machine helped of a DBMS completely integrated with the native file system , in the way that they can share authentication.

The obtained knowledge have been quite important, apart from allowing the establishment of other previous ones. From the process of the design of the system, selection of the data to store and the design of the database, operating system and platform hardware, it has allowed us to fix some ideas that will allow us in a future to make much more complicated developments, never forgetting that the user's comfort is one of the most decisive factors when allowing the expansion and use of a system.

The resulting final system fulfills the requirements with which it was outlined, so that we have a product that is comfortable for users while, at the same time, it features good access security. However, during the development, we have found some important elements outlined by library professionals we have worked with and who have advised us. These points are relevant not from the technological point of view but from the perspective of the final user. Some of the points that should be revised are: Modification of the current system database so that it follows the MARC format standards. Improvement of the user interface to make it more friendly to final users, making it slightly different from classic designs in this kind of systems. Inclusion of new presentation formats for the information of the elements stored in the database, such as images of the covers of the books and sound files with descriptions of the publications.

Abstract: This paper discusses the approach and achievements of T3 (Telematics for Teacher Training), a European project in the field of online teacher training, from the point of view of the Italian partner. The courses developed during the project are used to exemplify and discuss the pros and cons of the various design choices. The project developments support the conclusion that the European dimension has greatly contributed in two directions: towards the practical aim of setting up a network of institutions that collaborated and will continue to collaborate in the delivery of teacher training; and towards the methodological objective of striking a balance between different culturally and nationally biased teacher training approaches.

1. Introduction

This paper examines a project called T3^[1] (Telematics for Teacher Training) funded by the European Commission within the Fourth Framework Programme, and in particular the “Telematics Applications - Education and Training” sector. T3 lasted three years (from January 1996 to December 1998) and was carried out by a consortium of universities and research institutions across eight European countries; it also had the support of a number of private companies such as national telecommunication providers and hardware and software producers. The T3 partners “researched and developed the infusion of telematics applications into courses, such that good practice with telematics was modelled in teacher training” [Davis & Prosser 1999]. Over 5,500 teachers and others were trained in Great Britain, The Netherlands, France, Portugal, Finland, Belgium, Ireland and Italy. The most tangible results that T3 produced are online courses dealing with languages, technology, environmental education, mathematics, and educational use of ICT (most of which have become ongoing courses offered by some of the institutions involved) as well as a number of web-based resources for teachers, teacher trainers and librarians.

Rather than providing a detailed description of the project and its activities, which can be found in several documents and publications (complete list at <http://telematics.ex.ac.uk/T3/deliver.htm>), this paper looks at T3 from the point of view of one of the partners involved, namely the Institute for Educational Technology of the Italian National Research Council (ITD/CNR). It describes ITD's role in the project, and provides an insight into how the project developed and how, in the author's opinion, the complex process of mediation between the very different approaches taken by the various institutions involved lead to progress in the teacher training approaches and to awareness of the advantages and drawbacks of running Europe wide teacher training initiatives.

2. Getting Started with T3

In late 1995, ITD/CNR was invited by Exeter University in Great Britain to join the T3 consortium in the development and testing of teacher training courses, resources and services based on computer networking. ITD/CNR was not asked to manage a specific initiative within the project but to test training courses developed by other project partners (In EC parlance, the group of institutions proposing a project is generally referred to as a 'consortium' while its members are called 'partners').

[1] Website at <http://telematics.ex.ac.uk/T3/>

Although this was an unusual role for ITD and presumably a rather passive one, we nevertheless accepted the proposal. Our acceptance was, so to speak, sight unseen, in that the courses to test had not yet been planned and their characteristics were to a large extent still unknown even to their designers. What was known at the time was the consortium's composition and partners' responsibilities: Exeter University was in charge of managing the project and responsible for the training courses addressed to mathematics teachers, Dublin University (Ireland) for those addressed to science teachers, Utrecht University (the Netherlands) for those addressed to language teachers and Oulu University (Finland) for those addressed to technical education teachers. A number of inter-disciplinary initiatives were also planned, including courses for teacher trainers (Exeter), courses for primary school teachers (Minho University in Portugal) and others for library managers (Exeter). The reason for addressing librarians too lies in their being in close contact with teachers and student teachers, and therefore being in a position to contribute directly to teachers' professional development by illustrating and demonstrating the phenomenal potential of communication technologies for retrieving reference material and consulting databases and/or virtual libraries.

As it stood, the project reflected situations within the various partner countries, some of which contrast sharply with the Italian context. So, working on a project of this kind also involves making an effort to overcome, or even make the most of, cultural and organisational differences which would otherwise undermine the development of fruitful collaboration between partners. For example, in many European countries teacher training means pre-service training, i.e. graduate or post-graduate specialisation courses which are a prerequisite for embarking on a teaching career. Based on the assumption that knowing a discipline does not mean being able to teach it, these courses offer future teachers specific training in the pedagogy of the discipline and also cover the study and field testing of high-potential new technologies in the teaching of the various subjects. The institutions offering this kind of training often have specialist libraries with staff that support and guide students. By contrast, teacher training in Italy almost exclusively takes place on the job (though things are changing and pre-service teacher training has recently been introduced). Most of the time, teachers joining training courses are seasoned professionals who have strong ideas about the didactics of their discipline and who feel the need to develop professionally and update their knowledge; training offers them an opportunity to break out of the cultural isolation that all too often the school or work setting casts them in. Quite clearly, therefore, training courses addressing student teachers are not always applicable to the context of in-service training, even though the creation of a virtual community of teachers and student teachers may have distinct advantages.

3. Project Development

Going back to the T3 Project, January 1996 marked the official start of phase one, which ended in 1997 with course planning and production of related teaching materials. During phase one, each partner contributed to the development of the various initiatives by providing feedback and suggestions about the methodology, with special attention to aspects affecting applicability to the national context. Despite this mediation effort, each course has a distinct «house» style which on the one hand reflects its designers' ideas about how telematics should be applied to teaching and, on the other, indicates how teacher training is approached in each country.

Following the withdrawal of one of the partners from the project in September 1997, ITD took over a sub-project focusing on environmental education, a field in which the institute has gained considerable experience through its involvement in nationwide teacher-training projects. In addition to its original tasks, the institute was to lead the development of an on-line course in environmental education for teachers and student teachers in partner countries.

In the second and final phase of the project, completed in December 1998, the various courses produced were tested and evaluated at an international level. The individual partners handled the delivery of their own courses and co-ordinated their own country's participation in other partners' courses. For instance, ITD led a course in environmental education called EuMEDEA involving Italian, Dutch, British, Portuguese and Finnish teachers [Midoro et al, 1998]. At the same time, it promoted Italian participation in the other courses, following the guidelines agreed on with the respective leaders and using the educational material they provided. Needless to say, one of the main sore points in all this was language: all the course material was to be produced in English and, what's more important, the courses called for synchronous and asynchronous interaction between participants and tutors through computer networking (email, computer conferences or video conferences) that was conducted exclusively in English.

3.1 Features of the T3 Courses

A full description of the various courses developed within T3 would be way beyond the scope of this paper. However, something ought to be said in order to clarify the various features of the approaches adopted. As mentioned above, various disciplinary and inter-disciplinary subjects were involved. The courses covered a range of school levels from primary to upper-secondary. Finally, the role of computer networking was freely interpreted by the partners: for some, it merely represents a way to reach a vast audience quickly and effectively; for others, it works as a dissemination tool and a study topic at the same time. For example, the T3 mathematics materials are web-based but nonetheless reflect a teaching methodology that mostly ignores the use of communication technology. By contrast, the courses addressed to foreign-language teachers focus almost exclusively on the use of this technology in teaching a second language.

3.2 Collaborative Learning versus Individual Study

The very concept of a course seemed to differ as widely as the geographic co-ordinates of the various institutions. Take the Italian (and Finnish!) idea of a course: something with starting and closing dates, a modular structure and specific activities to be carried out by students, whether individually or in a group, guided by a tutor or an expert in the contents.

In stark contrast, the British partners who headed the sub-project for librarians see a course as a set of materials and resources for individual learning that can be accessed by visiting a purposely set up web site; consultation is thus free of time and method constraints, and totally independent of any structure (excepting that of the web site itself)[Pye & Myhill 1997].

The way in which computer conferences and discussion forums are utilised also varies substantially from course to course. Some adopt collaborative learning strategies and impose a well-structured (mainly asynchronous) communication process which is generally designed to support project work or pursue pre-set objectives within a given time frame. Other courses adopt a less directive approach, allowing free discussion areas though not encouraging interpersonal communication, which isn't considered essential for learning. Obviously, this divergence reflects different use of the potential of telematics: in the former case, the potential of interpersonal communication is exploited to the full, while in the latter telematics is mainly used as a means for accessing information.

As is often the case, the projects that have been the most successful are those that have struck a balance between the two extremes. Let's consider the Design and Technology course [Pulkkinen & Ruotsalainen 1997] developed by Finnish researchers. This course was run by an international pool of tutors addressing some 150 participants of four different nationalities: Finnish, Dutch, Italian and British. The tutors' role here is to set tasks to be carried out within a deadline, comment on participants' work, and stimulate and co-ordinate discussion.

It is imperative, especially in courses with so many students, that the virtual community should quickly acquire a social structure of its own, and that all community members are clear about their duties and are able to establish appropriate relationships with their interlocutors. Each student in the Design and Technology course was set a series of tasks to perform:

- selecting a subject to focus on, obviously related to the course contents; a brief essay or assignment was to be produced on the subject and published on the WWW by the end of the course (the technology used is the Proto environment, developed at Oulu University, which allows development of web-based environments including a course website, a structured discussion area and a web editor for students);
- deciding whether to handle the subject individually or in a group, and in the latter case choosing the other group members in accordance with the topic for investigation;
- locating a peer or group of peers outside one's own work group that is dealing with a similar subject and then exchanging feedback on the respective work, both at the end of the course and, even more importantly, while work is in progress;
- producing and publishing on the WWW a report on the chosen subject with the help of tutors and the peer group, or any other participant wishing to join in the discussion and provide comments.

During the project, it became clear that participation in courses of this kind requires a certain familiarity with the methods and technologies involved, as well as a certain degree of autonomy in learning. In the approach adopted, contents are not served up on a silver platter by a teacher or expert, but rather they are explored by each participant with the aid of tutors and peers. Tutor support is more oriented towards offering advice or perhaps posing questions than providing solutions. The Finnish students, who were obviously more accustomed to this working method, came through with flying colours. But the others too, after some understandable initial floundering, eventually managed to get to grips with the course. Many remarked in hindsight that this kind of approach puts the process before the product and is most effective when the participants are professional people (for instance in-service teachers), who often have much to learn but also a lot to share with peers and tutors.

3.3 Synchronous and Asynchronous Communication

From the above description, it is probably quite clear that asynchronous communication was used much more frequently than synchronous communication, and that textual communication prevailed over multimedia communication. The main reasons for this are that the language problems are more easily solved in asynchronous communication, that few schools (let alone individual teachers) in most European countries have access to videoconferencing systems, and that institutions and education systems in these different countries vary widely in terms of pace and organisational structure, so that a loose synchronisation is easier to achieve than a tight one. Nevertheless, the establishment of virtual communities such as the one created within ITD/CNR's EuMEDEA course can undoubtedly be hindered to some extent by the lack of face-to-face interaction and direct verbal exchange with 'eye contact'. This lack of human contact with peers and tutors may have a strong effect on some of the participants. In previous, smaller scale national projects it had been possible to organise some face-to-face meetings, held either at the outset to encourage and speed up ice-breaking, or at the end to support and focus the final effort of evaluating the whole process. Conversely, with an international project involving thousands of European students, organising face-to-face meetings for course participants was unthinkable. Nonetheless, it was possible to resort, at least in some cases, to fairly satisfactory surrogate events based on video conferencing. For instance, students enrolled in the EuMEDEA course for environmental education were able to participate in a multipoint videoconference with students in Utrecht (Holland), Oulu (Finland), and Exeter (England), and with tutors and students in Genoa (Italy). Although multipoint video conferences call for fairly disciplined interaction and require a discussion moderator to direct traffic, one such event can achieve a better effect (in terms of familiarisation) than a series of introduction messages from the various participants. It has to be said that in our case, however, the less than perfect audio and video quality limited this effect to some extent. The desktop video conferencing system we used [2] and a bridge made available by the Dutch telecommunications provider allowed us to try out two different working modes: all four participants displayed simultaneously in distinct sections of a large window; or the mode where only the person (or group) speaking at that moment is visible to the others (as one speaker or group hands over to another, the image on all the monitors changes accordingly). Of course the first mode is more convenient when there are four interlocutors. Anyhow, no preference emerged for one mode or the other, the main problem being the time needed to get accustomed to the way the bridge switches from one interlocutor to the other. There are in fact two aspects that participants need to get used to: the first is that the bridge switches over automatically to a new speaker when he/she starts to talk, and this means that participants need to keep silent while somebody else is talking unless they really want to take the floor. The second aspect is that there is a gap of a few seconds when the bridge switches over to a new speaker, so speakers must be aware that their first few words may well be clipped off. In the absence of a bridge for multipoint videoconferences, the next-best option is to hold several point to point videoconferences between tutors and participants, but of course this rules out student-to-student interaction and is therefore only satisfactory where socialisation is not the primary aim.

[2] The Olivetti Personal Communication Computers provided by our sponsor Olivetti.

3.4 Virtual Laboratories

Some of the above-mentioned courses provide certain environments that we defined as 'virtual laboratories'. One example can be found in the Design and Technology course, which focuses mainly on the application in lower-secondary school of LegoLogo language, a programming language for controlling models made out of plastic Lego bricks - Legologo programs operate small electric motors allowing the model to move. The course designers developed a toy train located in Oulu, Finland which participants can operate by remote control through the Internet. The virtual laboratory has a specially-designed window where users write a program that can either move the train or raise and lower the bars of a level crossing. The program is sent to Oulu and executed in the actual laboratory. A camera focused on the train records the movement and this outcome is relayed back through the Internet and displayed in another window. In this way, the course's remote students can investigate problems in LegoLogo programming without the expense and waiting time involved in buying the original kit.

The combination of virtual laboratories (based on a constructivist approach to learning by trial and error) and collaborative learning (based on Vygotsky idea of the importance of social construction of knowledge) not only proved to be very effective but also supportive from the tutor's point of view: in many cases answers to students' questions were actually provided by other students before the tutors got a chance to read them!

4. Conclusions

The T3 project has adopted an experimental approach on a fairly large scale to address a series of areas that are of particular interest throughout Europe and especially crucial in Italy - areas such as pre-service teacher training, educational technology used for teachers' professional development and as a tool for innovation in education, distance learning, and so on. It's no coincidence that these areas are receiving generous funding from the European Community, as well as attracting considerable debate in journals. The idea is that great strides can be made through synergy between European countries that goes beyond the research field to involve large sections of the productive population as well as those working in education. Hence a project like this can have a remarkable impact but the effect may be even greater if an effort is made to create something that will last beyond the project's closing date. As mentioned before, some of the T3 courses have been adopted by their originating institutions and are being offered to students even after the end of the project. A number of these have attracted the interest of students in other European countries, even outside the original consortium. Nevertheless, the costs of these courses remain high and commercial marketing seems an unrealistic option, especially considering that in Europe the education sector has yet to become a real market [Davis 1999].

From the point of view of the institutions involved in T3, I believe one of the major achievements was managing to strike a balance between the various approaches in order to create courses that can be used in different countries by students with different learning habits and cultures. Limits in the transferability of approaches are often related to limits in learning ability, and proposing Europe-wide courses may help each country to overcome its individual limits (seen for example in the fact that Italian students were less autonomous than Finnish students and were forced to overcome this problem when tackling a course designed by the Finnish partners). A second, important achievement of this project is the creation of a network of institutions able to develop and run international courses jointly. This network is, hopefully, only the kernel of a future wider network of teacher training institutions.

Abstract: This paper describes a Hypermedia Educational Information System for Faculty that aims at designing a knowledge pool about the use of NICT (New Information and Communication Technology) in an educational framework. This System addresses teachers, and is created and maintained by experts (teachers, pedagogues, technicians), it's a user-friendly tool, allowing remote authoring, consultation and collaborative work via the WWW. The first part of this paper reports on a design approach to construct such an information system on distance education themes (techniques, solutions, products, advantages etc.), while the second part proposes to validate the approach with a prototype based on a multi-dimensional document authoring tool.

1. Introduction

Nowadays the WWW has captured a great interest for educators simultaneously around the globe because current available technology allows a great easiness in real time access to interactive classroom and causes teachers to re-think the very nature of teaching and learning.

It has become evident that there is a need to help teachers use technology effectively. Not only do they need to become proficient as users (acquire new technical skills), but they also need to learn to use the technological means efficiently as an educational tool. As the teachers are the main promoters of any innovative activities in education, it is of vital importance to facilitate their efforts to integrate new technologies - like multimedia software and telematics - into their work. The answer to the question: "why should I bother with new technologies? I have got classes to teach, assignments to grade, faculty meetings to attend..."[6] is not the matter of this paper, we propose instead to give an information system whose aim is to share knowledge between experts and teachers in order to satisfy the need of information on the questions: "Why?, How?, Where new technologies in education?". In this paper we illustrate a scientific design approach for the organization of the information system on NICT(New Information and Communication Technologies) in educational applications and its implementation in a hypermedia educational information system built to facilitate the access for faculty and to allow collaborative work between experts. Many projects at present deal with the creation of an Information System for faculty development in NICT (NEPTUNO¹, CPTIC², FACILE³, LTDI⁴), but as far as we know, none of them give a collaborative environment in which experts as well as novice from all over the world can contribute with information from pedagogy to technology on distance teaching and learning. The public who will benefit from this Information System is the vast category of teachers who need to know the impact of using NICT for their courses, or those who already know the advantages, but need specific technical solutions.

In section 2 we will delineate a knowledge pool on distance education to approach all the aspects, from pedagogical to technological, to highlight the multi-dimensional structure of the information and the need of an authoring system to support its generation and the non-linear access. For this purpose, in section 3 we will describe the function of an Hypermedia Educational Information System for faculty, built on the WWW platform. The Information System will be fed by many experts with pluridisciplinary competences to create a shared competence pool. To realize the Information System we used a multidimensional hypermedia authoring tool (MDAT) developed in the framework of MEDIT project [1]. MDAT is an authoring system conceived to allow the design of multidimensional hypermedia documents. It allows an easy organization of the content in a three structure, and the automatic creation of its consultation system. We conclude the paper with a description of the present state of the project and the planning for the future evaluation and works.

2. A knowledge pool for the use of new technologies in education

The technology skills development for faculty willing to integrate the use of technology in their teaching can be modeled in a four phases process:

Awareness Goal Development: The focus of this first stage is instructional. It provides the educator with an in-depth experience with the educational hardware and software available in his/her teaching area. Faculty will feel comfortable in using some technology based teaching in their classroom. They develop skills in adapting standard software to classroom needs. With this experience comes the development of skills necessary to use technology efficiently in teaching.

Curriculum Integration: The focus of the second stage is the development of curriculum enrichment with educational technology. It offers the opportunity to integrate technology based learning into the regular curriculum of the classroom.

Strategy Integration: During stage three, faculty review their present curriculum and course management needs. Faculty begin to integrate appropriate educational technology applications and management strategies. This stage provides the framework necessary for the educator to develop out-reach opportunities to share their expertise with other colleagues.

Implementation Evaluation: Once there is a significant mass of faculty incorporating educational technology applications into their teaching, it is possible to provide continuous evaluation and updating. Faculty share their knowledge with other colleague. There are various benefits in supporting this model for the faculty members, such as the opportunity to develop educational technology skills that can be used in the classroom, and the skills acquisition in upgrading and restructuring their curriculum. The teachers' approach to the integration of NICT in their teaching material, can be seen from two points of view: pedagogical and technical.

Pedagogical aspects: The pedagogical aspect deals with the organization of the knowledges in order to effectively use the NICT in educational context, the re-engineering of the course content [4], as well as the reorganization of the roles of involved actors [7]: teachers and students. Teachers have to get acquainted with the use of technology, learning to reorganize the course content to go toward a student-centered teaching. They have to learn to keep an affective interaction and motivation in students, depending on the level of integration of technology in the course. Students on their own, have to learn to use technology in a self-paced, autonomous and self-directed way. The course content has to be re-engineered in order to satisfy demands and needs. The re-organization strongly depends on the level of integration of learning technologies in instruction [5] and involves all the traditional course components [4].

Technical aspect The technical level deals with the problems of choice of technologies and media suitable for targeted pedagogical purposes. This is not merely a classification of available system to allow integration of technology in education, but a complex investigation of technical platform, services available and applications in order to improve the effectiveness of learning.

Figure1: Pedagogical and technical aspects

BEST COPY AVAILABLE

Fig. 1 shows a representation of the relation between pedagogical methods and objectives to attain in teaching [3], with respect to three categories of technologies (distributive, interactive and collaborative). Distributive technologies (for instance video-conferencing to support lectures) allow an information transfer for a typical instructor centered approach; interactive technologies (for instance simulations) allow knowledge transfer for a learner centered approach, while collaborative technologies (for instance group decision making system) allow knowledge sharing for a team centered approach. In order to be effective and successful, an educational system has to integrate all these technologies.

Figure 2: Three-dimensional Information System space

A three dimensional representation of the information structure (Fig. 2) can be the base for the development of the information space, relating pedagogical methods and technological solutions in order to analyze for each teaching aim, the benefits, the applications, the examples, the constraints of a specific solution. This relation can be parameterized with respect to the communication type that the medium can support. The communication type between teachers and students in a generic education environment (distance or traditional) can be classified as [8]: individual study (01), tutoring (1 1), teaching (1n), discussion (n n). Depending on the type of communication supported or available, a teacher can attain different aims with different solutions. Referring to figure 2, different competences can contribute to this Information System in different plans of the space; instructional designers and technicians will cover the aspects of technical solutions compared to pedagogical methods (Plane(PM,TS)) etc. This approach allows an easy access to the a specific view depending on the targeted interest. This information may be seen using a table layout as a projection, mapping the multi-dimensional logical structure into a two dimensional visual space. Very often dimensions are identified by table headings; intersections of rows and columns provides then the relationship between items and headings [10].

Figure 3,4: Two views of the Information System

BEST COPY AVAILABLE

Figure 6: The tabular navigational interface

Authoring system: it is a complete environment for management and consultation, allowing remote management functions (create, modify, delete etc.). It allows a simultaneous remote edition of the same document by a collegiality of authors [2] geographically separated, writing on the same subject. The system is easy to update in the conceptual organization of branches and leaves of the tree. Fig. 5-left part, illustrates the interface for the creation of the tree structure. Once the tree has been constructed, the Information System automatically creates all the files corresponding to the combination of the leaves. Files can be edited with the edition system shown in Fig.-5 right. The authoring system supports the on-line edition directly in HTML, or the uploading of HTML or LaTeX files from the client. This solution leaves the freedom to the author to choose

User friendly navigational support: the main reason of the success of hypermedia system is the navigational easiness in an information network. However the goal of these kind of systems remains the customized information retrieval in order to avoid the disorientation effect. There are two complementary approaches; navigation which allows a free and informal exploration, and interrogation, in which information are stored in a database and access is made by requests. This Information System offers a navigational access allowing a non-linear exploration of the content with two graphical representations: the tree and the table access. The access to the relevant information is provided by the navigational interface (Fig. 7-top). Fig. 7-bottom shows the browser with information concerning the themes chosen with the tree control (highlighted items). The content (file, images, links etc.) has been taken from the NEPTUNO Open Distance Learning Laboratory⁶ and has been introduced in the Information System using its authoring tool. his/hers most suitable editor (WYSIWYG HTML, HTML, LaTeX, Word, etc.). The user can also preview the final layout of his/her document and has the possibility to easily insert additional formulas, images and links.

4. Future work and Conclusion

In this paper we firstly described a model for the representation of a knowledge pool on the use of Information technology in education, organized in a multi-dimensional information space. The most interesting feature was the idea to represent a n-dimensional space in a tree structure organization, allowing the creation of a forest of trees which can be projected in the space giving two access to the same information (tables and trees). We then presented the implementation of this Information System based on MDAT (Multidimensional Data Authoring System). The originality of this tool lays on the fact that it doesn't impose a conception methodology of hypermedia products, but on the contrary it offers a great easiness letting each users to create his/hers own document structure. Moreover this system offers easy support features, collaborative work, remote authoring and user friendly navigational systems. At present the Information System is not yet completed; the pool of experts and authors is being formed within the framework of the Swiss national project CR2000⁷, and it has been the object of a European project proposal for the Information Society and Technologies Vth Framework Program. The Information System will also be used in framework of the program TRIO-TELEFOR⁸, to support teachers development in the thematic network for higher education and life-long training with new technologies. Many points have still to be developed in the next future; the improvement of the authoring interfaces, the inclusion of new navigational interfaces (hyperbolic tree and mind map) the management of collaborative functionalities and privileges, and the tracking of the user's navigational paths, which will make the navigation easier and customized.

Abstract: This paper describes the design and development of The Shuffler, a software system created to help remove the conventional shuffling of paper from the routing of forms in the workplace. It is designed to run entirely via the WWW, either on Intranets or using encryption on the public Internet. The software allows a set of administrative offices to create, edit, route, verify, and archive paper forms. It includes a security system to authenticate the identity of the users as well as to authorize them. The system software is designed to be as generic as possible in order to allow it to be used by any office as well as on almost any computer and operating system.

1. Introduction

There are many reasons for building WWW-based software that mimics the process of using paper forms. Major motivations are the desire to reduce or eliminate the use of paper and the desire to reduce the amount of time necessary to complete the processing of a form. This paper covers the creation of The Shuffler: what it is, how it was designed, and preliminary information about how effective it is.

What is The Shuffler

The Shuffler is a WWW-based form routing system. Businesses require large quantities of paperwork, most of which is based on standard forms. Forms are necessary for consistent management of approvals, authorizations, purchasing, and other functions. The business chain-of-command often requires that these forms must be approved and viewed by a varying number of people.

The Shuffler allows an administrator to replace existing paper forms with electronic versions that are routed automatically. The benefits of saved paper and time are obvious. In addition, an electronic workflow management system allows one to track a form, avoid lost paperwork and tardy processing, and allow efficient management.

The Shuffler's purpose is to:

- 1) design and implement a form via the WWW
- 2) provide authentication of users involved with the creating and routing of forms
- 3) provide a means of notification that an action is requested on a form
- 4) provide a scalable and efficient database for storage and retrieval of forms
- 5) provide an electronic archive that can be searched and efficiently archived for long-term storage purposes.
- 6) ensure the security of sensitive business information.

The Shuffler is made up of a number of components including the interface, database, and routing mechanism.

A Shuffler Scenario

A purchase order is a good example of a form that is typically implemented in paper and is easily modeled in The Shuffler. A typical pattern that a purchase order follows is that the purchaser fills out the purchase order form with pertinent information. This form is sent to one or more supervisors for signatures, then routed to a purchasing office for processing. It is also not unusual for multiple supervisors to sign off on the form. The Shuffler can be used to replace this entire process by 1) allowing the form to be created electronically, 2) taking care of the routing and notification, and 3) providing a means for proper authentication and authorization. In addition, The Shuffler can perform the processing that is necessary at the end such as entering the purchase information into a master purchasing database in the purchasing office.

2. Interface

The Shuffler utilizes a World Wide Web-based interface. Use of modern browser and server technologies facilitates a efficient client-server application and a consistent well-known user interface methodology. Other than basic browser requirements, custom software does not have to be manually installed on client machines. In a large business environment such as a University, this is a valuable advantage.

The interface has six main sections – security, the user manager, form creation screens, form initiating and routing screens, status screens, and viewing screens.

2.1 Security

The login screen must precede all access to any function, except certain guest functions, in The Shuffler. The existing system utilizes Secure Socket Layer so that all transmissions between the client's browser and the WWW server are encrypted. This provides integrated security, which is difficult to circumvent.

The Shuffler has an internal authentication system and can also accommodate external systems such as Kerberos or X.500. This dual authentication capability is implemented in the secure server environment by providing a check in the authentication scripts for any outside authentication agent. Use of the Shuffler in multiple departmental environments with varying security requirements led to the installation of this more flexible authentication structure.

2.2 User Manager

The user manager allows an administrator to add and remove users in The Shuffler database. As a security sensitive system, The Shuffler must have authorized users explicitly identified. User maintenance is done one user at a time, though group management features have been suggested as future additions to the system.

2.3 Form Creation

Creating a new form in The Shuffler is not a system-administrative function. Managers and business administrative personnel create new forms. Consequently, form creation must be an easy-to-use process.

To create a new Shuffler form, the user fills in the necessary information using a browser-based form creation interface. The interface allows the user to enter a name for the form, a description, an *annoyance factor*, a routing method, and a default mail-to person.

The name and description are self-explanatory. The annoyance factor is the number of hours that The Shuffler will wait before sending an additional message to a routed-to person. This feature is described in The Shuffler Scheduler (see section 6.3).

The routing method is the type of routing that is desired for a particular form. There are two routing methods available: serial and parallel. Serial routing is the default method. In a serial route, the initiated form travels from one user to the next in the listed order. During parallel routing, the initiated form is sent to all people in the list of selected users simultaneously. In the preliminary usage of The Shuffler, the parallel routing method, though available, has not been used at all.

The default mail-to person is a user that can be selected to receive the completed form by default. This implies a one-stop shuffle. That is, when an instance of the form is created and filled out, the completed form is routed only to the default mail-to person. This is useful for actions that only require one step (e.g., a requests for a ream of paper).

Once the initial configuration information is provided, the user can then add fields to the form. There are two types of fields that can be placed on a form: system fields and user fields.

System fields

System fields are optional fields that are common in form designs and will be dynamically completed by The Shuffler. The system fields are FROMFIELD, CURRENTDATE, USERNAME, USERADDRESS, EMAILADDRESS, and PHONE. As an example, FROMFIELD provide a means of dynamically placing the form initiator's name and department on the form. At initiation time, the initiator's name and department will automatically appear. The rest of the system fields are similar in that by placing them on a form, at initiation time, the dynamic information will be displayed.

User-defined fields

There are three types of user-defined fields – static, regular, and editable.

There is only one static field, the 'static text' user field. It is used to provide fixed information such as instructions, headers, or other information that will appear the same way every time a particular form is initiated.

Regular user fields are those that are defined at design time, but are initialized at form initiation time. That is, the initiator fills in the values for these fields. There are six regular user fields as follows:

Paragraph

This provides a user with a variable sized text area for typing in text.

Date	This prompts the user to enter a date.
Number	This prompts the user to enter a number (it expects numeric input).
Checkbox	This prompts the user for a yes/no style answer.
Textbox	This prompts the user for input. It is a one-row text line.
Selectbox	This provides the user a list from which they are expected to choose an item.

Editable user fields

Editable user fields are those that are defined at design time, but are completed during the routing of the initiated form. That is, at some point during the routing of the form, one or more users will set the values for editable fields.

There are six editable field types that are identical to the regular field types listed above. The difference between the two is that editable fields are filled in *during* routing. Editable fields are not available at form-initiation time. They are only available on routing steps after initiation.

At this point, the form-creation editor is very simple in its methods of adding information to a form. Subsequently, it is difficult to do much customization at form-creation time in terms of adding logos or editing exact placement of fields. As this would not be sufficient in most cases to provide the needed look and feel to an electronic form, a customization feature exists. All created forms are stored in the database as HTML with Shuffler directives embedded. To customize a form, one only needs to edit the corresponding HTML with a favorite HTML editor while being careful not to remove the Shuffler directives. This customization requires some additional skill, but is easily accomplished.

2.4 Form Initiating and Routing

Once a form has been created, it can be routed. To initiate the routing of a form, a user selects the form from a list of available forms and fills in the appropriate information. At the bottom of the form is a field for selecting to whom the form should be routed. This field consists of two parts. One is a list of possible users, and the other shows the list of users chosen to receive the form. The user double-clicks on the users to select them. The order in which users are selected is the order that the form will be routed. When all information has been completed, the 'Start Shuffling' button is pressed, and The Shuffler begins routing the form. If there are editable fields on the form, The Shuffler will then request that the user indicate which of the chosen users gets to fill in information and which fields they are allowed to edit.

The Shuffler performs validity checking at all subsequent stages of processing after the selection of "Start Shuffling". Validity checking is implemented through validity scripts. These are scripts (files) that The Shuffler will execute in order to ensure that a form is filled out properly. For example, if there is a date field on the form, a validity script can make sure that a proper date was entered, not a string or integer. Validity scripts are an advanced feature of The Shuffler and are typically created by a system administrator. There is a standard set of scripting templates provided with The Shuffler to make the creation of validity scripts simpler. Upon submission, The Shuffler checks for the existence of a validity script and if one is found, executes it. Validity scripts are particularly useful for ensuring specific formats of user and inventory ID values, preventing duplicate purchase order numbers and many additional customization functions.

2.5 Form Status

Once a form instance has been routed, status information becomes available. The status information is retrieved from one of three screens. The first screen shows information about forms that are currently being routed. Immediately available from this screen is information describing the name of the form, the date and time the form was initiated, who initiated it, the current status of the form, the subject of the form, and the response of the user. The subject field reflects the type of the form that is en-route. In addition, a hyperlink on this field will take the user to a form viewing screen described in the next section. The second screen shows information about forms that are complete, meaning they have completed their routes. This screen offers a way to revisit completed forms.

The third screen provides a search facility for the Shuffler forms database. This is particularly useful when attempting to answer questions about forms that have been moved to archival storage. The Shuffler dynamically provides a query-by-example type screen based on the fields in the database.

2.6 Form Viewing

The form viewing screens can be reached in two ways. The first way (the way that most people are expected to view the forms) is via a specific URL that is provided in the email message a user receives. This URL, when provided to a WWW browser, takes the person first to a login screen, and then directly to the form indicated. There are two views in which a user may see form information – Edit-Mode and Read-Only. The only way a user may see a form in Edit-Mode is if it is currently that user's turn in the route. If the form is currently pending another user's interaction, then a Read-Only view is displayed.

Viewing in Edit-Mode

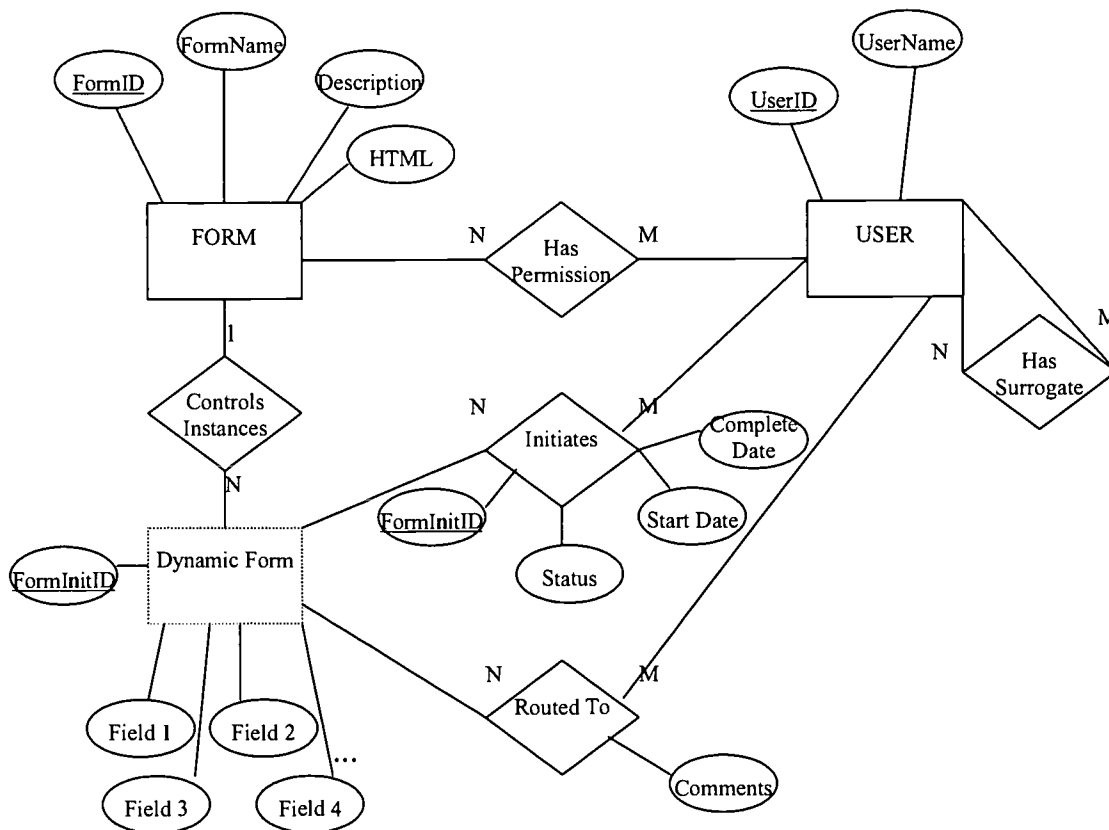

When viewing a form in edit-mode, fields that are meant to be edited by the current user are editable. The edit-mode screen always provides a field for entering comments as annotations on the form. Even when there are no other editable areas on the form for the user, the user is able to enter comments. Areas that are editable by a particular user are indicated with his/her name displayed next to the area.

Viewing in Read-Only Mode

Any user involved in a routing process can view a form in read-only mode. All edits made by users during routing, as well as all comments made by users, will be displayed. The current read-only status for each user is determined by the routing mechanism and dynamically changes as the form proceeds through the routing process.

3. Database

The database for The Shuffler was designed to work via Microsoft Access or Microsoft SQL Server. Smaller installations use the significantly cheaper Microsoft Access while Microsoft SQL server allows for scalability to larger installations. The choice of which database system to be used is selected during installation of The Shuffler. For either database system, the design of the tables that hold the information for the created forms as well as the form instances is the same. Following, is an entity-relation diagram of The Shuffler database.

4. Routing Mechanism

The strength of The Shuffler is in its routing mechanism. This mechanism includes The Shuffler Engine, The Shuffler Mailer, and The Shuffler Scheduler. This mechanism controls everything users see and maintains the data for all Shuffler forms.

4.1 The Shuffler Engine

The routing mechanism for The Shuffler is a program that processes forms as they are being initiated and subsequently routed. The program implements the security features, provides the display screens, controls the mailing of notifications, and handles errors.

As mentioned earlier, there are a number of security features designed into The Shuffler. All of these features except the Secure Socket Layer are implemented via The Shuffler Engine. The engine provides a login screen and controls authentication and user access to system functions. In addition, The Shuffler Engine dynamically creates the HTML for the various screens seen by users.

Any errors that occur are trapped and monitored by The Shuffler Engine. An error log is maintained that aids in solving software problems in The Shuffler system.

4.2 The Shuffler Mailer

When a form is routed from one user to the next, an email message is used to notify the routed-to user that a form is waiting to be checked over. Currently, only the NT Server edition of IIS has a mailer, and the NT Workstation edition does not. As NT Workstation is a much less expensive platform for implementation and testing, a mailer was created that is bundled with The Shuffler.

The Shuffler Mailer was created as a Component Object Model (COM) object. The Shuffler Mailer provides methods for setting the Simple Mail Transport Protocol (SMTP) server, the subject of the email, the from-address, the recipients, and the text of the email. The Mailer then manages the transmission of the message. The email module was created as a COM object to ensure seamless integration with ASP programming.

4.3 The Shuffler Scheduler

After a form has been routed to an individual, the route stalls until the individual processes the form and continues it on its route. This could lead to a time consuming situation where one individual could hold up the completion of a form indefinitely. To combat this, The Shuffler Scheduler was created. The Shuffler Scheduler wakes up every hour and checks the main Shuffler database to see if anyone is delinquent on pending forms. If any user is delinquent, then an additional email message is sent to that person. For example, if the annoyance factor (set during form creation) on a particular form is set at 24 hours, then a new email will be sent to people who have waited more than 24 hours to respond. Additional email messages will be sent every 24 hours until the person responds.

5. Design Decisions

In the initial development of The Shuffler, many different implementation choices were available. This section describes the primary tools that were used to design and implement The Shuffler.

5.1 Tools

The primary tools used to create the WWW interface for The Shuffler are Microsoft's Internet Information Server (IIS), Microsoft's Active Server Page (ASP) technology, Java, Visual C++ (VC++) 5.0, Microsoft Visual Basic (VB), Microsoft Access and Microsoft SQL Server, and finally Microsoft Interdev 1.0. Also considered, were the various WWW browsers that might be used to act as client front-ends to The Shuffler. The browser choice was narrowed by the need to build for browsers that supported JAVA and cookies. Once that was decided, all browsers that fit were considered to be appropriate client front-ends.

Ultimately, the decision to use Microsoft's IIS influenced the rest of the choices made on tools. One may notice that the rest of the tools and design decisions are Microsoft based. The initial implementation of The Shuffler was created mainly using ASP. The Shuffler Mailer and The Shuffler Scheduler were implemented using other programming languages (VC++ and VB respectively). Within the ASP programming, JAVA was used to create a versatile selection box described earlier for use on forms when selecting users a form is to be routed to.

As described earlier, Microsoft Access and Microsoft SQL Server are the databases of choice for The Shuffler. The main reason for choosing these database systems, aside from the reasons described earlier, is that both of these databases are easily connected via ASP programming.

Finally, Microsoft Interdev is an editing tool specially designed for developing WWW applications of this nature. Interdev provided a simple arena for organizing, programming, compiling, and executing The Shuffler.

6. Preliminary Testing Data

The Shuffler is currently being used by Michigan State University's Enrollment Services division. Enrollment Services has six forms that are used in a production environment with nine more in various stages of development. Of the six forms that are in production, three are one-step shuffles. They are forms that an initiator fills out and shuffles to a processing person where they are completed. Two more of the forms are two-step shuffles. They are initiated, verified by authorized personnel, and then completed by a processing person. The last form has a more complex processing route that takes input from an initiator, sends the information by a processing person, and then the final stage of the shuffle is to update information in a master database.

7. Conclusions / Future Work

The Shuffler provides a WWW-based form routing system to a group of users. Because it is WWW-based, there are fewer restrictions on the choice of computers and WWW browsers that may be used in conjunction with it. In addition, The Shuffler database holds a record of all instances of all forms. Therefore, forms can be easily archived for storage and simple future retrieval. By deploying The Shuffler, almost anyone can provide an electronic means of routing paper in an efficient, secure, and user-friendly way.

The Shuffler is considered to be in its first fully operational version. It has many areas that can be improved for use in production. Some of these are:

1. *An improved form creation interface.* The current form creation interface is entirely HTML based and as a result is limited by the boundaries of HTML code. An interactive Java-based interface would be user-friendlier and allow greater functionality. At this point, the HTML interface will not allow a user to back up and alter field definitions. A Java-based interface would allow many additional editing functions.
2. *A form editor* (something to edit forms after creation). This is related to the previous item and perhaps would be addressed with the same Java-based interface.
3. *Addition of groups.* This would allow security to be provided at a group level and user level as opposed to just the user level. As soon as the number of users in the system becomes large (greater than 50) it may be desirable to split the management. Currently, The Shuffler allows only one administrative user.
4. *Addition of dynamic shuffling.* This is the situation where the next person to be shuffled to is chosen during the routing. This will alleviate the situation where the entire route is not known at initiation time.
5. *An ability to attach a document to the routed form.* People may want to attach external documentation.
6. *Data archival.* The ability to age archival data to a data warehouse facility allows for future review, but does not increase the primary database size.

Abstract: An increasingly large number of WWW sites are employing the use of "site maps" as navigational aids but relatively little is known about the benefits such devices bring to the user. This paper presents a review of current site map technologies from a usability perspective. The intention of this review is to provide a sounder basis for future research and development of WWW site maps tools by clarifying existing research and identifying important issues for the future. The paper provides researchers with a classification that may be used to not only categorise new work in relation to existing research but will assist in evaluating new site map designs in terms of suitability for task.

1. Introduction

A WWW site map is essentially a visual representation of the structure of the web site. It has been suggested that such maps improve spatial context and reduce disorientation (Schneiderman, 1997), provide a sense of the extent of a particular Web site without giving detail (Tauscher & Greenberg, 1996), act as a continuously visual surrogate for the user's short-term memory (Cockburn & Jones, 1996) and support the task of browsing by providing orientation within a Web site (Morville, 1996).

There are however a number of problems associated with the current use of site maps especially those applied to sites with a large number of nodes and links, frequent changes in the network, slow or awkward responses to user control inputs and non-visually oriented users (Conklin, 1987). Foss (1989) further identifies the problem of loss of semantic information due to the nature of site maps. Kerr (1990) also suggests that few users actually use navigational aids such as site maps preferring instead to construct a personal mental model through sometimes inefficient browsing. Sullivan (1996) believes that many site maps provide no inherent clues to their navigational nature and that they cannot substitute for text-based navigation methods. Hoffman (1996) has identified a number of limitations of the use of site maps for navigation including speed, complexity and maintenance. Finally, Bieber et al (1997) describe the problems of navigating site maps themselves especially when they are large or complex.

Research has yet to resolve these conflicting claims and few empirical studies have addressed the key issues relating to the use of site maps to augment WWW navigation. Instead, research has concentrated on the technical development of novel site map tools overlooking the nature of the problem that such tools purport to solve.

This paper critically reviews work done over the past few years on the application of site maps to the World Wide Web. The paper initially analyses web usability problems and proposes a method of classifying site maps. A further classification of goals based on the types of questions users ask whilst interacting with the Web is also described. Finally a 'User Goal to Map Type' matrix is created providing the framework for a subsequent discussion of the suitability of each site map type in supporting different demands placed on users of the World Wide Web.

2. WWW Navigation

2.1 Disorientation

One of the central WWW usability problems relates to the vast amount of information that the Web contains and the limited methods by which a user can access this information. As a consequence of these two factors, users are prone to suffer from disorientation whilst navigating through the WWW (Nielsen, 1990; Rivlin et al, 1994). The symptoms

of WWW disorientation are "where users cannot get an overview, cannot find specific information, stumble over the same information again and again, cannot identify new and outdated information, cannot find out how much information there is on a given topic and how much of it has been seen, etc."(Kappe, 1995).

Current WWW navigational tools compound this disorientation problem. Web browsers do not provide the facilities to visualise the inter-relationships between pages preventing users from answering questions such as "Where am I?", "Where can I go from here?" or "Which pages point to this page?" (Bieber et al, 1997). This lack of knowledge of the overall structure of the site results in confusion and cognitive overload when users jump from one location to another in the WWW (Mukherjea & Foley, 1995) or encounter multiple paths to the same or different endpoints (Hedberg & Harper, 1991).

2.2 Cognitive Overhead

A major reason that users feel disoriented is that they must perform several tasks simultaneously as they navigate through a hypertext system (Conklin, 1987; Foss, 1989). The navigational task of planning and executing paths through the hypertext system may be regarded as meta-decision making process, since it is subordinate to the actual task of reading and understanding. These meta-tasks provide cognitive overhead above that of simply reading linear text where the sequence of material has been pre-determined by an author.

These additional cognitive tasks compound the already limited capacity of the human information processing system (Thuring, et al, 1995). Empirical studies (Wright & Lickorish, 1994, Nilsen et al, 1992) that navigational tasks impose an additional cognitive load which can be detrimental to task performance. Careful interface design utilising appropriate cognitive aids can reduce substantially the amount of mental effort required to interact with systems (Preece, 1994). Optimally, systems should minimise the overall memory demands through the use of intuitive interfaces.

3. WWW Site Maps

General hypertext research has raised awareness of the problems of disorientation and cognitive overhead and has subsequently developed a variety of navigational mechanisms, tools and interfaces that can be deployed to assist users. One interface tool that has been developed from research into general hypertext systems is the 'Overview Diagram'. Overview diagrams provide a graphical representation of the system topology and are a common feature in many hypertext implementations. Such diagrams assist the user in the task of navigation by allowing them to generate an appropriate mental model of how the hypertext system is structured (Simpson, 1990). Mental models are cognitive mechanisms that are dynamically created through experience as people interact with others and their environment (Norman, 1988) allowing predictions to be made about events before carrying out actions. Overview diagrams also relieve the overhead on user's short-term memory by providing visual clues to the structure of the system and their relative location within it (Cockburn & Jones, 1996). The use of overview diagrams, better known in Web terms as 'site maps', as a technique of overcoming disorientation and allowing users to obtain a visual overview has been suggested by many researchers (Bieber et al, 1997; Cockburn & Jones, 1996; Mukherjea & Foley, 1995; Shneiderman, 1997; Tauscher & Greenberg, 1996).

4. Classifying Site Maps

There have been a large number of different types and styles of site maps developed since the conception of the WWW each utilising different interface techniques and each addressing different user needs. One method of classifying site maps is to examine the representation of links and nodes and base the classification on the extent of connectivity represented. This method of classifying site maps yields four main categories:

4.1 Map Type A: All Nodes & All Links

'All Nodes & All Links' maps (Figure 1) display the complete topology of a web site in a graphical node-link diagram. They are usually automatically generated utilising computational techniques which scan sites noting all

nodes and links (Mukherjea et al, 1995). Such methods are relatively primitive and usually produce highly complex structures which are of questionable usability. For example, large maps give rise to the need to use of scroll bars to enable the user to change views of the map causing the user to perform sub-optimally (Beard and Walker II, 1990). Site maps are also typically too complex for real use, (Nielsen, 1990) even with the addition of filtering tools they are difficult for people to gain an appropriate working mental model within short-term memory limitations. Further problems in relation to size, loss of semantic information and manageability have also been identified (Foss, 1989).

Figure 1: Example Map Type A

Figure 2: Example Map Type B

4.2 Map Type B: All Nodes & Partial Links

All Nodes & Partial Links maps (Figure 2) present a simplified abstraction of the full detail by removing 'less important' links. The mapping tool essentially imposes a simpler topology onto the full map hence reducing complexity and thus increasing navigational performance (Parunak, 1989). These types of abstractions generally result in a hierarchical representation where the number of alternatives that must be considered at any one time has been reduced (Norman K., 1991). Research suggests that even in the most random topology, users will tend to impose a hierarchical structure to try to make sense of the structure (NcNamara et al, 1989). Applying a hierarchical representation to the network topology of a hypertext system may result in loss of some information. Not all links can be displayed and some semantic connections between sections of the system will be lost.

4.3 Map Type C: Partial Nodes & Partial Links

Partial Nodes & Partial Links maps (Figure 3) present a true "overview" to the user by removing most of the detail leaving only a high-level representation of the site structure allowing the user to obtain a sense of the extent of the hypertext system (McAleese, 1989). It must be remembered that the purpose of an overview map should be to provide an overview and not a fine grain picture. Topographical maps used for physical navigation usually show an abstracted version of reality in order to convey the high-level conceptual layout of an area rather than a photo-perfect image of everything. Therefore it may be suggested that WWW site maps should only provide a high-level overview of the structure of the site and should not contain detail.

4.4 Map Type D: History Only

Ayers & Stasko (1997) differentiate between an 'Exploratory approach' that involves a pre-search of a site to build a map and a 'Reflective approach' where the map is constructed during a browsing session. This distinguishes between full site maps and history based maps (Figure 4). Full site maps are pre-generated either manually or automatically by the site map designer. History based maps augment the web-browser by building a graphical map as the user moves through the site creating a view of all pages visited in a session. The visual representation matches the user's mental mode of the relationships between the documents thus lessening the cognitive load on the user to recall pages by title.

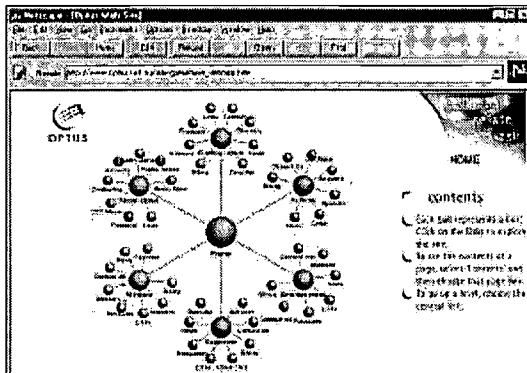

Figure 3: Example Map Type C

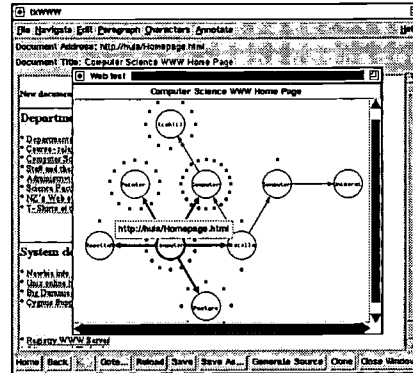

Figure 4: Example Map Type D

5. User Goals

5.1 Information Retrieval

Information retrieval is the identification of units of information within the information space that are relevant to a particular information need. There are two general categories of users with respect to information needs (Duncan & McAlyeese, 1987):

- (i) Users who know what they want and are able to express their need in a precise way.
- (ii) Users who are unsure of what they want, who think they have a gap or discontinuity in understanding, and who cannot because of a lack of domain expertise express this need formally.

This classification is probably not bipolar, but rather a continuum based on the level of 'goal-directness' the user exhibits.

The type of information need or task is also relevant to the way that users will interact with the information retrieval system. Tasks may be either closed or open. Closed tasks have a discrete answer or set of answers and once achieved will result in closure of the need. Open tasks such as broad fact finding or exploration of availability of information on a topic do not have a finite answer and hence will not have a specific point of closure where the information need is satisfied. Shneiderman (1997) extends this classification of tasks to four categories: i. Specific fact finding, ii. Extended fact finding, iii. Open-ended browsing, and iv. Exploration of availability.

There are a variety of methods of classifying the goals of users whilst interacting with hypertext based information retrieval systems such as the World Wide Web. These classifications are typically coarse grain as the specificity of user's goals varies widely (Canter et al, 1985; McAlyeese, 1989). One classification method focuses on the decision making process as a user moves through a system. This may be likened to the process of 'wayfinding' as people find their way to a location in the physical world. Wayfinding is defined as "the purposeful, oriented movement during navigation" (Darken, 1996). This process is linked to a series of questions that users constantly ask whilst making their way to their destination: "Where am I?", "Where do I want to go?", "Am I on the right path?", "Am I there yet?" (Bachiochi et al, 1996). In the context of the virtual world of the World Wide Web, further questions are constantly asked: "What does this site contain?", "How large is this site?", "What else is there about?", "Where have I come from?", "Where is?".

5.3 General Goal Types

Five general goal types may be identified providing a classification that may be divided into two major categories each relating to a particular user question type:

5.3.1 Goal-based

- (a) Connections – e.g. "What is related to.....?"

These type of questions attempt to establish what relationships exist between the current node and other nodes. This is an essential element of hypertext where one element of information triggers an association with another element (McAlyeese, 1988) thus providing incidental learning and the identification of serendipitous connections.

(b) Search – e.g. “Where is?”

This is a focused question where the user has a reasonably well-defined goal. The user therefore may navigate toward a target node by selecting a particular sequence of links. Specific search strategies are usually employed which are heuristic, interactive and data driven (Marchionini, 1995).

(c) Overview – e.g. “What is this site about?” & “What is the extent of this site?”

These types of questions are generally asked by first-time visitors to a web site in order to allow them to determine the suitability of the particular site to their interests.

5.3.2 Positional

(d) History – e.g. “Where have I come from?”

This question is asked by users when they backtrack over previous paths.

(e) Current Location – e.g. “Where am I now?”

A non-specific question which indicates the user is disoriented.

6. Goal-Map Type Matrix

The following matrix (Figure 5) suggests a relationship between the type of site map and the goals of the user. Detailed site maps display all links and are hence allow the user to establish and follow connections between different sections of a web site. Abstracted site maps usually present the map as a hierarchy supporting search strategies. True overviews only display the key nodes and hence allow a user to quickly gain an appreciation of the content and extent of a particular site. History-based maps support the user in the process of backtracking.

		Goal Type			
Map Types		Overview	Search	Connections	History
	Detailed			✓	
	Abstracted		✓		
	Overview	✓			
	History				✓

Figure 5: Goal-Map Type Matrix

7. Conclusion

An increasingly large number of WWW sites are employing the use of "site maps" as navigational aids but relatively little is known about the benefits such devices bring to the user. The intention of this review is to provide a sounder basis for future research and development of WWW site maps tools by clarifying existing research and identifying important issues for the future. The paper provides researchers with a classification that may be used to not only categorise new work in relation to existing research but will assist in evaluating new site map designs in terms of suitability for task. The proposed 'User Goal to Map Type' matrix provides an essential reference point for developers of new site map tools allowing them to justify and focus design. This paper also highlights the need for empirical research into the fundamental issues of WWW navigation in order to substantiate the variety of site map designs currently evolving.

Abstract: The aim of the work reported in this paper is to provide an environment where users exploit the Web as a platform to communicate using simple conferencing tools at the same time that have the memory of that communication registered as structured hyperdocuments for later retrieval and reuse. We present DocConf, an extensible tool to support Web-based conferencing that provides the registering of the communication occurring in a conferencing session as an XML-structured hyperdocument, as well as relies on such hyperdocument to present all the previous activities of a session to newcomer users.

1. Introduction

Douglas Engelbart, one of the visionaries of computer science and technology, was among the first to discuss the advantages of exploiting structured hyperdocuments to provide for interoperability between CSCW tools. His proposal, the Open Hyperdocument System (OHS), would provide standards and facilities to the creation, storage, retrieval and interchange of knowledge by using hyperdocuments [Engelbart 90]. Engelbart's recent view is that the World Wide Web (Web) can expand to provide a platform for the goal of augmenting communities of collaborating knowledge workers. His suggestion is that the Web should grow towards to become the OHS, which would demand, among others, integrated object oriented applications, explicitly structured documents and view control of form, sequence and content [Engelbart 95, 98].

Commenting on the benefits resulting from combining the technologies of hypermedia and computer supported collaborative work in the early 90's, Streitz suggested that such a combination would result in multi-user distributed hypermedia systems at the same time that CSCW tools could benefit from the use of structured hyperdocuments. In the same context, Ishii specifically suggested the use of structured documents to register the memory of the group in CSCW applications [Streitz 91].

There are many efforts being made in terms of allowing for the specification of the structure of the documents in a standardized way, a case in point is the XML specification recommended by the World Wide Web Consortium (W3C), as discussed in Session 4.

Moreover, recent work has been done in order to exploit the Internet as an environment for synchronous communication that supports collaborative work. An important reference is Habanero, a software suite designed to facilitate the development and integration of collaborative Internet applications [Chabert 98].

We have been working in the development of an extensible software suite that provides infrastructure for synchronous and asynchronous collaborative work over the Internet in general, and the Web in particular. In this project, we investigate flexible ways to support the automatic generation, storage, retrieval and presentation of the information generated in a collaborative working session. In this context we have build DocConf, an extensible tool to support Web-based conferencing that provides the registering of the communication occurring in a conferencing session as an XML-structured hyperdocument, as well as relies on such hyperdocument to present all the previous activities of a session to newcomer users.

The aim of the work reported here is to provide an environment where users exploit the Web as a platform to communicate using simple conferencing tools at the same time that have the memory of that communication registered as structured hyperdocuments for later retrieval and reuse. An important requirement is that the document generated be structured according to an open recommendation to allow information interchange and manipulation.

The basic conferencing services provided include a chat tool for exchanging typed messages, a common whiteboard and support to synchronous voting. The environment is easily extensible to facilitate the integration of tools related to other media (such as audio and video) or tasks (e.g. shared Web browser).

The remaining sections of this paper are organized as follows. The next section states the requirements defined

for DocConf, as well as presents information on its current stage of implementation. The following section details aspects of the architecture of communication in DocConf. Next, the advantages of using XML to formalize the structure of the generated documents are listed, preceding a section that details the XML specification for a hyperdocument of a DocConf session. Following, a section gives an overview of typical steps taken by a user when entering a session, relating them with the generation of the underlying hyperdocument. Sections on related work and final remarks conclude the paper.

2. Requirements and Current Stage

This section lists the functional requirements specified to DocConf, as well as describes how the functionality is delivered, if implemented, or the current stage of its implementation, if under development.

Support to synchronous sessions. A session begins when created by the first participant (the owner) and ends when the last participant leaves: the server module of DocConf keeps track of logins and all other requests.

Registering the exchanged communication in a structured hyperdocument. XML was chosen as the specification language given the advantages discussed in [Advantages of Using XML], and a specification named DocConf DTD was defined to support a DocConf session, as shown in [The DocConf Specification]. The DocConf server registers all messages exchanged among the clients as the corresponding XML elements.

Support communication by a chat tool, a common whiteboard and a voting tool. Three tools were implemented and can be loaded as part of a session or not, depending on the configuration given when the creation of the session. However, a tool not requested at the time of the creation of a session can be loaded at any time during the session.

Presence reporting. DocConf may be set to indicate all the users present in any session at a given time. This type of information is important to support small and large groups [Benford 97].

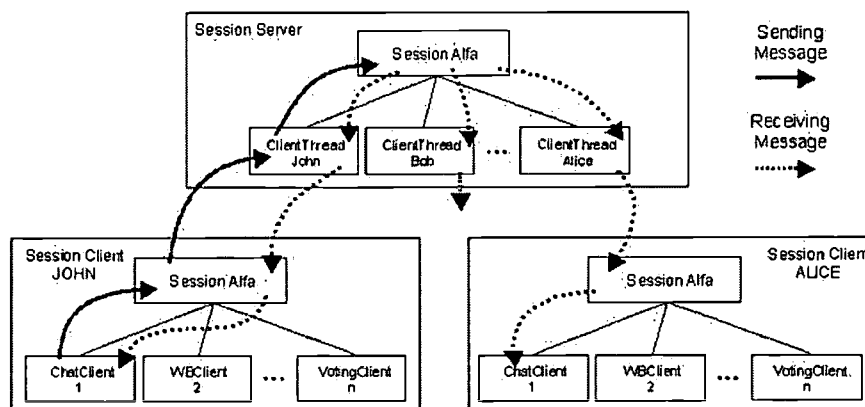

Allow late login: when a user enters an open session, the conferencing tools (chat, whiteboard and vote) show the information previously discussed: the client module of DocConf requests from the server the information XML document corresponding to the session.

Support to asynchronous sessions. Support in DocConf to asynchronous sessions is currently under development, and exploits the component-based architecture of the current implementation.

3. Architecture of Communication

DocConf is being implemented in Java: Swing is used for the implementation of the graphical user interface, and sockets TCP/IP are used to provide fast and reliable client/server communication.

DocConf uses an architecture of communication based on components, which correspond to the rectangles illustrated in [Fig.1]. A "Session Server" module has one component for each session it controls ("Session Alfa" in "Session Server" of [Fig.1]), which in turn has one component has one component to each user logged in the session ("ClientThread" in the "Session Server" of [Fig.1]).

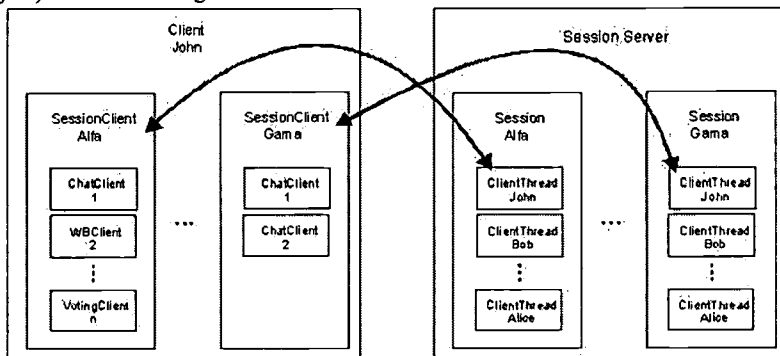

The flow of information between DocConf client and server modules

Similarly, each "Session Client" module has one component for the session it corresponds to ("Session Alfa" in the "Session Client" of [Fig.1]), as well as one component for each tool used in the session (e.g.: "VotingClient").

The functionalities of DocConf are implemented using components, each component having two objects: interface and message. Messages are objects generated by the interface and are sent to/received from the server. A server forwards the information received without processing it: specific processing is done on the interfaces in the client modules (as indicated in the flow of messages in [Fig.1]).

The interface is responsible by interacting with the user, communicating messages and implementing the functionality of the tool (e.g.: drawing in the whiteboard) with the server. Messages correspond to all data exchanged among modules, including control information (e.g.: user login in) and content (e.g.: user identification).

A user can participate in more than one session simultaneously, and several types of objects manage the underlying communication. As illustrated in [Fig.2], a user runs one instance of the object "Client", which owns one object "SessionClient" for each session the user is in. Similarly, the object "Session Server" owns one object "Session" for each session managed. A "Session" object creates a "ThreadClient" object for each user (a "SessionClient" object) communicating in that session.

Class hierarchy for DocConf client and server modules

4. Advantages of Using XML

Referring to the work of the World Wide Web Consortium, Rada et al. state that standards are the body and soul of the Web [Rada 98]. The World Wide Web Consortium (W3C) has been investing many efforts in order to guarantee the growth of the Web in an open and standardized way, for instance by defining recommendations regulating the formalization of the structure of documents and their presentation format. Specifically, the Extensible Markup Language (XML) helps domain application designers to provide a logical structure for the supported documents [XML 98], while Cascade Style Sheets (CSS) and Extensible Style Sheet Language (XSL) help those authors to standardize the presentation format and reuse of their document [CSS 96] [XSL 99].

Although XML aims at supporting intra-domain interoperability, there is still the problem of providing distinct domains a way to cross communicate. To solve the latter, the W3C has just released the specification of the Resource Description Framework (RDF), a foundation for processing metadata and make information exchangeable across application domains on the Web.

The structuring and storage of the information produced during a session using a standard markup language such as XML bring the advantages described below, some of them common to any XML based-application as discussed in [Bosak 98] [Connolly 98] [Glushko 98]:

Interoperability among applications. It is not necessary for applications, mainly third party ones, to know details of a particular database structure, which could be used as an alternative to XML for internal storage purposes.

Distributed processing. Besides third party authorized applications, which may require access to the XML document produced during a session, all the clients, representing the participants of the session, are continuously receiving from the server the events of the session. Hence they are able to keep updated their local version of the XML document, which reflects the state of the session until the considered moment, and to promote local processing in order to recover and manipulate particular information.

Customized view. As a result of the flexibility given by the XML, the clients can customize the presentation of the partial document during the session, or of its totality, afterwards. That is quite handy to help and support their participation in the cooperative work and for posterior analysis of the session. As an example, a participant of a meeting might want to keep in her screen, during the session, a particular view referring to her interventions.

Semantic attribution. For the more structured or formal sessions, even for the asynchronous ones, or for those related to a specific area, participants may find useful to contribute with marked up contents in order to allow

semantic attribution to the information and facilitate its automatic processing. In such a situation, structuring all the session as a XML document is likely to be a good and homogeneous approach.

Independent searching. Taking a chunk of information as a XML document allows any application to browse freely the document and to extract the information needed.

Reduced traffic. The possibility of browsing the document locally, at the client side, may be more efficient, in terms of network traffic, for applications that would instead require several queries to a remote database.

Fast searching. Another advantage of browsing the document locally is speeding searching procedures.

5. The DocConf Specification

The DocConf Document Type Definition (DTD) shown in [Fig.3] is the specification for the documents generated in the DocConf sessions. Each document is composed by the elements <head> and <body>. The <head> element stores information relative to the creation of a session (<name> and <moderator>). The <body> element contains control and content information corresponding to the communication that occurs among the users, and as such contain the elements <login>, <logout>, <chat>, <whiteboard> and <vote>.

Within the <body> element, many elements have other control information specified in terms of attributes of the corresponding element, such as identification information <compid> or a timestamp <date>.

The element <start> stores information about the initialization of a new component. It may have some <param> elements which hold extra information like component layout or initializing options.

The <chat> element contains information manipulated by the chat tool, and has elements <message> and <from> for each message exchanged. The element <whiteboard>, in turn, keeps information manipulated by the whiteboard tool, and has elements such as <shape> for empty shape, <filledshape> for filled shape, <text> for typed text, and <polyline> for polygons. Among the attributes of these elements are <type>, for specifying whether a shape is a circle for example, <coords> for specifying the position of the element on the whiteboard, <foreground> for specifying the color of the object, and <background> for specifying the filling of a filled shape object. The element <vote> keeps the votes for voting situations; the voting options are defined in the <start> element.

<!ELEMENT session (head,body) >	<!-- Chat tool elements -->
<!ATTLIST session date CDATA #required >	<!ELEMENT chat (from,message) >
<!ELEMENT head (id,moderator) >	<!ELEMENT from (#PCDATA)* >
<!ELEMENT id (#PCDATA)* >	<!ELEMENT message (#PCDATA)* >
<!ELEMENT moderator (#PCDATA)* >	<!ATTLIST chat compid CDATA #required date CDATA #required >
<!ELEMENT body (login chat whiteboard voting vote logout)* >	...
<!ELEMENT login (#PCDATA)* >	<!-- Voting tool elements -->
<!ATTLIST login date CDATA #required >	<!ELEMENT vote (#PCDATA)* >
<!ELEMENT logout (#PCDATA)* >	...
<!ATTLIST logout date CDATA #required >

6. DocConf Interaction and Document Creation

The typical steps taken by a user to participate in a session are presented to illustrate how the associated structured document is created. In each case, the elements for the DTD involved in the registering of the associated information are indicated using the name of the element within angular brackets, as in <moderator>.

Welcome window: In the Welcome window, users provide their identification (name and password) as well as of the client and servers machines. New users give registering information in additional window.

Access window: The Access window presents options relative to Session, Users and Tools. The Session options are Create, Enter and Close. When creating a session, the user specifies whether there is a moderator (<moderator>) and which tools are to active (<chat>, <whiteboard> and <vote>). When entering a session, the DocConf client generates an application corresponding to the specification for that session, and sends information to the server that the user has logged (<login> and <date>). When a user is the only one in a session, the option for closing session is activated and, if selected, this information is sent to the server, that stores the associated document.

DocConf window: The DocConf window has a child window for each toll selected to the corresponding session, as illustrated in [Fig.4]. The users can use the chat tool send a message to all participants (<chat>, <from> and <message>), draw or write on the whiteboard (<whiteboard>, <text>, <shape>, <polyline>), or have a voting session

(<vote>). A portion of the DocConf document generated by the session illustrated in [Fig.4] is shown in [Fig.5].

It is important to observe, at this point, how important is the provision of a DTD for the design and implementation of a suite such as DocConf. As suggested by [Pimentel 98], such a provision can be used to guide the development of the associated application.

DocConf Client for John in session Alfa, with Alice and Bob using chat, whiteboard, and voting tools.

7. Related Work

Developed by the National Center for Supercomputing Applications (NCSA), University of Illinois, Habanero provides a platform for collaboration over the Internet, specially aimed at the educational and science domains. Habanero is implemented in Java, and provides an API with a set of objects that can be used by the developer as the underlying communication mechanism to the target application. The proposal is to allow the programmer to develop a collaborative application by altering an existing single-user application or by developing a new one from scratch.

Habanero provides arbitrators for applications that need locks or turn taking and, at this point, Habanero is being extended to allow asynchronous participants. DocConf shares many requirements with Habanero, in particular the aim of allowing easy extensibility and reuse of existing tools.

Prospero is a toolkit for developing groupware applications that focuses on flexibility. In this case, flexibility is understood as the range of applications that can be developed with a toolkit, which must be flexible enough to support the many ways of interactions that may occur between people [Dourish 98]. To manage the flexibility, Prospero proposes a new architectural approach - Open Implementation - where the programmer not only specifies how the application will use the toolkit infrastructure, but also can examine and modify this infrastructure implementation. In this way, the toolkit developer does not have to preview all the future uses of his system and the programmer can adapt the application to its best interest. DocConf is not implemented in such an open architecture approach; however, the component model on which it has been built provides some of the related benefits: supporting extensibility being the most important in the context of this project.

When compared to those and other work reported in the literature, DocConf is the only suite to be built upon an approach for supporting structured documents.

8. Final Remarks

In a complementary view to Engelbart's, Gaines remarks that the growth of the Web, and the evolution of their underlying technologies, may contribute to the foundations of the knowledge science [Gaines 96]: there is no doubt that facilitating human-to-human communication in such an environment may bring contributions.

We presented DocConf, an environment where users can exploit the Web as a platform to communicate using simple conferencing tools such as a shared whiteboard, a chat tool and a synchronous voting tool. A unique feature of DocConf is that the memory of a session is registered as a structured hyperdocument for later retrieval and reuse. DocConf has been built in such an approach that allows for easy extensibility and reuse of existing tools. DocConf have been successful integrated as the communication tool in a Computer Supported Collaborative Learning (CSCL) project [Macedo 99]. Future tasks include full provision for asynchronous sessions and support to other media.

JavaBeans, Java, Java Servlets and CORBA Revolutionizing Web-Based Enterprise Application Development

Dr. Gilda Pour
San Jose State University, U.S.A.
Email: gpour@email.sjsu.edu

Jiebo Xu
Adobe Systems Incorporated, U.S.A.

Abstract: World-Wide Web has provided organizations with an opportunity for competitive advantages. Consequently, there is a fast growing demand for rapid and cost-effective development of Web-based enterprise applications. This has motivated the use of component-based enterprise software development (CBESD). CBESD has the potential to reduce significantly time-to-market and development cost of software systems, and enhance maintainability, reliability and overall quality of software. In this paper, we present a new CBESD approach that integrates JavaBeans, Java, Java Servlets and CORBA. We also describe one of our R&D projects in which we have developed a three-tier Web-based enterprise application using this approach. In addition, we discuss the lessons learned from the project and future plans. The background information required for understanding the issues and technologies involved is covered in the paper.

Keywords: Web-based enterprise applications, component-based enterprise software development, three-tier architectures, CORBA, JavaBeans, Java Servlets, Java, JDBC.

1. Introduction

The Internet and the Web have provided all organizations with an exceptional opportunity for competitive advantages. This has resulted in a fast growing demand for rapid and cost-effective development of Web-based enterprise applications—a major challenge! Traditional software development approach is not sufficient. The rapidly emerging trend is component-based enterprise software development (CBESD).

The focus of this paper is on a new CBESD approach that integrates JavaBeans, Java, Java Servlets and Common Object Request Broker Architecture (CORBA) for Web-based enterprise application development. Java and the Enterprise Java APIs provide the glue for holding legacy systems and Database Management Systems (DBMS) servers together with the next generation of Web-enabled, multi-tier distributed systems that are written in the Java and exploit component technology and techniques [Pour 1999c].

The paper is organized as follows. Section 2 provides an overview of CBESD. Section 3 reviews Web-based application architectures. Section 4 describes major CBESD approaches to developing Web-based enterprise application. Section 5 provides an overview and evaluation of the key technologies. Section 6 presents the new CBESD approach and our R&D project using the approach. Section 7 discusses the lessons learned and future plans.

2. Component-Based Enterprise Software Development

Component-based enterprise software development (CBESD) is based on the selection and integration of a set of pre-engineered and pretested reusable software components within appropriate software architectures [Pour 1999b]. CBESD delivers the promise of large-scale software reuse by promoting the use of reusable components, which are developed by commercial software vendors or in-house developers, as the building blocks of a new software system [Pour 1998c]. CBESD has the potential to: (1) reduce significantly the cost and time-to-market of software systems allowing the systems to be built by assembling a set of reusable components rather than from scratch, (2) enhance the reliability of software systems because each reusable component has gone through several reviews and inspections in the course of its original development and previous usages, (3) improve the maintainability and flexibility of software by allowing new components to replace old ones, and (4) enhance the quality of enterprise application by allowing application-domain experts to develop components, and the software engineers who are specialized in component-based software development to assemble the components and build software systems [Pour 1999c, 1999a].

3. Multi-Tier Architectures for Web-Based Enterprise Applications

The architecture of a software system defines that system in terms of computational components and interactions among those components [Shaw 1996]. Web-based enterprise applications consist of three groups of components: presentation, application logic and data. Presentation components are primarily used for interaction with users. Application logic components perform calculations and determine the flow of the application. Data components manage information that should persist across sessions, planned shutdowns, and systems failures. The idea of using a distinct unit for each component group has motivated multi-tier architectures for Web-based enterprise applications. The components interact through client-server protocols and database-accessing protocols.

In two-tier client/server architectures, presentation and application logic components run together on the client side and data components on the server side. Application components read data from the server, perform application logic and send data back to the server. Two-tier applications usually work fine in departmental-scale applications with modest numbers of users (under 100), a single database, and secure and fast networking. Two-tier architectures fall short for a large number of users and databases, and non-secure network environments because databases must maintain connections to each active client, and connections consume machine resources. In addition, the security model does not work well outside of trusted LAN environments.

In 3-tier architectures, each component group (i.e. presentation, application logic and data) forms a distinct unit. Presentation components manage user interaction and make requests for application services by calling the application logic components in the middle-tier. The middle layer manages the connections to back-end servers as well as the client applications that rely on multiple heterogeneous server connections. The middle tier performs business logic and makes requests to data components in databases and other resources using their native interfaces (e.g. SQL for relational databases). Additionally, the middle layer handles services such as security, authentication, and client software distribution. Using three-tier architectures, the scalability, reusability, security and manageability of applications can be enhanced significantly. Load balancing can also be improved.

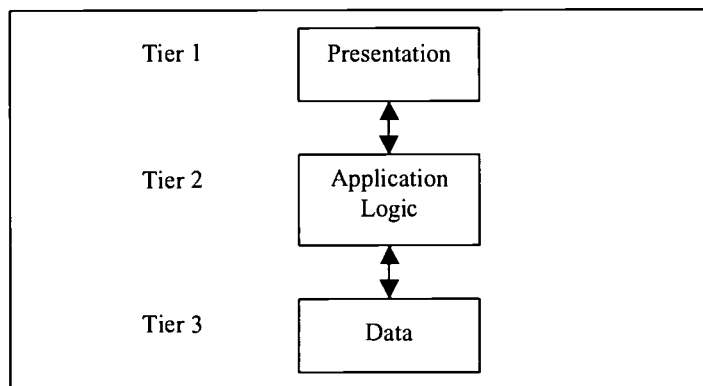

Figure 1: Three-Tier Client/Server Application

It is difficult to reuse and maintain application logic components in two-tier architectures because those components are tightly bound to presentation components. In addition, a user of a two-tier system can only access one database system at a time. Access to other database systems and back-end servers, or mainframe applications must be done via gateways, which create a number of new issues [Xu 1998]. Furthermore, due to lock contention the scalability of two-tier applications is good up to a point and degrades quickly from that point on. Moreover, lock resolution is independent of the server's speed. Therefore, even installing more powerful database servers does not provide significantly greater performance [Liu 1997].

Three-tier architectures are often called server-centric because they allow application components to run on middle-tier servers independent of presentation interface and database implementation. Three-tier architectures are suitable for Web-based enterprise applications due to the following major benefits: (1) system administrators can replicate application components and run them on different machines simultaneously, enhancing the software availability, scalability and performance; (2) application components can share database connections, improving software performance by lowering the number of total sessions that a database server must support; (3) providing access to other resources through native protocols and application interfaces rather than data gateways, improving performance and allowing application owners to control the access to their data; and (4) allowing developers to make the most of reusable application components for software development and maintenance.

4. CBESD Approaches to Web-Based Enterprise Application Development

Web-based enterprise applications should be able to cross the boundaries of different hardware platforms, different network protocols, different operating systems, and different programming languages. Development of such applications is challenging. The best approach is to integrate Web with distributed objects. The backbone of distributed object-oriented systems is Object Request Broker (ORB), which provides location transparent communications between clients and servers. In three-tier Web-based enterprise applications, Web browsers (Web clients) operate in tier 1, ORBs (Web servers) in tier 2, and DBMS servers and legacy applications in tier 3. There are two key trends to Web-based application development: (1) integration of Java-based technologies and CORBA, and (2) ActiveX and Distributed Component Object Model (DCOM) [Pour 1998a].

5. Overview and Evaluation of Key Technologies

5.1 Java

Java introduces a new model for developing Web-based applications. The explosion of the Web and the need for a solid way to bring its interactivity created the perfect climate for an innovative technology like Java [Morrison, 1997]. The mission statement of Java is "Write once and run anywhere". Java offers an elegant and efficient solution to the portability and security problems through Java bytecodes. A Java program is an applet or an application. A Java application runs under the operating system of the computer while Java applets can run inside Web browsers. Java compiler located on the server side compiles Java programs into platform-independent bytecodes. Bytecodes can be downloaded on the client side, and then executed by the Java interpreter. Compiled bytecodes can run on any system supporting Java Virtual Machine (VM); making Java codes portable. In addition, the use of Java bytecodes and the concept of trusted and untrusted Java applets are the key to higher level of Java security.

5.2 JavaBeans

JavaBeans--the Java-based component technology--is used to develop new software systems more rapidly and economically [Pour 1998a]. The mission statement of JavaBeans is "Write once, run anywhere, reuse everywhere." Beans are platform-independent and reusable components (i.e. beans can be created, reused, modified, and assembled into new feature-rich applications using visual builder tools).

5.3 JavaBeans versus ActiveX

ActiveX is the competing technology to JavaBeans. Both technologies are designed for the Web. They have major differences. JavaBeans is platform-independent and language-dependent while ActiveX is Windows platform-dependent and language-independent. The Internet market share of Java and JavaBeans has been significantly expanded due to their platform independency. Furthermore, language-dependency of JavaBeans does not seem to be a problem because Java can run on any platform with Java VM (practically all platforms).

ActiveX relies only on the digital signature verification method to provide security while JavaBeans uses sandboxing and trusted servers in addition to digital signature verification, resulting in higher level of security for Java codes. ActiveX has been roundly criticized by computer security professionals since its approach to security is seen as lacking [McGraw 1999]. Hence, JavaBeans leads ActiveX in terms of security and portability. However, ActiveX leads JavaBeans in its existing code base due to its underlying OCX technology that is widely used by the Windows software community. This may change over the next few years as JavaBeans takes off.

5.4 Java Database Connectivity (JDBC)

JDBC is the Java wrapper for SQL. It provides portable and cross-platform database access for Java programs. It eliminates the need for a gateway program, as it handles connectivity to relational databases, fetching query results, committing or rolling back transactions, and converting SQL types to and from Java program variables. JDBC consists JDBC API and JDBC manager driver API. The JDBC API sends JDBC manager driver API various SQL statements. The JDBC manager driver communicates with various third parties' drivers that are connected to database, and returns the result of query to the user, or performs the action specified by the query.

5.5 Java Servlets

Java Servlet Development Kit (JSLK) was shipped with Java Web Server in mid-1997. Many corporate developers use servlets for a variety of purposes over Intranets, extranets and the Internet. Servlets are small pieces of Java code that can service HTTP requests and generate HTML dynamically. Servlets also extend Java-enabled servers. They combine Java strengths on the server as a portable, platform-independent and network-centric language with the accessibility of HTML clients to deliver database applications that are accessible to any client running a browser. Java servlets have lower deployment and maintenance cost.

Servlets are often used in the middle tier of enterprise networks so they can interact with relational databases via JDBC for storing and accessing user account and merchandise information [Bergsten 1998]. Servlets can keep data persistent between requests. A pool of database connections can be shared by multiple requests, and frequently requested information can be cached. Threading and persistence makes it much easier to develop high performance solutions [Bergsten 1998].

Unlike Java applets, servlets are faceless objects (without graphics or a GUI component), and they can write to files and open sockets very quickly because they are invoked as threads in a demon process. Servlets are to the server-side what applets are to the client-side. Like CGI scripts, servlets are executed on the server. CGI creates a new process for each request while servlets handle requests in the same process through separate threads. Hence, servlet-based applications avoid overhead processing. Additionally, servlets address such problems as non-extensible scripting solutions, platform-specific APIs, and incomplete interfaces (associated with server-side programming). Servlets and CGI have similar functionality. However, servlets are faster, cleaner, and easier to use.

Figure 2: Servlets Application Architecture

5.6 Common Object Request Broker Architecture (CORBA)

CORBA is a set of specifications that provides a standard architecture and communication protocols for interoperability between objects in heterogeneous distributed environments. CORBA was introduced by the Object Management Group (OMG)—the largest industry consortium. CORBA has taken a stronghold in the computer industry, primarily because it is a standard architecture that provides common interfaces and description for objects [Pope 1998]. A growing number of business developers are turning to CORBA object middleware to bring enterprise scalability to their Java applications [Radding 1999]. CORBA has two major components: Object Request Broker (ORB) and Interface Definition Language (IDL). ORB manages location transparent communications between clients and servers. CORBA IDL is a declarative language for defining interfaces of components to become recognizable by CORBA-compliant ORBs. More information on CORBA can be found in [Pour 1994] [Orfali 1997] [Pope 1998].

5.7 CORBA versus DCOM

Distributed Component Object Model (DCOM), like CORBA, is language-independent and has its own Object Description Language (ODL). Compared to CORBA, DCOM has several major shortcomings including being Window-platform-dependent and controlled by one company—Microsoft. This greatly reduces the options of tools and features for DCOM, and significantly limits the use of legacy codes and the scalability of DCOM applications. Furthermore, the messaging and transactions that were provided by CORBA a few years ago are now being considered in DCOM. However, DCOM is integrated with other Microsoft products, which makes it free and attractive to some users.

5.8 CORBA IIOP versus RMI

Remote Method Invocation (RMI) allows a Java client to instantiate objects that may be located on a remote server that is also written in Java. RMI can be used only for communication between Java objects. CORBA has no such restriction. CORBA also offers a set of object services, but RMI does not. Furthermore, RMI does not include any object activation policies such as those used by CORBA-based ORBs. Additionally, server objects written in Java using RMI may suffer from poor performance due to limitations inherent in the Java VM. Java/CORBA-based servers perform better than Java/RMI-based servers do. While RMI is a viable option for smaller-scale Java applications, CORBA is a useful alternative for cross-platform applications. Additionally, CORBA IIOP has a wider acceptance. Sun has also publicly stated its long-term goal to allow RMI objects to communicate via IIOP.

5.9 Servlets versus CORBA/IIOP

Servlets, CGI and sockets, each provides a primitive form of middleware in the client/server architecture, which makes creating own command formats for marshaling and unmarshaling the programmer's responsibility. Servlets can be implemented as CORBA or RMI objects. Servlets interact through a generic API. They lack some of the features expected from a scalable server-side component infrastructure. For example, servlets do not support transactions that are now a standard feature of the CORBA and Microsoft Transaction Service (MTS) server-side component models. Furthermore, servlets do not support a dynamic deactivation mechanism [Orfali 1998].

5.10 Interoperability

The technologies covered in the paper are on their way to become more powerful. This has motivated development of the following bridges that provide interoperability between those technologies: (1) COM/CORBA bridge by Iona, (2) JavaBeans/ActiveX bridge by JavaSoft, and (3) JDBC-ODBC bridge by JavaSoft [Pour 1998a].

6. Our R&D Project

We have adopted the CBESD approach that integrates JavaBeans, Java, Java servlets and CORBA to develop Web-based enterprise applications. The coding and the test of the Web-based application were completed as a part of a graduate research project. The results of the project have been integrated to our on-going research project.

6.1 Project Description

We developed a three-tier Web-based enterprise application for conducting the entire survey process—from the survey form design, data collection and analysis to survey results presentation. The Web-based enterprise application was intended for an automobile company; however, the application can be used by organizations and companies. Three groups of users were identified: managers, salespeople and customers. The requirements in terms of the application functionality include: (1) managers can create/update survey questionnaires, and view the survey results periodically, (2) salespeople can generate a password for each new customer, and add/update customers' information in the company's database, and (3) customers can update their own information and fill out a survey form available on the company's web site only once. In addition, the application has some quality requirements in terms of scalability, portability, platform-independency, flexibility, maintainability, extensibility, manageability,

usability and performance. The co-author completed the implementation and test of the Web-based application as a part of her master research project [Xu 1998].

6.2 Hardware and Software Resources

The project was carried out in the Client/Server Laboratory at San Jose State University. The lab has a network of 25 NT machines. The following software products were used in the project: (1) Visigenic's Visibroker for Java 3.02, (2) Microsoft Windows NT 4.0 Server, (3) Symantec Visual Café PDE 2.1, (4) JavaSoft JDK 1.1.6, (5) Microsoft SQL Server 7.0, (6) Java Web Server 1.1, (7) Netscape Communicator 4.06 with JDK1.1 patch, and (8) Netscape Enterprise Java Web Server 1.1. The above software products were updated routinely.

6.3 Evaluation

The results were evaluated by industry representatives and several faculty members (including the author) having industrial experience. The Web-based application has met the project functionality and quality requirements.

7. Lessons Learned and Future Plans

The number of clients who can connect to a server is restricted by the capacity of the database connectivity. The scalability is improved as a result of using servlets. Furthermore, with the inherited threading and techniques like database connection pooling and caching, servlet-based solutions handle the pressure [Bergsten 1998]. Additionally, adopting JavaBeans technology helps to reduce significantly the application development time.

Such R&D projects provide the opportunity for students to gain valuable experience in developing multi-tier Web-based applications and adopting rapidly evolving Java-based technologies and CORBA. It helps significantly if students gain experience with JavaBeans and ORBs in a couple of smaller projects before they work on similar projects. The results of the project have been used in our on-going CBESD research. Based on our experience, conducting such R&D projects at the university provides students with a beneficial educational opportunity, and industry is supportive. That is why the author has continued to supervise similar graduate research projects.

Abstract: This paper presents our approach towards creating a Web-based Spatiotemporal Geographic Information System, in particular, the creation of the spatial data set and the component interaction. It explores the possibility of rendering Virtual GIS Worlds in near real time across the WWW using a standard Web browser as the user interface.

A "proof of concept" Web-based VGIS application was developed to investigate methods for the efficient transfer of high-bandwidth multimedia GIS content over the WWW, as well as providing a suitable development environment for research into Web-based Temporal GIS. This paper describes how VRML and Java were used to provide the visualisation of virtual worlds, interaction with individual objects inside the virtual world, and the query tools for adding, deleting, selecting or manipulating these objects or their associated attribute data.

1. Introduction

If "a picture is worth a thousand words", imagine what a virtual world is worth. Fully interactive real-time virtual environments and multidimensional data visualisation hold great potential for increasing our understanding of a wide variety of inherently visual data, as well as reducing the mean time taken to understand such information.

The project described in this paper investigates the feasibility of creating a Virtual GIS application in the constrained environment of Web applications. Our aim is to use existing Web technologies and protocols, rather than develop a proprietary solution, as one of the goals of the project is to develop an extensible, open system for visualising and sharing 3D data across the WWW. It is also our goal to extend this Web-based VGIS to support temporal operations, thus creating a 4D web-based Spatiotemporal GIS.

2. "Proof of Concept" System

In order to establish that the requirements of such a system could be met, and the complexity of such a system fully understood, a "proof of concept" system was implemented. This system, based on the model in [Fig. 1] below, provides a suitable development platform for investigating methods for the efficient transfer of high-bandwidth multimedia GIS and VGIS content over the WWW, as well as a suitable development environment for research into Web-based Temporal GIS.

Figure 1: "Proof of Concept" System

One of the goals of creating our Web-based Virtual GIS application was to remove as much of the complexity and expense from the client side as possible. Therefore, some of the issues that affected our choice of approach, included:

- Modularity
- Extensibility to handle complex data types
- Security over the network/internet
- Data integrity
- Minimise initial setup complexity
- Per seat licensing costs

Once a basic level of operation had been established, according to the model above, benchmarks and refinements were made in order to minimise client-side setup, bandwidth traffic, and computational complexity.

3. Components of the "Proof of Concept" system

A graphical user interface, with built-in support for WWW access, for interacting with the VGIS system was required. A WEB browser such as Netscape or Internet Explorer provides the necessary graphical interface with WEB access, and plug-in support for developing WEB protocols, built-in.

A Virtual Reality modelling and scene description language that is supported by WEB browsers was needed to provide an interactive environment as opposed to viewing pre-generated images, as is widely implemented by current GIS applications. VRML is currently the most widely available WEB oriented Virtual Reality modelling and scene description tool available, and VRML plug-ins are freely available for popular WEB browsers.

GIS functionality must be portable across platforms if it is to be truly WEB based. Currently Java applets provide the most logical solution and also introduce some interesting prospects for scaleable GIS systems. Due to the fact that each applet downloaded may access the scene graph, and may then effect changes to the scene graph independently, it is possible to create each GIS tool as a separate applet. Therefore, additional modular GIS

components can be purchased and/or downloaded to provide the user's required level of GIS functionality. Java and JavaScript can be used in conjunction with VRML through the External Authoring Interface (EAI) and SCRIPT nodes respectively, thus providing even more reason for the choice of VRML for modelling and scene description. However, it should be noted that one immediate problem with the use of separate applets for each GIS tool, is the way the scene graph interacts with the EAI. Each applet is only able to see/keep track of what happens to the base scene graph, and will not be able to see any nodes added to the base world using the `createVRMLFromString` or `createVRMLFromURL` by another applet. For further information about the restrictions on the accessibility of nodes using the EAI, please refer to [Marrin 1997].

4. Creation of the Spatial Data Set: Virtual Grahamstown

Maps of Grahamstown were obtained from the Town Engineers office, and scanned in. The outlines of the buildings and roads were "digitised" in order to provide a template for specifying the shape, size and spatial arrangement of these features. Using a specialised extrude tool, written by Professor Shaun Bangay [Bangay 1997], see [Fig. 2], created specifically for the purpose of creating the objects in the virtual world, the walls of buildings were raised to the appropriate levels, and then a roof was added. The resultant three-dimensional volume represents the outside of the building, and is stored as a set of polygons that make up the walls and roof of the virtual building. This model could then be used directly in RhoVeR, the Rhodes University Virtual Reality System, or exported to VRML for use in our VGIS.

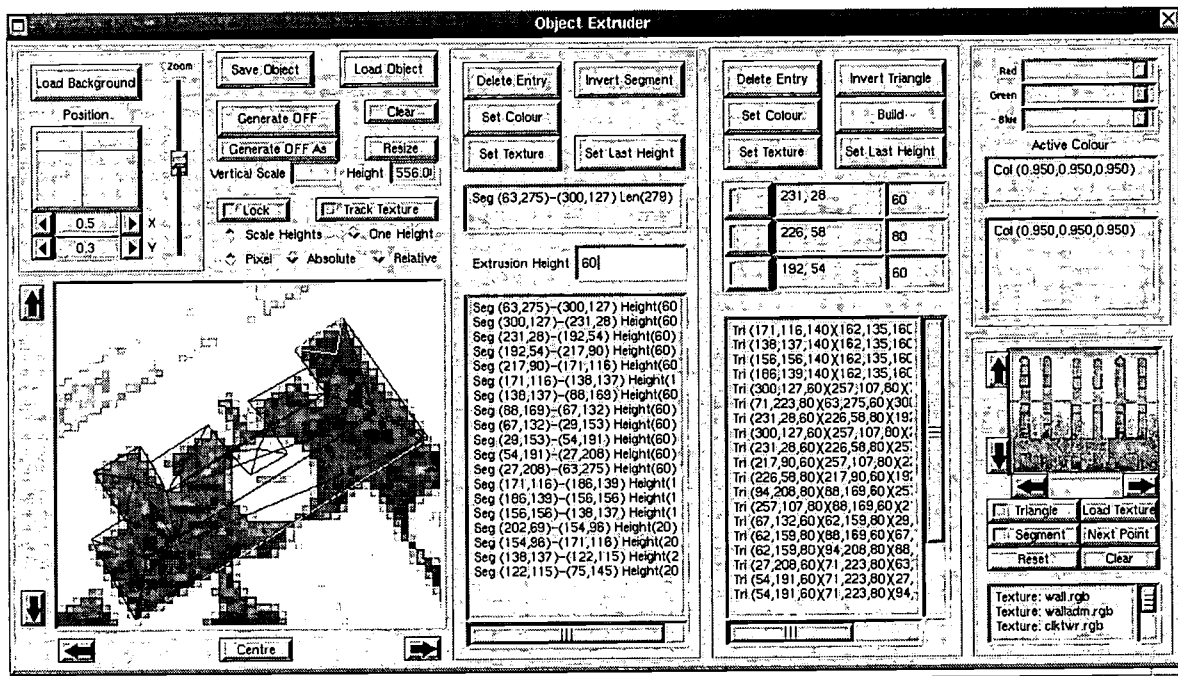

Figure 2: Screenshot of Extrude utility

Since each object will be used together with many other objects in a virtual world where the speed of interaction is important, there is a trade-off between the level of detail (LOD) of the structures and the final rendering speed. It is therefore assumed that a simplified outline for the building is sufficient for most objects. However, should more detail be required for a particular object, that object can also be created at a greater LOD and used together with VRML LOD and `InLine` statements to provide greater detail.

BEST COPY AVAILABLE

Once the structures had been created, it was then possible to add colour and to map textures to the buildings to add realism to them. See [Fig. 3] for a sample snapshot from Virtual Grahamstown illustrating the realism achieved by adding colour and textures.

Colour, as opposed to texture mapping, was used where the significance of the building was low, or the building was being drawn at a lower level of detail, or where the texture of an area would have been relatively plain. This reduced the scene complexity and increased the speed of rendering the scene.

The use of textures for important landmarks, however, is almost mandatory, and the resulting realism is extremely high. The texture maps for these buildings were obtained by taking still-shots of the actual buildings using a video recorder. While the use of texture mapping is relatively resource intensive, there are ways to minimise the effect of using textures within a scene, and to reduce memory usage at rendering time. These include:

- Repeating the texture both horizontally and vertically, allowing areas with repeated features to be efficiently generated from only a single instance of the texture of that feature.
- Selecting active areas of the texture allows reuse of the texture maps for cases where only smaller portions of the texture are required. For example a texture used for an entrance arch with window above, could equally well be used for a wall with just a window of the same shape.

Figure 3: A snapshot of Rhodes campus looking towards the Grahamstown Monument

5. Component interaction: Manipulation of the Spatial data

The user, using a standard WEB browser, will download the VGIS - both spatial information and Java applets implementing GIS tools - from a WEB Server that is specialised to deal with VGIS requests. From this point, the user's interaction with the VGIS will determine what events are triggered.

These events are not limited to, but may include accessing remote DBMSs to retrieve attribute information, and changing the user's view and/or interaction with the VGIS.

The Web page downloaded by the client contains an embedded VRML World and one or more Java applets that use the EAI to connect to the VRML World. In our application we make use of two applets: one displays meta data

about the attribute database; and the other allows the user to make SQL queries and manipulate the scene graph according to the results of the SQL query.

User selected, or "intelligent", negotiation with the VGIS WEB server regarding the level of detail (LOD) of a scene provides a means for optimising bandwidth-related download delays, and increasing rendering speed for near real-time interaction.

The results of an SQL query can be used to change which buildings are displayed, and/or change the attributes, e.g. colour, material, etc. of particular buildings within the scene. The ability to add, update or remove a single object from the scene graph allows one to perform "live" updates. Therefore, should new objects become available as part of the spatial data set, these new objects can be added to the scene graph automatically and/or manually.

6. Conclusion

This developmental system is intended to become a useful information tool as well as being an important research tool for combining GIS, distributed multimedia and temporal data. Our VGIS extends current GIS systems in that it is a scaleable, WEB-based, virtual GIS that is platform independent. All the above features are highly desirable on their own, but when combined, should provide enough functionality to attract commercial interest, while also providing GIS facilities to the Internet community as a whole.

Due to the graphics intensive nature of the VGIS, specialised hardware may be required to deliver near real-time interaction. However, even with an ordinary graphics card, interaction with the VGIS, while slow at times, would almost always outperform a similar system which downloads pre-rendered images according to the user's selection. The major bottle-neck is currently the bandwidth available on the WWW, especially in South Africa. The following optimisations, however, provide essential optimisation techniques for reducing the impact on limited available bandwidth and processor power:

- The decomposition of scenes into individual objects of user-defined granularity.
- The ability to select only the objects of interest for detailed analysis as opposed to having to download an entire GIS coverage.
- The use of VRML ShapeHints and level-of-detail (LOD) to decrease scene complexity, and increase rendering speed.
- The use of progressive LOD, which has the additional advantage of not increasing the bandwidth required to download objects of increasing LOD because only the increased object complexity needed to be downloaded, rather than the same object at the new level-of-detail.

7. Future Research: Integration of Temporal Data into VGIS

Spatial objects can change shape and/or position over time. Therefore one needs to be able to model these changes and also to be able to query the objects according to spatial and temporal criteria. The user must have the ability to perform a combined spatial and temporal query, e.g. how many objects were in a particular radius at a specific time. Where possible one must be careful not to duplicate information stored about these objects, i.e. one must not store information that can be formulated from relationships between other spatial, temporal or attribute data. Even though the spatial objects are changing with time, it is also essential to have some sort of history associated with these objects so that one may determine what happened in the past, and hopefully also to be able to make predictions. Predictions using statistical methods/interpolation would then, for example, allow one to ask how many objects one could expect in a particular radius, at a specific time, for which one does not have the actual data [Preston 1998].

Temporal databases are designed to reflect the changes that occur over a period of time by keeping records of past states. However, because databases may be manually updated, there is often a discrepancy between when an event occurred and when the transaction to record that event was processed.

Currently we are exploring the following two approaches to implementing temporal support in existing non-temporal object-oriented DBMSs, for implementing a temporal object database, for use in our "Proof of Concept" Web-based Spatiotemporal GIS application:

- *Creating a temporal front-end to a non-temporal object database.* One of the drawbacks of implementing an ADT for time, is that it becomes difficult to write temporal queries because the object query language does not support temporal queries. However, by creating a separate front-end which specifies that all queries should be evaluated temporally and all constraint checking performed by a temporal constraints manager, it is possible to provide an easier to understand and use, less error prone system. A similar idea was implemented in TimeDB [Steiner 1998], which is a front-end to an underlying non-temporal relational database. However, the advantages of using an object-oriented database merit research into the implementation of a temporal front-end to an ADT for time in an underlying non-temporal object-oriented database.
- *Implementing temporal support through the use of extensible object identifiers, an extensible query language and the possibility to overwrite algebraic operators for different ADTs.* This involves the possible implementation of the ideas developed in TOMS [Steiner 1998] using the OODBMS OMS. This will allow the overwriting of methods and operators at lower levels within the object DBMS as opposed to implementing a separate, higher-level interface to manage temporal ADTs. The ideal would be to have access to extensible object identifiers, an extensible query language and the possibility to overwrite algebraic operators for different ADTs.

The integration of a temporal database into our current "Proof of Concept" system, will create the need for further research into Spatiotemporal GIS applications. In particular, the concept of how the timestamps stored for each entity in the temporal database should affect the visualisation and spatial querying of these objects, must be studied.

Extensive Application of Electronic Mail in a Five-phase Computer-supported Meeting

Gitesh K. Raikundalia
School of Multimedia and Information Technology
Southern Cross University
Coffs Harbour, New South Wales, 2457
Australia
graikund@scu.edu.au

Abstract: Electronic mail (email) is undoubtedly a very widely used form of communication. Not only in government, education and business sectors, but also in day-to-day affairs of everyday people. Given its immense usefulness and relevance in communication, email is naturally applicable in a computer-supported meeting. Logan is a *Web Electronic Meeting Document Manager* (WEMDM) that specialises in provision of a wide range of document functionality for such meetings, for example, agenda and minutes development. Logan uses email extensively in meeting processes—more widely than found in other meetings support systems. For instance, four types of agenda-related messages and one type of message for rejected agenda contributions sent during the pre-meeting phase of a meeting. Such extensive use occurs because email is a vital mechanism required for Logan meeting processes.

Introduction

Electronic mail (email) has proven to be a highly popular method of communication nowadays. Email is widely used in business, education, government, and now, socially amongst everyday people. Email is useful where communication is asynchronous and thus users are allowed some time to respond to messages. Email is also beneficial in a workplace setting where many users keep their email inboxes open continually and may therefore be updated continually with important information. Users may also read and respond to messages independently of each other. Users may very easily store personal copies of messages for future use. For these reasons, email is appropriate and effective in support of processes during a computer-supported meeting.

Associated with email are issues of usability and user interface. Like other user interfaces, such as Web pages, email messages must be designed to provide all necessary information in an efficient and yet effective manner. However, as far as much email software goes, message content is presented in a very limited manner (e.g. ASCII text, single font size and type) and so content must apply ASCII text, spacing and other characteristics effectively to enhance user satisfaction. Messages must be as usable as possible for employees whose work involves a large number of other tasks that must be carried out in addition to reading and responding to email.

Logan is a *Web Electronic Meeting Document Manager* (WEMDM). A WEMDM handles a range of document issues associated with meeting processes occurring before, during and after a meeting. Logan has been developed by the author to handle functions such as collaborative, asynchronous development of the agenda by the secretarius with participant input or generation of *derivatives*—documents where content results from textual analysis of meeting discussion.

The WEMDM is used in tandem with a discussion tool (*Yarn* [Rees et al. 1993] was used in experiments with Logan) used to display and capture verbatim remarks. A meeting supported by Logan involves both the roles of

chairperson (the chairperson role in a traditional, face-to-face meeting) and a *secretarius*, who is a participant responsible for administrative meeting tasks like minutes creation.

A Logan meeting is described by the *meeting subphase model*. This model consists of five phases: pre-meeting, in-meeting and post-meeting phases, where the in-meeting phase consists of the three phases: startup, discussion and windup phases. This model is a variation of the general model put forth by [Dubs and Hayne 1992]. Logan handles document functionality across these five phases. Additionally, Logan handles *meeting chains*. A chain is a linear sequence of meetings, so that given any meeting in the chain, *A*, the meeting preceding *A* is the *last* meeting and the meeting subsequent to *A* is the *next* meeting. Meeting *A* depends on its last meeting for document input and provides documents as output to its next meeting.

Logan automatically generates and sends to participants a variety of email messages associated with meeting tasks. The tool derives message content automatically from its pages (such as the agenda) or configuration files (such as a file containing administrative details like date and time of a meeting, meeting name, etc.) and formats the messages appropriately. Messages are used for such purposes as informing participants of meeting details (not requiring an immediate response to the message) or for requesting some immediate response such as contributing items to the meeting agenda. Almost all messages are used within the pre-meeting phase. However, different instances of these messages may be used and sent multiple times during the phase.

This paper presents the types of email messages generated and sent by Logan during a full meeting. User interfaces of various messages are shown and described.

Meeting Tasks and Email

A Logan meeting consists of several tasks. Some tasks involve the email messages discussed in this paper. The tasks involving email, ordered chronologically and according to the phases in which they occur, are as follows:

Pre-meeting:

1. The secretarius initiates the agenda (including details such as tools for use in the meeting and the meeting purpose) requesting participants to contribute items to the agenda and indicate if available for the meeting at a date and time proposed by the secretarius.
2. Participants view and some or all of them respond to the message by contributing items to the agenda. For those items rejected from inclusion in the agenda, the contributing participants receive an email message notifying them of this rejection. However, participants use the reason for rejection as a guide to reformulate and re-submit more appropriate contributions (if they wish).
3. Participants use Logan to indicate availability for the meeting at the proposed date and time.
4. If one or more participants indicate that they are unavailable for the meeting at the proposed time, and if the presence of these participants is necessary, an email message is sent to all participants. This message contains a new date and time and requests participants to indicate availability for the meeting.
5. After the final date by which participants may submit contributions for the agenda, the secretarius finalises the agenda. The secretarius reminds participants of the meeting date and time .
6. If a finalised meeting needs to be postponed, a new email message is sent to participants notifying them of the postponement. Reasons for postponement include those such as network failure or a last-minute absence of the secretarius. A newly proposed date and time are included in this message.

Meeting:

Discussion occurs here.

Post-meeting:

7. The secretarius generates the minutes of the meeting. An email message containing these minutes is sent to participants to review the meeting.

An item contains an item number, item description, time for discussing the item, initiator and documents as shown for the items 1 to 8 in [Fig. 3]. Rejection of items can occur because of a few reasons, but it is usually because of irrelevance of the item for achieving the meeting purpose.

The secretarius uses Logan to send several types of email messages to participants in accordance with the above tasks. These message types, as shown in [Fig. 1], and the corresponding tasks in which they were described above (identified by task number) are:

- Request for agenda contributions—requests participants to contribute items to the agenda (1)
- Meeting reminder—to remind participants of an impending meeting; the date and time when it will as well as other details such as the agenda items (5)
- Request for new time and contributions—this message is sent requesting participants to indicate availability to a newly proposed time and reminds participant that they may continue to contribute items to the agenda (4)
- Meeting postponement—this message is sent after a Meeting reminder which was sent previously, and attempts to reschedule the finalised meeting for another time (6)
- Rejected participant agenda contributions—a message sent to a single participant informing him/her that one or more submitted item contributions were inappropriate for inclusion in the agenda (2)
- Minutes—a message sent to participants for their own personal review of the meeting (7)

The *Request for agenda contributions* email is sent out before any other message. Participants may then respond by voluntarily contributing items. Following this message, four other possible messages may be sent (as shown in the box). These messages can occur in any order, with the exception that a *Meeting postponement* message would only occur once a meeting has been finalised. A *Rejected participant agenda contributions* message is sent only to a participant who contributes items the agenda.

Figure 1: Types of email messages and points of distribution

Message Types

The first four of the six types of messages described are referred to as *agenda-based messages*. This is because their content is derived largely from the meeting agenda, e.g., discussion items, meeting purpose, etc.

Agenda-based Messages

Request for agenda contributions

[Fig. 2] and [Fig. 3] represent the first and last part of the RFAC message, respectively. The secretarius will set some agenda items before this message is sent out. The message invites participants to add voluntarily to the items shown in [Fig. 3]. The message also prompts participants to indicate if they are available at the proposed date and time in the message (shown within the subject). The participant will then log into Logan to use the appropriate mechanism for availability indication. In the body of the message, the first line identifies the meeting. This line contains three attributes in the order: chain name, number of the meeting in the chain and meeting name.

DSTC research (#4) --A new DSTC?

Agenda contributions are invited. Indicate availability by:
 * access Logan Central and click on "Future meetings" entry in Index,
 * on the "Future meetings" page, go to table of details for DSTC research,
 * in "Date" column, click on proposed time link
 This must be done by: 1000 on Thursday, 26 June 1997.

Participant list:
 * Chairperson: Michael Rees * Secretarius: Gitesh Raikundalia
 * Peter Stewart * Tim Mansfield * Ken Baker * Ashley Beitz * Gitesh Raikundalia

Meeting purpose: Feedback to items on Logan not covered last meeting
 will be briefly sought.
 The future of the DSTC in a new Cooperative Research Centre will be
 debated.

Tool selection: * Logan * Yarn

Figure 2: Request for agenda contributions—first part

The next component of the message indicates the purpose of the message. The five-line paragraph informs participants that they are invited to contribute to the agenda and provides instructions for indicating participant availability. In [Fig. 2], the date and time by which participants indicate their availability, in order to determine if the proposed time should be finalised, is 24 hours before the proposed time. In this example, the proposed time is 1000 on Friday, so participants have until 1000 on Thursday to indicate if available or not for the meeting. Details of participants, meeting purpose and tools for use in the meeting follow these instructions. These three sections will not need to be shown repeatedly in later Figures.

Agenda items			
Item number	Item	Time	Initiator
1	Apologies	1	Chairperson
2	New agenda items	2	Chairperson
3	Matters arising from minutes of last meeting	5	Chairperson
4	Participant agenda contributions page	5	Gitesh Raikundalia
5	Agenda Web page (carried over)	5	Gitesh Raikundalia
6	Minutes (carried over)	1	Chairperson
6.1	Web page (carried over)	6	Gitesh Raikundalia
6.2	Email (carried over)	5	Gitesh Raikundalia
7	Derivatives (carried over)	10	Gitesh Raikundalia
8	Other business	2	Chairperson

Gitesh Raikundalia,
 Secretarius

Figure 3: Request for agenda contributions—second part

[Fig. 3] displays the remainder of the message also found as the second part of the messages in [Fig. 4] and [Fig. 5]. The data of the table is placed in columns of varying width. Referring to the first item, the word "Apologies" is the only occupant of the column for indicating the item name. A space delimits the *Item* column and the *Time* column. An item's details are stretched across a row. In practice, an item at the most requires two lines for a row, where information on the first line wraps around to the second line. Lastly, the secretarius' sign-off is included.

Request for new time and agenda contributions

The Request for new time and agenda contributions email message is very similar to RFAC message. The differences include the following. A different subject ("Request for new time and agenda contributions") is

shown without the proposed date and time. Extra text is added to the beginning of the message purpose "Due to lack of availability for <date and time> a new meeting has been proposed". The date and time is therefore shown instead just above the meeting purpose to highlight the fact that a new date and times is the issue of the message.

```

Subject: Meeting reminder - Friday, 27 June 1997 at 1000

DSTC research (#4) - A new DSTC?

Please be informed of this meeting, and review the discussion
items (with associated documents) in preparation.
```

Figure 4: Meeting reminder

Meeting reminder

The meeting reminder is sent usually a short while before the meeting. Given that the time by which participants indicate availability is 24 hours ahead of the meeting, the meeting reminder will be sent usually within a few hours after this time. The meeting reminder is shown in [Fig. 4]. The only difference between the meeting reminder and previous messages is the second component of the body, informing participants of the meeting and reminding participants to view documents.

Meeting postponement

As explained above, reasons for postponement of a meeting exist (such as a network failure). This calls for a new time in order to carry out the meeting. An example of the email message sent to participants requesting availability to a newly-proposed time is shown in [Fig. 5]. Because the agenda is finalised, further contributions of items are not requested.

Figure 5: Meeting postponement

Rejected participant agenda contributions

This email may be viewed in [Fig. 6]. The body of the message begins with a statement indicating that the message contains rejected agenda contributions and the reasons for rejection. All contributions rejected by the secretarius are displayed in the message, one after the other. Details of an item are presented followed by the reasons for rejection of that item.

Minutes

The final email message to cover is that of minutes. An example of this message (partial capture) is found in [Fig. 7]. The message contains details of items as well as the outcomes, decisions and actions associated with an item. Logan allows the outcome of an item to be "Not discussed" where the item is not discussed in the meeting, and therefore the decision of such an item may be marked as "Carry over" to allow it to be discussed next meeting. Decisions and actions are optional for an item, such as for item 1 in the example.

Figure 7: Minutes

Conclusion

Logan generates a range of email messages for various tasks in a computer-supported meeting. Such communication is foundational for effective completion of tasks. This paper covered the different types of email and displayed user interfaces for them. Agenda-based messages, a message for notification of rejected agenda contributions and one for minutes were shown as well as points in the meeting of distribution to participants.

Abstract: Current portal services usually require a user to offer private information such as stock portfolio data or calendar events as a requirement to obtain useful services. Due to the ever increasing concerns over the lack of privacy protection on many web sites, such practices are becoming less attractive. This paper presents a *personal* portal implementation based on a client-side proxy server. Private information such as a user's web access history and stock portfolio is kept by the proxy, which uses agents to combine such information and rich content returned from portal companies to return personal and useful information to the user. We describe the architecture of the personal proxy server and several additional services that can be provided through this middleware approach.

This URL: <http://www.research.att.com/~iproxy/webnet99>

1. Introduction

Recently, there has been a heated competition among several companies to establish *portals*, websites that assemble an array of services and content to attract internet users. The consensus is that there will be only a few portals through which most customers access services and products on the internet [Wu 98]. Therefore, the most popular portals are likely to reap top advertisement dollars and E-commerce transaction fees. Existing portals such as My Netscape [Netscape 99], My Excite [Excite 99], and My Yahoo [Yahoo 99], are loaded with similar features such as search engines, stock quotes, maps, weather information, calendars, and news. However, many of these services have become commodities that you can obtain through companies like Infospace [InfoSpace 99]. Portal builders have been busy creating new services in a hope to retain existing customers. Examples include AOL's Instant Messenger [AOL 99], Netscape's Smart Browsing [Netscape 98a] and WebMail [Netscape 98b], InfoSeek's Express Search [InfoSeek 99], and Excite's Assistant. Many of these new services attempt to collect a user's profile information and detect the user's presence on the internet so as to create direct marketing channels to the user. However, none of these new services has the ability to combine the rich content from the portal server with sensitive and private information on the client side to provide a truly personal experience. For example, imagine that a user would like to get a list of stock quotes from the server and combine that with local stock portfolio information to compute and display the net gain/loss. Due to the ever increasing concerns over the lack of privacy protection on the web, the user may not want to give his or her financial details to the portal server, but this is usually required by all the portal implementations we know of.

This paper presents a personal portal implementation based on a client-side proxy server. Private information such as a user's web access history and stock portfolio is kept by the personal proxy, which uses agents to combine such information and rich content returned from portal companies to return useful and private information to the user. Section 2 gives an overview of iPROXY, a proxy server we have developed over the past few years as a research vehicle for developing new internet services using middleware. Section 3 describes a set of new services that can be provided through a client-side proxy. Section 4 describes how to put the pieces together to form a personal portal. Finally, Section 5 concludes with summary and future work.

2. Overview of iPROXY

iPROXY [iproxy 99] is a middleware for applications that access Web services. It can be installed as a personal proxy server running on an end-user's machine. It provides standard Web proxy API and functions of accessing,

caching and processing web data. iPROXY allows users to configure and program its functionality, including the selection of the routes to access web servers (e.g., choosing different proxies for different hosts), how to archive web pages, recording and analysis of web access history, and management of the proxy's cache. iPROXY also provides hooks to plug in new functions that are able to process Web data received from Web servers. Hence, data from servers can be condensed, compressed, encrypted, or patched. The corresponding filters will convert pages back to their original form, or synthesize new pages from web data and personal information stored on the local disk. Finally, with a built-in Web server, iPROXY can also accept HTTP calls from Internet and trigger local applications to perform various services like event notifications, alerts, and data pushing.

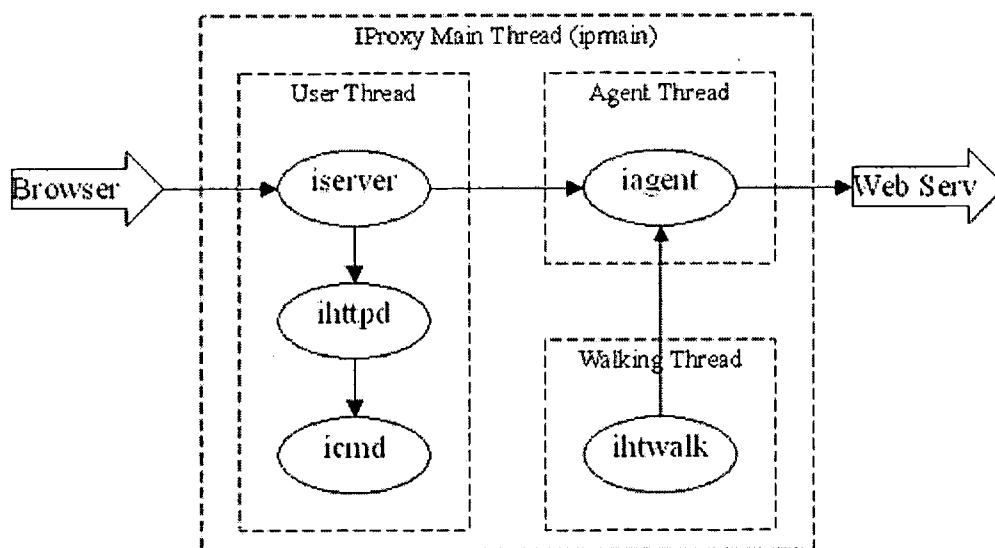

Figure 1: System Architecture of iPROXY

Figure 1 shows a high level view of the iPROXY system architecture. When iPROXY is started, the main thread listens on the proxy port and receives and responds to HTTP requests from clients (browsers or other proxies). The system creates a new user thread to serve each new request, which is delivered to **iagent** for remote web access or to **ihhttpd** for local access. **ihhttpd** implements a web server and will invoke **icmd** to interpret iPROXY commands embedded in html pages. **iagent** can also return pages to **ihhttpd**, an iPROXY facility to walk the html tree structure to collect and archive pages.

Figure 2 shows how filters can be applied to http headers, pages returned from the web, and pages returned from iPROXY's own cache. For example, an output filter can be used to add new components (menubars, etc.) or modify returned pages (replace some remote data with local data, etc.). As another example, a header filter can add a cookie and/or new header fields to an input HTTP request before forwarding it to Web server. These filters allow us the flexibility to implement several features in a personal portal, which will be described in the next section.

Most proxy servers are not designed with such flexibility in mind - one notable exception is IBM's **WBI (Web Browser Intelligence)** [Barrett & Maglio 99]. WBI is also a programmable proxy server that was designed for easy development and deployment of intermediary applications. However, it does not provide a built-in web server, or a simple scripting language that allows a programmer to mix HTML content with proxy-generated content.

Moreover, in WBI, filter functions are implemented as individual building blocks that are plugged in at initialization time. In iPROXY, however, filter functions are implemented as CGI-bin on Web servers and are named with regular URLs. Each filter function can reside on the iPROXY built-in server or any other remote web server. Compared with WBI, iPROXY's filter functions have a more straightforward API (i.e., CGI interface), a well-defined naming scheme (i.e., URL) and a more generic invocation method (i.e. HTTP).

Figure 2: iPROXY Filters

3. New Services Based on a Client-Side Proxy

Several new services can be provided with a client-side iPROXY that has access to the user's private information such as the web access history and personal finance information. In the following, we describe a few that we have implemented.

3.1 A Personal Web Archive

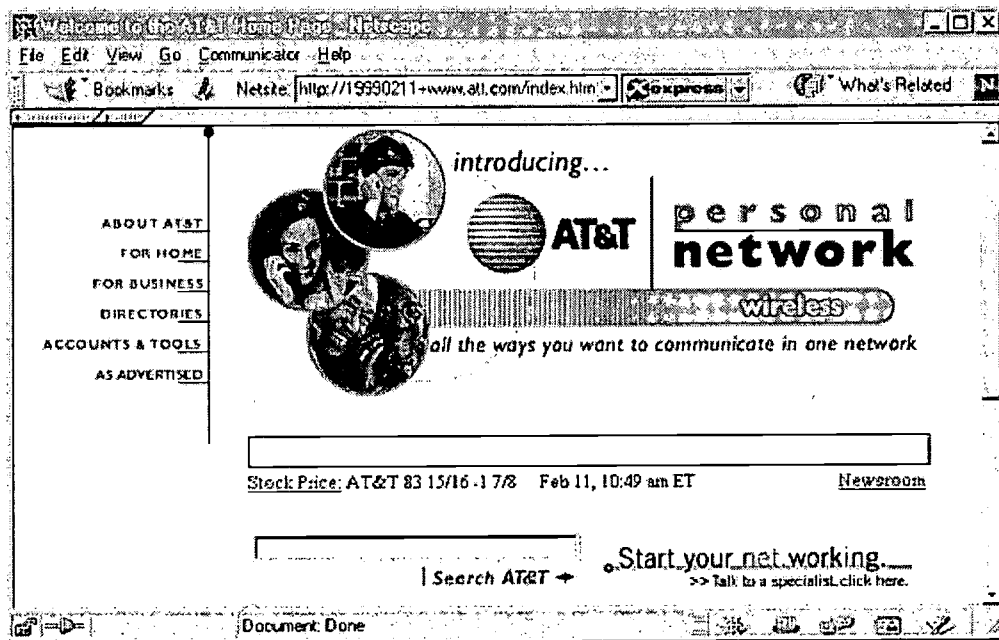

Figure 3: Using a *Persistent* URL to access AT&T's home page on February 11, 1999

While current search engines allow users to find pages of a certain topic easily, they do not offer much help in locating and viewing the pages a user has seen in the past, except for those that are still kept in the browser cache. Due to the sharp decrease of storage costs, a client-side iPROXY can afford to archive all the web pages a user has viewed so that any of these pages can be retrieved easily later on - without even bookmarking them. We can then

use existing tools like [AltaVista Discovery](#) to index and search these web pages. Our experience shows that an active web browser user can create a web archive of roughly 80-100 MB per month, including images and all sorts of documents downloaded. This amounts to around 1 GB of storage per year for all the pages a user has seen - increasingly affordable to many users.

Because iPROXY intercepts http requests, it can effectively extend the URL name space to address pages stored in the archive by adding a timestamp in front of the regular http address. For example, Figure 1 shows the February 11th version of AT&T's website captured that day. The URL is <http://19990211+www.att.com>. Even if the AT&T website goes through major redesigns, the above *persistent* URL will always give you the same content.

3.2 Personal Web Page Reminders and Hot Sites

Since a client-side iPROXY can log a user's web accesses, it can analyze the log and use the data to provide new web services that can help improve the user's browsing experience. Figure 4 shows two possible services:

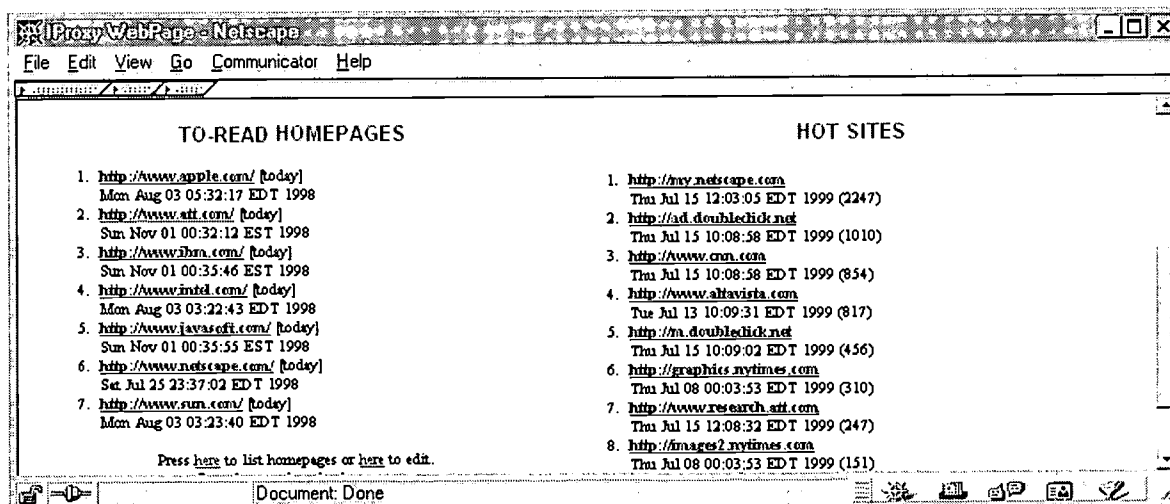

Figure 4: TO-READ Home Pages and Personal HOT LIST

- **TO-READ Homepages:** A user can specify the list of websites and corresponding frequencies when certain websites should be visited. iPROXY can check the last visiting dates and schedule a list of pages that the user should visit today.
- **HOT Sites:** iPROXY computes the number of visits to each website and lists the top 10 websites with their last visiting dates accordingly as soon as the user accesses his or her personal portal. There are several advantages of having such a list: the user might want to (a) know the last visiting time of a favorite site - the timestamp is displayed along the website link, (b) access the latest version by clicking on the link, and (c) compare the new version with the old using tools like [WebCiao](#)[Chen and Koutsofios 97] or [AIDE](#) [Douglis et al. 98] because iPROXY can keep previous versions of the web pages that the user has visited.

In Section 4, we discuss how iPROXY scripting commands can be used to generate these two lists

3.3 My Stock Portfolio

Most portals allow users to specify the stocks that they are interested in and display the latest prices when the user accesses the personalized page. However, they cannot compute your current balance or net gain/loss unless you provide private and sensitive information like how many shares you own and when you purchased them. Such practice is certainly not desirable to many users. Figure 5 shows a typical portfolio view on [Your WorldNet](#)[ATT 99]. In this case, the user claims that he or she owns one share of AT&T, [E*Trade](#), and Netscape stock each. No commission fees were paid and each stock was bought at \$30.00. The portfolio service then returns the current

market price and net gain/loss information.

Symbol	Qty	Purch Price	Market Price	Today's Change	Invested +Comm.	Market Value	Gain Loss	Update E.T.	Vol	
I	1	30.000	91.375	-2.188	30.00	91.38	+61.38	14:38	7.74M	
NSCP	1	30.000	70.750	-1.313	30.00	70.75	+40.75	14:42	3.03M	
EGRP	1	30.000	56.875	-5.563	30.00	56.88	+26.88	14:42	15.46M	
AUTOREFRESH					Totals (at 02/02/99 14:58 ET)		90.00	219.00	+129.00	

Figure 5: My Portfolio from *Your WorldNet* without Private Information

Now suppose that the real purchase price, commission fees, and the number of shares of each stock are stored on the client machine. By constructing an output filter for the stock page, iPROXY can retrieve the private information, combine it with stock quotes provided by the portal site to compute the balance and net gain/loss. This is done by a specification like the following in iPROXY's configuration file:

```
OutputFilter /bin/portfolio.cgi http://stocks.planetdirect.com/portfolio.asp
```

It instructs iPROXY to apply the Java class `portfolio` on the local server as an output filter whenever the browser issues the corresponding http request. The real numbers are shown in Figure 6 - visible to the client only, and not to the portal server. The user actually bought 267 AT&T shares, 50 Netscape shares, and 40 E*Trade shares at the prices of \$36.5, \$21.0, and \$39.38 each. The commissions were 0, \$19.95, and \$19.95. The total gain was \$17,799.02. The numbers replaced by iPROXY are shown in green.

Symbol	Qty	Purch Price	Market Price	Today's Change	Invested +Comm.	Market Value	Gain Loss	Update E.T.	Vol	
I	267.0	36.5	91.375	-2.188	9745.5	24397.13	14651.63	14:38	7.74M	
NSCP	50.0	21.0	70.750	-1.313	1069.95	3537.5	2467.55	14:42	3.03M	
EGRP	40.0	39.38	56.875	-5.563	1595.15	2275.0	679.85	14:42	15.46M	
AUTOREFRESH					Totals (at 02/02/99 14:58 ET)		12410.6	30209.63	17799.02	

Figure 6: My Portfolio from *Your WorldNet* with Private Portfolio Information

One problem with this approach is that an output filter has to be written for each portfolio service and the filter is susceptible to changes in the format of the portfolio service. The problem might be reduced if more portal service providers start using XML to represent content on their websites to ease data extraction. Alternatively, if a portal server is aware of the potential existence of a client-proxy, then the two can work together seamlessly. This scenario is discussed in the next section.

4. A Proxy-Based Portal - Putting All the Pieces together

A proxy-based portal integrates content stored on a proxy server with those provided by a regular portal server such as *Your WorldNet*. Consider the following scenario where a portal server works in concert with a client-side proxy: a user sends the an URL with a proxy directive (starting with `?iproxy&`), `http://www.att.net/?iproxy&action=portal`, to the browser. iPROXY first retrieves the home page from `www.att.net`, which has encoded iPROXY directives that instruct iPROXY on how to process the local data and merge it with server content. It then presents the personal portal page back to the user. In order to provide a non-intrusive behavior to other users who are not using iPROXY, we embed the iPROXY directives in HTML comments in essentially the following way to generate the portal page shown in Figure 4:

```
<!------- with iproxy only ----->
```

```

<!--:portal nop
      :portal version
      :portal to-read
      :portal dolog
      :portal top10
:portal nop -->

```

iPROXY intercepts these directives and performs necessary actions before returning the portal page. The directive *version* prints out the version number of iPROXY. The directive *to-read* constructs the list of web pages scheduled to be read. The directive *dolog* analyzes the current web access log to produce the statistics. Finally, the directive *top10* presents the results on the personal portal. All these directives, being embedded in a comment, are ignored by browsers not using iPROXY.

5. Summary and Future Work

This paper shows how new web services such as archiving web pages, retrieving persistent URL's, listing frequently visited web pages, and computing personal portfolio based on private user data can all be implemented with the help of a client-side proxy server - without changing the existing browsers. These services are glued together to present a truly *personal* portal experience. We are currently conducting experiments on website differencing and archive searching, and we hope to work with internet service providers to bring these new services to internet users. You can download a copy of iPROXY software and its API document from <http://www.research.att.com/sw/tools/iproxy>.

Improving Teaching and Learning Through Web-Based Feedback

Lieutenant Colonel Eugene K. Ressler
Associate Dean, Information and Educational Technology Division
United States Military Academy
West Point, New York 10996
ressler@usma.edu

Dr. Anita Gandolfo
Director, Center for Teaching Excellence
United States Military Academy
West Point, New York 10996

Abstract: The power of technology to increase efficiency and workplace productivity can obscure its potential for transforming traditional practices, especially in the field of education. While technology can provide access to increasing numbers of students through distance learning, for example, it can also enhance student learning in traditional settings when used to facilitate specific practices that research indicates are important for learning. Feedback from and to students is one critical aspect of learning that we have addressed through three web-based systems we provide for our faculty members.

Introduction

Our Center for Teaching Excellence is charged with general faculty development as well as the use of technology to improve teaching and learning. In the latter mission, we work in cooperation with our Instructional and Educational Technology Division. West Point is an ideal environment to explore the use of technology to enhance student learning, since we have a ubiquitous computing environment and a robust infrastructure. In addition, we have developed a vision for the use of technology for instruction, and our hardware purchases and software development are geared to the accomplishment of that vision.

Since all faculty members and individual cadets have desktop computers, our intranet offers rich opportunities for the instructional use of technology. While we are engaged in the development of course Web pages and customized multi-media programs, we are also using technology to enhance the classroom learning environment by providing instructors with tools that create more “pedagogically meaningful relationships” with their students (Shulman, 1988). According to Shulman, interaction with students in such relationships should provide the faculty member with a pedagogical content knowledge that differs from the generic teaching skills and subject matter expertise so often assumed to be sufficient for college teachers. This pedagogical content knowledge enables faculty members to select and sequence learning activities to more effectively meet students’ learning needs and more ably address student misconceptions and other difficulties with course material. Feedback from students has been documented as an important way to develop pedagogical content knowledge (Menges and Rando, 1998). We have developed three systems for USMA faculty members to use to elicit feedback from students, electronic tools to foster those “pedagogically meaningful relationships” that improve learning and teaching: end-of-course feedback, interim course feedback, and learning assessment.

End-of-Course Feedback

When USMA developed a model for centralized end-of-course feedback a decade ago, we eschewed the evaluative mode that has become so problematic in higher education (Gerstman, 1995). We opted for a purely formative system that provides information about an individual instructor’s class solely to that instructor. Program directors, department heads, and the Dean all receive only aggregate information at their respective levels, information that is helpful for assessment and planning but that does not allow for evaluation of individual

instructor performance. In its original paper and pencil format, student feedback was limited to responses to a standard set of questions, and the scoring of surveys delayed instructor access to survey information. Our electronic version has substantially expanded the system's potential to provide suitable information at every level easily and quickly. Originally begun as a cadet design project in a computer science class and further developed by one member of the design team as an independent student project, in 1998, the authors, drawing on the cadet work, took the system to this "next generation" providing its current flexibility.

In brief, the system protects the anonymity of instructors through a system of PINs used to control views of information. It operates in a cycle of phases. During phase 1, designated individuals in each department, the "trusted agents," organize the department's academic program as a hierarchy that reflects its organizational structure by creating "nodes" for designated units; that is, its programs, courses, and sections. They determine "who sees what" by setting access lists for each node. A faculty member with access to a node may write survey questions and receive a tailored report for each node. For example, the English Department head may write questions, and the report he receives will represent what every student taking an English course responded to those questions. The course director for freshman composition writes questions, and her report will contain the response of every student enrolled in freshman composition. Each composition instructor can write questions for his or her sections, and the reports will contain the responses of only the students in those sections. However, although the instructor can see how his or her students responded to the department head's questions and the course director's questions, neither the department head nor course director have access to information at levels lower than their own. The faculty members have most of the semester to create the department hierarchy and write questions because phase 2, student response, usually does not begin until the final week of class.

During phase 2, students respond to a unique, personalized survey for each class section they attend, created by the system on-the-fly by joining questions of relevant nodes. For instance, a student in the freshman computer science core course, CS105, hour D, section 1, will receive a survey potentially formed from questions written by the instructor particularly for this section, by the instructor for all his/her sections, by the course director of CS105, by the computer science program director, by the department head for all non-elective courses, and for the department as a whole. There is also a short list of standard questions for the entire Academy. While this may seem a daunting list, we have cautioned our faculty to make sure that individual student surveys not exceed a total of fifty questions and be closer to the thirty-question limit of our earlier paper version. Questions can be multiple-choice with or without a scale, with exactly one or any number of responses, and they can be "rank ordering" questions. Faculty members can ask for free text responses, which are delivered either only to the instructor (maintains high confidentiality) or "rolled up" at all nodes below the one where the question was asked (maximizes information). Questions can be "mandatory" or "optional" in the sense that surveys cannot be submitted while missing answers to mandatory questions. A sample of this system can be viewed at <http://www.dean.usma.edu/feedback>.

End-of-course feedback used as an evaluation of teaching is much criticized in higher education and remains largely because of what has been identified as the principle of *faute de mieux*, loosely translated as "lack of anything better" (Gerstman, 1995). A major problem is the tendency to mistake the numerical nature of the data with objectivity, ignoring the multitude of variables that affect student evaluation of instruction. However, when considered from the formative perspective, there is more of a tendency to see the feedback contextually, understanding it as the student impression of the learning situation and appreciating its value for certain types of information. For example, in our first semester core math course, the course director composed questions to obtain feedback on how well instructional intentions were meeting student learning needs, and he reported satisfaction with the results:

The feedback let us know that most of the cadets (71%) felt that technology helped them understand mathematical concepts, 77% indicated that the emphasis we place on concepts rather than formulas helped them learn mathematics, and the requirement that they communicate mathematics by writing and briefings helped them learn the mathematics (76%). We take that as an indication that we are doing what we hope to do. (e-mail message from MA103 course director)

This same faculty member asked different questions of his own sections, seeking information about his individual classroom practices. He reported that he confirmed the value of cadets “going to the boards” to work problems but also students advised that he should be “more patient in waiting for cadets to finish problems on the boards,” something he probably would not have learned without this type of feedback that allows free text responses.

Interim Feedback

While our end-of-course feedback system has proven valuable as a formative instrument, it has limited usefulness in promoting “pedagogically meaningful relationships,” since the students’ responses are available only after the teaching/learning events have concluded. Feedback is essential to learning, and if we want our instructors to gain pedagogical content knowledge, they need to be getting feedback at more regular intervals during the teaching/learning process. “Feedback used in this way not only improves the experiences of students. It also enhances the teacher’s sense of intentionality and control, factors essential to faculty well-being” (Menges and Rando, 1998). For some time, we encouraged our faculty members to do interim course feedback of their own design, but many were reluctant for a variety of reasons. They did not want to use class time. They believed that although students could report anonymously, they could be identified by handwriting (our classes are small) and would, therefore, not be candid. They were not sure how to do it properly; our Center for Teaching Excellence frequently received requests for sample questions to ask. We addressed all these issues by developing an electronic, web-based process that provides instructors with a simple, user-friendly, flexible means for obtaining student feedback that preserves student anonymity.

Complete instructions for use are available to faculty members on the CTE Web page (and can be viewed at <http://www.dean.usma.edu/cte>). This Web-based system is continuously available and functions with almost no administrative overhead. It provides an assortment of questions requiring free-text responses. In class (or via e-mail) instructors asks students to answer two or three from among the twenty questions the system offers. Students respond in private at their own computers. Responses appear anonymously in the instructor’s e-mail. Since instructors need not use class time for this process, can insure student anonymity, and have a set of questions available to select from, the perceived constraints to interim feedback have been eliminated, and USMA faculty members use this system freely. In addition, the use of interim course feedback increases the validity and value of end-of-course feedback because eliciting student feedback at regular intervals throughout the course contributes to the development of the “pedagogically meaningful relationships” that encourage students to be candid in their responses.

A key factor in the success of this feedback system with our faculty is its ease of use. It is deliberately low risk, insuring instructor autonomy. Complete instructions for using the system with students resides on the CTE Web page, easily accessible to all instructors. They can choose the use the system at any time without getting any permissions or notifying anyone (other than their students) of their intentions. In many cases, instructor satisfaction with this system has led them to use the higher risk Learning Assessment system (described below) which is just as easy to operate technically but is considerably more challenging pedagogically. As one computer science instructor reported: “I used the Interim Feedback system last semester with my CS105 students. I am using both the Feedback and Assessment systems this semester with my CS380 students. I have found both to be very useful and have been very pleased with the info I got.”

Learning Assessment

This instructor’s transition to the more challenging process of learning assessment is the result of our further development of the principle of student feedback. The low risk nature of the Interim Feedback system led us to address a critical learning issue with a similar system. On average, today’s students arrive at college significantly less well prepared academically than their counterparts in previous generations (Upcraft, 1995). They are often unfamiliar with independent studying, having done little homework in high school. This is a problem nationwide and a particular problem for us because our cadets do not have the luxury of “blowing off” a couple of years while they learn to study. They literally must “hit the ground running” when it comes to study and homework. We wanted to develop a system that would help the instructor guide learning by monitoring cadet class preparation.

Using the Classroom Assessment Techniques (CATs) developed by Pat Cross and Tom Angelo in the mid-1980s and used successfully throughout higher education (Angelo & Cross, 1993), we created a Learning Assessment feedback system for student homework assignments.

Classroom Assessment has proven valuable in helping instructors monitor and improve their students' learning (Cross, 1996). An important factor in the process is student anonymity when reporting on their learning in classroom situations. We use CATs to help our instructors monitor and improve their cadets' learning outside the classroom--that is, in their homework assignments--through a Web-based feedback process. Our system enables instructors to assess student class preparation before the class meets, so that they can modify instruction to address the specific learning problems in that lesson. We offer a menu of twelve CATs so that instructor can choose specific ones that help students deal with particular types of assignment. For example, if an English professor has assigned a non-fiction essay to be read and wants to focus students' attention on the essay's theme, the professor can ask students to complete a "One Word Journal" CAT on the Web. That selection asks the student to choose one word that encapsulates the theme of that essay and explain the significance of that word in no more than 100 words. When the professor accesses his or her e-mail in the morning, the computer will deliver the students' journal entries, although the identities of the individual journalists remain hidden. Student anonymity is the key to the assessment process because it frees the student from the apprehension of getting the "correct" answer and focuses the instructor on the nature of the learning rather than the task of grading.

Moreover, use of these CATs promotes metacognition among students. The physics student who is asked to identify the "muddiest point" in the reading assignment or the calculus student who is asked to apply a specific concept to a real world situation are improving their "learning strategies and study habits in order to become more independent, successful learners" (Angelo, 1991). And by planning the class session as response to assessment of student learning, instructors develop a more student-centered instructional environment. For example, one of our physics instructors reports on using "mud2," one of our "muddiest point" choices with his cadets:

I used the mud2 with the intent of getting feedback on the next lesson [that evening's reading assignment] but instead got feedback on the last couple lessons. The feedback told me to go back and clarify some cadet misconceptions I thought were clear.

We know from discussions with nationally known educators that our feedback systems, while simple technically, offer a rich resource for improving student--and faculty--learning.

Using SGML to Prepare Secondary School Distance Education Courses for Internet and Traditional Delivery

David W. Rogers
Open School, a division of Open Learning Agency of B.C.
Victoria, BC, Canada
drogers@openschool.bc.ca

Abstract: This paper describes the beginning of the OSCAR (Open School Courses and Resources) program: a multi-year project to create a high school graduation program that uses SGML (Structured Generalized Markup Language) and XML (Extensible Markup Language) to create courses with:

- Time- and place-independent or classroom learning.
- Content modularity permitting the repurposing of content
- Presentation to the student either with or without computer technology (one course, several options for delivery)
- Enforcement of good instructional design and planning.

This paper describes the origins of the project, pilot efforts that guided it, and some of its rationale. At the time of writing, the first student registrations are still eight weeks away. When the paper is presented, initial teacher and student reception of these courses will be described.

Introduction

Open School and its Distance Education Work

Now in their eightieth year, Open School and its predecessors have been the primary provider of distance learning for the public school system (Kindergarten through Grade 12) in the province of British Columbia, Canada. Open School originated, much as Australia's School of the Air originated, to meet the educational needs of children in the province's vast hinterland. Since 1980 its distance teaching or delivery function has been regionalized; Open School develops courses that are for the most part delivered through nine public schools that specialize in distance learning. More recently, Open School moved from being an internal branch of the province's Ministry of Education and is now a division of the Open Learning Agency of B.C., a 25-year-old institution of distance learning for post-secondary students and the workplace. Open School is thus the K-12 division of the Open Learning Agency; however, it continues to operate as a partner to public schools rather than as a school itself. Open School develops distance learning courses that align with the province's curriculum standards, and sells them to schools. About 21,000 school students take 47,000 Open School courses each year, the majority at the secondary level.

The Shifting Demands for School-Age Distance Education

The increasingly widespread Internet has opened new pathways for delivering Distance Education, and consequently a demand for courseware that exploits the medium. Research that demonstrates improved distance learning at the *secondary* level via the Internet is still sparse, but the medium's ability to reduce the Kearsley calls the "transactional distance" between the student and instructor holds promise for—and this is *the* crucial factor for youthful distance learners at the secondary level—motivating the students to complete their coursework successfully.

Two pilot projects reinforced Open School's optimism about the success of technology-mediated distance learning in the upper years of secondary school.

Between 1993 and 1998, Open School and its public school partners enrolled several hundred secondary students in "New Directions in Distance Learning" (NDDL). This program consisted of 25 Grade 11 and 12 courses which used synchronous and asynchronous delivery at a distance—computers with connectivity, audioconferences with instructors and fellow students, and other modalities such as print. Students in NDDL achieved a near-doubling of successful course completions compared to distance learners in the print-based equivalent courses, and equal course standings [McCauley, 1996]. NDDL demonstrated that technology-assisted learning is effective in the secondary setting. It also showed that synchronous sessions are generally not viable as part of the public school setting, and that with centrally managed mediation, it takes time to achieve economies of scale.

Since 1997, Open School's nine Distance Education (DE) School partners have successfully piloted another, asynchronous, technology-mediated CONNECT program, in the middle school grades. Students borrow computers from the DE School for use at home. They use email and the Web (and sometimes phone calls, but generally not conference calls or other synchronous media) for their connectivity with teachers and the school. About two thousand students have participated in the CONNECT program to date; educational results, though not yet rigorously compared to equivalent distance learners outside the program, are anecdotally very positive. This program is no more costly than classroom-based instruction, so economic viability is just another issue to manage alongside the others.

Open School's distance education products, though not designed specifically for the classroom, also find modest but steady use there. Apparently, courseware with enough student guidance built in for successful self-study also benefits some students in the classroom. This is especially true if the DE courseware is designed to incorporate technology, and the classroom has technology which needs course content. A key reason for Open School to leave government and become part of the Open Learning Agency was to address this classroom audience.

In summary, there is increasing demand in public schools for technology-mediated distance learning resources, both in the traditional DE community (insofar as it exists) and in the classroom. Their utility has been demonstrated, and occasionally measured, but there are constraints.

Constraints on Technology-Mediated Courses in Senior Secondary Schools

Besides the well-known problems of inadequate teacher preparation and erratic technology infrastructure, other aspects of the B.C. public school environment can reduce the effectiveness of courses that rely on technology:

1. In the final years of high school, the pedagogy is trending towards higher-level learning skills such as synthesis, reasoned conclusions, portfolio building, and problem solving. B.C.'s Grade 11/12 program has shifted decisively towards higher level learning, and also towards outcomes-based learning wherein teachers are to assess students' ability to perform those higher level skills. Commercial computer-based courseware does not always follow that trend; it is much less expensive to design and assess "factoid learning"[†].
2. A cardinal tenet of B.C. public education is equality of access for all. Accordingly, any courseware that relies on technology to meet the provincial requirements, would benefit (politically as well as in practice) from offering an equivalent stream which meets the same outcomes without needing technology. Dual offerings also allow a teacher to switch students away from technology, yet stay on track in the course, when the school's system is unavailable or the classroom has too few computers.

[†] For example, commercial algebra software tends to teach students to discriminate between a monomial and a binomial, or to state the definitions of tangents, rays, and congruency. This is lower-level, memorize-and-repeat learning that is easy to teach and assess by computer. By contrast, Ministry-prescribed learning outcomes for B.C. algebra students do not require the students to state any definitions and in fact discourage such practice; instead, the emphasis is on their ability to solve open-ended problems which require them to correctly *choose and use* binomials, or tangent properties, or congruency. It is much more of a challenge to facilitate that type of higher level learning via technology, since *how* the student arrives at the correct answer is what must be taught and evaluated.

3. Another cardinal tenet is universality of access. In practice, access to senior elective courses varies profoundly from one school to the next. Unless a B.C. school can muster 15 students for a course, the Ministry generally cannot provide funding to the school to provide the instruction. Many B.C. students enroll in DE because their public school does not provide the course they want. By bringing distance education courses into their classrooms, *some* teachers could manage dual-course or triple-course classrooms if the courseware met all required outcomes while not requiring constant delivery from the teacher.
4. Finally, the 'market' for senior-level courses is dispersed and costly to address: computer-assisted courseware is costly to develop and public schools have severely limited budgets. This combination of constraints means that senior level courseware needs to be developed in a systematic way, allow for a variety of presentation media without doubling the development effort, and insofar as possible, make use of pre-existing distance learning content.

At the confluence of these demands and constraints, Open School chose to adopt a course development system for the senior secondary grades that is based on Structured Generalized Markup Language (SGML) and its Web-oriented derivative, Extensible Markup Language (XML). Courses designed this way bear the acronym "OSCAR" (Open School Courses and Resources). In the next section, after briefly explaining SGML and XML concepts, explains how the SGML/XML approach addresses the above constraints on senior secondary learning.

The SGML/XML Model for OSCAR Distance Learning Course Development

A Brief Explanation[†] of SGML and XML

Both SGML and XML have the goal of storing human-readable documents such that computerized systems can discern, and thus properly render, their content. SGML is a standard way to describe a document via user-defined and machine-readable markup tags; the publishing industry has used it for a number of years. XML is a more recent subset of the SGML specification for use on the World Wide Web. They are compared to the more familiar HTML in Table 1.

<u>A memo header using HTML</u>	<u>A memo header using SGML or XML</u>
<pre><Bold><Center>Corporate Name, Inc.</Bold> <Bold>To:</Bold> <Bold>From:</Bold> <Bold>Date:</Bold> <Bold>Subject:</Bold></pre>	<pre><Logo>Corporate Name, Inc.</Logo> <To>To:<To-names> </ To-names></To> <From>From:</From> <Memodate>Date:</Memodate> <Memosubj>Subject:</Memosubj></pre>

Table 1: Contrast between HTML and SGML/XML when encoding (marking up) the same text.

The HTML version uses *procedural* markup to ensure that the memo header employs a bold font when displayed. Therefore, all the elements are bounded by <bold> tags. By contrast, the SGML version uses *descriptive* markup; each element in the header sports a different set of tags, and these tags describe the content inside the element instead of how to print it.

Descriptive markup allows both media independence and multiple media presentation. The SGML memo header could, for example, be rendered on paper (by a translator program) in a crisp, black sans-serif font; for a Web browser, a different translator program could render it in a larger serif font, and in dark brown against a cream

[†] This is a necessarily sparse definition of SGML. A good starting point for more information is www.oasis-open.org/cover/sgml-xml.html, and its links under "General Introduction to SGML." The Arbortext link there is a good starting place for the SGML beginner. For XML, see also Bosak and Bray (1999).

background. The versions for the visually impaired would use a larger font still. However, there is *only one source document* behind all rendered versions.

The user-defined elements are collected into an Element Dictionary (ED) and matched with a Document Type Definition (DTD) that specifies which elements are allowed in which parts of a document. In courseware, this facilitates:

- the creation of courses from instructional design to delivery
- a higher level of content quality, by requiring that course planning stages be recorded in the obligatory "planning information" elements.
- the creation of assessment types and mechanisms, including assessments for higher level learning
- the identification, association, and categorization of resources within the course architecture
- the creation of custom views of materials for different types of learners
- the storage and management of parts and pieces of course materials
- the creation of a user-defined catalog of the parts and pieces of courses, thus having many "learning objects" available for the digital economy.
- the output to both print and web, as well as to other media, from one base document.

The Markup Language of OSCAR courses

Input from instructional designers, writers, managers and teachers resulted in an SGML-based Element Dictionary (ED) containing hundreds of elements of use to secondary-level course developers, like <section>, <lesson>, <assessment.type>, <equation>, and so on.

To show briefly how this SGML-based schema or course meta-language addresses the higher level learning and assessment which constrains secondary public education, consider these elements from the OSCAR Element Dictionary: <rubric>, <exemplar>, <givens>, <scenario>, <action>. Educators will recognize those as ingredients of criterion-referenced assessment, applicable to higher-level learning activities like portfolio construction or participation in on-line debates. The DTD for OSCAR courses permits the use of these elements (once only) whenever the course assigns a <long.constructed> or <collaborative> type of student assignment. If used, those elements will appear in both the student and the instructor versions of the course, as a table of criteria by which student work on that assignment will be marked. Criterion-reference tables can be large, so the table that appears in the Web version will be formatted differently from the one in the print version, to better fit an 800x600 screen. But the table's content—all that lies between the tags—remains the same for both.

The SGML/XML schema also assists universality and equality of access, since it allows the same original content to be rendered in more than one medium as appropriate. The original learning outcomes are retained for all the output formats, so technology-poor students can access an appropriate version of the content, and achieve the same learning outcomes, as technology-rich students.

Finally, by reducing some of the content-repurposing process to simple machine translation of tags, the SGML/XML model reduces the economic constraints of multimedia course presentation. Put another way, the SGML schema enforces more course planning "up front" and facilitates more content customizing later.

Implementing the SGML model

With studied understatement, *Scientific American* summed up the creation of a set of XML tags this way:

Of course, it is not quite that simple. XML does allow anyone to design a new, custom-built language, but designing good languages is a challenge that should not be undertaken lightly. And the design is just the beginning: the meanings of your tags are not going to be obvious to other people unless you write some prose to explain them, nor to computers unless you write some software to process them. [Bosak and Bray, 1999]

Open School selected 14 courses [Table 2] for conversion or creation in the SGML model, and "grew" its ED and DTD on the basis of what went into these courses.

• Career and Personal Planning 11/12	• Film and Television Production 11	• Law 12
• Chemistry 11	• History of Film 12	• Visual/Media Arts 11
• English 11	• Information Technology 11	• Math 11 (Algebra)
• English 12	• Information Technology 12	• Social Studies 11
• Entrepreneurship 12	• Journalism 12	

Table 2: Courses in the first year of the OSCAR program (numbers indicate grade level)

These courses represent an academic Grade 12 diploma with a major in applied visual arts; most students would choose a few of them as needed for their own academic program. Ten of these courses represent re-purposing of existing print courses into the SGML format; the others have been newly written using SGML. Course development began in 1998 for introduction to the school system in September 1999. Open School's research department put together the ED and DTD; a team of about 25 Open School employees and contractors applied them to the 14 courses, and designed Web user interfaces, databases and print translators to render the resulting courseware.

Open School also posited two learner profiles [Table 3] for most of the courses. The intention is that more learner profiles may be added later, and special activities tagged for them.

<u>Learner Characteristic</u>	<u>Learner Profile 1</u>	<u>Learner Profile 2</u>
Demographics	Age 16-18; could be adult; seeking secondary school credit to B.C. standards. May be studying in a classroom, or at home but still part of a school system.	
Connectivity via technology	None; mail (two way) or fax (one way) is used.	28.8Kbps or higher modem; email account; Web browser version 4 or above.
Instructional media	Primarily print; audio cassette player is available; VCR and word processor are optional, will not be available to all students.	Web, email, and word processor are readily available to student. Print may also be used. VCR is optional. On line asynchronous conferences available, at teacher discretion.
Instructional feedback and support	Available via mail and perhaps by phone, but not much needed.	Available via email or in class, so more accessible and immediate.

Table 3: Two learner profiles that operationally define the OSCAR course "audience".

One lesson we learned early was that one cannot simply apply education-oriented tags to a group of existing courses "as printed", not even to good courses designed for distance learning by the target audience. We found that the tags appropriate for one course would not fit another. The universal elements of educational material, suitable for defining and tagging in SGML, lie more in the instructional design steps that are invoked to meet learner profiles when the course is first written, but then discarded. Thus it became necessary to "rebuild" each course with forms and constructs that fit the DTD and the two learner profiles; the result was (in general) neither better nor worse pedagogically, but it was different and so entailed re-writing. Naturally, the new courses could be designed right in the OSCAR DTD so this misfit did not occur.

We also learned that Bosak and Bray's admonition "the meanings of your tags are not going to be obvious to other people unless you write some prose to explain them" deserves much thought and planning. Open School actually created a *second* ED and DTD for internal use, containing tags like <element.name>, <rationale>, and <user.info>. Its purpose is to prepare documents that teach internal staff how to apply the main schema!

Educators know that amenability to on-line instruction (for Learner Profile 2) varies strongly with the subject matter or course content. The courses reflect the range of suitability:

- Information Technology 11 and 12 are delivered almost entirely on line, and in fact lack a Learner Profile 1 (no connectivity) version.
- At the other extreme, Mathematics 11 uses video clips on CD-ROM but otherwise makes little use of the computer; the student does all work by hand on paper and hands it or mails it in. This is necessary because the prescribed learning outcomes for Math 11 in B.C. *all* require symbolic manipulation skills which are frustrating to execute on a computer, but easy to perform with pencil and paper. Providing enough specialized algebra software to meet even a few of the learning outcomes is too costly for the DE scenario where the student works alone at home. Therefore, the "on line version" or Learner Profile 2 version of Math 11 relies heavily on print resources, and student work is done by hand.
- The remaining courses lie between these extremes, being available in both technology-enabled and print-enabled versions that maximize the advantages of their respective media for two learner profiles. These are the courses that most benefit from their basis in SGML: one course, multiple presentations. The key point is that any version uses *the most appropriate* media for its content, its outcomes, and the resources of its learners. If some parts of an on-line course appear in print, there is good pedagogical reason.

Conclusion (sort of)

At the time of writing, one course in the OSCAR program (Info Technology 11) has finished its second year of classroom and DE use; the remaining courses are being readied for their inaugural use in September 1999. 150 B.C. educators have registered for the three day OSCAR training session in August 1999. This dual-mode courseware is receiving considerable interest in the B.C. public school system, since it is seen as a meeting point between the province's challenging requirements for graduation on the one hand, and the educational wave of the future on the other. For Open School, OSCAR represents a new use of SGML technology which (if successful) will be adopted by the rest of the Open Learning Agency for course development. Extensive field evaluation is the next step for OSCAR.

Abstract: This paper introduces a new kind of Java-server, the Smart Data Server (SDS). It offers the accessing of data with function-calls to SDS-networks. This allows the building of lean clients with the shifting of functionality to the SDS-network. The server builds the middle-tier in a multi-tier architecture (Client - SDS-Network - Database). It offers a frame for easy-to-build environment-independent SDS-modules with multiple functionality. It is modular and easily scalable for different kinds of requirement.

1. Introduction

The Internet has witnessed some major steps of evolution in its history. The biggest step was carried out with the introduction of the World Wide Web (WWW). To access data via the WWW, a web browser asks an HTTP server for a document. This document may either be a static document that never changes its contents or may be generated dynamically, using CGI-Scripts. With CGI a user can transfer data to the server. The server uses CGI programs to manage the data and to produce the document displayed by the web browser. There are no restrictions towards CGI-programs. With the possibility for CGI programs to access databases, HTTP servers became the middle tier in a three tier architecture. Compared with the user-interface of native applications in a windows-based environment, the database access for users over the internet was very limited though. This changed with the introduction of Java and their applets.

Apart from the known advantages of Java-applets (running everywhere, offering a graphical user interface, running in the sandbox of the browsers), one other advantage of Java-applets is the possibility to open network-connections to the computer they were loaded from [Sridharan 97][Farley 98]. Thus, it is possible for Java-applets to access databases without any help from the HTTP server. But this is a two-tier communication with the known security problems [Dickmann 95].

Placing a database on the same computer as the HTTP server means placing the database in the internet. But data with some value should not be placed on a computer with direct access to the internet. There is no guaranty for the data not to be manipulated by hackers. This shows the need for Java-applets to access the data via a three-tier architecture with an (possibly insecure) middle-tier and a hidden database server.

Java-applets should be kept small to reduce the loading time over the internet. Thus, applets need to be generated as graphical user interfaces. The clever calculations have to be done on the server-side using function-calls. Because the functions operate on data and the data is sometimes placed on different databases with different access-restrictions, the need of function-routing is obvious.

Finally, there is a structural problem. To develop the middle-tier in a three-tier-architecture, one has to be aware of the possibility that the environment the middle-tier is placed in sometimes changes during the lifetime of the middle-tier. Therefore, the solving of a problem should be separated from the environment the middle-tier is placed in.

In this paper we introduce a new Java-server, called the Smart Data Server, SDS:

- It offers the accessing of data with function-calls to SDS-networks. This allows the building of lean clients with the shifting of functionality to the SDS-network.
- The SDS acts as the middle-tier in a multi-tier architecture (Client - SDS-Network - Database) so that secure access of data is guaranteed [Fig. 1].
- It offers a frame for easy-to-build environment-independent modules with multiple functionality.
- It is modular and easily scalable for different kinds of requirement.

First we will explain the main structure of the SDS with a short explanation of additional components. Then we will take a look at the configuration-file of the SDS and we will see how function-modules are registered to the SDS. We will show the data-structure which is exchanged between the clients and the modules of the SDS. The paper ends with a short conclusion with an outlook on the future of the SDS and the work related to it.

Figure 1: The SDS as a multi-tier

2. The Components

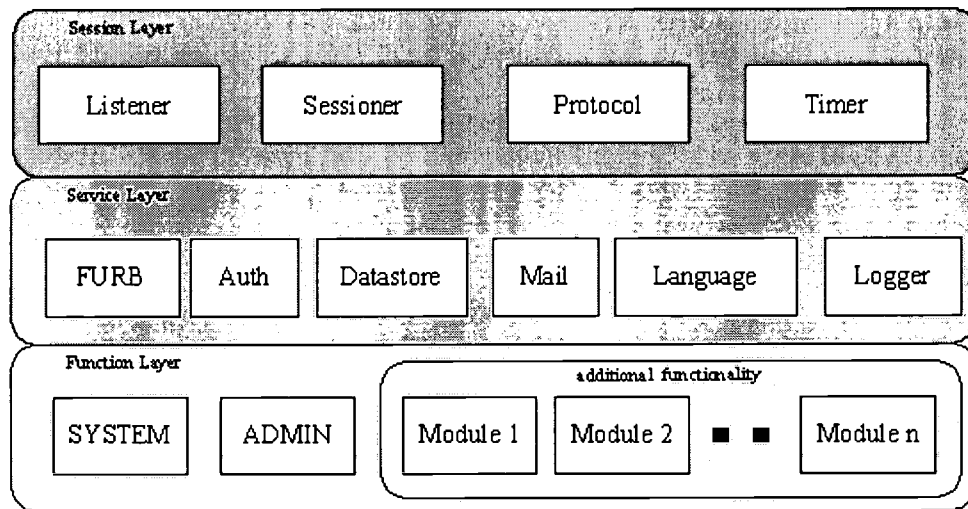

Figure 2: The structure of the SDS

The SDS is a server, written in Java. The core management of handling server-sockets is very similar to the way every Java-Server handles this process. The *Listener* of the *Session Layer* is a module waiting for communication in a defined protocol on a defined TCP-port. One or more Listeners can be defined, each with different protocols. After a client has connected to the port, the Listeners creates a *Sessioner*-Thread, depending on the type of the protocol. In our existing implementation of the server there is one specific *Sessioner*-module and one protocol defined module (IPTP = Information Package Transfer Protocol). Implementations of further

BEST COPY AVAILABLE

protocols can easily be added to the server. In this paper we will only give an overview of the protocol. To describe the implementation process would go beyond the scope of the paper.

First, the *Sessioner*-module asks the *Protocol*-module to read the request of the client. The IPTP-protocol itself is divided in a header and a body. The body holds the definition of the request, while the header holds information about:

- Which function-module has to answer the request?
- Who wants to access this function-module?
- Is this request part of a user-session (not a network-session), and which session is it?
- What type of body will follow?
- How is the body encrypted?

This catalogue reminds one a little of HTTP and the way it is implemented looks like HTTP as well but the aim of HTTP differs from our protocol in general. HTTP (as the name "Hyper Text Transfer Protocol" shows) is a protocol to access Hyper Text documents. Our protocol wants to transfer function-requests.

The module-name is part of the header because the decision which function-module has to be called takes place at a higher level. The decryption of the body on the other hand is the job of the modules themselves.

With the information of the header and the knowledge of the IP-Number of the client, the *Sessioner* decides whether the requests contradict any authorization-restrictions. This decision is supported by a module of the *Service-Layer*: The *Auth*-module. If nothing contradicts the request, the *Sessioner* asks the *FURB*-module (FUnction-Request-Broker) of the *Service-Layer* to handle the request. The *FURB* knows which function-modules are registered in the *Function-Layer* at the startup of the SDS. Dynamic registration of functions will be part of the future development of the SDS.

There are two ways to register a function-module to the SDS: Either as an internal module or as an external module. If the module is internal, the request is handled by the defined java-class. If the module is external the SDS knows which SDS in the SDS-network has to be asked to handle the request. In this case, the SDS acts like a client towards the second SDS. Without any change of the body, the request is transferred to the second SDS, and the result is transferred without any change to the original client. So the *FURB* is the main part of the SDS that allows the building of SDS-networks.

The *FURB* does not only manage requests from clients. It is also possible for each function-module to construct requests by itself and direct them to the *FURB*. The *FURB* makes no difference in managing requests from clients, from other SDS or from function-modules of the SDS itself.

This offers an interesting third way to register a function-module in the SDS: internal and at the same time external. In this case, the *FURB* tries to call up the internal function-module in the first place. Only if the function itself calls itself the function is routed externally to the function-module on the second SDS.

A different kind of request is the timer-based request. The *Timer*-module of the *Session-Layer* can ask for a specific function-module at a defined time or after a defined period of time. These requests produce no answers. Timer-requests result in side-effects of the function-call. To give an example: Session-based request of modules may read data from a database while timer-based request cleans the database once a night.

To make the function-modules easy-to-build, it is necessary to make them independent of the environment that the server is placed in. One part of the environment are databases. The *Datastore*-module allows to access a data-pool without any knowledge of the underlying protocol or name of the database-server. The configuration-file holds the concrete access-information of the database. The access of the *Datastore*-module is not connected to any knowledge of SQL-statements. In fact the request is transferred to standard-SQL but this is not transparent to the function modules. This makes a change of the underlying database easy without changing any line in the function-module. The *Mail*-module allows the transfer of mail to an SMTP-server or to read mail from a POP-Server. The *Language*-module transfers the body of a request into a Java-data-structure. This data-structure is explained in the [The Request]-section. The *Logging*-module allows the logging of information for each kind of module.

There are two function-modules that are part of every SDS and are not part of the additional functionality. The *SYSTEM*-module allows clients to open a user-session including a transmission of an account name and a password. As a result a user-session-id is transferred and the user is allowed to access every non-restricted function-module for the duration of the user-session. The *ADMIN*-module is responsible for creating and deleting user-accounts.

3. The Registration of Function-Modules in the SDS

We have to take a closer look at the configuration-file to understand how function-modules are registered in the SDS. The configuration-file is the place to configure each specific part of the server: It determines which modules are used, which protocols are understood by the server and how the database-server should be accessed. Most time the configuration results in an identifier, so that the modules only have to know the identifier to access the resource. This is the place where the environment of the SDS is described.

The configuration-file is loaded only at the startup of the server. Thus, dynamic registration of function-modules is not supported.

3.1 The FURB-Section

For each function-module there has to be an entry in this section, defining if the module is internal or external. For external modules it must be defined which SDS has to be accessed, and which protocol is to be used. The example shows the registration of two external modules "module1" and "module2", connected to the server "sds2" on port 1234 using the protocol "iptp":

- *job=load modules=module1,module2 external=yes url=sds2 port=1234 protocol=iptp*
Internal modules are defined by the implemented class. Here the module "system" is defined :
- *job=load module=system external=no path=ti.sds.server.module.function.system.System*

If the load of the server increases, it is easy to declare an internal function-module as external for the future. The relation of an external module to a known SDS remains static. For the future, a dynamic selection is planned.

3.2 The Timer-Section

Each module can not only be accessed via client-requests but also via timer-events. There are two kinds of timer-events. The first defines the time, that is when the event should happen (at-jobs):

- *job=at module=cron function=cleanup dayofweek=* month=* day=* hour=20 minute=17*

The second kind defines the period, that is when the event should happen again (every-job):

- *job=every module=cron2 function=rebuilt minutes=60*

3.3 The Auth-Section

This section defines additional limitation to access function-modules. While every module can only be accessed after having been authorized for the SDS, modules defined as "freeaccess" are free to be accessed without any authorization. The example shows that no registration is needed for the module "system":

- *job=freeaccess module=system*

Modules defined as "restricted" can only be accessed from computers with a defined IP-numbers, here the module "admin" can only be accessed from the 192.204.23.41 and 192.204.23.45.

- *job=restrictedaccess module=admin ip=192.204.23.41,192.204.23.45*

4. The Request

Until now, we have only seen how a function-module is placed in the structure of the SDS. In this section we will explain the structure of the request and the underlying data-structure. Every function-module receives the header and body of the protocol from the FURB. Depending on the encryption, the module has to decrypt the body first. Next, the data-structure has to be constructed using the Language-service. To transmit the result of the request, the data-structure has to be constructed and than it has to be coded using the Language-service. The data-structure "Struct" depends on three sub-structures: single elements (Java-String), lists (Java-Vector) and hashtables (Java-Hashtable) [Tab. 1].

A request and its results are, in the first place, hashtables. The hashtable keys of a request are "FUNCTION", "PARAMETERS", "DATA" and "RETURN". "FUNCTION" defines the function inside the module to be called.

While "PARAMETERS" defines the parameter of the function, "RETURN" defines which result is requested. The "DATA"-section is used if data is transferred to the SDS.

Struct ::=	String Vector Hashtable
Vector ::=	[Struct*]
Hashtable ::=	{ (String, Struct)* }
FunctionDef ::=	("FUNCTION", String)
ParametersDef ::=	("PARAMETERS", Hashtable)
DataDef ::=	("DATA", Hashtable)
ReturnDef ::=	("RETURN", Hashtable)
ResultDef ::=	("RESULT", Hashtable)
RequestDef ::=	{FunctionDef, ParametersDef, DataDef, ReturnDef}
AnswerDef ::=	{FunctionDef, ResultDef}

Table 1: The Data-Structur

Defining the "RETURN" section enables the function to calculate only the requested values. If no error occurs, every entry in the "RETURN" section has its corresponding entry in the "RESULT" section of the answer. The hashtables of "DATA", "RETURN", "RESULT" and "PARAMETER" are interpreted as pairs of variable names, that is the key of the hashtable, and its value.

To define the request-structure, the programmer has to know the signature of the function: the required parameter/data, the default-values of the optional parameter/data and the possible return-values. The client has to know which functions are possible.

5. Conclusion and Future Work

After all the technical descriptions of the SDS we have to take a look at the usability of the SDS. There are several aspects to describe the advantages of the SDS:

- **Scalability:** If the problem grows the SDS can grow too. It's no big thing to add new modules to the SDS. If too many calculations have to be made at the same time it is possible to built a SDS-network, each responsible for a different kind of problem to handle the burden of the SDS. Sometimes you only have to duplicate the SDS physically and make some minor changes in the configuration files.
- **Modularity:** The functionality is defined in independent modules. If the functionality has to be changed to solve a problem in a different way, only the module implementing the problem is affected. Problems can be split and implemented by different programmers independently. A programmer can focus on the main problems of the functions by defining the way a module has to be accessed, by deciding which functions have to be implemented, and by determining which resources the module can use (data-pool, mail, other modules, ...).
- **Flexibility:** The modules are independent of the data sources and data drain. Both can change without affecting the modules. The SDS is open to different kind of protocols or new services. If it is becoming necessary to implement other protocols (HTTP, FTP, SMTP, ...) or other service (encryption-service, gateway to CORBA resources, ...), the existing structure of the SDS is not affected. Those new core-modules can easily be added to the SDS by changing the configuration-file. Thus, the SDS can be customised if a different additional functionality needs different protocols or services.
- **Reusability:** The architecture is open to different kind of problems, whether for building a portfolio-management-system (like we did) or for implementing a weather-service or for solving other problems. This does not affect the core modules of the SDS.
- **Complexity:** The server is written in Java and uses the advantages of packages. The code of the server itself therefore can easily be read and understood. New developers don't spend much time in learning how to add new modules.
- **Performance:** The Server was tested in a small environment with about 10 persons. It runs with JDK1.1.7 on a Linux-computer. The responding time showed no significant difference in the number of persons accessing the server simultaneously.

The server is about 200kByte big without additional functionality. It uses the advantages of Java 1.1.

The development of the SDS is only at the beginning, however. In our future release we want to implement a better mechanism to route requests to other SDS. The static definition should be replaced by a dynamic one, depending on the load of the server or other indicators.

Another focus has to be put on the client. The client has to be as modular as the server to make it easy to build both of them simultaneously.

The first additional protocol we want to implement is the HTTP protocol and an HTML-service to allow the access of functionality without the use of Java applets.

The server at this point is a Java-Server. But the definition of the protocol makes it possible to change this decision in the future, if the performance should become a problem.

6. Related Work

The background of all this functionality is a database. This makes it easy to compare the SDS with stored procedure calls of databases, because both built complex functions on top of database-tables. One big advantage of the SDS is the independence of the underlying database. The service to access databases implemented in the SDS depends on standard SQL so that a change of the databases is possible. The restriction to standard SQL makes the implementation process a little hard sometimes. But you don't have to worry about the functionality of the SDS when the databases is updated or changed.

“Distributed functionality” sounds a little like distributed objects. Therefore the SDS has to be compared with CORBA (<http://www.omg.org>, <http://www.corba.org/>), DCOM [Brown 97] or Java's RMI [Sun 98]. But creating an object on a different computer with all its problems is something completely different from calling a function of a module on another computer. It is less complicated and therefore less code is needed to implement the functionality. The object-approach can also be seen by HORB (<http://ring.etl.go.jp/openlab/horb/>)[Duan 96], an object request broker by Satoshi Hirona written in Java, or by a Swift-Product (<http://www.swift.de/>) using the RMI of Java.

Remote Procedure Calls (RPC) [Srinivasan 95] are in some ways similar to the way a function is called up by the SDS but the development of functions for the SDS is a process that has to be done simultaneously with the development of the client. It's more like a service-platform for easy-to-built applets.

HALPIN : A Natural Language Information Retrieval System For a Digital Library on the World Wide Web

José Rouillard

Laboratoire CLIPS-IMAG, Groupe GEOD, Université Joseph Fourier –
Campus Scientifique, BP 53, 38041 Grenoble Cedex 9 – France
Tel : (33) 4 76 63 56 51, Fax : (33) 4 76 63 55 52, E-mail : jose.rouillard@imag.fr

Abstract: Designing computers with the ability to talk and understand a natural language (NL) conversation is a major field of research. We have developed the HALPIN¹ system to implement our multimodal conversational model for information retrieval in a digital library via the World Wide Web. This dialogue-oriented interface allows access to INRIA's² database, on the Internet, in a natural language mode. The inputs from the user, could be either oral sentences or mouse/keyboard actions. The results of the first experiments show that the HALPIN system provides interesting dialogues, in particular with beginners. It gives oral responses via standard browsers, for a more natural human-machine interaction according to the user's goals and skills. This leads to successful information retrieval, while searches with the original user interface (traditional web form) failed.

1. Introduction

Retrieving relevant information on the World Wide Web is not an easy task. As [HARDIE 96] observed, while seeking a document, "*some are looking for the ocean and some others for a grain of sand*". Pitkow and Kehoe remarked that these difficulties have four possible origins: "*The main problem people report when using the web are : (a) slow network or connection speed (b) not being able to find particular pages, even after they have been found before (c) not being able to manage or organize retrieved information and (d) not being able to visualize where they have been.*" [PITKOW 96]. We believe that with the exception of the connection speed, the other problems are mainly related to human-machine interaction. In addition, according to Conklin [CONKLIN 87], the two most important problems related to information access through hypermedia interfaces are disorientation and cognitive overload. To attenuate these problems, our approach is to integrate "human skills" to the actual systems. Indeed, natural language interfaces excel in describing entities that are not currently displayed on the monitor. These strengths are exactly the weaknesses of direct manipulation interfaces, and conversely, the weaknesses of natural language interfaces (ambiguity, conceptual coverage, etc.) can be overcome by the strengths of direct manipulation [COHEN 92]. "*Direct manipulation and natural language seem to be very complementary modalities. It is therefore not surprising that a number of multimodal systems combine the two*" [CHEYER & JULIA 95]. With the growing number of Internet users, efforts to make computer interfaces that are more simple and natural become increasingly important. We think that multimodal and natural language solutions for the World Wide Web should help people to accomplish their tasks more effectively than with traditional tools. The lack of real human-machine dialog corpus, especially in French, leads us to propose a usable incremental system for the Web rather than "Wizard of Oz" experiments. In the following, we describe the modelling and implementation of our system, designed for an information retrieval task in a large digital library of the Web.

2. HALPIN system description

Our work is based on the results of the ORION project³ which concerns new multimodal technologies for Web navigation and information research [ROUILLARD 97a], [ROUILLARD 97b]. The HALPIN system is an incremental one : after each connection period, the dialog files are analysed ; the missing or

[1] Hyperdialogue avec un Agent en Langage Proche de l'Interaction Naturelle.

[2] Institut National de Recherche en Informatique et Automatique (83297 documents available)

[3] <http://www.gate.cnrs.fr/~zeiliger/Orion99.doc>

misunderstood vocabulary is added or modified. This way, the system can be improved with each new version. It uses Xerox's morphological tools [GAUSSIER & al. 97] to convert the user sentences to a canonical form which may be analysed more easily by the HALPIN concept detection module. Figure 1 shows the interface of the HALPIN system for an information retrieval task on the World Wide Web.

2.1. Dialog manager cooperative model

There has been a great deal of research on information retrieval, but very little in which the NL plays an important role on the Web. Most of the classical user interfaces and search engines try to improve the efficiency of the search task with better indexing and retrieval methods. In such models, the human-machine interaction is limited to exchanges of the type: query => database access => reply. As information seeking and retrieval are interactive processes, we believe (as do [BATEMAN, HAGEN & STEIN 95]) that providing a flexible and cooperative human-machine dialogue is a complementary means of improving information retrieval systems. Inspired by the works of Brun [BRUN 98], our dialog manager uses a two-step algorithm of concept recognition which leads to an understanding of the user's queries.

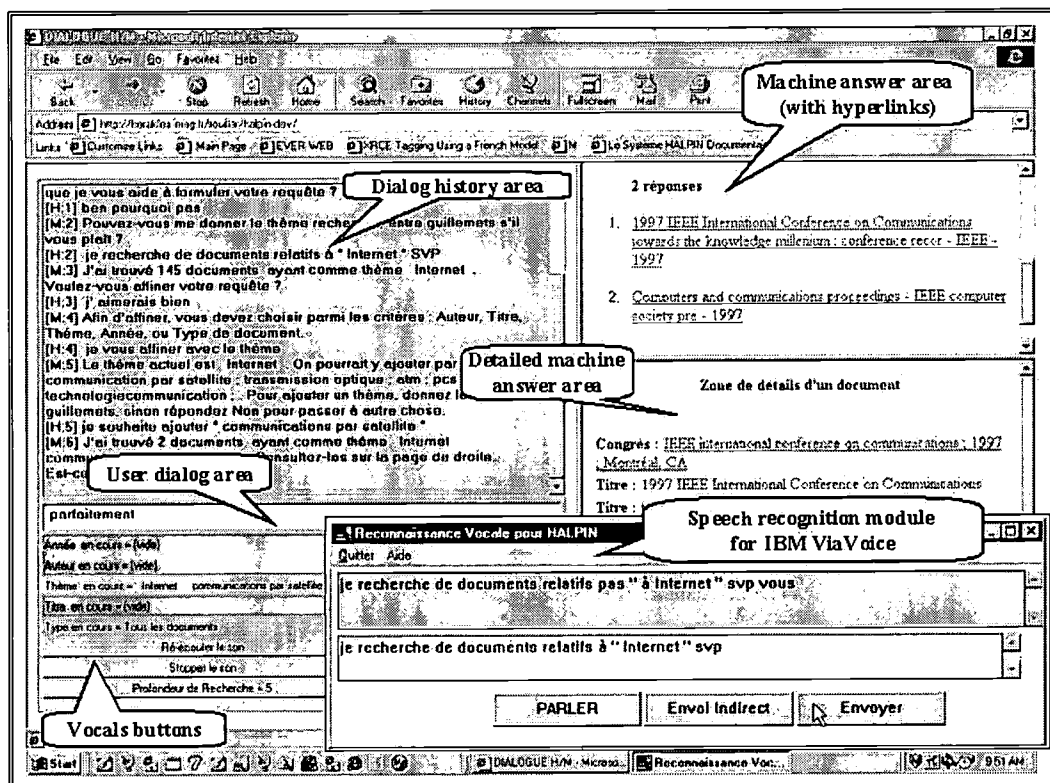

Figure 1 : The HALPIN system interface in a World Wide Web browser

An intelligent conversational system must be capable of adapting itself to the user's goals and capabilities, interpreting speech acts within the context and negotiating ambiguous information using a natural language interface [STEIN & al. 97]. In our previous papers, we have also shown that it is possible to gather interesting human-machine dialogues on the Web without using the Wizard of Oz strategy [ROUILLARD & CALEN 98], [ROUILLARD 98]. Having in mind these important observations in order to show that NL dialogue systems may improve interaction quality, we proceeded to create an interactive search and navigation environment (HALPIN) to incorporate adaptability and conversational capabilities to an existing digital library information retrieval system. Our goal was to propose a system which not only responded to the user sentences, but also proposed related information (similar authors or keywords) depending on user needs. This is why at the beginning of the *hyperdialog* [ROUILLARD 99], with this system, we have to determine the user profile (novice or expert) and her aim. The COR (Conversational Roles) model of

[STEIN & MAIER 95] proposed typical *Ideal* and *Alternative* dialogue sequences (cycles). For example, a dialogue between the information seeker A and the information provider B, can be formalised as :

Dialogue (A,B) → request (A,B) + promise (B, A) + inform (B,A) + be-contented(A,B)
Dialogue (A,B) → offer (B,A) + accept (A, B) + inform (B,A) + be-contented(A,B)

In the same way, our model is a kind of conversational roles and tactics (COR) model augmented with the knowledge about the user and her aims, so the model can react according to the user profile and the task in progress. We propose, for a finalized and cooperative defined task, to follow the rule:

[Profile]. [Goal]. [Speech Act]. [Concepts]. [Task] → [Reply]. [Justification]. [Suggestion].

A user profile (for instance novice or expert) is determined at the beginning of the session according to whether the user wants (or does not want) some help from the machine. This profile can change if the relevant elements are detected by the machine during a session. The goal of the user, which can be "finding an already known paper", "searching an unknown set of books", "discovering the site", etc., is also an important element used by the machine for the orientation of the dialogue. Speech acts and concepts are determined for each sentence given by the user. It is not only a keyword detection. For example, the concept recognition module is able to understand that "the man who wrote this book" has to be considered as the concept "the author", or that "why not" means "yes", which is not possible with a simple keyword matching. This method adds a robustness to the system in the understanding of some "imperfect" sentences given by the speech recognition module. For example, in Figure 1, we can see that the speech recognition module gave the sentence "H4 : Je vous affiner avec le thème" (I you refine with the theme) instead of "Je veux affiner avec le thème" (I want to refine with the theme). This is not really a problem for the dialog manager which understand the concept *Refinement (theme)* and which did not detect any negation in the sentence : the result of this analysis is a request to the digital library with the new criteria, that leads to the cooperative answer of the machine that proposed to the user some themes close to the first one (see M5 on Figure 1).

This way, the machine prepares a reply, a justification of this reply, and a cooperative suggestion if possible. The concepts database is divided into different files, according to the type of concepts. Indeed, certain concepts are common to all possible tasks (acceptance, refusal ...) and others are specific to a particular task. If a sentence is ambiguous, even when the goal of the user is known, the system proposes alternatives choices. For example, this French sentence : "je veux un livre d'algèbre de Boole" can be interpreted in two different ways : either the user wants a book talking about Boolean algebra or the user wants a book written by Boole. In the digital library that we used on the World Wide Web (INRIA), the first interpretation (theme=Boolean algebra ; author=?) gives 100 responses, while the second (theme= algebra ; author=Boole) gives only 1 response. So, we think that, rather than searching the database with an uncertain query, it's better to resolve the ambiguity in a cooperative way. The dialogue manager allows not only entries related to the current task, but also about the interface (screen, sound, speech synthesis) and system responses (called meta-information). The system tries to understand, according to the context and found concepts, if the user is speaking about the task (ex "The author is Turing"), about the interface (ex "I can't see anything on this screen") or about the meta-information (ex "Why do you ask me that ?").

2.2. Speech synthesis and recognition on the World Wide Web

The HALPIN system was developed using C, Java, Html and Perl languages. The users can hear the system responses thanks to software (Elan Informatique speech engine⁴) installed on our Web server which synthesises textual responses to a specific audio file⁵. This file is sent to the browser, and then played by the Java applet. We believe that for speech recognition on the World Wide Web, two different solutions are possible : a remote or a local solution. The first one uses a speech recognition server, so the user does not have to have its personal speech recognition software. An application must be installed on the client machine to catch the user's voice. It can be done in a free hand way, by using the vocal energy level to determine the beginning and the end of the sentence. The sound is then sent to the server and an ASCII string is received as the answer by the client. The second possibility is that every user installs speech recognition software on her computer, connected to the HALPIN system browser window. Each method has advantages and

[4] <http://www.elan.fr>

[5] Sun Java/Web format : 8000 Hz, 8 bits for our needs

drawbacks : for the user, the first solution is the cheapest, because no software is needed but it is also the slowest, because the voice have to travel on the Web to be recognised and interpreted. So the gain brought by the "natural interface" could be lost if the speech file takes too long to travel on the network. For the moment, we have implemented software that uses the IBM ViaVoice speech recognition. It's a push-to-talk solution that will shortly be replaced by a free hand tool.

3. First Results

We have tested our system with different types of users (novice, expert, with particular needs or not, etc.). Compared to the INRIA's traditional Web form, HALPIN gives some relevant information according to the needs and skills of the users. The following dialogues illustrate how the machine interacts with the user to determine her needs, asks her whether these have been met satisfactory and proposes alternatives when the results are not satisfying.

```

you me to look for authors close to Krakoviak ?
15:26:38:H=hum, yes
15:27:56:M=The authors close to Krakoviak are krakowiak, sacha; krakauer, Lawrence ;
Give a new name or say No to move on.
15:28:46:H=Well, I will test with Krakowiak this time
15:29:04:M=I've found 15 documents with Krakowiak as author. Do you want to refine your
request ?
15:29:24:H=Of course
15:29:38:M=To refine, you must choose among the criteria: Author, Title, Topic, Year, or
Type of document (...)
```

Capture 1 : An example of cooperative and relevant human-machine dialogue with HALPIN

In Capture 1, the user says that she is looking for a document she already knows ; and she accepts a help given by the machine. She believes the name of the author is Krakoviak, but this name gives no answer. The machine asks for a modification of the query, and proposes to choose among : author, title, theme, year or type of document. The user chooses to work on the author's name, and the machine proposes some names close to Krakoviak. Finally, using the relevant name of the author (Krakowiak with a W), she finds 15 documents, and the dialogue continues to refine those results.

From a critical point of view, this dialog is not optimum because the machine should have offered the near matches in 15:24.56 already. The principle of cooperation according to the maxims of Grice [GRICE 75] states contributions to the conversation should correspond to the waiting time of the other interlocutors and according to the status report and goal of the conversation. For that, four maxims are retained: 1) Maxim of method: to be clear, avoid obscure expressions, to avoid ambiguity, to be concise and to be ordered. 2) Maxim of relevance: to be relevant. 3) Maxim of quality: not to say what you believe is false, not to say something for which you have insufficient evidence. 4) Maxim of quantity: to make the contribution informative, but not more than is necessary. As we will see later, access to the digital library is an important

part of the time needed in the interaction. Searching for the authors close to the given one took, in our example, 1 minute and 18 seconds. If the user knows what the machine is doing during this time (as in our example), this latency is relatively acceptable. On the other hand, if the machine decides to be very relevant and do the same thing without informing the user, the problem of the extra time necessary for this operation could be a reason for the user to quit the dialog. The principle of transparency must be scrupulously respected : if the user knows what the machine is doing, length wait will be accepted more easily.

4. Statistical time evaluation of the system

A very important issue in the evaluation of a human-machine dialogue system available on the Web, is the time needed to reply to a user's sentence. In our system, there are four steps between the moment the user enters his statement in the dialog box and the moment he can hear and see the results. First, the sentence is sent through the Internet to the Xerox morphological tool. Then, the canonical form of this sentence is analysed by our concept recognition module in order to detect the important concepts to process. The third phase is a request to the INRIA's database accessible on the Web, and the last job of the system is to prepare a speech synthesis of the response and to send it to the Java applet client, with the hyperlinks and the textual information. In the following, we show some statistical analysis concerning the time needed for each module and the necessary time to provide a spoken interaction on the Web. We are not talking about the time needed for the speech recognition, because, at the moment, the module we are using is directly installed on the client machine, and connected to an IBM ViaVoice application; it is not therefore, possible to catch all these events from our server.

Time	Global	Xerox	% Xerox	Inria	% Inria	Elan	% Elan
Average	20.17	4.57	25.23	6.17	25.25	9.17	47.79
Standard deviation	6.12	0.67	7.83	3.40	14.40	4.94	12.23
Min	14.00	4.00	13.79	1.00	6.25	7.00	30.43
Max	32.00	6.00	37.50	11.00	47.83	19.00	65.52

Table 1 : Time statistics analysis of a man-machine interaction on the Web with the Halpin system

In our corpus, as we can see on Table 1 the average time needed for an entire interaction on the Web, from the moment the user validates his sentence till the moment he can hear the results, is 20.17 seconds. The morphological analysis represents 26 % of this time. The concept recognition is very quick (less than a ½ second and not mentioned on the figure). The access to the digital library is also 26 % of the time, and finally, the speech synthesis, with almost the half of the time, is the greediest module. In the case where there is no access to the database, the average time for a complete interaction is 12.36 seconds. It's about 45 % for the Xerox request and 55 % for the preparation of the speech.

5. Conclusion and future work

The HALPIN system is currently used by many people on the Web. The first results show that the users readily co-operate with the machine. This kind of multimodal natural language interaction is a valid answer to problems such as confusion, cognitive overload, and evaluation of the answer's relevancy. With the relative large number of real dialogs gathered on the Web by our system (more than 1000 files), we have a powerful tool for the study and development of a human-machine multimodal interaction model. We have shown that it is possible to dispatch through the Web a real time calculated speech synthesis, and we are now working on the integration of a voice recognition server module in our system. Some possibilities are currently being tested, such as the French "Janus system" [SCHULTZ 97] [AKBAR 98], in order to allow the user a free dialogue with the machine, in a more natural and effective way. We also count on the insertion of a large thesaurus, such as the French "Sémiographe" thesaurus from Memodata⁶, for a broader cover of the vocabulary in input as well as output.

Delivery of Computer Based Trades and Technology Training

Mike Schewe

Dean, Faculty of Trades and Technology, Okanagan University College, 1000 KLO Road, Kelowna, BC, Canada
Tel: (250) 862-5457, Fax: (250) 862-5469, E-mail: mschewe@okanagan.bc.ca, <http://www.cbtt.ouc.bc.ca/>

Randy Werger

Project Coordinator, Computer Based Trades and Technology
Faculty of Trades and Technology, Okanagan University College, 1000 KLO Road, Kelowna, BC, Canada
Tel: (250) 862-5494, Fax: (250) 862-5469, E-mail: rwerger@okanagan.bc.ca, <http://www.cbtt.ouc.bc.ca/>

Abstract: Okanagan University College (OUC) is a comprehensive multi-campus post-secondary educational institution, which strives for excellence in teaching and student achievement. The Learning Centre for Computer Based Trades and Technology (CBTT), within the Faculty of Trades and Technology, uses educational technology to enhance education by blending the features of distance and campus based learning that highlights a commitment to accessible and affordable training.

CBTT uses distance, telecommunication and information technologies to unite the instructor and the learners with services that transcend barriers of time and place associated with traditional instruction. CBTT provides a quality educational experience built upon the model of live classroom demonstration. It gives the learners the opportunity to participate frequently or intermittently, full or part time, from home, institutions, community or workplace. In the past, these students had no way to access sophisticated course offerings unless they travelled to our main campus in Kelowna, which proved to be too costly in time and money for most. CBTT technology includes audio-conferencing, audio-graphics, and inter-active multi-point distribution software.

A live interactive link with Okanagan University College's KLO campus in Kelowna, BC will be established to demonstrate technology that is being used to distribute courses throughout Canada and the United States. Conference attendees will be encouraged to participate in an interactive session using audiographics, white board and a voice link.

Following this demonstration, attendees are invited to ask questions and discuss the feasibility of implementing similar programs at their institutions

1. Introduction

Okanagan University College (OUC) is a comprehensive multi-campus post-secondary educational institution, which strives for excellence in teaching and student achievement.

Our mission is to provide a comprehensive range of high quality learning opportunities primarily for adult residents of the Okanagan, Revelstoke, Shuswap and Similkameen regions in the Province of British Columbia. Due to this large geographical region the Faculty of Trades and Technology at OUC were faced with an enormous challenge of delivering trades and technology program offerings to all its ten campuses. We had to find a way to

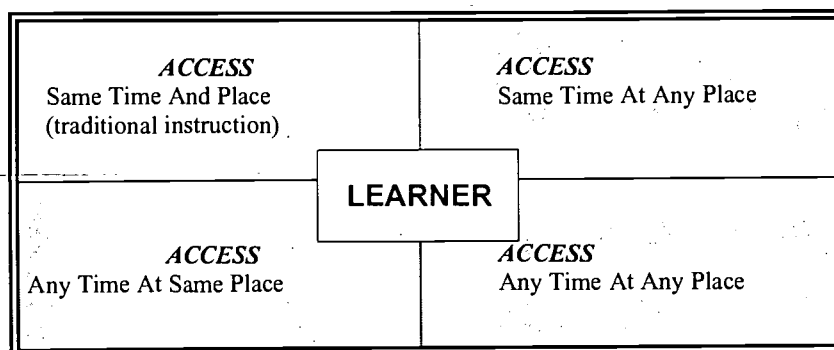

meet the needs of students in small communities where we could not offer traditional instruction on an economical basis. To meet these needs we developed a Learning Centre for Computer Based Trades and Technology (CBTT).

The learning culture of our society is forecasted to be significantly different in the coming years than at present. Learners of tomorrow will stand out for their proficiency in using technologies to access and successfully manage information and learning opportunities. They will expect a wide range and quality of opportunities and services, regardless of their location, and will have little tolerance for barriers to learning which are created by the system. A *virtual learning system* accommodates these changes.

Virtual learning systems use distance, telecommunication, and information technologies to unite the instructor and the learner with services that transcend barriers of time and place associated with traditional instruction.

It gives learners the opportunity to participate frequently or intermittently, full or part time, from home, institution, community, or workplace. The emerging learning culture shows growing evidence of demand for a different type of access to services. Access to training through technologies is viewed by a technically sophisticated public and the business community as essential to meeting accelerating demand and achieving cost effectiveness.

The dimension of time and place create four access windows to the learner: same time and same place, same time at any place, any time at same place, and any time and any place. The following chart illustrates the four windows of access, which are supported by a virtual learning system.

The majority of educational materials produced have traditionally been paper based, primarily to best serve the existing instructional methodologies. Historically this training has been provided through a same time and place (or face-to-face) classroom model of instruction and, to date, alternative approaches have not been viewed as viable. There are a variety of reasons for the disinclination to explore alternative methods. In some instances, no economic incentive has been provided to explore the options. As well, instructors' confidence in introducing other methodologies rests, in part, with administrative and organizational tradition.

Educational technologies however are giving us the opportunity to add value to traditional learning modes and, through the other three windows, increased access to educational services. A virtual learning system uses technologies to improve quality and access through all four windows.

The emergence of the Learning Centre for CBTT has tremendous potential to benefit students, employers, and the training system. In the past, these students had no way to access sophisticated course offerings unless they travelled to our main campus in Kelowna, which proved to be too costly in time and money for many.

Industry requires increasing access to relevant technical training and upgrading for its employees without sacrificing productivity. The increasing technology is reflected in longer technical training times that further exacerbates the dilemma of down time faced by the employers and employees. The use of CBTT significantly reduces the off-site training duration, in part, by producing workplace-training opportunities. This provides post-secondary instructors more time to reinforce upper-level psychomotor outcomes as opposed to more basic classroom theory; in effect, it allows the flexibility to redirect instructional resources for increased efficiency.

In the fall of 1994, OUC in collaboration with the University of Victoria and the Centre for Curriculum Transfer & Technology (British Columbia Government) completed the design and delivery of a pilot project in distance training. This project was designed to demonstrate how Trades Qualification (TQ) courses can be adapted for distance education delivery in a multi-campus institutional setting using audio-conferencing and audio-graphics technologies. Audio-graphics systems support visual learning and the combination of text, graphics, and audio-

conferencing components can accommodate a variety of learning styles. The strengths of the audio-conferencing medium are the live group interaction and learner support. Such interaction enhances self-esteem and self-confidence and helps motivate adult learners.

Since the original pilot program in 1994, the CBTT Learning Centre has partnered with many institutions and communities across Canada and North America.

2. Case Study

Okanagan University College in partnership with the Office of Learning Technologies developed and delivered two trades-based upgrade courses using computer based information technology. A total of 22 students each received 60 hours of training in Automotive Service or Recreation Vehicle Repair. Students received instruction simultaneously across five provinces: British Columbia, Alberta, Saskatchewan, Manitoba and Ontario.

Academic success and student satisfaction was monitored regularly using various evaluation methodologies. In addition, a comprehensive evaluation was conducted at the conclusion of the two programs. Following are the key findings of this work:

- Students were particularly complimentary about issues of accessibility to this training. In many instances this was the only training available to the learner. The format and timing of the programs allowed for a maximization of access opportunities.
- Students adapted quickly to the technology they were required to use in their training. Some students expressed surprise at how simple the technology was to use.
- No difficulties were experienced with issues of inter-provincial accreditation. In the case of the RV training no inter-provincial standard exists at this time. If the training is a part of inter-provincial curriculum and is intended for purposes of accreditation, prior consultation with accrediting bodies is essential.
- Academic outcomes are consistent with the outcomes achieved using traditional delivery methodology.
- The cost of providing this training was consistent between provinces with the exception of long-distance telephone costs. Providing the training during non-peak rate periods can minimize these costs.
- Once established, the location of sites for the training did not influence the training itself. The set-up of home and business sites required more initial effort. Institutional sites were generally better equipped beforehand. The number of individuals per site/computer station should not exceed five persons if basic hardware is used. Good collegial co-operation was evident at sites with multiple participants. Protocol for conversation was established early in the training to provide equal opportunity for participation.

These programmes have served to augment OUC's experience base in the delivery of trades training at distance. The learning experienced by OUC has been, and will continue to be, well articulated to educators, government, business and industry.

Overall these programmes have been very successful and will undoubtedly provide the platform from which other successful initiatives are launched.

Okanagan University College recently received the Bellwether Award for Instructional Programs and Services. The Bellwether Award was created to acknowledge excellence and innovation in community college programming for institutes across North America, sponsored by the Institute of Higher Education at the University of Florida and the National Council of Instructional Administrators.

3. Panelists

a) Mike Schewe, Dean of Trades and Technology

The Dean's educational qualifications include an MA in Education specializing in curriculum development; professional trades qualifications of Master Automotive Technician, as well as a Canadian Interprovincial Red Seal designation. Prior to becoming the Dean, Mr. Schewe taught the four (4) levels of Provincial Apprenticeship, the Commercial Vehicle Inspection Program and the Private Vehicle Inspection Program. Mr. Schewe is currently the Dean of Trades and Technology at OUC and the President of the British Columbia Association of Vocational Administrators. He has been involved with the Fiji National Training Council with an International Training Project in Auto Mechanics. He also participated as a member of the Provincial Modularization Review Team in the assessment of the Provincial Automotive Apprenticeship

curriculum, as well as a Writer for Years one (1) and two (2) of the new modularized Automotive Apprenticeship curriculum.

b) Randy Werger, Project Coordinator, Computer Based Trades and Technology

Mr. Werger's educational qualifications include a Provincial Instructor Diploma, a Technical Support for Business Certificate, a Carpentry Canadian Interprovincial Red Seal Certification, and a B.C. Steep Roofing Trades Qualification Certificate. Prior to becoming the CBTT Project Coordinator, Randy taught all four levels of Provincial Apprenticeship Training.

In Mr. Werger's capacity as the Project Coordinator for the delivery of Computer Based Trades and Technology training, he brings to the project a vast experience with PCs, local area network operations, wide area networks and distance learning technologies. He has solid knowledge of software including DOS, Windows 3.1, Windows 95 and related development software. His instructional background has prepared him well to assist in pedagogical issues. His demonstrated organizational and leadership abilities, combined with strong verbal and written communication skills, problem solving and supervisory skills, are invaluable to any project.

PANDA, a effective model of web based distance teaching and Learning Environment with integration of synchronous and asynchronous mechanism

Ruimin Shen , Dayu Ding
Computer science and engineering dept. of Jiaotong university, Shanghai , PRC.
Email: rmshen@mail.sjtu.edu.cn

Abstract: This paper presents a model of a web based distance learning environment with integration of both the synchronous and asynchronous mechanism----- a virtual classroom where synchronous and asynchronous tools are provided to support the teaching and learning process based on web: (1) Web auto answer and analysis, which helps students ask questions and automatically get answers asynchronously in their studying process. More over, it can generate new questions to clients by question hooking, merging and analysis. (2) Web testing ,which simulates the traditional testing process during web learning . It provides a real time reliable examination on web supporting both the text and the multimedia testing. (3) Web discussion with real time audio supporting, which helps teacher and students exchanging ideas using multiple interactive ways, such as sharing white board, URL broadcasting and real time audio multicasting ,etc. We think the model provides a good resolution to the problem of establishing a efficient environment on web.

1. Introduction

With the development of Internet and Web technology, Distance Learning now becomes a hot spot in the network research and application. And the idea of global education on net shows people a brand-new prospect of modern education. How to create a efficient teaching and learning environment on net, especially on Internet is one of the key problems should be resolved . And lots of research work has been done on the mode of distance learning on Internet. However currently, most of the distance learning mode on Internet are based on static and single way self-pace courseware browsing. To get the effect learning, it is evidently not enough because learning is an interactive activity between teacher and student. Generally, traditional education model is based on a class-oriented environment, in which teacher and students stay in one classroom where all kinds of teaching and learning activities, such as questioning&answering ,discussion and examination are held. However in the view of global education on network, classes are no longer local classrooms ,on the contrary ,students can be distributed all over the world and teacher is in a remote place far from the students. Under such a circumstance ,”classroom” becomes a virtual concept ,but not a traditional physical space, for the teaching and learning activities. We conclude that in the general study mode, 3 segments are important. That is, questioning and answering, examination and group discussion. Those 3 activities could be divided into 2 different types: Synchronous activity(group discussion) and Asynchronous activity(questioning and answering, examination). To establish a efficient teaching and learning environment on Internet(A virtual classroom) , it is crucial to apply those 3 aspects into our distance learning model. In an other word, a virtual classroom on Internet has to provide accordingly both the synchronous and asynchronous tools for the above 3 activities. According to that, we designed the distance teaching and learning environment with integration of both synchronous and asynchronous mechanism as 3 parts: Web auto-answering and analysis, Web based examination and Web based group discussion.

2. Model of distance learning with integration of synchronous and asynchronous

mechanism.

2.1 Web auto-answering and analysis

Questioning and answering is a quite important segment in the teaching and learning process. In Internet based learning, there are perhaps thousands of students learning the same courseware. Because coursewares are usually classical, which means that in general there are specific knowledge points in one specific courseware. So it is most likely that you meet the same question as those learning the same courseware. Although the questioning and answering between the remote teacher and student can be via Email, however it is rather boring and inefficient for teachers to answer the same, or even the similar questions again and again. There must be an asynchronous mechanism to support question auto answering. An Answer Web is the system designed for that purpose. 2 aspects are available in the answer web:

1). Questioning and auto-answering

Generally each web based courseware to be studied is equipped with one correspond auto-answering machine backend. Student in the virtual classroom can visit answer web while they are studying the specific courseware to ask their questions and get the answers through the answer machine. Multiple means of ways of questioning are supported: plane text, audio and mixture of them. Also, students can snap the question background(such as a snapshot of one video stream on web) and submit it with the question to the answer web ,which makes teacher get more information when starts to answer the question.

Answer web will answer the text form questions from the student automatically by searching and matching answers in the backend question and answer database. The way of answer web “understands” the meaning of the question from the student is not based on the entire natural language understanding. Instead, it is based on multi-key words and syntax words matching. To each specific courseware, multiple key words are predefined by teacher. Because the natural human language understanding needs a large fundamental dictionary, rule database and the complex sentence analysis. It is difficult to implement and has not the efficient process speed needed in the distance learning environment. But multi-key words and syntax words matching is an easier way and in the specific courseware studying environment, it can also achieve satisfactory searching result because:

(a), one answer web is related seamlessly to one specific courseware, and the questions from students are usually limited in few knowledge points, so the answer set is limited. Answer searching is localized in the knowledge points of one courseware.

(b), to one courseware, its keywords are limited(such as the concept, definition and technical term),so it is feasible to index questions with keywords and group them according to their keywords.

(c), general syntax words are limited, such as “what”, “how”, “why”, ”difference” ,”concept” ,etc.

Since answer web supports both English and Chinese question auto answering, there is a syntax words table maintained in the system, as Figure 1

Key words flag	Field name	Field type	Field length	Description
*	C_SyntaxWord	Text	50	Chinese syntax
	E_SyntaxWord	Text	50	words
	Synonym	Text	50	English syntax words
	SyntaxID	Integer	8	Chinese Synonym Serial number

Figure 1. Syntax table structure

Syntax words and its synonym has the same serial number, so all the synonyms are linked and “Synonym” field stores the Chinese syntax words that has the smallest serial number in the synonym link. When syntax words are successfully matched, if it has Chinese synonym, system adds the “Synonym Field” into the syntax word string. If not, system adds the “C_SyntaxWord Field” into the syntax string. System regards the question with the same syntax string as the same question.

If an answer to a student’s question is not found in the answer web database, system will notify the correspond teacher automatically. After the question is answered by a teacher, question and its answer will be stored into the database for the future searching. If another student asks the similar question, the answer will be found by key words and syntax words matching and returned to the student.

2).Question hooking ,merging and analysis

Besides feeding back answers to the client’s question, answer web server will also “push”

questions to the client site by question hooking and merging.

Answer web can not only search answers for a question from student, but also it can find out the relationships among the similar questions, generate a link among those questions and return the result link to the client. When a student asks a new question, he can observe its related questions and their answers. We call that a question hooking, which will help students get more information about one knowledge point to get full understanding .

With the adding of new questions and answers, the question and answer database will increase. Some questions on one knowledge point can be merged to generate a new question that no student ever has brought up. Answer web returns the new merged question to the student to help them deepen the understanding of a specific knowledge point.

When numbers of the stored questions are large enough, it is feasible to catalog them into different groups according to the key words and the knowledge points they belong to. Thus, when analysis results are returned to teachers, they can be used by teacher to evaluate their teaching effects. If there are too many questions on one knowledge point, mostly teacher should make emphases when teaching that knowledge .

Answer web gives students an auto- answering facility and by server site pushing technique, both students and teachers can make teaching and learning on web more efficient.

2.2 Web based examination

Examination is also a important segment in the learning process, so we also provide an asynchronous web testing system in our virtual class room model. 2 problems should be resolved in the designing. Since web is established on the stateless network protocol HTTP, while in a entire examination, we need to store information of each episode from registration, beginning of the test to the ending of the test. So we have to find a way to create a state sensitive application on the stateless connection. Besides, there should be a way to auto generate proper question sheet with the complexity control. And different types of question(such as multiple selection, blank filling and writing)should be supported along with the different media based questions (not only text based, but also audio and video based).

1). Using session to ensure the connection reliable

We use CGI script on the server site to add a session layer to the system. A session is process of examination from registration to quit . One unique session ID is assigned to each session .In every episode of the examination, a state is remembered using a state ID. A state conversion table is maintained in the system to indicate to which state one state can be converted . A unique session table is also maintained in the server site to store users' status, including Session ID, User ID ,State ID and other state parameters. On every interaction with the system, server checks the conversion table to confirm weather the state conversion is valid .If is invalid, the state conversion will be prohibited ,or if is valid, the conversion is carry out and new state ID is stored. Thus the operations of the users all under control of the server session. When testing is being processed , illegal operations will be projected by the server. If one student's examination breaks because of the breaking down of the network, its session will be stored on the server and when he log into the system again , server will recover the stored the session to continue last examination. A reliable examination thus can be held under the unreliable network environment.

Interaction between the client and server site is illustrated as Figure 2

1, interaction between user browser and the web examination system.

2,Web Server returns the user's result set the request to the CGI script.

3,CGI script calls the functionality of the session layer.

4,Session layer verifies the session and returns the result to CGI script .At the same time, it update the session table when session is legal.

5,CGI script returns the correspond information to the client according to the result from the session layer.

6,Web server returns the result page to the client's browser.

Figure 2. Interaction between the client and server site of web examination

2. Design of the testing question database

To make the generation of the question sheet efficiently, rapidly and randomly,

multiple process are provided on the question database.

a), Add complexity parameter to each question and select proper questions to generate one question sheet according to their complexity parameter.

b),As to multiple selection ,separate the question and its correspond selection items to increase the randomization.

c),Generate a random question table by accessing the question database once at the beginning of the examination other than access database each time when user finishes answering one question.

d),Store both the question context and the user answer status in the question table to support the question overview.

2.3 Web based group discussion

Besides the asynchronous question auto answering and web based examination. We also provide a web base group discussion system with synchronous real time audio supporting. Students can not only study by static browsing ,but they can interact with teacher by means of media, such as text image and real time voice. Properties of web based group are as following:

1). *Interactive.*

Group discussion is by no means a one-way activity. In fact, students retrieve the educational material offered by the teacher ,at the same time, they feedback to the teacher so that teacher could adjust the process of teaching

2). *Multi-points real time audio supporting .*

In addition to the text and image interactions, there should be more efficient way to support teaching and learning in group. Audio supporting is the best choice, which means the group discussion should support the real time audio interaction. In brief, voice of each end can be broadcast to the other ends in the same virtual group via Internet.

3). *Tools provided for the teaching and learning activities in one group.*

Robert M. Corderoy suggested that in on line education, “The methods which can be used are as varied as those used in any teaching and learning environment.” Since group discussion includes both the teaching and learning activities, multiple tools should be provided to make an efficient discussion.

According to above, we construct the general model of web based group discussion as Figure 3

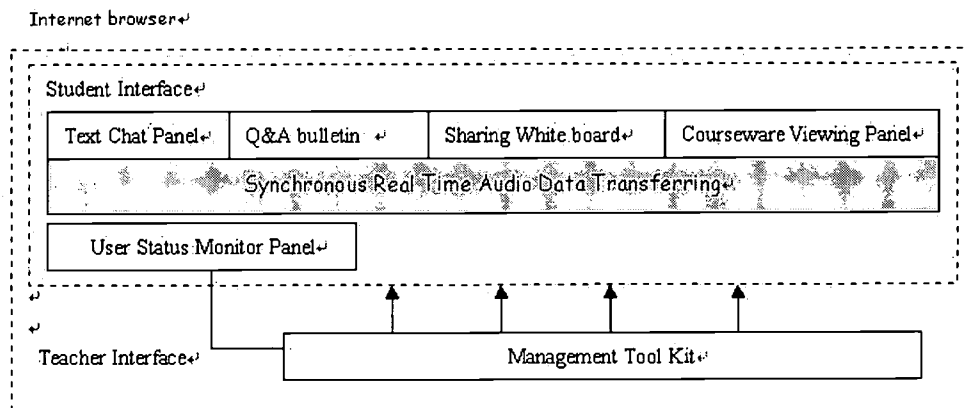

Figure 3. General model of web based group discussion

- *Text Chat Panel:* Text chat panel is a tool provided in the discussion group for purpose of text style intercourse . Just like other chat client in Internet, text chat panel support synchronous chatting ,including *private chatting*-----student or teacher could choose a specific user in the virtual classroom as his partner to chat with ,and *public chatting*-----every word one user typed can be shared by all the other users in the virtual classroom. Further more general text chat has been enhanced by the URL broadcasting . Teacher in one virtual classroom provide URLs linking to some helpful sites for study and can broadcast them to every student in the classroom that students can be guided by the teacher’s navigating ,surfing in the Internet.

- *Question & Answer Past Panel:* Each student can past his question on this panel. Teacher and the other students can see the question when they login , and past their replies. Process of questioning and answering is asynchronous and in addition to the teacher’s reply ,the others students can also publish their private answer to the question.

- *Sharing White Board:* Each teacher and student in the virtual classroom is sharing a white board

where they could not only past text but images . Also teacher could use drawing tools provided in the white board to sign marks freely on the image pasted on the white board in his teaching activity.

- *Courseware Tree-Viewing Panel* : In the virtual classroom , courseware are organized as a tree view list. Students can view the content of each chapter according to the tree view index with his Internet browser. Also teachers can make use of tree view index to past the pictures of the courseware onto the whiteboard for detailed discussion. At the same time teacher could control each student's browser window to show the specific chapter in the courseware. Thus, teacher could guide all the students studying the courseware in the virtual classroom just by navigating in his courseware viewing panel.

- *User Status Monitor Panel* : This panel list the status of the members in the virtual classroom, used by teacher for class management.

- *Synchronous Real Time Audio Transferring* : The virtual classroom we designed supports real time audio transferring synchronously. The voice data got from one site could be broadcast to each other sites in the one discussion group .Also ,teacher could grant or invoke speaking right to a specific student. Using real time audio can make question and answer activity synchronous.

- *Management Tool Kit* : Besides a courseware edit tool provided for teacher to create the courseware tree view list used in one virtual class. Management tools are provided for teacher to manage the whole group.

3. Conclusion and prospect

For the on line global education, it is crucial to create a efficient teaching and learning environment. Only using synchronous or asynchronous tools is far from enough in an efficient web based distance learning environment. We construct PANDA, a distance learning environment with integration of both synchronous and asynchronous mechanism and implement a prototype system-----Distance Discussion System in our Web school (<http://www.dlc.sjtu.edu.cn>). The whole system includes most of the important episodes in teaching and learning: questioning and answering , examination and group discussion.

In the future work, we plan to do more research on CSCW and technology of virtual reality to improve our model and later construct a more effective teaching and learning environment on Web.

EDI Transactions over the Web

Rong Shi, and Mohammad Zubair
Department of Computer Science
Old Dominion University, Norfolk VA 23529
E-mail: zubair@cs.odu.edu

Abstract: EDI expedites the transfer of business documents and allows a business to contact more trading partners and get more competitive prices on purchases and sales. In this paper we address the need of small businesses interested in working with big businesses and government organizations that mandate the use of EDI. We are proposing an architecture that does not require a small business to maintain EDI specific software. A small business only needs a Java enabled Web browser to facilitate use of EDI transactions with big businesses and organizations. The key idea in our architecture is to use Java applets (downloaded by small businesses along with EDI messages) to process EDI messages. The traditional way of encoding EDI message is in ASCII format, however, we also explore the use of XML for encoding EDI messages. The tradeoff is that handling of XML based EDI transactions by XML-enabled browsers are relatively simpler.

1. Introduction

Use of EDI (Electronic Data Interchange) dates back to early to expedite the exchange of business documents. The EDI standards addressed the problem caused by paper-based transaction, which is prior to EDI [Emmelhainz 90][Adam 96][Kimberley 91][ANSI 94][Swatman 92][Lavery 93]. EDI allows a business to contact a larger number of trading partners to get more competitive prices on purchases and sales. The VAN (Value Added Network) industry arose to serve those trading partners who could not afford to join a private network. VANs provide connectivity, mail box services, and act as a trusted third party for keeping logs of EDI documents. However, VAN services are still too expensive for small businesses. Hence, recently there has been interest in moving EDI messages over the Internet using one of the many TCP/IP based protocols.

In this paper, we address the needs of small businesses who are not connected to VAN and do not have EDI software, but do have access to the Internet. Big businesses and government have mandated the use of EDI because of the cost saving potential to them. They have deployed traditional EDI system and there are applications deeply coupled with it. However, many small business partners could not afford and maintain EDI software. Currently, small businesses pay VAN charges for EDI messages if they wish to participate in EDI transactions with big businesses or government. The VAN would either translate the EDI messages to ASCII electronic mail, or if the client is not mail enabled, print the message and fax it to the client. In the future, Internet based EDI software [Shih 97] may be available, but its use will also be too cumbersome for small businesses. In addition to acquisition, installation, and maintenance of this software, the small business proprietor will have to establish the trading partner agreement and customize his EDI software to reflect this agreement. Moreover, this software would become *bulky* to be able to support different types of transactions.

We are proposing an architecture that does not require a small business to maintain any EDI specific software. A small business only needs a Java enabled Web browser and Internet connectivity to participate in EDI transactions with big businesses and large government organizations. The World Wide Web is becoming a pervasive media and it is therefore reasonable to assume that a small business has Internet access. In our approach we are exploring two ways of encoding EDI transactions at the big business or the large government organization site. The traditional way of encoding EDI message is in ASCII format, however, we also use XML, an eXtensible Mark-up Language, XML, for encoding EDI messages [XML/EDI]. The tradeoff is that handling of XML based EDI transactions by XML-enabled browsers are relatively simpler. The Internet community is quickly adopting XML and has been already endorsed by W3C. As a result several vendors are working towards making their browser XML-enabled. XML is providing Internet developers with new tools for implementing E-Commerce and EDI solutions [Dowdie 98][Connolly 97]. Our work on XML based EDI system shows that together with XML, EDI will become more flexible, more powerful, less expensive and ultimately ubiquitous.

In another paper, we had reported our work on a Java based EDI system (JEDI) that handles EDI messages encoded in ASCII format [Bunting 98]. In this paper we focus on the XML based architecture. The rest of the paper is organized as follows. In the next section we discuss our approach. In Section 3, we review some details of Java based prototype to handle traditionally encoded EDI transactions. In Section 4 we introduce XML based prototype, and finally in Section 5 we have conclusions and future work.

2. Approach

For the small business, access to EDI documents requires three actions: 1) a transport mechanism to move EDI documents between the client and the server; 2) a compute environment to process that document; and 3) a display interface to present the document on the user screen. Two other implementations were considered prior to choosing the proposed architecture. First, using a Web browser plug-in from a trusted software vendor could provide all three required actions. The fundamental problem with a plug-in is that there are hundreds of different types of EDI messages (called transaction sets in EDI parlance). Furthermore, each message is quite complex, with a large number of optional and conditional segments. A plug-in would need to cover all the messages in their entirety, and hence will become a large and unwieldy piece of software. Also, any update to this software becomes a cumbersome process; a modular software design is more elegant and more maintainable.

The other approach is to use CGI scripts to handle translation and presentation of EDI files on-the-fly to a Web browser displayable format. The main problems with this approach are: (i) it is not scalable as the CGI scripts run on the big business machines, (ii) the interactivity is limited by the bandwidth available over the Internet, and (iii) the communication primitives allowed under HTTP are too restrictive to enable highly interactive applications. Another approach is to use MIME encapsulation for EDI messages as suggested in the Internet community and use the SMTP protocol to transport them [Shih 97]. Once again, the viewer software required to handle the messages once they arrive in the mailbox would be large for the reasons already cited.

In our approach, we use Java applets to process EDI messages. Also, we are working on XML based EDI approach which will be discussed in details in section 4. Both alleviate the EDI specific software requirements on the client side, which is a key benefit for small and medium business.

The overall architecture of a Web-based Java EDI system (JEDI) that is integrated with client and server side databases is illustrated in Figure 1. On the server side we need three major components: EDI Collector, EDI Publisher, and EDI Server Gateway (see Figure 1). The EDI collector receives EDI documents created by the small businesses using Java applets. The EDI server gateway integrates these documents with the existing big business' databases. The EDI publisher extracts EDI files from the big business' database, associates them with appropriate Java applets and makes them available on the Web. Optionally, it would also be desirable for some small businesses to have a method of integrating EDI documents with their databases. This is a motivation for using the EDI standard versus a proprietary format to transmit between server and client. Until recently within the Java applet framework, the client side integration was not possible as the Java applet had restrictions for accessing resources on the client machine. However, now with the introduction of secure applets (JDK1.1) it is possible for a user to allow digitally signed applets to interact with resources on the client machine. To address issues of security and access control support [Marcella 93][Menkus 92] we are currently exploring the use of Java Cryptographic APIs such as the Java interface to the Secure Sockets Layer (SSL) for providing security which conform to EDI Internet standard [Shih 97]. We are also looking at the high end Web servers like IBM Domino that provide sophisticated access control mechanisms. Details of access control and encryption are quickly becoming main stream technologies and can easily be added.

Figure 1. A Java Based EDI Architecture for the Web.

For XML based EDI (see Figure 2), in the server side we still need the EDI collector and EDI Server Gateway. As now the documents transferred between client and server are XML documents but not plain HTML files, we use an XML Author Tool to convert traditional EDI files to XML files. The author tool extracts EDI files from database, and then convert them to XML documents based on the rules stored in Global Repository. In the client side, an XML Parser parses the XML format EDI document first, and it can pass the result to an XML Document Browser for end user to read the document, or to Business Process Logic, which can be viewed as an engine that can integrate the coming XML files directly into other applications, like database, spreadsheet, or workflow system. All the necessary information is contained in the XML document.

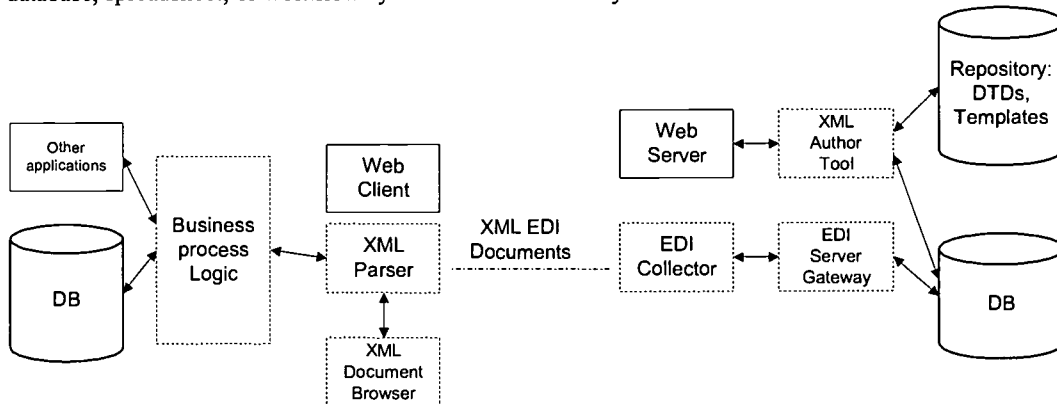

Figure2. A Java Based Architecture for XML-Encoded EDI Transactions.

3. Prototype For Handling Ascii-Encoded EDI Transactions (JEDI)

In this section, we briefly review the JEDI system. We have partially implemented the architecture of Figure 1. The components that we have implemented are: EDI applets to support 840, 843, and 856; a simple EDI Collector; and a simple JDBC based EDI client gateway. The following details relate to the applets for 840, 843, and 856. The EDI applet component is an extension of Java Electronic Data Interface (JEDITM 1.0¹). The applet runs in a Web browser that supports the Java virtual machine such as the Netscape Navigator or the Microsoft Internet Explorer. The current implementation is developed using the Java Development Kit (JDK) version 1.1 and the Netscape Internet Foundation Classes (IFC) version 1.0.

[1] JEDI 1.0 is a system that consists of a simple EDI Collector and applets for 840 and 843 and was developed by Bill Bunting and Mohammad Zubair.

The Netscape Internet Foundation Classes provide application framework and user interface components such as buttons, windows, text areas, and other on screen and application framework objects. The Netscape IFC greatly extends the Java Abstract Windowing Toolkit (AWT) library. The Netscape IFC is a feeder and predecessor technology to the Java Foundation Classes (JFC) which is currently under cooperative development between Netscape and Sun Microsystems. The Java Development Kit is planned to supersede the Internet Foundation Classes. Netscape anticipates that transitioning an applet from the IFC to JFC will not be difficult since the libraries will be similar in design.

In a typical scenario, a user (at a small business) clicks on a link pointing to an 840 transaction of his interest. As a result, he downloads the Java applet along with the 840 transaction. The Java applet displays the 840 transaction in a readable form and also helps the user to compose the reply (transaction 843). A user can also click on a link to compose a new 856 transaction. This downloads the Java applet for composing the 856 transaction. The reply to a transaction is transmitted from the applet back to the server through a custom Internet sockets protocol implemented by the *EDICollector*, a Java network daemon application. The network protocol implemented by the *EDICollector* is straightforward and based on the Simple Mail Transfer Protocol (one of the Internet's most successful protocols). For detailed information about the implementation, refer to [Bunting 98].

4. Prototype for Handling XML-Encoded EDI Transactions

We are now working on adding XML capabilities to our current EDI system. The Extensible Markup Language (XML) describes a class of data objects called XML documents, and partially describes the behavior of programs which process these objects. The combination of XML with EDI holds the promise of extending the advantages of Web-based EDI through an open standard to millions of small- and medium-sized enterprises. XML together with EDI provides a standard framework to exchange different types of data - for example, a RFQ, an invoice, an purchase order - so that the information be it in a transaction, exchanged via an Application Program Interface (API), web automation, catalog, a workflow document or message can be searched, decoded, manipulated, and displayed consistently and correctly by first implementing EDI dictionaries and extending our vocabulary via on-line repositories to include our business language, rules and objects. Thus by combining XML and EDI we create a new powerful paradigm different from XML or EDI [XML/EDI].

4.1 XML Introduction

The Extensible Markup Language, abbreviated XML, describes a class of data objects called XML documents and partially describes the behavior of computer programs which process them. XML is an application profile or restricted form of SGML, the Standard Generalized Markup Language. XML was developed by an SGML Editorial Review Board formed under the auspices of the World Wide Web Consortium (W3C) in 1996[16]. Every XML application relies on parser to process XML document. Parsers take the form of a code library that exposes software interfaces to developers using high level languages such as C++ or Java. Using these interfaces, developers can access the structure of an XML document, enumerate its elements and attributes, and play with stuff in the document prolog. A simple example would be an XML parser utility that checks for well-formed or valid documents, and serves as the XML equivalent of HTML syntax checker. Every XML development tool has an XML parser at its core, and the parsers are in turn based on some notion of an object model for an XML document. Now there are a lot of XML parser available in Java, C++, Perl, and other languages.

4.2 Approach

Currently we have defined a sample XML DTD for Transaction 840 (RFQ), and a sample XML file based on the DTD. A user can download the DTD and XML file using a standard browser, and a Java applet will help the user to parse the XML file and translate it to human readable format. The applet uses a Java XML parser (here we use Microsoft's MSXML) to parse the XML documents and gets the XML objects tree.

5. Conclusion and Future Work

In this paper we have proposed a Java based approach to enable small businesses to participate in EDI based transactions. This architecture does not require a small business to maintain any EDI specific software. Small business only needs a Java enabled Web browser and Internet connectivity to participate in EDI transactions with big businesses and large government organizations. The architecture and implemented prototype provide a proof of concept that demonstrate a potentially monetarily cheaper alternative to traditional EDI VAN services that leverage both Internet and EDI technology in place of proprietary solutions. The use of a modular Java object oriented design enhances the maintainability and portability of the implementation.

In future, we plan to work on a XML authoring tool, which enables automatically generating XML format EDI documents based on the information retrieved from back-end database or legacy EDI document. There is also a need to provide traditional EDI mailbox functionality for the small businesses. There are two possible approaches: one is to incorporate at the server side, and the second is to incorporate on the client side. We need to explore the tradeoffs between the two approaches.

Abstract: This paper addresses opportunities and issues related to the use of the World Wide Web and high-speed networks as a delivery vehicle for training educators who are geographically dispersed. The benefits and potential pitfalls of using networks as educational platforms are explored from the perspective of various systems specifically being developed to address the needs of practicing professionals in North Carolina and North Dakota. An overview of each of the projects is followed by a discussion of common issues among the projects, including a notion of future prospects for network-based professional development.

Introduction

Professional development in education is in an exciting period of challenge and change as we enter the twenty-first century. The realization of just-in-time distance training for educators is within reach, thanks largely to the ubiquity of the World Wide Web and increasing access to high-speed networks. States such as North Carolina and North Dakota benefit greatly from this type of training, which directly addresses the difficulty of reaching educators who are geographically dispersed in rural areas. This paper discusses initiatives in these states that impact instructors from the elementary level through community college and four-year colleges and universities. As [Fig. 1] illustrates, there are unique aspects as well as commonalities among these diverse programs. This paper will present the projects separately, and then conclude with a discussion of the intersection of these programs and what those common issues might indicate about the future of network-based professional development.

Figure 1: Network-based Professional Development Projects

The INSTRUCT Project

The Department of Mathematics and Statistics at the University of North Carolina at Wilmington has developed a teacher training Web site called INSTRUCT, which stands for *Implementing the NCTM School Teaching Recommendations Using Collaborative Telecommunications*. The site is located at <http://instruct.cms.uncwil.edu>. Since 1996, the site has been used by over 30 teachers from southeastern North Carolina to complete training at a distance that resulted in both licensure renewal credit from the state and technology credit from local school districts.

For the 1999-2000 school year, INSTRUCT is part of a statewide effort called Education Future Now (NOW), coordinated by the North Carolina School of Science and Mathematics (NCSSM). NCSSM has received a \$6.5 million Technology Challenge grant from the U.S. Department of Education to address the need for technology training of the North Carolina's K-12 teachers. A major component of NOW will be distance training, which will be carried over both the Web and two-way videoconferencing using seven locations across the state. As a part of NOW, the INSTRUCT program is being offered to up to 35 middle and high school mathematics teachers who have access to the Web. Those not teaching in North Carolina have the opportunity to participate in the program with no guarantee of stipend or licensure renewal credit. The site's resources are available for anyone to use, though to receive renewal credit teachers must be enrolled in the program.

The site contains the following major components:

1. A hypermedia version of the NCTM Standards for Teaching Mathematics contained in the *Professional Standards for Teaching Mathematics* [NCTM 1991], which includes such topics as Worthwhile Mathematical Tasks, Tools for Enhancing Discourse, and Analysis of Teaching and Learning;
2. Online educational resources that cover a wide variety of resource categories, such as Geometry and chaos, Internet project ideas, Lesson planning resources, Statistical data sources, Technology and Web publishing resources, as well as direct links to the state and national agencies;
3. A discussion and meeting area which uses WebBoard™ for posting discussion items or chatting online. The discussion board is open to the public; however, users must register to be added to the access list for chats.

Except for an initial two-way videoconference on navigating the Web and familiarization with Web-based communications tools, all training is conducted over the Web during a single semester. Teachers may opt to participate from either school or home. The INSTRUCT program takes approximately 12 weeks to complete, for a total of 30 online hours and 12 offline hours. During this time, teachers are expected to review hypermedia standards materials, participate in one chat per week, and carry out an ongoing implementation of the standards in their classrooms. Products of the implementation effort include lesson plans and activities reflective of both the NCTM standards and the North Carolina Standard Course of Study, as well as Check for Understanding forms submitted upon completion of each standard. Stipends for participation are made available through various grant awards.

Results from the project to date indicate that not only are teacher practices changing during the semester they are involved with the program, but those changes tend to persist once training is complete. In particular, teachers have noted their willingness to continue trying out ideas presented in the standards material, while at the same time regularly availing themselves of the online resources for mathematics teachers contained on the INSTRUCT site. Each semester, INSTRUCT participants point to the weekly chats they are involved in as the most unique and essential feature of the training, primarily because it keeps them in regular contact with their colleagues in a profession that is often very isolating. Participant comments include: "I enjoyed chatting and sharing ideas with other teachers the most. I don't feel so alone when I know others are experiencing the same things I am" and "I truly enjoyed the on line chats weekly. I think the ability to discuss weekly with other teachers that are working on the ideas that you are trying in your classroom was the most valuable."

In addition, for the last two years a small group of participants have volunteered to continue chatting during spring semester. Each year, one of these chats includes preservice teachers who are preparing to begin their practicum semester. The practicing teachers find the discussion stimulating because of the prospective teacher's enthusiasm, and the preservice teachers have the unique opportunity to ask veteran teachers about their concerns as they look forward to teaching. Nevertheless, the numbers of teachers voluntarily participating in chats once the primary training is complete represents only a fraction of the total number of participants. There is a strong sense that if teachers are not being compensated for their time, either through stipend or licensure renewal credit, it is simply unrealistic for them to make such a time-consuming commitment.

North Dakota Projects

Successful teacher inservice efforts in North Dakota are those that have continued and sustained programs teachers can count on for support when needed. One example is the Teach-to-Learn program. Teachers train teachers in the Teach-to-Learn Model. A Web site contains a database whereby a teacher can post the purpose and time for an evening workshop for others teachers to enroll online. The dependability of this system is illustrated by one second-grade teacher who stated, "Very little time is available for practice in the elementary classroom, that is, to sit down at the computer to practice such simple things as checking for e-mail. So I signed up for the same Teach-to-Learn topic three times until I mastered all the techniques. Learning along with fellow teachers is so important because we all have the same time restraints when tending to students during the school day." Although it was found that immersion with students and teachers is most productive for implementing training in instructional uses of technology, learning to utilize such classroom management technologies requires dependable forums to collaborate with peers.

The statewide laptop program supported by the USWEST initiative for all western states supported this view when data were collected from the 100 participating teachers in North Dakota. The initial workshop training evaluation scores were excellent. Teachers left training knowing how to use the laptop for networking. In the long run it was the bonding during the summer classroom sessions that prompted continued communications through a Listserv connection that provided sustained collaboration among peers. This continued self-enhanced activity was essential for growth and advanced computer utilization.

The same is true regarding the online network for school district instructional technology coordinators and directors. Their continued collaboration through online e-mail discussions and monthly meetings over the statewide Interactive Video Network has enhanced growth and expertise through peer support. These groups collaborated to develop successful regional workshops and a well-attended, weeklong conference held each June called TnT after Teachers and Technology.

The assessments clearly show that the advancements in North Dakota are teacher-based and not necessarily school-based. This means computer technology is not yet an integral part of the practiced curricula. This can best be portrayed by the following qualitative summary: "Our high school is deemed to be one of the most technologically enhanced in our state. It also appears to equal any technologically enriched 10-12 system in the nation, however, it is still possible for students to select a sequence of courses for their entire high school career and not be involved in these technologically-enhanced instructional opportunities we are known to provide learners. This is possible because teachers in every department have not changed despite being trained alongside peers who are models regarding exceptional integration of classroom technology."

Thus, as more and more teachers are learning and re-learning how to utilize computer-based technologies in their classrooms, there is also a need to increase the extent to which teachers are utilizing and extending the use of computers for instructional purposes on an across-the-curriculum basis to reach all learners. The answer for this sparsely populated state with 6,280 K-12 teachers is a \$7 million Department of Education Teacher Technology Training grant, which focuses on an intensive effort to continue to prepare teachers for classroom uses of computers during the next four years. This grant resulted from collaborative efforts, which had the capacity to deliver due to previously successful endeavors. This new initiative combines the Center for Innovation in Instruction and the State Board for Vocational Education in a process that selects regional trainers to work with new trainers, along with the teachers who will be receiving this training. Concurrently, state funds, Goals 2000 funds, and School-to-Work grants supplement specialized efforts to support and train select groups of teachers on how to employ specialized computer programs for classroom use.

The North Carolina Community College System DLD/M Project

The Distance Learning Design/Model (DLD/M) Project was funded to address the system-wide distance education needs of the North Carolina Community College System (NCCCS). DLD/M project activities started in October 1998 and ended in May 1999. The primary goal of the DLD/M project was to produce a plan to develop a training program that addresses NCCCS faculty/administrative training goals, and the competencies and infrastructure needed to prepare institutions to deliver distance education. Project outcomes include the development of a planning/training document, a design model, a set of distance learning resources on the Internet, and marketing material(s).

Topics and issues covered within the scope of the DLD/M project include: organizational and administrative design; curriculum design; team-building and personnel considerations; marketing and recruiting plans; student service concerns; and technological considerations of distance education. Since individual community colleges are already engaged in the design, development, and delivery of distance learning courses, we formed an Advisory Board with members representing 12 different community colleges around the state. The advisory board members actively contributed to the development of this project.

For this project, a Training and Needs Assessment Survey instrument was given to faculty, staff, and administrators at eight NCCCS institutions in February 1999. The survey was administered to ten individuals who were selected at each of the eight community college sites by the Advisory Board member affiliated with the community college. When asked if they had ever taken part in distance education training, we found that the responses ranged from 100% to 30%. This shows that distance education training currently varies widely from institution to institution. More significant is that fact that more than

80% of respondents on average would like to take part in distance education training. Perhaps even more surprisingly, respondents stated overwhelmingly that they wanted two or more days of training.

A few respondents indicated that they have already participated in designing, developing, and/or offering telecourses (mostly asynchronous in nature), North Carolina Information Highway courses (synchronous two-way video, time/place bound), and/or Internet-based courses (combination of asynchronous and synchronous). Surprisingly, when asked what they were most interested in working with in the future, most respondents indicated a strong preference for Internet-based courses over telecourses and NCIH courses. This result, taken along with the trend around the country to offer Web-based asynchronous rather than two-way video synchronous courses, indicates that instructor training is most needed in the area of Internet-based course development. For this reason, we emphasized online, Web-based instructional technology competencies/skill sets in our instructor online course development and training plan.

What follows are the training modules that were derived from a list of online teaching competencies/skill sets for NC Community College Instructors as developed from an extensive literature review as well as comments solicited from experts in the field of distance education. These training modules are intended to prepare NC Community College instructors to develop and deliver high quality education at a distance (details of individual training modules have been omitted due to space restrictions; however, a more detailed report can be viewed at <http://www.uncwil.edu/people/vetterr/ncccs/>).

I. Basic Internet Competencies

- A. Unit 1: Introduction to the Internet and Email Use
- B. Unit 2: Internet Browsers
- C. Unit 3: Research and the Internet
- D. Unit 4: Authoring on the Web

II. Using the Internet for Instruction

- A. Unit 1: Intro to Teaching Online
- B. Unit 2: Administration of Online Courses
- C. Unit 3: Course Planning and Organization (Instructional design/pedagogy)
- D. Unit 4: Tools for Online Courses

III. Advanced Internet Instruction

- A. Unit 1: Advanced Technical Competencies
- B. Unit 2: Advanced Multimedia for Internet Instruction

Comprehensive system-wide recommendations for NC community colleges included development of a Distance Education Faculty and Staff Development Center, a competitive grants program for collaborative online course development activities that span across multiple institutions, and a detailed list of competencies/skill sets for two-way interactive video courses (NCIH courses) as well as for telecourses.

Common Issues and Future Prospects

We believe the experiences and lessons learned from the network-based teacher professional development projects described in this paper can be successfully adapted to the needs of other states as well. Already today, the explosive growth of the Web and access to high-speed networks are having a dramatic effect on the way educators view professional development.

We see an increasing role for the hybrid use of synchronous two-way interactive video with asynchronous Internet-based learning systems. This combination provides considerable flexibility (as well as reduced network costs) for the instructor, student, and institution. In addition, as IP-based video systems become more widely available (for example, Microsoft's Netmeeting software system), the need for expensive classrooms with high quality video capabilities will diminish, at least in terms of providing distance educational opportunities to students.

[Shotsberger 1999] notes three distinct advantages of Web-based professional development, which could be extended to include the hybrid model just mentioned:

1. Consistent opportunities for reflection and sharing with colleagues;
2. Shortened cycle for training, implementation and evaluation of new practices;
3. Teacher empowerment through direct access to information.

Teachers are already embracing the World Wide Web in increasing numbers, making the process of training at a distance that much simpler. As the Web continues to mature and evolve in the next few years, enhanced network and software technologies needed for carrying out effective group and collaborative work applications will hopefully encourage greater teacher participation in network-based professional development.

During an intensive, summer-long, faculty-centered Web-based course development effort, [Vetter, Lugo & Ward 1998] discovered that the thought process involved in putting a course online was itself a good model for professional development as it encouraged faculty to re-think the way they teach, interact with other faculty, and develop the support systems needed to retain skills learned. We need to re-think faculty professional development with more emphasis on teaching and learning outcomes, and focus on collaborative development (Web teams, collective reviews and assessments) as a model of learning organization.

In addition, the transition from print-based learning materials to electronic, interactive, nonlinear, network-based learning modules requires further investigation and study [Sologuk, Stammen & Vetter]. Writing professional development Web pages requires a very different style and more dynamic presentation. For example, online materials must be designed with navigational links built in to them and organized in an easy-to-follow fashion. Techniques for creating effective paper-based professional development materials are already well developed. Additional research is required to develop efficient techniques for going from static paper-based models to dynamic electronic-based models.

In the near future, we expect network-based instructional software technologies will mature to the point where many of these issues are satisfactorily addressed. In particular, we expect to see the standardization of instructional systems and knowledge content, improved instructional Web page design, and an increase in software support for collaborative, team-based, teacher training models.

Perspectives on the Implementation of Instructional Technologies into University Environments: Faculty, Administrator, Student

Basia Siedlecki, Instructional Technology - University of Lethbridge, basia.siedlecki@uleth.ca

Amber Nicholson, Psychology – University of Alberta, Canada, adn@gpu.srv.ualberta.ca

Abstract: Institutions of higher education have been struggling with various models of implementation of Internet and network technologies. This paper reviews five popular and emerging implementational models and examines three perspectives on these models – specifically, that of a faculty member, an administrator and a student.

The use of Internet and computer technologies in university teaching and learning has provoked institutions of higher education to re-think some basic organizational issues. The scope of the technological undertaking, especially in the context of world wide networking that is facilitated by the Internet, is daunting. Many of the mechanisms underpinning and enabling work in this area must be centrally implemented and supported. And while traditionally, academic units (faculties and departments) at universities have enjoyed and indeed thrived with varying degrees of autonomy, the cost, including the physical, human resource, and transactional of implementing teaching augmented or supported by network-based technologies can be staggering. Thus, new models for university structures are emerging, which are changing traditional political and academic activities, imperatives, motivations and procedures. This paper addresses implementation issues by first setting a context of some accepted models for technology deployment in institutional contexts, and then addressing these models from three vantage points. The emerging models of higher learning and the implications of these transformations transcend societal boundaries – involving the taxpayer, the student or prospective student, the parent, the university employee, faculty member and administrator. Within the boundaries of a classical university, this paper relates the views of a cross-section of direct participants, including a student, a faculty member and an administrator. All are involved in technology at the institutional level and both the faculty member and administrator are involved in systemic, provincial implementations and co-ordination of technological decision making.

Network technologies and the Internet, wedded with the traditional academy, have produced hybrid institutions of learning. In the following pages five models of institutional technological deployment will be described to set a context for the subsequent discussions. There are real world examples of each model, and the list is by no means exhaustive. Many hybrid models exist. As the academy evolves into the new technological environment, there is no doubt that new models will emerge and that increasingly, institutions will feel compelled to adopt an optimal choice for their technological activities to meet their mandated responsibilities.

- **Low Tech:** A number of institutions, especially smaller ones, are finding it difficult to compete with the technological innovations of larger institutions. Since technological infrastructure is expensive, as are initial investments in network infrastructure - switching and server costs are not necessarily directly correlated to student enrollment - the cost of installing and maintaining instructional technology is often not within the means of smaller institutions. There are a number of other compelling reasons that institutions may not choose to invest in instructional technology, including:

- \$ an institutional plan to occupy a niche market may mandate an investment in faculty instead of technology. A guarantee of small classes and personal attention may serve to situate a small institution very favourably in the post secondary market

- \$ an institution may decide to upgrade traditional learning support systems - libraries, etc. - rather than transform them through technology

- \$ an institution may decide to identify and support it's existing technological strengths, rather than work towards a ubiquitous deployment of technology. This type of clustered technology plan mandates investing in existing specialized high output research projects (ie. electron microscopy, particle acceleration, magnetic resonance imaging, radio astronomy, physics simulation, biometrics, etc) rather than student labs, faculty and staff computing facilities, etc.

- \$ risk avoidance

- \$ uncertainties about the future of any given technology

- \$ funding sources may not permit the deployment of expensive pilot programs

This low-tech campus option, the option to not deploy technology, is often overlooked in technology planning.

- **Lab:** The Lab campus reflects a standard model for the distribution of technological resources in an institution. Computers are kept in labs which are monitored by proctors, and are available for general use when not booked for specific classes. The upgrade and maintenance of lab machines has traditionally been an issue affecting the effective deployment of this model. Centralized machines are easy to access, and track. Software and hardware upgrades to desktop computers are however, labour intensive and repetitive, as each machine must be individually maintained. Lab machines are usually replaced every three years. Students in most institutions are more and more reliant on computers for course work, composition, and research and so the demand for the machines rises, as does the demand for software, maintenance and support. Thus institutions working with this

model are constantly expanding and upgrading general-purpose computer facilities. The cost of maintaining the facilities rests solely with the institutions. Pedagogically, and socially, the lab is an odd place. The designation and most lab deployments reflect its historical use as a scientific research area. Modern computer labs host a great variety of activities (lectures, synchronous and asynchronous conversations, interactions with curricular software, etc). Additionally, the popularity of e-mail has turned the computer into a means of social communication, so that often, a lab hosts curricular and social interactions simultaneously.

- **Laptop:** The concept of the laptop university is quickly gaining popularity. In this model, the institution provides a network infrastructure that connects all the spaces used by both faculty and students. The student bears the cost of buying the machine - a portable version of the desktop. The multifaceted activity taking place in the lab is thus no longer constricted in terms of space, and can take place in more appropriate or intuitively attractive settings. Researchers can work in the Library with access to the appropriate reference materials, some assignments can be done at home and writing love letters can be a private process, carried out in an appropriately secluded part of campus, or on a grassy hilltop surrounded by the bounty of nature. Laptop universities however, require a fairly elaborate infrastructure to support a successful deployment.

§ Students are faced with a steep learning curve when they first encounter the system, and the mechanics of taking the technology-augmented courses need to be addressed in the introductory curriculum - necessitating an additional curricular development project. This is an even greater issue when instructors choose different courseware packages to deliver their on-line courses.

§ Deployments of laptop universities generally rely on a corresponding, centrally mandated conversion of curriculum into electronic format.

§ A fairly elaborate customer service model for the maintenance of the machines must be implemented to technically support students and professionally develop faculty.

- **Virtual:** Virtual institutions are becoming more and more prevalent. The designation can denote a number of real institutional configurations. Most virtual institutions are Internet-based schools delivering web-based courses, with varying degrees of opportunity for face to face traditional classroom-based instruction. Some exist only on the Internet, relying principally on lifelong learners as a student base and work at expanding the traditional distance education markets. Some, like Western Governor's University, use seconded faculty and have no permanent faculty members. Virtual institutions are geared towards providing an educational service to clients who, for geographical, lifestyle, work, or other reasons, do not want to or can not attend a traditional campus. This is the traditional distance learning market, but the virtual institution is offering a more refined, quicker, more satisfying, more academically and socially engaging experience than print-based distance courses have achieved. Virtual campuses generally strive to gauge the needs of traditional students and deliver comparable services to remote students.

- **Networked System:** A new model for politically mandated integrated post-secondary systems is being examined in a number of geographical areas, among them the province of Alberta, in Canada. This model demands that curricular material and credit be fluid and systemic. It depends on the notion that students need not be tied to an institution and that they would be better served by a system consisting of discrete, identifiable parts. It also depends on an integrated and co-ordinated deployment of technological tools to facilitate an individualized learning system. This model requires a great deal of political decision making, and negotiation, but affords students the opportunity to build degrees, diplomas and certificates from a wide range of possible providers. Students, as consumers of the system, are empowered to choose the mode and content of the courses they take.

While each of these models can be compelling, simple and perhaps even obvious, and each provides a solution to an identified problem, each also is rife with implications that are pervasive and stand to transform academic institutions as we know them. Because the impetus driving the incorporation of network technologies into the teaching and functioning of universities around the world is political and economic as well as academic, these models of institutional uses of technologies or institutional refashioning are compromises that seem to please few involved in the transformative processes. The function of planning has changed in the technological environment along with the relative importance of various institutional plans. More importantly, the need to integrate various plans, always a goal of institutions, has become a necessity without which, universities can founder and fail. Additionally, the emergence of technologies as mediating agents in curricular, social, economic and support transactions has encouraged a degree of interdisciplinarity and integration, an imperative for institutions, departments and individuals to trespass over boundaries that are seminal to the traditional academic institution's operation.

Perspectives

The perspectives of three individuals from stakeholder groups strongly affected by technological refashionings in educational institutions are represented in this section of the paper: a faculty member, an administrator, and a student. All three have been involved with network-based technologies and have seen their environments adapt in response to them. Each will comment on the technology models described and each will provide their unique perspective on the process of incorporation as well as the day to day use of these technologies in the context of an academic institution. As well, each will address concerns and hopes for the technologies and speculate on the future of their roles within the greater academic and institutional environments.

Faculty Member

As a faculty member at the University of Lethbridge, I lead technology planning and implementation and help other faculty to integrate appropriate technologies into their curricula. I also research and assess new instructional technologies. Additionally, I

sit on the Alberta provincial Advisory Committee on Educational Technology, and participate in the affiliated Standards Task Group.

My background and current position lead me to believe that centralized, cross-disciplinary and long-term planning for technology implementation is vital to the success of any institution considering a technological renaissance. Each of the models included in the panel summary has its merits. Some are economically efficient, some are elegant and simple, and some are flexible. My enthusiasm for them is tempered by my concern about traditional academic values and the traditional academic environment that has proven so conducive to the creative pursuit of new knowledge.

As a faculty member and a stakeholder in the higher education system, as well as a taxpayer and parent, I am concerned that academic autonomy, so fundamental to the academic culture, is being compromised in the process of implementing technology. The new forces molding the academy include business concerns and political pressure – both forces traditionally involved with administering and funding higher education, but not with the development of curricula. In some of the models listed in the introductory paper, it is apparent that curricular change is being mandated systemically. This flies in the face of academic freedom, which is fundamental to the institution of the university. Although I recognize the need to rework the methods of implementing technologies to take advantage of economies of scale optimizing both physical and intellectual resources, I feel that caution ought to be exerted and much thought devoted to the larger implications of these changes on scholarship, creativity, critical inquiry, and intellectual development.

The Low Tech option, for instance, is naturally appealing, especially to faculty members at small institutions. This model seems to leave intact the fundamental structure of the university, preserving it in time so to speak. However, what of faculty who wish to pursue technologically augmented teaching? What of students who need to be comfortable with technology in order to be job ready? Again, institutional motivation comes into play. Are we serving the taxpayers who foot the bill? Are we serving students, who also pay? Are we serving the greater good by developing new knowledge? Are we accountable to the politicians who dole out the funds? Are we responsible to corporate bodies who donate research funds? University policy, in fact, treads a fine line of compromise winding between these and other forces.

Fundamentally, these teleological issues need to be resolved before the issue of technology even begins to be addressed. Once an institution has established its purpose, and fundamental motivation, the rest of the issues are academic. For instance, if the focus is on students, as clients of the university, their experiences and education, then obviously small classes are important – students learn better with more. As well, technology is important, since students need to have access to it in order to do their work and qualify for jobs. As custodians of their money and futures, we should create an environment optimal for students.

However, the situation is never simple. Institutions of higher learning function in a multifaceted context. As faculty members we are rewarded generally, for our work in research first, teaching next, and service to the university and community last. This necessitates working in an environment that streamlines the production of curricular materials. The economies of scale can work for us here, ensuring that the technological context for our work is centrally implemented and supported, that our research and curricular assistants are working in a single technological context, minimizing the need for technical re-training.

Another issue that must be reflected upon before embarking on any scheme to refashion the academy is the relationship between the content and delivery of curricular materials. Two of the models initially discussed, the Laptop and Virtual, mention the redesign of curriculum. In the spirit of acknowledging the relationship of the medium and the message, institutions must accept that redesigning curriculum for delivery in a technologically augmented or mediated environment means tampering with course content. Instructors must be free to choose the best mode of delivery for a content area, rather than try to fit a subject into a context that may not be conducive to the delivery of that particular subject. Even more disturbing is the assumption that existing course materials can be handed over to an outsourcing agency, which can "transform" them into a format suitable for electronic delivery.

Granted, the realities of the modern academic environment dictate that long term technological planning be visionary and binding. However, it also has to be integrative and thorough. It needs to take into account the mission, goals and underlying purpose of the institution. It has to acknowledge the complete cost of the work – including the increased workload on faculty, who ultimately, are the front line workers in the enterprise. Any externally mandated curricular transformation must be accompanied with tangible faculty rewards and a complete technical and intellectual support system. Furthermore, it must include professional development for faculty who need to work with new and different paradigms for instructional design.

Ultimately, it is hard to conceive of an academic future where technology plans are not centrally developed. Economic realities are compelling institutions to adopt centralized and comprehensive planning policies that include curricular changes. It is vitally important, however, to acknowledge in these planning processes the academic structure and atmosphere that has facilitated the scholarship, critical and creative, to date. I predict that future institutions will attract faculty not just through strongly developed research opportunities, but also through well developed and implemented planning, especially technological planning which will set a context and environment for their teaching and professional growth.

Administrator

I work in a senior administrative position at the University of Lethbridge and focus on the areas of project management and institutional planning. My responsibilities include maintaining awareness of both internal directions and external issues, trends, and policy directions for the provincial post-secondary system. I serve on various institutional and provincial technology integration planning committees, and provide liaison between government policy makers and university administrators and faculty members.

While the range of learning and educational technology options increases, so too does the potential for misunderstandings and accusations of unrealistic expectations among the various stakeholders. From the perspective of a seasoned post-secondary institution and government administrator, I will present some of the economic, political, and administrative considerations that must inevitably, and hopefully consciously, factor into the selection any of the identified technological options.

To set a context for my position, I will first identify some of the relevant characteristics of the Alberta post-secondary system and, more specifically those of the University of Lethbridge. I will not, however, identify a preferred option. I do not have a recommendation for the provincial system, nor for that matter for the U of L. To do so would also presume some planning decisions that are outside my area of expertise and purview. Inarguably, all post-secondary institutions are in the business of providing educational and/or skills training opportunities that best address student needs, meet their mandated responsibilities and the demands of the economy. I see the administrator's role as helping to facilitate, plan for, and implement the option identified as being the most pedagogically and conceptually sound by the educators who have conducted the research necessary to determine which are the most appropriate learning environments.

Twenty-six Alberta institutions, ranging from vocational/upgrading colleges to four universities, compete for dwindling tax dollars that are earmarked for publicly funded post-secondary education. The U of L is a relatively small institution (approximately 5400 students) that is mandated to deliver liberal education and professional preparation through its five faculties and schools (Arts and Science, Health Sciences, Education, Management, and Fine Arts).

In 1994 the provincial government set out a new direction for its publicly funded post-secondary institutions. It identified numerous initiatives that focused on increasing responsiveness, accessibility, accountability, and affordability (both for taxpayers and students). What was very apparent, and new to the system, was the increased emphasis on:

- ♦ reducing system-wide duplication of programs and services;
- ♦ rewarding institutions for developing collaborative undertakings;
- ♦ increasing the number of student seats in high demand program areas;
- ♦ increasing rewards for learner-centred practices including, for example, seamless student services (electronic application service);
- ♦ providing only for rationalized infrastructure expenditures;
- ♦ standardizing reporting processes; and,
- ♦ promoting innovative practices e.g. integration of technology and recognizing more business oriented credentials ie. those with either a significant co-op or practicum component such as post-diploma and applied degrees.

Another of the major changes was the move from formula-based (percentage based strictly on student enrolment numbers) to envelope funding which required that institutions adopt a more entrepreneurial orientation and compete for various funding envelopes. At the same time, institutions were struck with a 21% (over 3 years) cut to their operational budgets. More market responsive and business driven decision-making was obviously required. Cost effectiveness became the focus of post-secondary administration. Regular business, technology integration, research, and accessibility plans were required from institutions in order to regain maximum funding. Within an increasingly competitive environment, the requirement for enhanced inter-institutional collaboration became, and remains, an anomaly. Student tuition fees were also capped at 30% of operating costs.

Faculty and student expectations, without the benefit (or disadvantage, depending on perspective) of being in direct contact with policy makers and funding agents, were slower to respond to the changing requirements and assumed that business would continue as usual. Personal objectives and goals, due to economic necessity, became subordinate to achieving institutionally mandated responsibilities including what were presumed to be technological efficiencies in educational delivery. Faculty members, in the absence of having had the opportunity to develop their knowledge and expertise or even conduct research into the pedagogical implications, felt pressured to adopt technological alternatives either on a broad or limited scale. A kind of 'shoot the messenger' mentality seemed to emerge as administrators were seen as being responsible, if not wholly, in part at least, for not being able to re-deploy resources in a way that would not impact the teaching/learning environment.

Due to external politically- and economically-imposed pressures, institutions sought the means by which to enhance accountability results in order to secure higher funding allocations. In this context, alternative means of educational delivery via technological assistance were examined. Universities started to pay greater attention to market demand - students, their advisors, and parents were increasingly seen to be *customers* of institutional services. Streamlining and simplifying administrative procedures, as well as student and support service delivery, generally expedited through some technological assistance for such important processes as financial, counselling, and registration, required that internal processes be more widely understood and communicated. Responsiveness to market demand and competitive pressures, despite the crassness of its ring to educators, became necessary. It would probably not be an overstatement, for some institutions at least, to say that institutional preservation continues to depend on making good, fiscally sound choices - with little room for error. Administrators, by virtue of their 'watchdog' status, have the appearance of presuming to interfere with academic delivery. Preferably, theirs could be viewed as more of a mediational role - communicating and interpreting external constraints while appreciating and respecting internal educational preferences and directions.

A few of the specific considerations that administrators are obliged to address that directly relate to the various technological options include:

- ♦ physical space change requirements - more, less, or different use
- ♦ collaborative arrangement coordination
- ♦ one-time and setup vs. lifetime costing
- ♦ approval processes
- ♦ policy implications

- ♦ project management
- ♦ process planning
- ♦ timeline coordination
- ♦ publication and communications requirements
- ♦ effect on total program array and/or change in student numbers
- ♦ professional development and/or training considerations
- ♦ maintenance, upgrading, and replacement costs
- ♦ intellectual and/or product ownership implications
- ♦ impact on student tuition and/or other transferred costs
- ♦ staff and faculty number and location implications
- ♦ funders eligibility criteria, guidelines for disbursement, and subsequent reporting requirements
- ♦ revenue generation opportunities
- ♦ coordination of response time with market demand forecast
- ♦ consistency with strategic direction
- ♦ risk management

These represent only a few of the considerations that are possibly less evident to faculty members as they select from the presented, or other, technological options. Some are undoubtedly unique to the Alberta post-secondary system; others are likely common regardless of jurisdiction or type of institution. They are presented to provoke discussion and indicate the range of administrative considerations that are inevitably important to complement educational delivery change decisions. Consultative planning, which implies developing an appreciation of all stakeholder perspectives, is necessary prior to decision-making to minimize unpleasant surprises and maximize positive outcomes.

Student

In September 1995 I became a University-transfer student of Concordia University College and transferred in 1997 to complete my BA (Honours, Psychology) in May 1999 from the University of Alberta in Edmonton. I have not taken any distance courses, but I have been exposed to an array of classroom technologies. I have made extensive use of computers, both in the student labs at University and at home. When I graduate, I expect that computers will be part of whatever career path I decide to pursue and that I will constantly have to learn new applications and deal with different interactions involving computers.

My use of computer technology while attending College and University was mostly directed at my studies. I used word processors, databases, spreadsheets, statistics programs, and presentation software regularly. I also used a variety of tools to access the Internet for research, library and other. As well, e-mail was, and continues to be, a fairly important part of my life – both for academic and career research work as well as for social purposes.

I can see that there is real and undeniable value to technology - especially the kind that lessens the on-campus residency requirements - perhaps more for other students than for myself. For instance, disabled students, who are unable to go to campus for regular face to face instruction, mature students returning to school, at-home parents, or those with full time jobs have access to a world of education that circumstances had kept them from before. As well, computer communication allows people to easily keep in touch with people anywhere in the world. This is important not only to students looking for mentors or information in remote places, but also to people whose interests are not shared with those in their local communities. The typical student however, like me, values the campus experience mostly for its social opportunities. The university is a setting where we meet peers, socialize with like-minded people, argue and persuade, learn from each other and enjoy each other's company. This is not something I would be willing to give up, even for very effective communications technology. Although e-mail is a social tool for me, I would not want it to be the only one.

The five models described in the introductory paper are all ones that I have heard mentioned by students and professors alike in discussions of possible futures for the University and possible ways of conducting courses. My comments are based on my presumptions about the benefits and deficits of each option. I have attempted to briefly point out the most significant positive and negative aspects from a student's point of view.

University Model	Benefits	Deficits
Low Tech	♦ tuition <u>should</u> be cheaper	♦ restricts students' future opportunities ♦ employers may pass over this type of experience in a high tech society
Lab	♦ cheaper than having to buy your own computer	♦ chaotic environment, in many labs there is no privacy for e-mail or quiet work ♦ students who own computers subsidize those that don't and rely on the labs

Laptop	♦ students can work, study, and do their research in a variety of settings, for instance, at home or work	♦ expensive – tuition is already too high, and students are graduating with too much debt
Virtual University	♦ limits some costs and provides convenience	♦ limits some day to day social interaction
Networked System	♦ convenient for students who want to mix on-line with regular courses and who don't want to leave their homes to attend school	♦ maintaining the value of the credential ♦ limits options for individual course selection i.e. reducing duplication also reduces choices

As you can see, no single model emerged from this exercise as a clear winner. I think that I can unequivocally say that I would not want to get my degree from either a Low-tech or Virtual University. I need and want technology in my education, but I do not want it to be the focus of what I do. I am first and foremost interested in psychology, in its course content and the related research. I want psychology to be the focus of my career and for technology to enable me to be the best I can be in that field. I worry that the emphasis on technology in delivering university education will divert it from what's important to students, from what keeps students like me at university. Technology will not be the focus of my life, but I do appreciate and enjoy its utility in helping me learn, research, share information, keep in touch with friends, be entertained, write, and I look forward to whatever else it will do in the future.

Technology has the potential to make student life much less complicated. It could eliminate lineups for student services, and streamline the bureaucratic entanglements that students have to clamber through. It could help students who are transferring from one school to another to know exactly what to expect in terms of credits, services and requirements at the new institution. It could give students more choices about their own education. I hope that this is what technology ends up doing in universities. The possibility exists that it could also just add another layer of cost and intricacy to the whole experience, which is already expensive and complicated. It could, potentially, free up time to 'learn'.

Future Considerations

Clearly, technology is very much a matter of concern and contemplation for various stakeholders in university education. Each considers the academic and professional impacts, or potential impacts of technology. The selection, deployment, and implementation of technology in university curricula have far reaching consequences, and it seems that these consequences will affect us whether or not we choose to participate in the processes. Pressure from students, governments and industry will eventually ensure the integration of network technologies into portions of all university curricula.

The three individual perspectives provide a sample of the some of the more general concerns that face university faculty members, administrators, and students. Probably the most important point prior to making any far-reaching, resource intensive decisions that will have significant professional and academic impacts is to have a clear understanding of the expected educational outcomes. The stakeholder perspectives need to be confirmed and elaborated or refuted by a representative cross-section. Perhaps equally as important is that this feedback be complemented with perspectives from those not as directly involved in technology integration (parents, business community, other university staff, college personnel, government employees, potential students, etc.) to develop a more comprehensive picture. Presumably then, confidence will be enhanced in the suitability of the chosen option, resources to support the change will be more readily forthcoming, and there will be greater assurance that educational benefit will be realized.

Using Standards to Realise the Vision of a World-wide University

Phil Siviter, University of Brighton UK. Phil.Siviter@brighton.ac.uk

Mark Resmer, IMS, US. resmer@earthlink.net

Bill Olivier, UK IMS Centre, UK. b.olivier@bangor.ac.uk

Abstract: This paper presents a vision of a world-wide university and describes some features/scenarios that we expect to find in such a future. It then points out that the current lack of technical standards in educational technology presents an insurmountable barrier to the realisation of this vision. On a more hopeful note, the paper introduces several significant initiatives that are attempting to address this issue, and enumerates some of the benefits and costs to the key stakeholders.

1. Introduction - the Vision

Many agents in the academic, commercial and military sectors share a vision, referred to variously as "The Global/Virtual University/Campus". Our preferred term is the world-wide university (WWU). This vision is of a world-wide education marketplace in which vendors can sell their educational offerings to learners, using Internet technology as the medium for marketing, trading and delivery. In this market place, vendors may range in size from small startup companies to large consortia of institutions. They may spring from traditional universities, from industry-based training agencies, or they may be completely new enterprises. The units of learning may be as small as a single "lesson" on a very specific topic, perhaps offered by a lone academic, either direct to learners, or indirectly via a larger commercial entity. Alternatively, they may be as large as a full honours degree, perhaps offered by one of the new virtual universities. Similarly, learners may register and pay for units of vastly differing sizes, and on successful completion of those units be awarded internationally (and electronically) recognised credits of appropriate value. Learners may enrol as individuals or as members of larger groups, perhaps organised by intermediary organisations who can offer value-added services.

This vision has sprung from more than one source. On the one hand, there are idealistic academics (in the positive sense of the term) who have seen the potential of technology for transferring power from teachers and institutions, to learners. In a world-wide university learners will no longer have to put up with learning programmes designed for the administrative convenience of the institutions which offer them. Instead they will be able to pick and choose modules to create learning programmes tailored more closely to their needs.

On the other hand however, the vision may be seen as a response to a perceived crisis. A crisis in which increasingly complex societies, facing an accelerating rate of cultural and technological change, require ever more sophisticated workforces with constantly updated knowledge and skills. Addressing this problem requires the adoption of a lifelong learning culture, and educational systems, which can deliver lifelong learning on a massive scale. Not surprisingly perhaps, the technology which is in part responsible for the problem, is turned to in search of a solution, as our governments hope that the idealists' attempts at realising their visions might provide the pillars to support a lifelong learning culture.

Certainly, an impressive array of educational technologies has been developed or refined over the last decade, including:

- Computer Aided Learning (CAL) software (time and location independent learning)
- Videoconferencing (location independent learning, useful where visual cues are crucial to the interaction)
- Computer based simulations (e.g. of hazardous, complex or expensive laboratory experiments)
- Computer based assessment (time and location independent, and efficient from the assessor's viewpoint)
- Collaborative learning environments, enabling synchronous and asynchronous collaboration between learner and learner, learner and tutor, or tutor and tutor, even when the participants are geographically dispersed.

- The use of the Internet, especially the World Wide Web (WWW) as a delivery medium for all of the above.

Wherever the vision may have sprung from, in many parts of the world we can see initiatives using communication and information technologies in its pursuit. In the UK for example there are the Computers in Teaching Initiative (CTI), the Teaching and Learning Technology Programme (TLTP) and the National Grid for Learning (DfEE, 1998). In the European Union there is the Fifth Framework Programme, while in the US there is the Advanced Distributed Learning project (ADL).

2. Standards

Given the impressive developments of recent years, and the growing list of initiatives such as those listed above, it is tempting to believe that the above vision is close to becoming a reality. We do, indeed, believe that this vision will become a reality, but there are serious inhibitors, which still need to be overcome. One major inhibitor is a lack of technical standards for managing online educational content and courses. Look inside the educational technology developed in any of the projects cited above and you will find similar functionality being implemented in different - and incompatible - ways, making it difficult to use resources from different projects in an integrated, coherent manner.

A lack of standards for managing online educational resources means that:

- teachers (and learners) cannot easily locate suitable resources, even though the resources they need are almost certainly "out there somewhere".
- teachers (and learners) cannot easily create bespoke educational offerings using resources from diverse sources (even if they can find them)
- information from one resource cannot easily be used by another (e.g., results from an online assessment component cannot easily be used by a presentation component to determine a learner's level of knowledge, and therefore the most appropriate path to take through the presentation).

A lack of standards for managing online courses means that:

- institutions cannot easily engage in sharing of administrative records necessary to form virtual partnerships
- learners cannot easily transfer credits among institutions and between institutions and employers.

The good news is that the world is finally waking up to these issues, and the need for standards to address them. There are currently two relatively mature projects, both US-based, attempting to define standards for educational technology. These are IMS and the IEEE Learning Technologies Standards Committee (LTSC). In addition, the European Union has recently issued a standardisation mandate (see section 2.2).

2.1 IMS

IMS is a global coalition of educational, commercial and government organizations that is driving innovation in the distributed learning marketplace. Its goal is widespread implementation of a set of technical specifications for software that will make it easier to publish distributed learning content and for people to use the content in multiple ways and on multiple learning systems. IMS is part of the EDUCAUSE National Learning Infrastructure Initiative, and makes all of its technical specifications and other released deliverables available at no cost. It does not endorse member products and, at this time, is not certifying product conformance with the specifications. IMS has centres in the United Kingdom, United States, Singapore, and Australia, as well as members in a number of other countries.

2.1.1 The UK IMS Centre

In early '98, the UK's higher education Joint Information Systems Committee (JISC) decided to become an IMS investment member. Immediately prior to this, there had been some quite large scale funding of content development in the higher education community, most notably through the CTI and TLTP programmes. The point had been reached where it was becoming more widely understood that:

- content needed to be able to operate cross platform rather than be tied to a specific delivery or learning management platform, for which Web standards were emerging as the best candidate for building on
- large volumes of online content would need separate management tools to find, store and organise them into courses prior to delivery
- learning management systems needed to interoperate with administrative enrolment and student record systems to provide the start and end points of units of learning, and this should be in a non-proprietary way
- learning management systems needed to support interactions between teachers and learners and between learner peer groups before and during the learning process, as well as to provide facilities to tailor learning more closely to the needs of learners

Recognising the need for standards to enable the above, the JISC sought bids from UK higher education institutions to run a Centre whose task it would be to represent the viewpoint and needs of UK higher education to IMS, as it developed its specifications, and to inform UK higher education institutions of these specifications and their significance, and provide early access to them as they developed. A joint bid between the University of Wales Bangor and the Open University won the contract and the UK IMS Centre was set up in May '98.

The UK IMS Centre was the first such non-US based centre to be set up. IMS in the US had already recognised that to be effective, the specifications they put forward would need to be acceptable on a world-wide basis. It is very difficult when working within a particular culture, to recognise what is unique and specific to that culture and what is more universally shared. A case in point was that in the early versions of the IMS specifications, it was proposed that all distance learning would be carried in real time over the Web, connected to a Learning Management System mediated through a Web server. The assumption behind this, true in the US but not (yet) elsewhere in the world, is that everyone has free local phone calls and therefore pays no charges to access the Web via their local internet service provider. Elsewhere, where learners are trading 'earning time' for 'learning time', this would cause an immediate barrier to the use of ICT for distance learning. Another case was that by the end of '98, the candidate for v1.0 specifications only supported individualised delivery of learning with no support for learning in classes or for group learning. The UK IMS Centre worked hard to get support for these included.

In addition to a number of awareness raising exercises, the UK IMS Centre has begun workshops on the emerging IMS specifications, and is now planning to work with small groups interested in trialling the draft specifications through interoperable implementations, building up experience of their use, feeding back any findings in to the IMS process and providing prototype tools which can be used to start using the specifications on the field.

2.1.2 The Singapore and Australia IMS Centres

The Australasia IMS Centre is funded by the Department of Education, Training and Youth Affairs, and operated by the University of New England. It serves the entire higher education community in the region, and has been active in promoting industry relationships, workshops and other activities. The IMS Asia Center is operated by the Kent Ridge Digital Labs, on behalf of the National Computer board, and serves the entire Asian region, including such countries as China, Japan, Malaysia, Thailand, Korea and others.

2.1.3 The IMS Developers Network

In addition to the aforementioned Centres, IMS operates a world-wide Developers Network with around 200 member organisations. New chapters of this organisation are being set up in several European countries, including the UK, Finland, Greece, Italy and Ireland.

2.2 The European Standardisation Mandate and Memorandum of Understanding

In November 1998 the European Union, with input from IMS and other groups, decided to take action in this area and issued a standardisation mandate in the domain of "Learning and Training Technologies & Educational

Multimedia Software". It also issued a Memorandum of Understanding - a declaration of intent, with over 300 signatories - to work towards specifications of requirements for standards for multimedia learning technologies. This initiative has now been named PROMETEUS. Associated with this activity is a CEN/ISSS Learning Technologies Workshop that constitutes the standards effort within the EU.

2.3 The Learning Technologies Standards Committee

The IEEE working group P1484 (now renamed the Learning Technologies Standards Committee - LTSC) is another prominent US initiative developing standards for various aspects of learning technologies. As an IEEE initiative the LTSC can be seen as setting "de jure" standards. The process of defining these standards is carried out by a number of working groups, each of which addresses a different aspect of the problem. For example, a Learning Objects Metadata working group is defining standard ways of describing learning resources (this working group recently released Version 3.0 of the IEEE LTSC LOM specification document for public comment prior to balloting).

With three prominent initiatives all addressing standards for learning technologies, one might be forgiven for recalling the old computing industry adage "of course we like standards - that's why we have so many of them!". However, all of these standards initiatives are actually talking to each other, so we can hope that the situation will not get out of control. IMS is in the process of developing an "official liaison" with the CEN/ISSS activity, and has worked extremely closely within the IEEE group, so in actuality there is less divergence than the presence of several groups might suggest. It should also be noted that IMS, CEN/ISSS and the LTSC are all "open" initiatives that welcome participation from whoever is willing and able to contribute. A notable example of this collaboration is the significant contribution made by the European Union project ARIADNE to the LTSC metadata specifications, which also built on the Dublin Core metadata specifications [Dublin Core Metadata Initiative]. It therefore seems probable that the "de jure" standards eventually ratified by the LTSC will incorporate specifications from IMS and CEN/ISSS, as well as other sources.

3. The Role of Standards

It needs to be clear however, what role technical standards are intended to play. Essentially their function is to enable communication between all the various pieces of an integrated learning technology solution. A key function in the new scenario is that of learning management. This provides support for the learning process as it takes place, and is distinct from, for example, student enrolment, student fee and student record systems. However it critically needs to communicate with these functions, so standards are needed to enable the exchange of information about class enrolment, access permissions, and outcomes. A learning management system also needs to provide learners with access to appropriate online resources. These range from simple web pages, through software packages to complex online systems, such as databases and simulations. It therefore needs to communicate with metadata systems which describe a whole variety of learning resources, with a content server, with test systems and with student learning profile systems. Again both the format of the data and the method of communicating it needs to be defined. There are several other areas that also need to be defined to enable groups of learners to collaborate, and for information about groups to be exchanged. Running through all of these are issues of security and eCommerce for which efforts are also underway.

Stepping back from this, and remembering that the standards efforts are aimed at effecting communication between systems, it becomes clear that such standards do not specify what should be happening inside these sub-systems or even the kinds of system that emerge from their use. It is especially important to recognise that the standards are not intended to specify or in any way constrain the pedagogical approach taken by the author of a learning resource, nor the user interface adopted. To illustrate this, two contrasting systems are outlined, both of which could make use of the same specifications.

The first focuses on the delivery of content and automation of testing as the primary aim. The role of teachers and subject experts here becomes one of content and test creation. They work as part of a multi-skilled production team including psychologists, UI designers, graphic artists, animators, programmers and AI experts. Learners pass through online systems which elicit their learning goals, test their current knowledge and skills,

and provide them with appropriate learning programmes which they then work through, taking tests at the end or along the way which either cause remedial alternatives to be offered, or add to an accumulating score on the way to an electronic certificate.

In contrast to the first system, where communication between teacher and learner is programmed out of the learning loop, the second system seeks to enhance this communication and add in peer communication between learners. There are still resources available or to be searched for as the need arises, but in this system learners are enabled to determine and undertake collaborative projects. The emphasis in this system is to minimise time-consuming routine tasks, allowing teachers to focus on the unique value they add which is to understand the complexities of the subject and of the learners, helping them develop new conceptual structures and overcome mental blockages, often through identifying misunderstandings, to convey insights and enthusiasm.

4. Costs and Benefits of Adopting Standards

From these examples it becomes clear that there are no simple cost/benefits to be derived from the adoption of learning technology standards. In each case the impact and demands on the various stakeholders is different, and we need to bear in mind that these are just two of a range of possible ways in which learning technology and learning technology standards can be harnessed. It depends on the nature of what is being taught - the first of the above examples being better for factual learning within an existing conceptual framework and for developing skills; the second for helping learners integrate new understanding and possibilities, developing their abilities to work in teams, to analyse and devise ways of dealing with new problems, etc. It also depends much more on what vendors choose to support within the learning management systems they offer, and how easy or difficult they make it to perform the tasks involved in various different approaches to learning.

Nevertheless, the success of any standards depends upon the willingness of the relevant stakeholders to adopt them. This in turn requires that these stakeholders can see an attractive costs/benefits ratio; i.e., that they can see significant benefits in adopting the standards and that the costs of doing so will not be too onerous. It is therefore worthwhile to attempt to identify these costs and benefits even though, as we have seen, it is not always a straightforward task. The set of stakeholders can be broadly characterised as learners, teachers, resource developers, technology vendors and academic institutions. This section attempts to outline the costs and benefits of adopting technical standards for educational technologies, for each of these stakeholders.

3.1 Learners and Teachers

The benefits to learners and teachers have already been enumerated in earlier sections of this paper and will not be repeated here. As for costs, it is difficult to see any real costs at all. As in other areas, a standards-enabled educational market place is a win-win situation for the consumers.

3.2 Resource Developers

It takes an enormous effort and a great deal of human resources to produce a high quality learning resource, whether it is a multimedia presentation or a collaboration-enabling device. Large, monolithic resources have not, in general, proved successful, largely because it is difficult to produce a large resource in which all parts fit well with the teaching and learning styles of many different teachers and learners. Modular, interoperable learning resources can greatly alleviate this problem by allowing teachers and learners to “pick and mix” their resources from diverse sources. This greatly enlarges the potential market for resource developers, whose standards-enabled, interoperable resources can be used in a much wider range of scenarios, and on a much broader range of platforms, than is currently the case. With regard to costs, there are some implications for resource developers. One example is the requirement to understand the standard metadata schemas and to make their metadata conform to these schemas. The more technical issues (e.g., of courseware interoperability) should be taken care of by the tools used to develop the resources, and so are the concern of the technology vendors.

3.3 Technology Vendors

Just as resource developers benefit from a market that is enlarged by the existence of open standards, so do technology vendors. Developers of educational resources currently have to make decisions about which tools to use, based on which tools target their chosen platform, and what other tools and systems can utilise the outputs from the tool under review. This means that technology vendors are currently competing in small fragmented markets. In a standards-enabled market, these fragments coalesce into a larger more unified market, as technology vendors ensure that their tools can be used alongside all the other standards-compliant tools. There are very real costs for technology vendors in adopting standards however, as they must re-engineer their products. Those vendors who join in early with the standards building initiatives will have a definite edge when it comes to selling their products in the new standards-enabled market.

3.4 Academic Institutions

The benefits to academic institutions have also been described in earlier sections of this paper and will not be repeated here. Of course, implementing the necessary gateways to enable the exchange of standardised student related information will require investment by the institutions, but those managers who see this in negative terms will have to consider the cost (of isolation from the global education marketplace) of not making this investment.

5. Conclusion

The potential of educational technology for transforming the educational market place is immense. Learners can be empowered, access can be extended, teachers can be even more creative and can “reach” many more students than before. But the world-wide university is not yet a reality! The vision will only be realised when an effective set of technical standards have been adopted which enables educational resources to be located, obtained and integrated, and student information be transferred between institutions, real or virtual. As set out early on by IMS, learning technology standards should not dictate what is taught or how, but rather should be generic and inclusive enough to support a wide range of pedagogies. This is a very useful touchstone for judging learning technology standards, and is crucially important in terms of the longer term development of learning technology. We are at a very early stage of the use of information and communications technology to support the teaching and learning process. Everyone recognises that it offers great potential but that it is yet to be harnessed. As we learn how to do this, the technology will become better adapted and the teaching and learning process will change - probably in a variety of ways. We are at the beginning of a long journey.

Implementing Virtual Robots in Java3D using a Behavior Based Architecture

Nathan Smith, Christopher Egert, Elisabeth Cuddihy and Deborah Walters
Department of Computer Science and Engineering
State University of New York at Buffalo, Buffalo NY 14260-2000 USA
{npsmith,egert,ecuddihy,walters}@cse.buffalo.edu

Abstract: New web-based technologies for 3D graphics such as Java3D provide tools for creating autonomous virtual reality agents for educational, entertainment, and simulation software. Such agents need to be responsive and reactive to their environment in order to maintain a steady appearance of behaviors. A behavior based architecture from robotic agent control literature, can provide the basis for these requirements. This paper discusses issues in the design of a virtual reality robot implemented in Java3D and the problems that may be encountered with 3D platforms that provide virtual reality development environments. The virtual robot we describe is able to successfully perform a set of behaviors within its environment. Virtual sensors and actuators are implemented within Java3D, allowing the virtual robot to sense and interact with its environment. Overall performance of the system is taken into consideration.

Introduction

The potential for creating interesting virtual reality based agents has become more feasible with the introduction of various high-level 3D graphics standards for web-based applications. Virtually-embodied autonomous agents can be created using these tools for education, entertainment, and simulation software. The difficulty in creating such agents is providing a robust control architecture which is capable of maintaining the appearance of continuously believable, life-like behavior. An interesting autonomous agent needs to be responsive and reactive to its environment. Furthermore, it should select actions that appear intelligent with regard to its situation. This poses the problem of how to create an autonomous agent that “thinks fast on its feet.”

Much work in robotic control architecture research has been devoted to creating fast, reactive agents that are capable of responding to their environment swiftly and in a manner that appears intelligent. The subsumption architecture [Brooks 1985, 1990] and later developments in behavior based architectures [Maes 1994] were specifically designed to create a reactive control system for mobile robots. The subsumption architecture is a computational architecture that allows tight coupling of perception to action via a substrate of computational incremental layers. The substrate consists of networks of augmented timing finite state machines [Brooks 1990]. Thus, the agent is defined by a set of behaviors it exhibits and by the relationship between those behaviors. The appeal of this architecture is that it doesn't rely on planning or complex internal knowledge representation in order to make decisions on what to do next. Instead, the control architecture continuously selects actions for the agent to perform based on the agent's immediate perceptions of its environment and on the agent's current internal state. This allows the agent to react to its environment and provide a steady appearance of life-like behavior.

Using virtual reality to develop such a control architecture is quite advantageous even though behavior based architectures have seen little use in applications involving virtual, rather than physical, robots. Virtual robots can be rapidly and inexpensively reconfigured to create new ones. Similarly, environments can quickly be redesigned to embody different sets of interconnections. Virtual sensors can be created to provide different sensory experiences, such as image capture and processing as a virtual analog to video capture and analysis techniques currently being explored at a hardware and firmware level [Lorigo 1997]. Brooks has argued against the possibility of an adequate simulation of a physical system claiming that complex agent behavior is a reflection of a complex environment and that virtual reality is not rich enough to provide this level of stimulus [Brooks 1992]. Although this viewpoint is valid for the development of real world robots, if an agent's purpose is to ultimately function within a virtual environment, then the most appropriate place for its development is in virtual reality.

This paper describes issues in using Java3D to develop a behavior based architecture similar to Brooks' subsumption architecture for controlling a virtually embodied, rather than physically embodied, autonomous agent. We describe the implementation of a virtual reality robot with insect-like behavior. The virtual robot is designed to

incorporate a simple set of behaviors that enables it to wander freely on a playing field but never wander off of the field, avoid other objects while wandering, and return to a nest area after wandering for a sufficient amount of time.

VRML vs. Java3D

In order to concentrate on the behavioral design issues of the agent, it is desirable to use a high-level development framework. Using higher-level abstractions, such as Java3D or VRML is advantageous because they facilitate strong project design. These languages are also attractive because they facilitate an object-oriented approach to design. After making the decision to use a high-level 3D platform for a virtual environment and virtually embodied autonomous agent, it is important to choose one that would support the implementation of the behavior based architecture. Most particularly, the platform needs to support simulated sensory devices and simulated robotic actuators. Two packages worth consideration are the Virtual Reality Modeling Language (VRML) [VRML 1997] and Java3D [Sowizral 1997].

VRML's main advantage is that it is currently the de facto standard for web based 3D visualizations. VRML allows for easy definition of geometric shapes in hierarchical groupings and it also provides many advanced 3D graphics functions such as lighting models and surface materials. VRML allows for simple interactions between a user of a virtual world and the various objects within the world, such as clicking on an object to activate an object's script. VRML is currently well supported with various end-user browser and modeling programs, simplifying the task of both creating and viewing virtual worlds.

There are, however, numerous difficulties in using VRML as a basis for a virtual world that can support interesting autonomous agents. The first problem is the lack of a mature collision handling mechanism within VRML. Although VRML supports collision handling between the user's viewpoint and the scene objects, there is no support for object to object collisions. This creates a serious limitation when trying to implement virtual touch sensors for a VRML-based agent that is viewed from a third person perspective. The second problem with VRML is the relationship between the virtual objects and the VRML browsers. VRML is only a scene description language. In order to create a complex and dynamic environment with VRML, it is necessary to use the Java External Authoring Interface (EAI) [VRML 1999] to programmatically control the visual representation of the environment. Originally developed as an addendum to VRML, EAI does not have a tight enough coupling between the user and the browser to extract useful runtime information about either. Although it is possible to use EAI to determine property and coordinate information about objects in a scene, it is not possible to determine the user's viewpoint or to capture graphical frames from the point of view of a simulated visual sensor.

Java3D provides a purely object-oriented language-based approach for designing 3D systems. Built as an extension to the Java language, Java3D offers a high-level Application Programming Interface (API) for 3D scene description and graphical control. In this sense, it offers some of the same advantages of VRML while also providing tight integration with a fully capable programming language. Furthermore, because it is a Java API, Java3D allows for a fully object-oriented approach to defining and controlling the virtual agent, and its environment. It is capable of providing better integration of three-dimensional content, interface and events within the system. Java3D's sophisticated event model allows for interesting object interactions, such as object to object collisions, as well as a unified interface between timer and scene change events. Java3D is also designed to take advantage of multi-threaded programming techniques, allowing for better performance from the implementation.

Although Java3D provides better mechanisms for the construction and control of a virtual environment, it does present some difficulties. The relative newness of Java3D versus VRML along with its complexity means that development of a system would have to include appropriate measures to train developers in Java3D's use. Also, due to the lack of 3D modeling programs capable of exporting to Java3D, initial environment designs would be simplistic. Java3D also suffers from a lack of support within web browsers. Many of these difficulties are problems regarding technical and implementation issues and are rapidly being overcome. The release version of Java3D includes support for VRML models within a Java3D scene as well as Java plug-in support to include Java3D applets on the web.

Java3D VR-Bot Design

Two different approaches can be taken in the design of the virtual robot using Java3D: event-based and thread performance-based. The first is a strong object-oriented model with object-level event handling. This

approach may be taken in order to support hierarchical component abstraction within the system. At the highest level, separate objects encapsulate the functionality of the environment, obstacles on the field, and the virtual robot. This functionality includes methods to retrieve object status and to enact object actions. Any object in the scene is instantiated as a specialized case of a general base object. The virtual robot's construction consists of several sub-objects, including the body, sensor array, individual sensor elements, event handlers, and a visual platform binding for first person navigation of the world. The strong object-oriented model allows for easy reconfiguration of the virtual robot at the base class level and it also provides a useful learning tool, as many are only familiar with physical implementations of behavior based architectures and not Java3D. This model separates the virtual robot from its intermediate control layers, allowing development of different layers to proceed separately.

Although the object model's abstraction does prove advantageous for visualizing the hierarchy and dependencies within the system, it is less than optimal with regard to performance. This could be attributed to non-optimized event handling from the Java3D event system. The abstractions of individual handlers tend to be counterproductive to performance, and the dependency on events does not encourage the exploration of multi-threaded designs. In order to counter these effects, the second approach focuses on the development of a robust thread model to achieve a higher degree of parallel and asynchronous activity. The advantage of this new model is that more reliance is placed on native Java threads that can be managed and optimized manually, rather than Java3D threads to which application programmers have no access.

The major components of this model are the environment, the sensors, the behavior based control architecture, and the robot. The control architecture receives, as input, signals from the sensors whose states change as the environment changes. Signals coming out of the control architecture are interpreted as commands to move the robot around in its environment. The environment consists simply of a few elements: a field, a set of obstacles, target regions, and a set of perimeter markers. The obstacles are there to test the robot's obstacle avoidance behavior, and the perimeter markers are there to test the robot's penning behavior. The robot's obstacle sensors are sensitive to every obstacle on the field, and whenever an obstacle is in a sensor's range, that sensor is made active. Any sensor whose field is empty of objects to which it is sensitive remains inactive. Similarly, the robot's perimeter sensors are sensitive to all the perimeter markers, and their activity status depends on the presence of perimeter markers within their range.

The behavior based architecture itself consists of four behaviors: a wandering behavior, a penning behavior, a homing behavior, and an obstacle avoidance behavior. The wandering behavior's output directs the robot to randomly explore the field, the penning behavior keeps it from wandering off the field, the homing behavior causes the robot to return to a particular location, and the obstacle avoidance behavior keeps it from colliding with obstacles.

The wandering behavior has no input, since arbitrary wandering doesn't require any information. This behavior chooses a direction and then moves in that direction for a random amount of time. After that time runs out, it chooses another direction and starts over. The penning behavior has access to the perimeter sensor array. It polls these sensors, and whenever any of them becomes active, it maneuvers the robot directly away from the vector sum of all active sensor regions. Since only perimeter markers can activate these sensors, this has the effect of moving the robot away from the perimeter when it gets too close. The homing behavior also has access to the perimeter sensor array. When activated, this behavior causes the robot to move in a straight line until it encounters the field perimeter. It then follows the perimeter until it reaches a home station. This behavior would be useful if the robot was collecting objects and depositing them at a nesting location or if the robot had an energy source that needed recharging at a home station. The obstacle avoidance behavior operates in an almost identical fashion as the penning behavior behaves. Whenever any of the obstacle sensors become active, it maneuvers the robot in a direction that is slightly different than directly away from the vector sum of all active sensor regions. A slight random variation is added to this direction because of a special case. If the robot were to wander into a position directly between two obstacles, the obstacle avoidance behavior would calculate their vector sum, find it to be zero, and tell the robot to stand still while suppressing the wandering behavior. Thus the robot would be trapped in that position indefinitely. The random variation in direction assures that the obstacle avoidance behavior isn't continuously telling the robot to not move.

Technical Considerations

The development of this system has brought to light some Java3D issues and difficulties Java3D programmers are likely to face. Foremost of these is a problem involving collision detection. In the current implementation of Java3D, collisions can trigger events. The event model can report the initial entry of an object into a collision state, the removal of an object from a collision state, and the continuance of an object involved in a

collision. One of the limitations occurs when two objects are in a collision state and a third one enters. Currently, the Java3D implementation will not indicate that a new collision has occurred. This problem has a direct impact on the implementation of our touch sensor since the use of a single sensor object can not indicate that multiple collisions has occurred. This makes it difficult to determine whether an object is in a sensor's field or not when many objects are moving in and out of it. In order to eliminate this problem, two measures must be taken. First, the sensor region must be divided in into smaller sub-regions, each to be allocated a smaller sensor. This decreases the likelihood of more than one object passing through a sensor region at a time. The quantity of sensors, configuration, and granularity can be adjusted in order to examine the capabilities of the sensor array. Second, each sensor contains information as to what objects in the scene it can sense. After any collision event, a sensor checks to see if it is intersecting any of the objects to which it is sensitive. This extra computation is expensive, and if this multiple collision issue isn't resolved in new releases of Java3D, it could very well defeat the purpose of using Java3D's own collision detection.

Java3D's collision model introduces another difficulty to agent development. Currently there is a lack of separation between the collision engine and the render engine. In the design of a system, it is desirable to defer as much of the interaction with the environment to the Java3D package. This allows Java3D to handle object collisions, since it can perform these operations in a device-independent manner. Although using these pre-built mechanisms simplifies the design task, it does not provide for an optimal model. The difficulty lies in the fact that the current Java3D implementation can not perform off-screen processing. This problem means that the limiting factor for an implementation is the speed of the graphics accelerator, as collision detection and object manipulation require that objects be physically painted to a display device. Not only does this create a bottleneck for simulation, but it also implies that a dynamic world can not continue to operate without a viewer present. To date, we have tested our implementation on two platforms: a Pentium II 300 system with a Matrox Millenium II graphics accelerator, and a Sun Sparc Ultra 60 with a Creator 3D option. On both platforms, profiling indicates that even though simulation timing is controlled by timer events, the graphics pipeline speed creates a ceiling for the computational speed of the system. It is our recommendation that current discussion in the Java3D interest newsgroup [Java 1999] continues to treat off-screen rendering as a high priority in the next release.

Another important consideration in the development of an agent is that of interface and view perspective. During the development process, it is often very important to gain different visual perspectives of the environment. It is sometimes necessary to maintain an overhead view of the simulation field in order to view movements. It is also important to view the profile of the field in order to view collisions and representation issues. In other circumstances, such as simulating visual systems, it would be important to create a view from the perspective of the virtual robot. In order to support these different views, a generalized viewing model for the world must be implemented. The basis of this model includes a viewpoint bound to a null geometry, to act as a "disembodied" point of view. The null geometry of the viewpoint could either be bound to an event handler, such as a keyboard event handler, or to a portion of a pre-existing geometry. By generalizing the interface, one may switch between various perspectives, allowing for both first person and third person visualizations of the world with respect to the virtual robot.

Conclusion

At present we have constructed an autonomous agent that is capable of displaying interesting, reactive behavior in Java3D using a behavior based architecture [Fig. 1]. Using this implementation we are able to demonstrate Arkin's action selection and avoidance algorithms for behavior based agents [Arkin 1998]. We also plan to use it to evaluate Goetz's recurrent behavior networks [Goetz 1997].

Java3D and the Java language platform are in a state of evolution, and many of the difficulties currently encountered due to the language are already scheduled to be addressed in future releases. Java3D provides for many of the elements required by simulated robot systems, including physicality through representational geometry, sensors through event handlers, and action via dynamic changes to the scene graph. Java3D's evolution means that it will be able to address the needs of web based 3D visualizations as well as handle the needs of distributed graphical simulations. Already, there are signs that both of these issues are being addressed, even in a limited fashion. As of this writing, Java3D applications can be run as Java applets over the web via the use of Java plug-in as part of the Java 2 runtime environment. Additional research into the use of distributed Java3D has been stimulated by groups working on shared data abstractions for Java, including the JSDT Development Project at SUN Microsystems [Burrige 1999].

Not only is Java3D appropriate for interests in artificial agent research, but it serves another purpose in that it allows developers to present their work in a manner that is easy to understand. The power provided by Java3D can give a student enough visual stimulation and interactivity to more effectively learn about the nature of behavior based architectures than through a less complex two-dimensional model. The idea of complex emergent behaviors can sometimes be difficult to grasp, but this system is capable of showing students the simplicity of the control architecture's components as well the complexity of the behaviors they produce. Also, Java3D immersive experiences can allow researchers to obtain more insight into their own systems.

There is still much that can be done with this implementation. More behaviors could be added to the control architecture to give the robot a richer set of behaviors. Noise could be added to the sensors in order to test the robot's tolerance for bad data. Also, different behaviors for the architecture could be engineered to fail arbitrarily in order to view the effect such a situation would have on the robot's performance. Due to the virtual nature of this testbed, all of these changes could easily be made, and the effectiveness of the simulation would clearly show any results.

Figure 1: Virtual robot in its environment. The robot (sphere surrounded by six translucent sensor regions) is avoiding obstacles and navigating to fixed positions (circular pads) within the environment.

Abstract: The World Wide Web has become the new shopping medium for many businesses and industries. This paper discusses the current and possible future trends related to international consumer and business to business electronic commerce.

Introduction

The easing of commercial restrictions of the Internet in the 1970's and the evolution of the World Wide Web in the 80's and early 90's has set the stage for the next phase of the Internet: E-Commerce. E-Commerce can be defined as business transactions based on the electronic transmission of data over communication networks such as the Internet (Dryden 1998). It is the communication network and the affordability of such systems that is driving the expansion of E-Commerce, especially in the United States.

Two types of E-Commerce dominate the electronic landscape, consumer and business to business or B2B. Consumer E-Commerce gets more press and attention than business to business, although business to business E-Commerce makes up 80 percent of E-Commerce revenues. This paper discusses the important current and future trends of that affect global E-Commerce.

Who's on-line now

Internationally there are over 100 million Internet users. Approximately 60 million of the connected use the Internet on a daily basis for work, entertainment, shopping, and research. As you can see from chart 1, Internet users from the United States make up 53 percent of the world wide total and 90 percent of all internet users come from only 13 countries, primarily from western European nations. The United Kingdom (UK) and Germany make up 50 percent of all Euro users.

Chart 1: World Wide Internet Users

According to Henry Heilbrunn, European acceptance of the Internet can be broken down into five levels: 1. highly advanced, 2. coming on quickly, 3. muddling through, 4. not sure because of infrastructure, and 5. emerging. The northern European countries such as Scandinavia are considered to be highly advanced due to a high adopter rate and more centralized Internet planning. The UK and Holland are considered countries that are coming on quickly. UK users make up 30 percent of all Euro connections. In these second level nations the Internet is becoming a true form of mass media. It is predicted that by the year 2000, 50 percent of all people in the UK will be connected. Due to their size and lack of focus France and Germany are considered to be third level countries. In these countries national monopolies for telephone service are making connection financially out of reach for many. In addition to the customary Internet service connection charge, all phone calls are charged on a per minute basis ranging from an equivalent \$1.60 - \$3.00 / hour. Consumers are so frustrated by the rates that the Association of Unhappy Internauts organized a 24-hour strike in December of 1998. France has also refused to embrace the Internet because of its investment in its antiquated online system Minitel. The French make up only 2 percent of Euro Internet users. The fourth and fifth level countries are primarily southern and eastern European countries.

Five million people in Asia are connected, this number is expected to grow to 10 million by the year 2000. Asian weakness in the Internet community can be attributed to three factors according to Foley (1998): 1 low PC ownership in Japan, 15 percent, 2. China's worry over the Internet as a conduit of politically sensitive material, 3. high poverty levels in many Asian countries. Some commentators suggest that America may be reaching its saturation point, opening the door for Euro and Asian dominance in growth and eventually the Internet market.

Demographic Profile of EC Consumers

The United States is regarded as the earliest adopter of the Internet, subsequently the majority of the web pages on the net are in English and the majority of business is conducted in English. Internationally the majority of users, 77 percent, come from Ireland, UK, Canada, United States, New Zealand, and Australia.

Internationally, Internet users have been predominately young, well- educated, professional, and affluent males. This trend is beginning to change and Internet populations are beginning to be more representative of the entire population. In the United States and Britain, countries leading the way of more representative populations on the Net, female users make up approximately 37 percent Net subscribers. Elsewhere in the world males make up 80 percent of Net users, in Japan 90 percent of the users are male (NOP Research Group 1997). The average age of Internet users in the U.S. and Europe is between thirty and thirty-five years old. As more users come on-line the average age will begin to mirror the general population. Internet households are typically more affluent than the general population, the average income of an Internet household in the U.S. is \$55,000 whereas the average U.S. household income falls around \$42,000 (Diamond 1997).

Consumer E-Commerce

In 1998 16.8 million American Internet users made at least one purchase on-line. This is 31 percent of all Internet users and 7.8 percent of all Americans 14 and over (eMarketer 1998). Predictions for the 1999 on-line commerce season from the E-Commerce Retail Shopping Report indicate that the number of on-line shoppers will double to 36 million buyers or 16.6 percent of the U.S. population 14 and over. By the year 2002 it is estimated that on-line shopping will swell to 64 million on-line shoppers in the U.S. or 28 percent of the population 14 and over.

World wide, consumer on-line shopping revenues are expected to rise from 1.7 billion dollars in 1997 to more than \$35 billion dollars in 2002 as represented in chart 2. In 1998 the United States accounted for more than 84 percent of worldwide E-Commerce. Predictions indicate that U.S. market dominance will begin to shrink as Europe becomes more Internet E-Commerce connected. If current E-Commerce trends continue the U.S. international market share will shrink to 77 percent by 2002.

In 1998 on-line shoppers in the UK spent 406 million pounds buying goods and services on the Net. This represents 0.2 percent of all UK retail sales, it is expected that UK shoppers will double that amount in 1999. The Verdict report predicts that within five years more than 6 billion pounds worth of goods will be sold over the Internet representing 2.5 percent of all UK retail sales. In 1997 Internet sales in France were almost non-existent, they were in more of an experimental stage. In 1998 more than 50,000 Net shopping sights emerged and French shoppers spent more 3 billion francs (US\$84 million) this up from 1.2 billion francs (US\$212 million) in 1997. According to Suzan Nolan of Bluesky International the Europeans are waking up to the potential of the Net not only in terms of profit potential but also in protecting their markets against the American invasion.

Chart 2: Consumer Online Shopping Revenues

Far more people are using the Internet to assist in making purchasing decisions than actual buying. These “window shoppers” are 33 million strong and use the Net to compare pricing, features, warranties and etc. The question facing Net sellers is how to capitalize on those window shoppers. The interest is there, the next step is convincing people to buy.

Consumer E- Commerce in the U.S. and internationally is on the edge of what may be the first boom of the 21st Century. Electronic commerce at the retail level is fueled by three interrelated “A” factors: Access, Acceptance, and Advantages (eMarketer 1998). Access refers to the number of people connected and it places the upper limit on participation. The number of Americans connected has been steadily increasing over the last decade, whereas the international market is where the U.S. was about five years ago. Access will increase as communication networks, PC technology, and modem technologies become more affordable and efficient. Acceptance refers to the changes in perception, attitude and behaviors related to the Internet. For acceptance to occur people must feel secure in their use of the Internet as a shopping center. On-line users must know that their transactions and personal information are secure. The bandwidth must be available to make the shopping experience an enjoyable and realistic one through the use of richer presentation and demonstration techniques of the goods and services on-line. As people encounter more positive shopping experiences on-line the trust factor of buying on-line will rise as the fear factor decreases. Advantages of e-commerce relate to real and perceived benefits of shopping on-line versus traditional shopping methods. For the advantages to be apparent on-line retailers must ensure that shoppers easily recognize how convenient it is to shop on-line and there are significant benefits for doing so. This may include consumer-centric shopping malls that help with and enhance comparison-shopping, choice, and convenience. As more countries come on-line it is expected that the shopping experience will become a global one increasing the advantages of shopping on-line with more choices. With the expansion of goods and services being available it is also important that more sophisticated front and back end as well as more reliable delivery systems are in place to ensure increased convenience and reliability of shopping on the Internet.

What’s Selling On-line

Goods and services selling on the Net can be broken down into seven major categories: 1. Computer products, 2. Travel, 3. Entertainment, 4. Apparel, 5. Gifts and flowers, 6. Other (eMarketer 1998). Computer products, software and hardware, are the most popular products for on-line shoppers. As chart 3 indicates between 1996 and 1998 on-line consumers spent more than \$1.1 billion on computer related products. It is predicted that by the year 2000 on-line consumers will spend more than \$2 billion on computer related products. Travel is the second most popular service on-line accounting for more than \$570 million in on-line sales in 1998, revenues are expected to rise to \$1.5 by the year 2000. Entertainment revenues in 1998 totaled \$420 million and are expected to increase to \$1.2 billion by 2000.

Projected Online Shopping Revenue by Category, 1996 - 2000					
	1996	1997	1998	1999	2000
Computer prod.	\$140	\$323	\$701	\$1,228	\$2,105
Travel	126	276	572	961	1,579
Entertainment	85	194	420	733	1,250
Apparel	46	89	163	234	322
Gifts & flowers	45	103	222	366	658
Food & drink	39	78	149	227	336
Other	37	75	144	221	329
TOTAL	\$518	\$1,138	\$2,371	\$3,990	\$6,579

source: Forrester Research

Chart 3: Projected online shopping revenues between 1996 and 2000.

When shopping on-line how much money do shoppers spend at one time? According to Foley's (1998) survey of Web shoppers in 1997, 36 percent spent less than \$10, 20 percent spent between \$10 and \$99 and 29.5 percent spent over \$100 on Web purchases. Driving the on-line purchases is convenience, shoppers indicate that the lack of crowds, 24 hour shopping, and not having to wait in line were the major reasons that they had turned to on-line purchasing.

B2B Commerce

Business to business electronic commerce (B2B EC), the very big brother of consumer electronic commerce, does and will continue to rule supreme in the E-Commerce universe. In 1998 consumer E-Commerce totaled \$4.5 billion world wide, B2B EC generated \$18 billion worldwide. B2B revenues are expected to top \$32 billion internationally by the end of 1999. Consumer E-Commerce is expected to rise to only \$8 billion in the same time frame.

The United States is the dominate force in the B2B arena, in 1997 the U.S. accounted for \$4.7 billion of the \$5.6 billion generated world wide. In 1998 the gap widened even further with the U.S. generating \$12.5 billion in revenues compared to the \$3.4 billion generated by the rest of the international market. According to eMarketer (1998) the U.S. will continue to dominate B2B E-Commerce through the year 2001 as demonstrated in chart 4.

Chart 4: Projected global business to business electronic commerce growth by the year 2002.

It is estimated that the U.S. will generate revenues in excess of \$22 billion in 1999, \$52 billion in 2000, \$87.9 in 2001. International revenues are not expected to exceed U.S. revenues until the year 2002. eMarketer predicts that the U.S. will generate \$131 billion in revenues and the International market will generate \$136.9 billion.

Business involvement in B2B E-Commerce falls on a continuum ranging from being connected to the Internet to maintaining an active, purposeful web site, and finally to engaging in electronic commerce (eMarketer 1998). At the farthest end of the continuum, business involvement in actual electronic transactions is still very much dependant on the size of the business. As can be seen in chart 5

Stage III: Percent of Business Type Conducting Sales Online	
Small (under 100 employees)	1.8%
Medium (100 - 1,000 employees)	12%
Large (1,000+ employees)	38%
Total = 100%	

Source: eStats

Chart 5: Types and percentages of businesses conducting sales online.

38 percent of “large” businesses are involved in some form of electronic transactions, this drops to 12 percent of “medium” sized businesses, and is only 1.8 percent of “small” businesses. A lot of this can be attributed to the set-up costs. In 1999 Staples (the office supply super store) is planning on spending \$10 million on personal, technology, and marketing to develop a strong B2B web presence for the purpose of conducting on-line sales. It is interesting to note that their budgeting decision is based upon the surge of small businesses being online (the first stage on the B2B continuum). Most small businesses have been taking a “wait and see” attitude in regard to the Internet. As larger businesses have shown the benefits of B2B E-Commerce it is expected that more small businesses will see the advantages of making the initial investment. 1999 is expected to be a very large growth year for small business involvement in B2B E-Commerce by many market analysts.

E.C. Controls

Leading companies from around the world have argued that the Internet should be a self-regulation zone for the time being. In 1995 the Federal Trade Commission called for self-regulation among Web marketers (Bayne, 1998). What has most Internet users worried is the right to privacy, what information can be collected and how it can be used. To avert legislative regulation 50 companies have formed an alliance to promote and set standards that would govern commercial behavior on the Web. Microsoft, Hewlett-Packard, America Online, IBM Corp are the companies spearheading the alliance that has agreed to create privacy guidelines. By introducing and following guidelines many in the industry feel that it would boost public confidence in E-Commerce. The goals of self-regulation would include making sure that the public knew about the regulations, that companies comply with them, and customers would have an avenue available to them in addressing injury resulting from non-compliance.

On the tax front, according to a Forbes report the Internal Revenue Service is very concerned over new encryption software and the creation of electronic money, making it difficult to follow the money trail. In a Department of Treasury document entitled “Tax Policy Implications of Global Electronic Commerce” it is suggested that taxpayers would be required to obtain a digital identification number that would allow the IRS to track electronic transactions and minimize the potential for tax evasion. Another major concern for E-Commerce is that of state and local taxes. It is conceivable that as a transaction bounces across the Internet it could be taxed along the way as it passes through states, cities, and counties. Instead of lobbying for a no tax policy for the Internet, corporations have opened dialogue with states to work on an equitable tax formula. The focus is to create a tax system according to Interactive Services Association that is “uniform, consistent and fair.”

Summary and Implications

What’s in store for E-Commerce in 1999 and beyond? According to eMarketer (1998) the World Wide Web will truly live up to its name, it is predicted that by the end of the year the number of international Internet subscribers will out number the number of Americans on-line. Their prediction is that the Net population will be 110 million, 56 million residing outside of the U.S. 1999 will be the year of the small business on-line. The middle to large corporations have broken the ice in the B2B arena, leaving a clear and clean path for small businesses to follow. Small business E-Commerce revenues will rise just over 6 percent, giving small business 30 percent of the

E-Commerce market by 2000. Hyperintermediation will be the magnet that brings buyers and sellers together in a mall like atmosphere. As the first of these sites catch on it is predicted that more and more will pop up. These intermediaries will provide shoppers with what they want, convenient and trustworthy one-stop shopping. Although consumer E-Commerce will expand B2B E-commerce will continue to be king of the hill. B2B revenues are expected to top \$32 billion by the end of 1999, consumer revenues will top out at \$8 billion. To draw the window shoppers into the E-Commerce fold, customer service will be the number one goal of E-Commerce retailers. Speedy delivery, accurate billing, on-line service will be the focus to earn the trust of on-line shoppers. Security questions and concerns will be answered; technologies are advancing at a pace that makes giving out your credit number over the Web safer than giving it out over the phone or counter. By the end of the year over 60 percent of all Internet users in the U.S. will have made at least one purchase on-line, this will be an increase of 27 percent over a year ago.

What implications does the expansion of E-commerce have for higher education? An obvious implication is it is increasingly important that students become Web-savvy. They need to be able to conduct effective and efficient searches utilizing the Internet. In addition, they need be familiar with business uses of the Internet including basic web page design and creation. A not so obvious implication is that exposure to International curriculum (including business, marketing, finance, culture, and humanities) will need to be a part of the core curriculum, not an elective choice. E-Commerce will break down geographic and financial barriers that have limited International trade to larger companies with more resources. Even the small mom and pop business can become involved in International markets using the Internet as their distributor.

"In only five years, the world wide web has emerged as a new channel for consumer shopping which will fundamentally change not only where people buy, but also how, how often, how much, when, what and even why" (eMarketer). "Electronic commerce is set to be one of the driving forces behind the global economy. It is a potentially positive force, which can improve the ways people participate in society as citizens, consumers, workers, and entrepreneurs"(Dryden, 1998).

A VRML and Java-Based Interface for Retrieving VRML Content in Object-Oriented Databases

Ingo Soetebier, Ralf Dörner
Fraunhofer Institute for Computer Graphics
Darmstadt, Germany

Norbert Braun
ZGDV Computer Graphics Center
Darmstadt, Germany

Abstract: Storing VRML and VRML-related content in an object-oriented database enables VRML scene authoring with reusable components. A 3D metaphor is designed to search and retrieve these components. The 3D metaphor is realized using VRML and Java. As the 3D interface is integrated in the same VRML scene an author currently has under construction, the query results may be presented in this scene and may be seamlessly used by the author. To achieve this goal, VRML-related content needs to be represented in an object-oriented database. Furthermore, the communication with the database is implemented using a Java applet that also provides an author with authoring features and extracts the authored scene.

1. Introduction

The specification of the Virtual Reality Modeling Language (VRML) [VRML 1997] encourages the use of components to construct complex 3D scene descriptions. There is, e.g. the EXTERNPROTO construct that allows the storage of custom-tailored VRML node descriptions in library VRML files. There is also the inline construct that allows the use of a VRML scene file to build another, more complex VRML scene file. Moreover, certain parts of a VRML scene description are stored in external files with different formats like images, textures, sounds, movies or Java classes.

Thus, a VRML scene file may be created in a fast and cost-effective way, by using predefined components and taking advantage of the benefits of reusability. This is especially true as VRML plays an increasing role as a 3D exchange format. Integrating geometry, animation, interaction behavior, multimedia and hypermedia description, VRML comprises all elements needed to author animation, multimedia applications and virtual environments.

As the number of components rapidly increase when one makes extensive usage of reusability, the problem of efficiently storing, searching and retrieving components arises. These tasks are the realm of database systems which provide solutions for data security, accessibility, consistency, concurrency, recovery and efficiency. Our idea is not only to store VRML components in databases in a suitable manner, but also to make use of VRML and Java to define the human-computer interaction between a VRML scene author and a database. The first major advantage lies in the potential for designing a 3D graphical user interface to the database and making the usage of a database transparent for the author. The second major advantage has to do with the possibility of a seamless presentation of the query results within the VRML environment. Other advantages include the potential to have a distributed, network-based VRML components library that even supports collaborative authoring by two or more authors.

The paper is organized as follows: in the next section, the problems of and requirements for storing VRML and VRML-related content in databases are discussed and the selection of an object-oriented database management system is constituted. The third section describes a suitable 3D database query interface based on VRML, while the fourth section focuses on the presentation and usage of query results. Finally, the implementation of the whole system and our experiences with VRML and Java are the topics of section five.

2. Storing VRML Content in Databases

There has been much effort in the VRML community to link databases and VRML [Walczak 1996]. Research has been conducted on how to embed database query languages like SQL in VRML, especially in a dedicated VRML working group [ET WG 1998]. There are even some applications like data warehousing [Massari 1997] or geographic information integration [Coors 1998] which utilize databases in VRML scenes. Although ways of connecting VRML to databases [Oracle 1998] have been explored (mostly using Java interfaces like the EAI and Java Script Node, as well as JDBC), far less effort has been dedicated to storing VRML itself in a database. In our application scenario, we do not want to visualize information stored in databases, but rather components of VRML scenes that may be used to build VRML scenes more efficiently.

Designing a data model for VRML content is a non-trivial task. A VRML file contains links to other files in the form of URLs. Storing a VRML file as simple text together with its associated files implies an overhead, as data may be stored multiple times. Moreover, the associated files, such as images or sounds, are of interest for VRML authoring itself and should be explicitly accessible, not just via a VRML file in which they are contained. Further, different prototype definitions in the same file should be individually accessible for the use of external prototypes.

Our solution is to parse a VRML file prior to storage. The parsing is not done on node level, it is done for extracting links to other files and prototype definitions. The information gained during parsing is stored separately and is collected in specific objects. These objects are completed with information about formats (e.g. image formats) and information used for retrieval like keywords, categories, author data, copyright information. Thus, VRML-related content is represented in the database:

1. the content itself is stored in a file system (e.g. an image file, the text that denotes a VRML scene) and
2. an object is constructed that represents meta-data about this content (e.g. the path where the content is stored in the file system, the relationship to other content, the descriptive data).

The first part, the content itself, is stored in the file system as the links to other files and prototype definitions used have to be replaced during parsing in order to retrieve the content without database queries. The database is allowed exclusive access to this part of the file system in order to guarantee consistency.

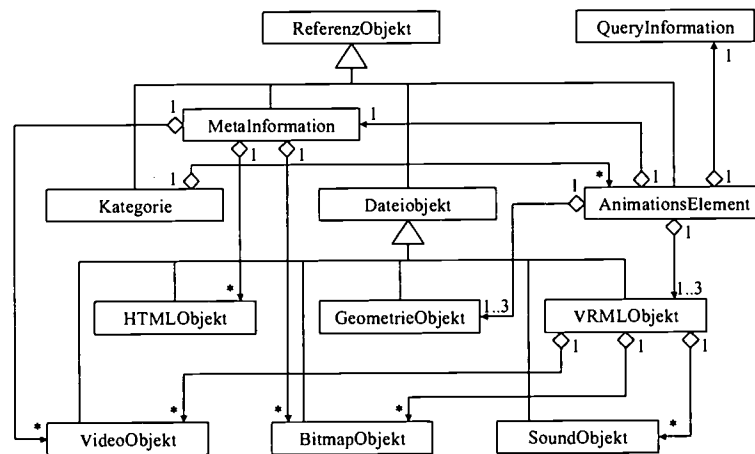

Figure 1: Database scheme (using UML [Fowler 1997])

The natural way to represent the second part, the object graph, is to use an object-oriented database and not to split it up in relations. The classes of the objects used are in an inheritance relation according to the object-oriented paradigm. This leads to the database scheme depicted in [Fig. 1].

3. 3D Database Interface

One of the advantages of VRML lies in the possibility of defining the authoring system in VRML itself. Thus, our idea is to have the interface to the component library in the VRML scene that is currently under construction. Accordingly, the design criteria for conceiving a 3D database interface are:

- Manageability – the interface should have a small, geometrical extension and thus should be handy and convenient to operate. It should be used analogous to a physical tool (e.g. a hammer) to construct the virtual world; for example, the user should be able to lay it down.
- Flexibility – the user should be able to define the search in terms of categories which are important to him. Thus, the categories should be selectable by the user. Information regarding the category in which a component falls is provided during the import process in the database (see Section 2).
- Weighting – the author should be able to express the degree of relevancy a certain category has for his current query
- Browsing – the author should be able to browse the database in order to get an impression of what components are available to him. On the other hand, it should be possible to directly access a certain component.

Considering the design criteria and the metaphors discussed above, a keyword-based approach seems to fit best. The metaphor relies on keywords and consists of two parts. First, the author selects the properties of the component he is interested in by clicking on buttons of a stick-like object (see [Fig. 2]). Steering elements can be found on the top side of the column. Using these elements, the author can initiate a query, redefine the properties he is interested in, and save property selections.

Figure 2: Interface for Property Selection

In the second step, a panel is automatically created for each property selected. The panels are arranged in a circular fashion (see [Fig. 3]) and are labeled with the property name. A dial button can be found on each panel. The dial button may be used in order to weight the relevance of each property for the user. Then, the query can be posted and the results shown beneath the circular object. The user may switch between these two interfaces in order to refine the search. Viewpoints are used in order to present the 3D interface in an optimal way.

4. VRML-Based Presentation Environment

A suitable presentation of the query results should provide a good overview of information relations without an overload of information for the author. If she selects a component this component should be ready to be used for constructing the scene the author is currently working on.

Query results in common search tools are displayed as lists with descriptions of the 3D components or as tables with thumbnails. Often, the components are ordered, showing the best matching results first. In a 2D environment, only a few relations between the components can be displayed.

In a VRML environment, more relations can be shown. The distance between components, or components and keywords, can be used to represent the degree of similarity. For example, in [Hemmje 1994], results are presented on a so-called relevance sphere. The keywords are written on the surface of the sphere and, inside the cone, the query results are shown as symbols. The distance of the symbol to the surface is proportional to the degree of relevance and shows how well the result matches the query. However, a ranking of components cannot be easily recognized in a relevance sphere. Moreover, if a query result matches all keywords, it is near the center of the sphere, regardless of whether it fits well or badly.

Thus, we suggest a linear presentation as shown in [Fig. 3]. Each query result is represented by a scaled element or by a symbol, if not possible otherwise (e.g. behavior description). The relevance value of a query result can be calculated proportional to the similarity of the elements (taking the weights into regard), as well as to the total interest in the properties:

The author can recognize:

- Which components match best regarding all properties
- Which property is fulfilled best
- Whether a component is high-ranking because it matches all properties well or because it matches one property extremely well.

Figure 3: Query Interface and Result Presentation

The author can easily modify the weights using the dial buttons still present in the scene. For a new query, only step 2 has to be executed. Further, the author may determine how many query results are shown by scaling the length of the main axis.

When suitable components have been found, the author will want to use them in her virtual environment. We propose the use of two presentation areas marked with different colors. These can be used for detailed comparisons to elements when unclear which query result to use. If a component is made available at the presentation area, it has been completely represented in the VRML environment. Thus, the component may be immediately used without further database queries. The database makes meta-information available to the authoring system in order to determine how the component is presented to the user and how it may be used by the author. For example, if the meta-information shows "the component currently presented is a texture map",

this information may be exploited by the authoring system in that the texture is applied to the next surface the author touches.

5. Design and Implementation Using VRML and Java

Before implementing the database interface, a database was selected and an import tool was designed. The database should be object-oriented and should be accessible via Java. These criteria are fulfilled, for example, by ObjectStore PSE [ObjectStore 1998]. Java classes have been implemented according to the database schema depicted in [Fig. 1]. These classes are used in the database, as well as in the import tool. During import, objects of the corresponding components' class are instantiated and information provided by the user and the parsing of the component are stored. A special parser needs to be written searching for the keywords "url", "PROTO" and "EXTERNPROTO" and integrated in the import tool.

Figure 4: Functionality of the Server Client Connection

The 3D interface is implemented as a Java applet relying on different Java APIs like the remote method invocation API (RMI) [Gosling 1996] and the VRML external authoring interface (EAI) [EAI WG 1998]. The functionality of the applet is rather complex (see [Fig. 4]).

1. it establishes a connection to the database and translates the query information gained from the 3D interface to database queries submitted via network (using RMI) to the database. The query results are received by the applet and made available to the VRML scene.
2. The applet implements the behavior of the 3D query and presentation interface, e.g. how many properties need to be displayed on the graphical representation of the 3D interface. Here, the EAI is used in order to control a VRML browser, manipulate the scene and observe the scene for events.
3. The applet provides authoring features. It allows the user to place, arrange or apply components retrieved from the database in the scene in a component-specific way. For instance, if a sound component is retrieved, the applet will not only play the sound, but has to assure that the sound is represented graphically as a 3D icon. This is the prerequisite to the author attaching the sound to an object or modifying sound parameters.
4. If the author has finished constructing the scene, the applet has to write the authoring result to a VRML file. Therefore, the applet has to accomplish the inverse task of the "CreateVrmFromString" method of the EAI, i.e. it has to transform the scene graph dynamically created in the VRML browser into a text representation. In addition, as the 3D database interface and its functionality are part of the very scene that was authored, the authoring result needs to be extracted from the entire scene.

6. Conclusion and Further Work

In this paper, we described a 3D interface metaphor to a database of VRML-related content. The interface may be used to search the VRML-related content for components needed to construct a VRML scene efficiently. As the 3D interface is integrated in the same scene an author currently has under construction, the query results may be presented in this scene and seamlessly used by the author.

Technically, we described how VRML content is stored in an object-oriented database. The features of the Java applet which control the VRML scene, communicate with the database, and extract the authoring results were also presented.

Due to its ability to describe all types of components necessary for authoring a 3D environment, VRML proved to be well-suited as a format for storing reusable components. From an application point of view, VRML can be improved by explicitly declaring all components used in a VRML scene description. The external authoring interface used as an interface between VRML and Java could be extended by a method that traverses a VRML scene graph and outputs the scene graph in text format. Furthermore, no support for the administration of references to dynamically created nodes is present in the EAI. This enforces the scene graph being represented in Java, as well.

In future work, the 3D database interface is to be integrated in a full-featured authoring tool that, for example, visualizes the scene graph or is not limited to the usage of elements that are already present in the database. The most challenging task, however, is to find a standardized description and classification of the content that enables the user to specify fuzzy queries.

A Hybrid CD-ROM/Internet Introduction to Music Course

David Sonnenschein, Northeastern University, USA

Abstract: This paper attempts to describe the design of courseware for a self-paced, non-major music course, and a novel method for its delivery. The courseware for this course was designed as a stand alone, self-paced, computer mediated, interactive, multimedia program. Its central didactic objective is to develop in the learner skills needed to recognize auditorily details of structure in a composition and thereby attain some cognition of form in music without the use of musical notation. Learning takes place in a 'virtual class' and the Internet serves as a communication vehicle between students and instructor as well as between students and their peers.

POW! Perspectives On the Web

Gerry Stahl

Center for LifeLong Learning & Design and the Institute of Cognitive Science
University of Colorado, Boulder, CO 80309-0430 USA
Gerry.Stahl@Colorado.edu

Abstract: The perspectives mechanism described in this paper provides a flexible approach to organizing information in a shared repository for the use of individuals and groups engaged in collaboratively constructing knowledge. The perspectives approach builds on a long history of ideas for personalizing access to information within large hypertext spaces, but the POW! perspectives server is the first example of implementing this approach on the WorldWideWeb. After reviewing the concept of perspectives as a support mechanism for Web-based collaboration, this paper will present the main features of the approach and describe common functional types of perspectives. The POW! perspectives server is currently being used in two educational applications: one an environmental course in middle school and the other a graduate seminar in cognitive science. These two collaborative learning applications will be discussed briefly. At the WebNet '99 Conference, evaluation results from these two courses will also be presented.

1. Perspectives: A Collaboration Support Mechanism

The concept of perspectives comes from the hermeneutic philosophy of interpretation of Heidegger (1927) and Gadamer (1967). According to this philosophy, all understanding is situated within interpretive perspectives: knowledge is fundamentally perspectival. This is in accord with recent work in cognitive science that argues for theories of socially situated activity and collaborative learning (e.g., Lave & Wenger, 1991; Winograd & Flores, 1986).

Collaborative work typically involves both individual and group activities. Individuals engage in personal *perspective-making* and also collaborate in *perspective-taking* (Boland et al., 1995). That is, people and communities construct not only elements of domain knowledge, but also their own “take” on the domain, a way of understanding the network of knowledge that makes up the domain. An essential aspect of making one’s perspective on a domain of knowledge is to take on the perspectives of other people in the community. Learning to interpret the world through someone else’s eyes and then adopting this view as part of one’s own intellectual repertoire is a fundamental mechanism of learning. Collaborative learning can be viewed as a dialectic between these two processes of perspective making and perspective taking. This interaction takes place at both the individual and group levels of analysis – and it is a primary mode of interchange between the two levels.

While the Web provides an obvious medium for collaborative work, it provides no support for the interplay of individual and group understanding that drives collaboration. First, we need ways to find and work with information that matches our personal needs, interests, and capabilities. Then we need means for bringing our individual knowledge together to build a shared understanding and collaborative products. Enhancing the Web with perspectives may be an effective way to accomplish this.

As a mechanism for computer-based information systems, the term *perspective* means that a particular, restricted segment of an information repository is being considered, stored, categorized, and annotated. This segment consists of the information that is relevant to a particular person or group, possibly personalized in its display or organization to the needs and interests of that individual or team. Computer support for perspectives allows people in a group to interact with a shared community memory; everyone views and maintains their own perspective on the information without interfering with content displayed in the perspectives of other group members.

One problem that typically arises is that isolated perspectives of group members tend to diverge instead of converging as work proceeds. Structuring perspectives to encourage perspective-taking, sharing, and negotiation offers a solution to this by allowing members of a group to communicate about what information to include as mutually acceptable. The problem with negotiation is generally that it delays work on information while potentially lengthy negotiations are underway. Here, a careful structuring of perspectives provides a solution, allowing work to

continue within personal perspectives while the contents of shared perspectives are being negotiated. We believe that perspectives structured for negotiation is an important approach that can provide powerful support for collaborative use of large information spaces on the Web.

The idea of Perspectives On the Web traces its lineage to ideas like "trail blazing" (Bush, 1950), "transclusion" (Nelson, 1981), and "virtual copies" (Mittal et al., 1986) – techniques for defining and sharing alternative views on large hypertext spaces. At the University of Colorado, we have been building desktop applications with perspectives for the past decade (McCall et al., 1990; Stahl, 1993a). With the implementation of the POW! perspectives server we can now use perspectives on the Web.

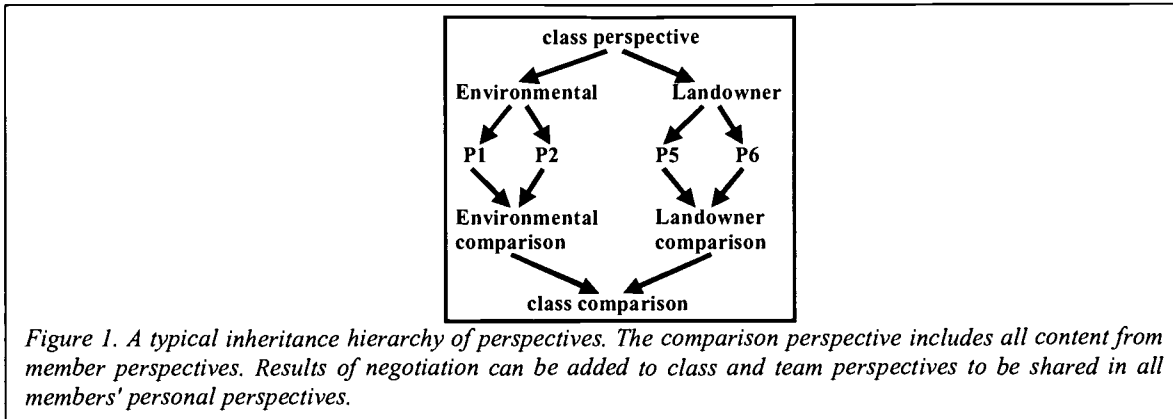

2. Features of the Perspectives Mechanism

The perspectives mechanism that we have been exploring (Stahl, 1993b) incorporates the following features for a community of users:

- Individual community members have access to what appears to be their own information source. This is called their *personal perspective*. It consists of items from a shared central information repository that are tagged as being visible within that particular perspective (or in any perspective inherited by that perspective). This provides a workspace for perspective-making.
- Community member A can integrate an item from B's perspective into A's personal perspective by creating a *link* (or virtual copy) of the item. If B modifies the original item, then it changes in A's perspective as well. However, if A modifies the item, a new item is actually created for A with the modified content, so that B's perspective is not changed. This arrangement generally makes sense because A wants to view (or inherit) B's item, even if it evolves. However, B should not be affected by the actions of someone who copied one of B's items.
- Alternatively, A can *physically copy* the contents of an item from B's perspective. In this case, the copies are not linked to each other in any way. Since A and B are viewing physically distinct items now, either can make changes without affecting the other's perspective. Linking and copying notes from other perspectives allows perspective-taking to occur.
- When A creates a virtual copy of an item from B's perspective, A can decide if she will also get virtual copies of items related to that one, or if she will create her own sub-network for her copy of that item. Arbitrarily large sub-networks of information can be inherited with no overhead using the linking and inheritance mechanisms.
- Items of information can be created, edited, rearranged, linked together, or deleted by users within their personal perspective without affecting the work of others.
- There is an inheritance tree of perspectives; descendants inherit the contents of their ancestor perspectives. Changes (additions, edits, deletions) in the ancestor are seen in descendent perspectives, but not vice versa.
- New perspectives can be created by users. Perspectives can inherit from one or more existing perspectives. Thus, a team perspective can be created that inherits all the content of the perspectives of the team's members. A hierarchy of team, sub-team, and individual perspectives can be built to match the needs of a particular community.

This model of perspectives has the important advantage of letting team members inherit the content of their team's perspective and other information sources without having to generate it from scratch. They can then experiment with this content on their own without worrying about affecting what others see. This is advantageous as long as one only wants to use someone else's information to develop one's own perspective.

However, if one wants to influence the content of team members' perspectives, then this approach is limited because one cannot change someone else's content directly. This limitation is overcome with the linking/copying functions and the definition of certain types of perspectives, as discussed below. It is of course important for supporting collaborative work that the perspectives maintain at least a partial overlap of their contents in order to reach successful mutual understanding and coordination. The underlying subjective opinions must be intertwined to establish intersubjective understanding (Tomasello et al., 1993; Habermas, 1981). When we set up a new application using POW!, we structure an initial hierarchy of perspectives to support both divergent and convergent discourse among perspectives. The innovation in our collaboration applications – compared for instance to CSILE (Scardamalia & Bereiter, 1991) – is the flexible perspectives mechanism, in which content is automatically inherited down a hierarchy of perspectives and in which this hierarchy can itself evolve to meet changing user needs.

3. Types of Perspectives and Practices

A typical POW! application provides several functional types of perspectives within a multi-layered graph of perspective inheritance to help students compile their individual and joint research (Figure 1). Certain social practices for using the application are associated with these different types of perspectives:

The *class perspective* is created by the teacher to start everyone off with some initial pointers and suggested topics. It typically establishes a structure for classroom activities and provides a space for collecting the products of collaborative intellectual work.

Team perspectives contain items that have been accepted by the members of a team. This perspective is pivotal for collaboration; it gradually collects the products of a team's effort.

A student's *personal perspective* is a private work space for constructing the student's personalized perspective on the shared information. It inherits a view of everything in team perspectives of the teams to which the student belongs. Thus, it displays the owner's own work within the context of items proposed or negotiated by teams and the class – as modified by the student. Students can each modify (add, edit, delete, rearrange, link) their copies of team items in their personal perspectives. They can also create completely new material there.

The *comparison perspective* combines all the personal perspectives of team members and the team perspective, so that anyone can compare all the work that is going on. It inherits from the personal, team, and class perspectives. Students can go here to get ideas and copy items into their own personal perspective or propose items for a team perspective.

Students each enter notes in their personal perspective using information available to them: the Web, books, encyclopedia, CD-ROM, discussions, or other sources. Students can review the notes in the class perspective, their team perspectives, and the personal perspectives of their team mates. All of these contents are collected in comparison perspectives, where they are labeled by their perspective of origin. Students extract from any of these perspectives those items which are of interest to them. Then they organize and develop the data they have collected by categorizing, summarizing, labeling, and annotating. The stages of investigating, collecting, and editing can be repeated as many times as desired. Team members then negotiate which notes should be promoted to the team perspective to represent their collaborative product.

The class project ends with each team producing an organized perspective. This year's research products can be used to create next year's class perspective starting point, so new researchers can pick up where the previous generation left off – within a Web information space that will have evolved substantially in the meantime.

4. Negotiating Environmental Perspectives

This Fall we piloted the use of POW! in a classroom at the Logan School for Creative Learning in Denver, using both HTML and Java applet interfaces to the perspectives server. For the past five years, this class of middle school students has researched the environmental damage done to mountain streams by "acid mine drainage" from deserted gold mines in the Rocky Mountains above Denver. They actually solved the problem at the source of a stream coming into Boulder from a mine site by building a wetlands area to filter out heavy metals. This year they are investigating the broader ramifications of their past successes; they are looking at the issue of acid mine drainage

from various alternative – and presumably conflicting – perspectives. The students interview adult mentors to get opinions from specific perspectives: environmental, governmental, mine-owner, and local landowners.

The POW! application serves as a medium through which students collaboratively research these issues with their mentors and with each other. Each student and mentor has their personal perspective, and these perspectives inherit from one of the content-based team perspectives (environmental protection, governmental regulation, etc.), depending upon which intellectual perspective they are working on constructing. Even email interactions happen through the application and are retained as notes in its perspectives.

A tree of discussion threads was “seeded” in the application with question categories, such as “Environmental Analysis Questions”. Within these categories, the teacher posted specific questions for the students to explore, like, “Do you believe that acid mine drainage is a serious threat to the environment?” Students can send an email to one or more mentors asking for information related to this question. When replies are sent back, they will be automatically posted to the discussion thread under the original email. When someone clicks on a title in the discussion, the contents of that item are displayed in an HTML frame below the applet (Figure 2).

A student works in her personal perspective, which might inherit from the class, student team, and landowner team perspectives. She can add, edit, and delete ideas in her perspective, as well as sending email in it. Because she is a member of the landowner team and the student group as well as the class, she can browse ideas in the student team comparison, the landowner team comparison, and the class comparison perspective.

For this application, the teacher has decided that negotiation and perspective-taking will take place in live classroom discussions, rather than within the Web application. After a team or the whole class reaches a consensus, the teacher will enter the statements that they have agreed to into the team or class perspective.

Figure 2. An interface to the POW! perspectives server. A Java applet shows a student notes in his personal perspective. An HTML frame below displays the content of a selected note.

The goal of the year-long course is not only to negotiate within teams to construct the various positions, but also to negotiate among the positions to reach consensus or to clarify differences. The teacher designed this class to teach students that knowledge is perspectival, that different people construct views, compilations of facts, and arguments differently depending upon their social situation. He hopes that his students will not only learn to evaluate statements as deriving from different perspectives, but also learn to negotiate the intertwining of perspectives to the extent that this is possible.

As an initial field testing of our system, this trial has resulted in valuable experience in the practicalities of deploying such a sophisticated program to young students over the Web. The students are enthusiastic users of the system and offer (through the application) many ideas for improvements to the interface and the functionality. Consequently, the software is benefiting from rapid cycles of participatory design. The differing viewpoints, expectations, and realities of the software developers, teachers, and students provide a dynamic field of constraints and tensions within which the software, its goals, and the understanding of the different participants co-evolve within a complex structural coupling.

5. Constructing Perspectives on Computer Mediation

We have also recently begun an interdisciplinary graduate seminar on computer mediation of collaborative learning. The seminar uses a POW! application in several ways:

- *As the primary communication medium for their internal collaboration.* The seminar takes place largely on-line. Limited class time is used for people to get to know each other, to motivate the readings, to introduce themes that will be followed up on-line, and to discuss how to use the software within the seminar.
- *As an example system of computer-mediated collaboration to analyze.* Highly theoretical readings on mediation and collaboration are made more concrete by discussing them in terms of what they mean in a system like ours. The advantage of using a locally-developed prototype as our example is that we not only know how it works in detail, but we can modify its functionality or appearance to try out suggestions that arise in the seminar.
- *As an electronic workspace for members to construct their individual and shared ideas.* Ideas entered into the system persist there, where they can be revisited and annotated at any time. Ideas that arise early in the seminar will still be available in full detail later so that they can be related to new readings and insights. The record of discussions over a semester or a year will document how perspectives developed and interacted.
- *As a glossary and reference library.* This application is seeded with a list of terms that are likely to prove important to the seminar and with a list of seminar readings. Seminar members can develop their own definitions of these terms, modifying them based on successive readings in which the terms recur in different contexts and based on definitions offered by other members. Similarly, the different readings can be discussed and interpreted on-line.
- *As a brainstorming arena for papers.* The application has already been seeded with themes that might make interesting research papers drawing on seminar readings and goals. It allows people to link notes from anywhere in the information environment to these themes and to organize notes under the themes. Thus, both individuals and groups can use this to compile, structure, and refine ideas that may grow into publishable papers. Collaborative writing is a notoriously difficult process which generally ends up being dominated by one participant's perspective or being divided up into loosely connected sections, each representing a single perspective. Software with perspectives may facilitate a more truly collaborative approach to organizing ideas on a coherent theme.
- *As a bug report mechanism or feature request facility.* Seminar participants can communicate problems they find in the software as well as propose ideas they have for new features. By having these reports and proposals shared within the Web-based medium, they are communicated to other seminar participants, who can then be aware of the bugs (and their fixes) and can join the discussion of suggestions.

The seminar version of POW! incorporates a built-in permissions system that structures the social practices surrounding the use of the system. Seminar participants each have a home personal perspective in which they can manipulate notes however they like without affecting the views in other perspectives. They can add quick discussion notes or other kinds of statements. They can edit or delete anything within their home perspective. They can also make multiple copies or links from notes in their personal perspective to other notes there. Anyone is free to browse in any perspective. However, if one is not in ones own perspective then one cannot add, edit, or delete notes there. To manipulate notes freely, one must first copy or link the note into ones own personal perspective. The copy or link can optionally include copying (or linking) all the notes below the selected note in the tree as well. These rules are

enforced by the user interface, which checks whether or not someone is in their personal perspective and only allows the legal actions.

The fact that an individual note may have different edited versions and different linking structures in different perspectives, that notes may have multiple parents within a discussion thread, that new perspectives can be added dynamically and may inherit from multiple other perspectives sets our systems apart from simple threaded discussion media. It also makes the computations for displaying notes rather complex. This is a task that definitely requires computers. By relieving people of all this bookkeeping, computer support may help people to collaborate.

The seminar application emphasizes the use of perspectives for structuring collaborative efforts to build shared knowledge. The goal of the seminar is to evolve sophisticated theoretical views on computer mediation within a medium that supports the sharing of tentative positions and documents the development of ideas and collaboration over time. A major hypothesis to be explored by the course is that software environments with perspectives can provide powerful tools for coordinated intellectual work and collaborative learning. For instance, it will explore how the use of a shared persistent knowledge construction space can support more complex discussions than ephemeral face-to-face conversations. We will explore the effectiveness of this application as a computationally-active tool to augment the knowledge construction work of a community, and report our findings at WebNet '99 in the Fall.

Abstract: People can easily determine whether or not a given document is interesting just by glancing through it. However, when asked to explicitly list the rules upon which such a decision is based, they are unable to do so. This is because our personal interests are examples of tacit knowledge. I have implemented a prototype agent-based retrieval system, capable of finding web documents matching a user's interests and connecting users with similar profiles. Based on empirical findings from this prototype I claim that agent-based retrieval systems may be used to capture our professional interests, thus making otherwise elusive tacit knowledge tangible. By using agent-based retrieval systems two otherwise troublesome obstacles are avoided: interests may be defined by examples instead of specific keywords, and there now exists a natural incentive for creating and maintaining a search profile.

1. Introduction

Epistemologically, knowledge can be split along several dimensions. One way, as suggested by [Polanyi 1966], is to distinguish between tacit knowledge and explicit knowledge. Though others have since explored this separation in greater detail, I shall stay with Polanyi's definition for the scope of this paper. By explicit knowledge, I mean knowledge that has been captured and codified into manuals, procedures, and rules, and when using the phrase tacit knowledge, I refer to knowledge that cannot be easily articulated and thus only exists in people's bodies and minds.

An interesting but also troublesome property of tacit knowledge is the inherent tension between its value and its elusiveness. The high value stems from the fact that most of the body of knowledge is made up of things we know but are unable to express. Michael Polanyi explains: "We can know more than we can tell" [Polanyi (1966) 1998]. One of the objectives of Knowledge Management is to bridge the gap between tacit and explicit knowledge, and any technological solution that could assist in this process would be highly appreciated.

The elusiveness of tacit knowledge can be derived from at least two reasons; we are ourselves not fully aware of it, and there is a lack of inventive on the individual level to make it explicit. First, tacit knowledge "incorporates so much accrued and embedded learning that its rules may be impossible to separate from how an individual acts" [Davenport & Prusak 1997, p.70]. In our daily activities, our tacit knowledge governs our activities without us thinking of it as knowledge. We know how to ride a bike, or what cinnamon smells like, but we cannot document it in a manual, nor explain it to others.

Second, our knowledge is something that resides within us, and manifests itself through our actions, and we therefore have no reason to document it. We just use it. Should we have to express our tacit knowledge in words, it would not be for our own sake but for the benefit of someone else in our organisation or community. [Grudin 1987] has argued convincingly that situations where one is forced to do the work and someone else gets the benefit very often result in failure.

Our interests are an instance of tacit knowledge. Though we may be unable to produce an exhaustive definition of our interests, we usually have no problem in determining whether or not any given document is interesting. Therefore, we intuitively know what we are interested in when we see it but we are unable to make our interests explicit for others to learn. Yet our professional interests govern much of our daily office activities. It dictates what reports we read, which documents we write, which discussions we engage in, and what we search for on the web. If we could somehow capture some of those activities and derive our underlying interests, we might be able to externalise some of our tacit knowledge, and thus make it - if not explicit - at least "touchable". Such a

possibility would be useful to an organisation, as it would enable people to locate knowledge instead of only information.

I argue that agent-based web retrieval systems can be used to solve the two problems mentioned above; they help articulate tacit knowledge, and they create an incentive to try to do so. By identifying certain documents as interesting, an agent-based retrieval system could maintain a dynamic profile that represents some of my tacit knowledge without requiring explicitly defined keywords or manually updated records. Since this profile is used to provide me with information that is more accurate and search results that are more precise, a natural incentive exists for me to give feedback and thus cultivate the profile. The resulting profile, as I will show, represents part of my tacit knowledge, which in a sense becomes tangible.

Research concerning agent-based retrieval systems has focused mainly on user-to-object or user-to-information objectives, but has sometimes also addressed the user-to-user considerations. See e.g. [Resnick & Varian 1997] or [Fagrell & Ljungstrand 1998] for references to various recommender systems and their implementations. No one, however, has approached agent-based retrieval systems from a knowledge management perspective; i.e. discussed what knowledge governs the individual activities or how tacit knowledge may be put to use in the community. My work contributes to the field of KM research by proposing an interpretation that explains how tacit knowledge is activated, and how it may be made tangible. Since my work is focused on the usage of information technology (IT), I have studied how people interact with IT rather than the technology itself. To study whether agent-based retrieval systems could assist us in defining our true interests, I needed an intranet retrieval application prototype. Therefore I used a commercially available tool to implement the prototype, but the choice of tool was not significant for the research - any agent-based product would have worked.

In the next section I will describe the domain in which I performed our empirical study and explain my research methodology. I will then present the fundamental features of the recommender system prototype before reporting the results. In the last two sections I discuss the results and suggest more general interpretations and conclude with a summary.

2. Domain and Research Method

The empirical fieldwork took place at Volvo Information Technology, an IT service company within the Volvo Group. Volvos intranet consisted of some 450 web servers and had approximately 400,000 documents. Most of the content was official or semi-official information, such as department presentations, project reports, frequently-asked-questions (FAQ's), and online help material.

I invited approximately 80 users to participate in the study, which ran from August to November 1998. Most, but not all, of the 48 users who actually registered and participated in the test were Volvo IT employees and their job descriptions varied from technicians and system developers to content providers and administrators. All were experienced computer users. The users were invited to a 2-hour introduction meeting, where I explained the purpose of the research, the concept of agent-based systems, the design of the application and how to operate it, how to register and login, and how to set up and run individual agents. I also asked the participants to keep informal records of particular incidents that they considered worth noting, and informed them that I was going to contact them during or after the test to collect their viewpoints. The seven users that were unable to attend either of the three introduction meetings received the above information via email.

User experiences have been collected in several ways. All users were invited to a group interview but only eight showed up. The remaining users were then sent an email questionnaire, which again only some answered. After a first analysis, based on the so far received answers and the application log files, I conducted seven semi-structured qualitative interviews, each lasting between 28 and 66 minutes. This data was again analysed, using the grounded theorising approach suggested by [Hammersley & Atkinson 1995], where the body of data is used to generate concepts which in turn helps develop typologies and theories.

3. Choice of Tool and Design Decisions

Recommender systems are able to anticipate which items a user is likely to be interested in and can thus, in a hopefully intelligent way, recommend such items. How this "anticipating intelligence" is implemented varies from product to product and is not relevant to this paper. Academic research as well as the success of commercial products has shown that such systems do work and we may safely assume this to be true in this

particular case. The aim of my research was not to develop and study new agent technology *per se*, but rather to examine *how* such a technology could be used in an innovative way. To speed up the development process I therefore wanted to build on existing software tools, if such were available. The product used in the research used neural networks and advanced pattern matching techniques to identify text patterns in profiles and look for similar patterns in other profiles or web documents. Each web document was synthesised into a 0.5K digital representation, a "fingerprint", and the characteristics that give the text meaning were determined. Once the fingerprint signature was created, the reasoning engine could perform concept matching (e.g. finding documents relevant to each other), agent creation (e.g. setting up agents that can find relevant documents), and agent retraining (e.g. adapt the agent to a set of relevant documents).

The prototype was designed and implemented to support the following features:

- Offer agents that could be set to find documents based on user profiles, e.g. a richer representation of an interest than just a keyword-based query.
- Provide mechanisms to enable retraining of the agents based on positive user feedback on retrieved documents.
- Enable users to locate colleagues with similar job descriptions or organisational roles by matching user profiles.
- Display users with similar interests by matching their agents.

Since each user was to be offered personalised agents they had to identify themselves by logging in. In addition to personal agents we also decided to offer *general agents*, i.e. publicly available agents pre-trained by us. [Figure 1a] depicts the log-in screen with the three general agents to the left and the private section to the right.

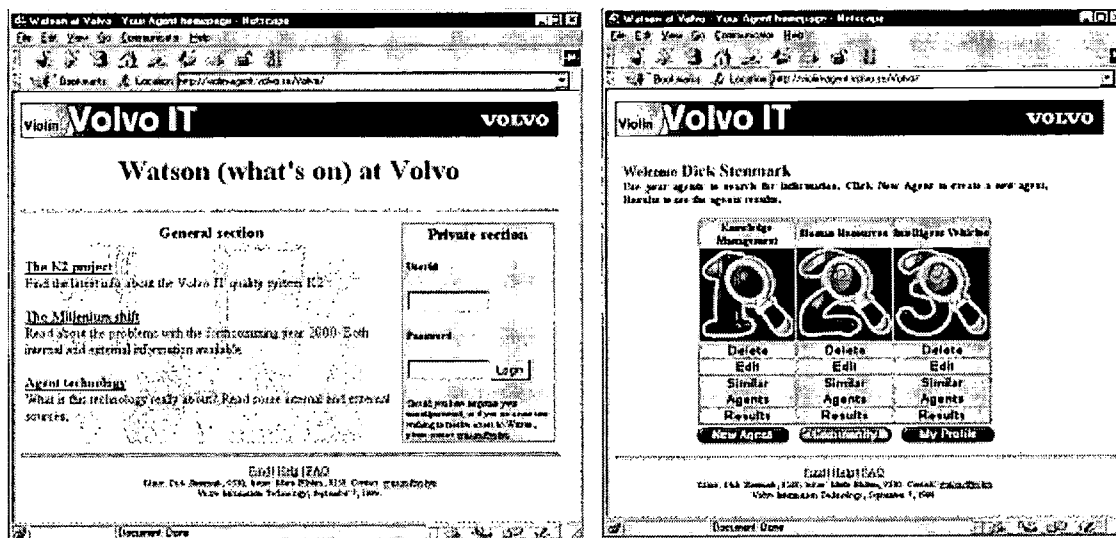

Figure 1: a) Watson's start page with the three general agents (the K2 project, the Millennium shift, and Agent technology) and the private login section. b) The individual agents available for inspection. The user may also create new agents, browse the community, or update the profile.

Once logged in, the users can create a *New Agent*, try to locate other employees with similar profile by invoking *Community*, or create/update their profiles by clicking *My profile*. When creating an agent the user gives the agent a name and assigns it a task. The task, equivalent to a search engine query, is not limited to keywords and Boolean connectives but may, and should, be expressed in natural language. In fact, the more text entered the better. The best result is achieved when the user cuts and pastes a large chunk of text from a relevant document and asks the agent to find more similar documents. After the agent is created, it is displayed on the screen. The example in [Figure 1b] shows a user with three agents; Knowledge Management, Human Resources, and Intelligent Vehicles. For each agent the user can delete it, edit it, find similar agents, or check the result. The number of individual agents was limited to five per user.

One of the first things a new user should do is to create a user profile. In the profile, the user can describe his or her professional interests in a free text fashion. If the user already has a CV stored elsewhere, it may be pasted

into this field. The profile, once saved and stored, will be converted to a fingerprint and used when the Community function is invoked.

When clicking on *Community* or *Similar Agents* the user profile or the agent profile is matched with other users' or agents' profiles and the matching users are listed as seen in [Figure 2a]. The user may now display the email address or the profile of the found users (by clicking the *e-Mail* or *More info...* buttons, respectively) and can use this information to contact them.

The search results from the agents are displayed in a simple list, similar to those generated by most search engines [Fig. 2b]. However, when the user has verified that one of the returned documents is indeed relevant, the user can provide the agent with *positive feedback* by marking the document and clicking on the retrain button. The fingerprint of the agent will then be merged with the fingerprint of the selected document(s) and the result will become the new agent fingerprint, replacing the previous one.

Figure 2: a) A click on the "Similar Agents" button displays a list of users who have created agents with similar profiles (i.e. users who have similar interests). b) The agent shows the 10 best matching results. By checking a document and clicking the retrain button, the agent can be re-trained.

4. Results

The users typically used the application frequently, sometimes heavily, during a couple of days and then stayed away from it for a while before returning for the next session. Usage was especially high right after the release of the application, and then declined slightly before settling on a stable level throughout the rest of the test.

Overall, user reactions were very positive. The respondents said they believed in this technology and considered it to be "an extremely important asset" with a "great potential". The most frequently reported reasons for these beliefs were that it was "easier to construct queries" and that it "saved time not having to search". One user put it this way; "In the future we're gonna be bombarded with even more info and this may be the only way to stay ahead". More specifically, several users expressed their appreciation of not having to come up with descriptive keywords, since "they never really contain the meaning you have in mind anyway", to use the words of one respondent.

Despite the general claims that this sort of "unattended help" with information retrieval is welcomed and appreciated, the users actually mainly reported negative experiences. Many users report what they refer to as "strange" or "unexpected" results. "[It is] hard to get something useful out of it. After retraining it with relevant documents it comes up with nothing" as one user put it. However, the users tend to blame these bad results on their own inabilities. One user having received very little useful information says "The rather shallow results may depend on me not using the right words. Otherwise I like the idea. Keep improving!"

Our recommendation system prototype differed from how conventional Web search tools, such as search engines, are operated, and the users initially had problems adjusting. A common problem was that the users overtrained their agents. Some commented that they felt the way the agent worked had to be better understood by

BEST COPY AVAILABLE

1037

the users in order for them to be able to interpret and anticipate the outcome of the search. The users who attended the introduction all appreciated the information and claimed that it helped them to use the tool in a better way. The answers from the users *not* attending the initial kick-off also clearly indicate that training is required. One non-attending user said: *"It took some time before I understood [how to set up the agents] ... I think the instructions should be even clearer, so that you understand what the agent is and how it works"*.

Not many of the test users exploited the Community feature, i.e. the feature that locates users with similar role description profiles. The reasons given for not using the function were that the test users already knew enough people doing similar jobs or that most users with similar profiles worked in the same department as the respondents. Alternatively, as one user put it, *"What's the use of hooking up with people doing the same stuff I do [...] It would probably be better to team up with those who know stuff I don't know."* This last remark was an opinion shared by several users, who suggested that an opportunity to search for users with *complementary* profiles would have been more useful. Of those who actually did try the Community feature, all but one considered it to be working. One user, however, claimed to have been connected to people with whom he had nothing in common, and this he referred to as *"a bug"*.

The Similar Agent feature was however much more frequently used though it was built on pretty much the same sort of knowledge as the Community feature. *"It's really interesting to see who else is searching for these sort of thing"*, one of the users commented. Many respondents reported that they were surprised to find certain people sharing their interests, or that the Similar Agent feature returned users not expected to be interested in a particular topic. These comments were not expressed negatively. On the contrary, the users regarded this result as a useful new insight and no one questioned the correctness of the result.

5. Discussion

The users clearly preferred exemplifying their interests by pointing to relevant documents rather than having to invent clever keywords. This, I argue, is because the former involves tacit knowledge while the latter requires a translation to explicit knowledge. I further suggest that this distinction between tacit and explicit knowledge also explains the different ways in which the Community feature and the Similar Agents feature were used.

The Community feature, which is based on explicit knowledge, has not been used much at all. There are several possible reasons: Firstly, this research is carried out on a corporate intranet and not on the World Wide Web. The whole organisation may see itself as a community of which the users are already members, and the need to be associated with sub-communities may not be particularly strong. This I find not very likely. Secondly, conventional office tools, e.g. word processors or email programs, do not support a community concept and the users are thus not familiar with this way of working. They do not see themselves as community members, and do not appreciate the full potential of the concept. Tangible business benefits may first have to be experienced for this new way of working to be appreciated. This alternative seems more plausible than the first. However, none of these two are strong candidates.

The third and most feasible explanation is that the Community feature was built on static profiles provided by the users themselves to mirror the official responsibilities placed upon them by the organisation. These profiles are presumably already known to the members and experienced as fictitious, since people are often viewed as performing their jobs according to their formal job descriptions though everyday practice provides evidence of the opposite, as shown by [Brown 1998]. This is consistent with the findings of [Argyris & Schön 1974] who refer to the worldview and values that people believe their behaviour is based on as *"espoused theory"* as opposed to *"theory-in-use"*. The users rightly or wrongly assume that they know what the Community feature will return and they dismiss it as uninteresting.

The *"Find similar agents"* feature is different from the above in that it does not rely on static profiles but on the dynamics of retrained agents, initially created for a totally different purpose. The prompt *"Enter your profile"* connotes an official question equivalent to *"what is your profession?"* and the user enters the supposed official answer that corresponds to his or her role description. The agents, on the other hand, are created for personal benefit only and no official considerations are taken into account. Instead, real professional interests govern the choice of topics, which makes these profiles more *"alive"* than the previous ones.

The most notable observations from the interviews are that when matching job profiles built on explicit knowledge and espoused theory of work, the user, being linked to unexpected colleagues, referred to the result as *"strange"* in a negative meaning. At the same time, the users matching agents built on tacit knowledge and practice commented similar results as *"interesting"* in a positive meaning. The tacit theory-in-use is obviously regarded as more trustworthy. Setting up and training personal agents create search profiles that are able to

represent valuable tacit knowledge in a non-intrusive way. Since the primary objective for the agent is to find the user relevant information the incentive to create and maintain agents exists naturally, and the otherwise hard to overcome problem of having to set up profiles for somebody else's benefit is neatly avoided.

To be able to find this knowledge is, however, only a first step; it only helps to identify people within the organisation - it does not prevent these people from leaving the organisation nor guarantee that they will have time to share their knowledge on request. [Davenport & Prusak 1997, p.81] observe that "mapping who knows what in an organization creates an essential knowledge inventory, but does not guarantee the ongoing availability of knowledge". To achieve such permanent capturing and storing of knowledge, other measures that fall outside the scope of this paper must be deployed.

6. Summary

I have argued that agent-based retrieval system technology could act as a facilitator in the knowledge managing process of capturing tacit knowledge on an intra-organisational web. There are two main benefits of such an approach: i) the otherwise hard to solve problem of being able to produce an exhaustive definition of one's interests is replaced with the much simpler task of determining whether or not a given document is interesting, and ii) since a good profile results in more accurate information, a natural incentive to maintain the profile by giving feedback is created.

Previous research on agent-based retrieval systems has studied how to connect users with information or users with other users. While this study shows that both these goals may be achieved simultaneously, it also introduces a third, and until now unnoticed, aspect of agent-based retrieval systems. My contribution to the field of KM research is the observation that profiles based on the tacit knowledge of practice are conveyed as more trustworthy than the espoused theory-based job description profiles. The former profiles can be used to facilitate the sharing of tacit knowledge without having to make knowledge explicit.

Abstract: This paper focuses on the purposes, theoretical model and functionality of the SMILE Maker - a web-based problem-solving tool. From instructional design point of view, an attempt to establish a balance between constructivism/ instructivism, content-treatment interaction/aptitude-treatment interaction, and user locus of control/system locus of control has been made. The model behind the SMILE Maker consists of four sub-models: user, content, instructional events and facilitator as each of them is being built up from four components. A new concept mapping method has been developed and experimentally validated. Four instructional scenarios are being discussed.

Introduction

The SMILE Maker is aimed at assisting people in perceiving, analysing and organising information when ill-structured problems occur. SMILE stands for Solution Mapping Intelligent Learning Environment. SMILE Maker as a problem-solving tool is a synergy between mapping approaches and creative problem solving techniques. As a learning tool the attention has been paid on optimising the way users learn how to use this tool. From a functional perspective SMILE Maker implies a multi-agent approach to provide intelligent and efficient system-user interaction. The current version of SMILE Maker implemented in Java is a portable and platform independent tool.

In this paper concept mapping has been mentioned in two aspects: as a problem solving technique and as an ontological formalism describing the behaviour of an intelligent agent-based facilitator. Concept mapping is being considered also as a generic term standing for all mapping approaches - classical concept mapping, mind mapping, cognitive mapping, flowscaping, etc. Concept mapping has been defined as a knowledge representation graphical technique that uses a very simple conventional means of nodes, links and labels on the links to explore a problem solving space. However, knowledge representation is rather narrow predicate to express these phenomena. Concept mapping might be defined as a cognitive, affective, meta-cognitive, synergetic, and problem solving tool [Stoyanov 1999]. These functions of concept mapping are complementary to each other, as problem solving is the most subsuming category. The effectiveness of concept mapping as a problem-solving tool depends on the effectiveness of concept mapping as cognitive, an affective, a meta-cognitive, and as a synergetic tool.

Concept mapping is a *cognitive* and *affective* tool. Concept mapping is one of very few if not single graphical techniques that represents the way human mind organises information in problem solving. Moreover, concept mapping is an external extension of the cognitive and affective structures of personality. It enlarges, for example, the natural limited capacity of working memory. That reduces cognitive overload, improves the quality of problem solving production and enhances the speed of the ideational processes.

Concept Mapping is a *meta-cognitive* tool. It externalises cognitive processes and structures when problem solving occurs. Concept mapping stimulates self-appraisal (self-reflection), and self-management (control and monitoring), giving a sense of distance and ownership.

Concept mapping is a *synergetic* tool. It enables all psychological processes (attention, perception, memory, thinking, and language) to be involved (*process synergetic*). Attention directs perception, perception frees up memory, and memory makes reasoning processes more easy and flexible. Concept mapping integrates two kinds of coding - verbal and visual (*code synergetic*). The technique capitalises on the advantages of graphical representations without losing the flexibility and the power of natural language system. Concept

mapping provides a whole picture of problem solving space and shows the relationships between components (*product synergetic*).

Concept mapping is a *problem-solving* tool. It is not only information representation technique (*information collection tool*), but it is also idea generation (*divergence tool*) idea selection (*convergence tool*) and idea implementation technique (*planning tool*). Concept mapping communicates very well with creative problem solving techniques and supports the generation of unusual problem solutions (*lateral tool*).

Most of the mapping approaches are founded on a particular theory. Classical concept mapping approach is based on assimilation theory [Aussubel 1978; Novak & Gowin 1984]. Mind mapping [Buzan 1996] is associated with radial thinking theory. Flowscaping is grounded on the lateral thinking theory [De Bono 1994], and cognitive mapping interprets the Kelly's personal construct theory [Kelly 1955; Eden et al. 1995].

Some special software applications for concept mapping have been made available in order to improve the effectiveness and efficiency of concept mapping technique in a problem solving. Thus, Decision Explorer software supports cognitive mapping, MindMan uses mind mapping strategy, Inspiration is appropriate for applying the classical concept mapping conventions in problem solving

SMILE Maker differs essentially from above mentioned otherwise very attractive tools in two points:

- SMILE Maker is web-based tool.
- SMILE Maker supports the synergy between problem solving and learning.
- SMILE Maker uses an agent-based approach in order to realise a user-friendly and efficient human-system interaction.

SMILE Maker Rational

There are some theoretical trends SMILE Maker is based upon:

- SMILE Maker is both an individual and a group tool. There is a special component, called 'Partner' where all group activities are accumulated.
- SMILE Maker is both a content-treatment interaction and an aptitude treatment interaction tool. The tool proposes a new concept mapping method as a content to be acquired. It is also sensitive to the individual preferences in learning and problem solving.
- SMILE Maker is both external and internal locus of control tool. At the one extreme of this continuum are people that prefer to be guided (external locus of control) and at the other pole are persons who want to construct their own learning environment (internal locus of control).
- SMILE Maker is designed on the basis of the 4-AID generic agent-based model [Kommers, Aroyo, & Stoyanov 1999]. It consists of *four* sub-models: content, instructional events, user and intelligent agent-based facilitator.

Content sub-model is about a new concept mapping method. It includes *four* units: map information collection, map idea generation, map idea selection, and map idea implementation. Each map can be identified by purpose and particular components, supported by some specific creative problem solving techniques.

Map information collection is purposed to assemble all available information in problem space. The problem solving environment is explored in the terms of scientific facts, statistical data, personal experience, assumptions, metaphors and analogies, feelings, etc. Map idea generation is aimed at generating as many problem solutions as possible. With the map idea generation problem solving space is explored in the terms of ready-made solutions, suggestions, elaboration, unusual or "crazy ideas". Map idea selection purposely has to find the best candidate among the alternatives. The objective of map idea implementation is to operationalise a problem solution in the terms of sequence of activities and events, to present the needed steps in order to put solutions into practice.

Learner sub-model is defined by *four* learning styles: activist, reflector, theorist and pragmatist [Honey & Mumford 1992]. The large-scale complexity of the instructional strategies might be reduced to a representative sample of *four* instructional events: explanation, example, procedure, and practice. Each learning style manifests the subject's preferences to one of the instructional events. Theorist is very likely to choose an explanation. Reflector should look for an example. Pragmatic should start with procedure, and activist should go directly to the practice.

Agent-Based Support Layer

The Facilitator - an agent-based component, provides flexible and user-oriented assistance to the user in learning and problem solving. Many different roles are delegated to a number of agents, which in combination produce the behaviour of the facilitator as a user instructional designer, user navigator, system processes co-ordinator and adaptive content provider.

From a methodological point of view, the behaviour of the facilitator is premised upon the assumption that everybody has a potential to be complex and flexible in problem solving. From an ontological point of view, the behaviour of facilitator is formalised as a master concept map containing all components of content and instructional events in declarative knowledge format. This way the complexity in reasoning and extensive knowledge processing is simplified to reactive agent behaviour based on concept mapping formalism [Aroyo & Dicheva 1998]. A particular combination of Content units and Instructional Events constitutes a user's map. The facilitator identifies the gaps between the master map and a user's map and reacts according to specific production rules. One of the most important principles is that the cycle of Content units and the cycle of Instructional Events have to be completed. Thus, the facilitator creates more versatile problem solving style capitalising on the strong points of a particular style and minimising its weak points.

From a functional point of view the facilitator works on the basis of multi-agent layer within the architecture of the SMILE Maker tool. The multi-agent paradigm provides means to characterise processes, which occur in different modules of the system that is responsible for their performance. It creates an advantage for the facilitator - system instructional designer - to act as a reasoning and knowledge-based component not explicitly presented at the user interface. The users get only the result of its decision processes.

The modelling and the design of the facilitator layer is based on compositional development method for multi-agents systems called DESIRE and implemented in the AI department of Vrije Universiteit, Amsterdam. DESIRE stands for DEsign and Specification of Interacting REasoning components [Brazier, Jonker, Treur 1999]. This way both external and internal agent functionality are explicitly defined. The internal agent functionality concerns the expertise (knowledge requirements and reasoning capabilities) for performing domain tasks for which the agent is responsible. The external agent functionality concerns the social abilities in terms of co-ordination, guidance, co-operation and other forms of social behaviour.

In Figure 1 processes and architecture components are presented within the framework of the multi-agent support layer. Result of their activities is presented as behaviour of the system facilitator within the four scenarios described. It is a generic architecture, which supports process interaction and co-ordination in the frame of a user request and the adaptable system support provision described above. Some details and examples of facilitator's behaviour are also added later in the paper.

Figure 1: Compositional design of multi-agent support layer.

New Concept Mapping Method Validation

Two steps were undertaken in order to validate the new concept mapping method and to make it legitimate for the SMILE Maker. At first, a new concept mapping method was proposed as a tutorial in the framework of Ed-Media & Telecom conference [Kommers & Stoyanov 1998] and as a workshop during the conference Information Technologies and Programming [Kommers & Stoyanov 1998]. The purpose was to catch

the strong and the weak points of the methodology and to take a general impression of how the people perceive the method. The audience attended these events expressed positive attitudes to the method.

Secondly, an experiment was conducted to get more strong evidence supporting the assumption that the new concept mapping method is an effective and efficient tool for problem solving [Stoyanov 1999]. The experimental design was factorial including as first independent variable concept mapping method with two levels: the traditional and the new one. The second independent variable was learning styles with two levels - doers and thinkers. The dependent variable was concept mapping production. 32 students from Faculty of Mathematics and Computer Science at University of Sofia were randomly selected and then randomly assigned to the experimental and the control groups according to their learning styles. The experimental group was trained in the new concept mapping method, and the control group was treated in the traditional method. Then the subjects were asked to solve a case.

The new concept mapping method proved to be more effective from the classical one as a significant difference was found on the main criteria such as broad perception, divergence, convergence and planning.

SMILE Maker Functionality Description

At the top level, SMILE Maker presents several functional components available for the user: Introduction, Guide, Resources and Scenarios. 'Introduction' provides with general information what the SMILE Maker tool is about. 'Guide' gives hints as how to navigate in the site. Apart from this general remarks each page has navigational tips with more specific information. 'Resources' contains opportunities to select some available concept mapping software for problem solving, to choose some creative problem solving techniques, to see some templates taken from a broad scope of subject domains, and to make a search in a gallery of stored maps. Although these variables are very important, in this paper we will focus on the 'Scenarios' component. A special attention will be paid also to the group work mode called 'Partner'.

Learning Scenarios

There are four types of scenarios: Ready-made, Tailor-made, Self-made, and Atelier. 'Content' and 'Instructional Events' are parts of each scenario but they are treated in a different way.

Ready-made Scenario

Ready-made scenario is purposed for the people who like to be guided. The 'Content' units are considered in predetermined order starting with 'Map information collection' and finishing with 'Map idea implementation'. The order of 'Instructional Events' is also fixed. 'Explanation' is the first and 'Practice' is the last one. A user might start with map information collection and than each page is associated with particular instructional events. When a user enters the 'Practice' a graphical editor is opened automatically and he/she could apply what has been learned.

Tailor-made Scenario

'Tailor-made' scenario is challenged to provide an instruction according to the learning preferences. The locus of control is still on the system in respect to content providing, but it gives more freedom for an instructional event selection. This scenario is designed for the users that prefer to be leaded but the instructional path is predefined according to their learning preferences. Thus, a user gets the opportunity to identify him/herself as one of learning style and than follows a specific pattern. The patterns are 'Explanation', 'Example', 'Procedure' and 'Practice'. The source of variation is only 'Instructional Events'. The four user types are included as a common knowledge of the multi-agent system and this provides facilitator with the reactivity to the initial user's selection of an instructional event.

What makes differences from the first scenario in respect to 'Instructional Events' is that each path (pattern) is self-contained. It is dominated by one of the instructional events, but also includes pieces from other

instructional events. For instance, the 'Explanation' pattern includes some 'Examples' and gives some 'Procedures' before suggesting the 'Practice'.

Self-made Scenario

The sources of variation in the 'Self-made' scenario are both 'Content' and 'Instructional Events'. There is not predefined sequence of problem solving maps. However, the content is still SMILE concept mapping method. The user can start picking up any of the maps and then select any of the instructional events. The assumption is that the user selects a specific option because of need to perform specific actions. When a user chooses 'Map idea selection' simultaneously with an introduction to this kind of map, a pop-up message from the facilitator appears on the screen providing with some advises. The facilitator reacts also when a user skips some of the 'Instructional Events' and goes directly to the 'Practice'.

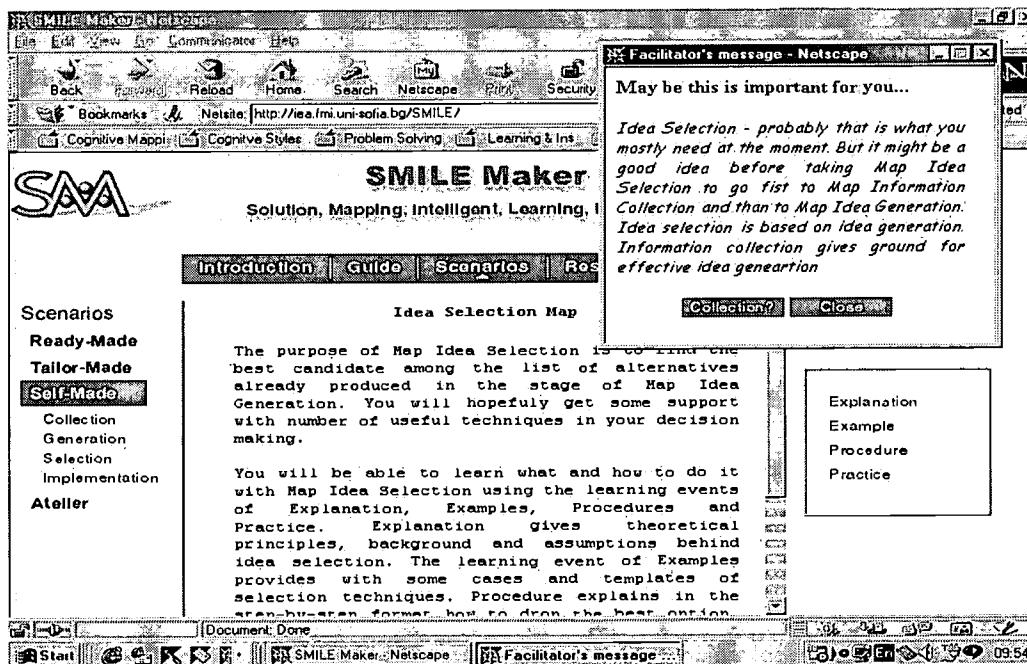

Figure 2: Screen-shot of self-made scenario

Atelier Scenario

'Atelier' scenario is presupposed to serve for people who are self-confident in building up an own concept mapping approach. There are several components which a user could select from: Ideas, Maps, Templates, Method, and Practice. 'Ideas' stands for creative problem solving techniques. 'Maps' presents some mapping approaches like concept mapping, cognitive mapping, mind mapping, and flowscaping. 'Templates' presents some examples of combinations between mapping approaches and problem solving techniques. 'Practice' provides a graphical editor for maps drawing. 'Method' proposes the new concept mapping approach with four problem solving maps to be drawn. If a user selects this scenario and then goes to the practice, the facilitator reacts with a suggestion to her or him to have a look at other options such as Ideas, Maps and Templates in order to construct more effective strategy.

Group-work Mode - 'Partner'

There are three different sub-modes of collaborative work in the 'Partner': exchanging of individually produced maps (Pin Sub-Mode), creating a common map within shared workspace (Brainstorming Sub-Mode) and moderating the group consensus through collecting, creating and sharing maps (Delphi Sub-Mode). With the first sub-mode, users take benefits getting some insights when looking at others' maps. The second sub-mode is an on-line collaborative work. A group solves a problem, making a common map(s) on the shared workspace. The SMILE Maker facilitates the group composition, interaction and work regulations. Different group problem solving techniques are available as well. With the third sub-mode a group member or the tutor could take the role of moderator. Individuals or small groups produce their concept maps solutions of a problem and then send them to the moderator. The moderator draws an adjusted map containing the main features of the individually produced maps. Then she/he sends it back to the group members that initiate a new stage of problem solution until a consensus is reached.

There are three main options available in 'Partner'. "Send a map" automatically opens e-mail box for sending individually produced map or a sequence of maps to another user, or to the moderator. "Gallery" gives an access to a pool of concept maps, created by other users, sorted by content (topic) or the type of map. The process of problem solving and the final map products are visible. SMILE Maker provides the option of saving several steps of maps' production and presenting them as a sequence on user request. When user initiates a problem solving, she/he could use "Gallery" to search for similar problems and models of solutions.

"Shared workspace" offers several options: group composition, techniques, rules, communication, and history. 'Group composition' gives some hints on the group size and homogeneity/heterogeneity in the terms of level of expertise, personal style and professional status. 'Techniques' provides information about group creative problem solving techniques. 'Rules' are about conventions of participation, self-presentation, timing, steps and procedures in creative problem solving techniques, some restrictions as well. 'Communication' supports a user to specify topic, objectives, rules, and techniques, to use some facilities such as a chat and to make an evaluation. 'History' saves not only the final concept mapping production but also the steps in creating a map(s).

"Shared Workspace" is based on Java Shared Object metaphor. Each common or shared map is composed of several linked-shared objects. A master copy of such a map is stored on the central server and this copy is replicated to all clients in a single collaborative session. When the user makes some changes in the nodes, links and labels within a common map these changes become immediately visible to all users.

Extending and interacting with the ITC system

Georgios D. Styliaras, Sotiris P. Christodoulou and Theodore S. Papatheodorou
High Performance Computing Lab, Computer Engineering and Informatics Dept., University of Patras, 26500 Rio, Greece
{gds, spc, tsp}@hplab.ceid.upatras.gr

Abstract: The paper presents various enhancements to the ITC system, a system for defining the structure of Thematic Catalogs, populating them with information items and providing access to end-users, such as navigation and searching through its categories. The system has been extended, so as to provide multiple presentation formats of its categories and multiple ways for inputting data. Additionally, the system can now be used as a simple Web authoring system. Finally, some examples of the system's use are presented.

1. Introduction

The ITC (Interactive Thematic Catalog) system [Styliaras 1998] is an automated tool, which can be used for constructing Thematic Catalogs. The system helps in defining the structure of the catalog, populating it with information items and offering some basic services to end-users. These services include browsing and searching through the catalog's categories, viewing the content in multiple languages and contributing new information items to the system. From a structural point of view, in every ITC system, there are some basic categories that act as roots of the various categorizations. Every basic category is analyzed through a hierarchical tree of subcategories. In some of these subcategories near the bottom of the tree structure, information items can be classified. In most cases, an information item is just a hyperlink to a Web site page. A database is used for storing both the catalog's structure and the associations of information items to the catalog's categories.

In this paper, we will present some enhancements added to the basic features of the system, concerning both the internal structure of the system and the services provided and affecting both content providers and end-users, who simply browse and search the system's contents. These enhancements, which will be analyzed in the following sections, have been inspired by the use of the system in various applications, as it will be discussed in Section 7. Each of these applications provided us with valuable requirements regarding the way information should be defined, related, accessed and manipulated by different categories of users such as end-users, specialized content providers and technical users. The major enhancements include allowing multiple representations of some categories' contents and implementing multiple ways for data input according to both the experience of the content provider and the characteristics of the data. Finally, the ITC system provided an excellent testbed for experimenting with different technologies, such as Java / Swing (4.1), Dynamic HTML (3.1), XML (4.2) and Visual Basic (system core), and understanding how these technologies can inter-operate. In every case, we examine each technology's strengths and weaknesses and we manage to integrate these technologies into a single system.

2. Changes in the structure of the ITC system

Taking into account the application of ITC into some real-life projects analyzed in Section 7, we have concluded that it was necessary to enrich the internal structure of the system, which is the underlying database, by allowing two main extensions. Firstly, it is now possible for an information item to have more than one classifications according to a certain basic category. For example, assume a time-based categorization that is analyzed in small, independent chronological periods. An information item spanning more than one periods will have multiple classifications in this basic category. This enhancement gives the opportunity to the content provider to classify more precisely and accurately the information items according to the various categorizations. The second main enhancement deals with the main role of ITC in a Web site. Typically, an ITC system, as every Thematic Catalog, is used for classifying a set of pre-written HTML pages in a set of categories. Apart from this capability, ITC can act as a simple authoring environment, allowing the content provider to be able to compose the main content of the information item, during the association of the items to different categories. In this way, the content of the

information items, the catalog's structure and the association of items to categories are all stored in the system's database. Additionally, all this content is automatically generated by the system, which enhances its portability. This enhancement has been embedded in ISTOPOLIS [Papaterpos 1999], a network-based educational system.

3. Multiple representations of the categories contents

Most Thematic Catalogs use a text-only representation of their content. Sometimes, if the context of the categories permits to do so, it is possible to provide alternative representations of these categories' content. In this way, end-users are offered a more efficient way to perceive the relationships among the different categories and information items. It is obvious that, as yet, this is a process that cannot be fully automated and an expert developer is required to embed the alternative representations in the system. Examples include basic categories analyzing geographical regions, chronological or scientific data. In the first case, maps may be used for displaying information items upon them, filtered by the classification of the items according to the rest of the basic categories. Concerning chronological categories, a time-based navigation tool may be defined for locating chronological events. In this way, multiple presentation formats are allowed according to the context of the basic category.

3.1 Geographic Tool

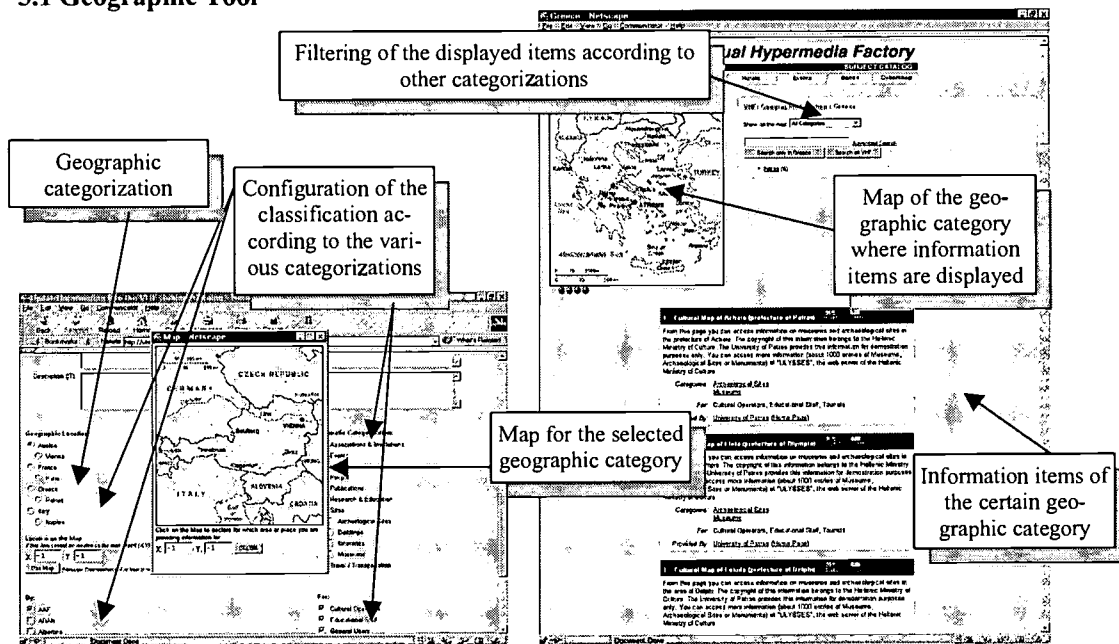

Figure 1: Map-based navigation subsystem

As an application of the previous idea, we have implemented an interface for map-based categorizations and embedded it in ITC. This geographical tool affects both the data-entry and navigation processes. During the definition of the geographic categories, which are usually geographic areas, the content provider has to supply a map for every area and enter its URL, allowing him/her so to use the map of his/her preference for a certain area. Additionally, as the subcategories of a geographic category are usually sub-areas that can be located on the category's map, the content provider should enter the coordinates for these sub-areas. In this way, it is possible to define hot spots over the maps and navigate, therefore, through the different levels of the geographic categories by using only their respective maps. This information is stored in the system's database, along with the rest of the data concerning the categories. During the population of ITC with information items, the content provider should supply, apart from the usual data (title, description and classification), the coordinates of the information items on the appropriate maps, provided there is classification according to geographic categories. This information is used for enhancing the navigation, by using hot spots on maps.

We have used a rather simple approach for implementing the map-based navigation in the ITC system. More specifically, the interface is built using Dynamic HTML and layers, which are supported by both commercial browsers. Prior to the appearance of Dynamic HTML, this kind of interface could be implemented using either server-side scripting for implementing the hot-spot capability on the images of the maps or Java. We have found out that both these options have drawbacks such as overload of the server, or speed. With the use of Dynamic HTML, we define one clickable layer for every information item or subcategory that is located on a geographic category map. There are many systems that implement similar map-based navigation techniques, such as the one described in [Orendorf 1996], but we have implemented a quite simple subsystem in order to test how easy is to integrate alternative presentation formats in ITC. The geographic subsystem has been embedded in VHF's [VHF] Web site, which is described in Section 7. In Figure 1, we can see two instances of the subsystem. On the left, the content provider can configure the coordinates of an information item by simply clicking on a map or providing the exact coordinates. On the right, the map is embedded in the generated page of a geographic category.

4. Various input types according to the level of the users

4.1 Graphical definition of categories and associations

As described in [Styliaras 1998], a simple HTML interface has been initially used for analyzing every basic category into subcategories. This process is convenient if a basic category is analyzed through a low-depth, rarely changeable tree of few subcategories. Otherwise, a more sophisticated tool is needed for configuring and updating, later, the categorization of information items. We have implemented a graphical tool for defining the categorization of the catalog and the classification of information items according to the defined categories. A hierarchical-like menu is defined that the content provider can use for defining the tree's basic and intermediate categories. Then a pool area is used where the content provider can drop newly defined information items by providing a title and description. Finally, in order to classify information items to categories, a similar interface is used, where categories appear in read-only mode and a special notation is used for recognizing in which categories it is prohibited to assign information items (e.g. red nodes in the above figure). The interface has been implemented using Swing's [Java] JTree graphical component.

Figure 2: Data input process using JTree

4.2 Batch input of categories and associations using XML

When a basic category is analyzed in a large number of subcategories, it is tedious for an experienced user to de-

fine the structure of a basic category by entering one subcategory at a time. Therefore, there is need for an automated tool to be offered to content providers in order to define the structure of the basic categories. Instead of defining a special notation language, we have decided to use XML [XML], which is suitable when defining a hierarchical structure of data elements. It allows an experienced user to define a simple XML file with the categories that will be included. This file is parsed by an automated tool and generates the appropriate category's definition table in the system's database. We have used the XML object shipping with Internet Explorer 5 for implementing experimentally this capability. The XML elements have attributes, defining the type of the category. For example, to define the category structure shown in Figure 2, the following XML file should be used:

```

<basic>
  History
  <category type="intermediate">
    Ancient History
    <category type="intermediate">
      Geometric Period
      <category type="intermediate">
        Art
      </category>
    <category type="final">
      Philosophy
    </category>
    <category type="intermediate">
      Geometric Antiquities
    </category>
  </category>
  <category type="intermediate">
    Archaic Period
    <category type="intermediate">
      culture
    </category>
  </category>
  <category type="final">
    Roman Period
  </category>
  <category type="final">
    Ancient Antiquities
  </category>
</category>
</basic>

```

Figure 3: An XML file defining the structure of a category

The above extra features embedded in the ITC system illustrate clearly that no single kind of user-interface is suitable for every user and kind of data. On the opposite, multiple formats of varying difficulty should be provided in order for the content provider to be able to insert the data more efficiently.

5. User-defined templates for displaying leaves and categories

The ITC system has a pre-built template for building the interface of both the categories and leaves' pages. This process is not flexible enough if someone wants to use ITC in a site where all the pages have to comply with a certain look-and-feel. Therefore, data providers should have the ability to customize the appearance of ITC's pages according to their needs. Until now, an expert developer had to change and recompile the pages' generating code in order to change the default appearance of the pages. As we wanted to allow a more flexible use of ITC, even by non-programmers, we have defined a simple template-based notation, which can be used for configuring the appearance of ITC's pages. Our approach uses some special markup tags embedded in HTML, which are preprocessed in order to generate ITC's pages. Under this view, our approach resembles that of the special markup languages (such as ASML [Owen 1997], CFML [CFML], VBScript [VBScript]) used in some popular research and commercial web authoring systems. In our case, though, we enable the user to change only some specific properties, as the actual content of the pages is automatically generated. This fact helped us to determine a wizard-like sequence of steps that will guide the content provider to customize the appearance of ITC's pages. A typical ITC page consists of four main parts: the *header*, the section where *categories* are displayed, the *information items* section and the *footer*. Apart from these sections some global parameters may be configured by the data provider and applied to all pages in which they are included in the form of a style sheet. Consequently, five steps are needed for determining the appearance of a typical ITC page, which are now shown. If

The ITC system has been also used in a pan-european research-oriented Web site [VHF] where partners from all over Europe have been contributing in a specialized edition of the ITC system, focusing on Tourism and Culture, in which the geographical tool has been embedded. The challenge here has been to implement an efficient multilingual tool for the various content providers from different countries, which could be used for simultaneous manipulation of both the structure and the contents of the Thematic Catalog. The user interface in all content-providers' and end-users' forms is multilingual and is automatically generated by the system. The only data requested by the user in an initial bootstrap-phase was the translation of some key-phrases prompted by the system in all desired languages. The feedback received by the content providers has shown that ITC has proved to be an efficient system for displaying and manipulating the structure and the contents of a catalog.

Finally, ITC has been used in an educational, client-server based environment used for teaching Ancient History in high-school students. The environment is called ISTOPOLIS [Papaterpos 1999] and is currently going under evaluation in some selected High schools. In this case, apart from simply classifying the pages of a Web site, ITC has been used to organize the whole Web site of the environment, that is the content of the information items. The Web site of the environment consists of pages, each of which describes a certain issue in the Ancient History. Before writing the actual content, content providers have used ITC for defining and categorizing the topics that would be covered by the material provided. They defined, in this way, the basic categories and the subcategories of the catalog. The multiple organization of the content in the form of categories provided a *Table of Contents* to content providers that helped them determining what kind of information items it was necessary to write in order to cover every aspect of a certain portion of the Ancient History (in this way similar knowledge areas may be covered). At this point, content providers had to fill the system with the titles and classifications of these information items and write the actual content of these items in a special area embedded in the input form. This application is an example of how the ITC system can be used to help the authoring process of a Web site, apart from its main use, which is the classification of pre-written information items.

7. Conclusions

In many Web sites, Thematic Catalogs constitute an efficient way for navigating through the site's contents. ITC helps automating the process of building such catalogs. Based on the system's application on different sites with varying needs, we have collected valuable feedback that helped us improving many features. One of the main outcomes of this attempt is that given a system with a certain internal structure and functionality, an efficient multilevel interface has to be provided in order for the system to satisfy the various end-users' needs.

lars.svensson@udd.htu.se

Abstract : This paper reports on a distance education project where a threaded discussion board was used for interaction amongst students and teachers. The experiences from the first year of the project shows that such a forum can be an important complement to other evaluative resources in order to monitor student's expectations and experiences. Vital properties of the discussion board are that it is continuous, online, public, asynchronous and auto-structuring.

1 Evaluation in Distance Education

Evaluation is an important tool in higher education, guiding faculty and management towards better courses with improved methods of teaching and administration. The literature describes many formal techniques and instruments for this purpose (i.e. Oliver 1997). Since most methods for evaluation require substantial resources for measuring as well as analysis, the dominating instrument is probably a simple written post-course questionnaire with multiple choice questions and/or open-ended short comments (Hall 1997). In addition to the results from formal evaluation, teachers have a rich flow of more informal and sometimes sublime feedback arriving continuously from a variety of sources. Casual conversation with students and colleagues, the atmosphere in classroom and corridors and student's body language and degree of attention during a lecture can all be viewed as carriers of evaluative feedback. In a distance educational setting, with students and teachers separated in time and space, these signals are drastically reduced. To compensate for this type of informal communication with computer-mediated interaction is difficult, if even possible. Whittaker et al (1994) addresses the general issue of designing IT to support informal workplace communication, arriving at the conclusion that a shared workspace is an important aspect and that rich synchronous video-media and asynchronous text based media should be combined and integrated when aiming for an acceptable design. The focus of this paper is a threaded discussion board where students and teachers meet to discuss and course related issues. This is an informal arena where students can express their attitudes, opinions, perceptions and experiences. Such a forum can serve as a valuable complement to traditional post course questionnaires, even making it possible for teachers to challenge and manage these student-opinions. The arguments are based on experiences from a distance education project at a university in Sweden. The empirical data of the study are the entries made by students and teachers to a web-based computer conference (discussion-board). This conference is integrated into a web-education system, called DisCo, developed at the University. The entries have been analyzed with respect to evaluative factors like topic and nature.

2 The Case Setting

The object of the study is a distance education project where 60 students from six small communities in the outlying districts of a Swedish university can take a degree in System Analysis (B. Sc.). The participating communities were committed to provide some basic facilities such as access to modern computers with Internet-connection, a prescribed set of software packages, a videoconference(VC)-studio and room for collaborative work.. The number of students in the various communities varies from five to 17. The study covers the courses during the first year of the project. All courses had different teams of teachers and different methods of teaching and examination. The courses were in order: (1) *Mathematics and Statistics, 10 weeks*, (2) *Computer Science, 10*

weeks, (3) Business administration, 10 weeks, (4) Finance, 5 weeks and (5) C++ Programming, 5 weeks.

A common denominator in all courses was the use of learning technologies. Multiparty VC-sessions were used for lectures, seminars and presentations, and a web education tool (DisCo) was used for distribution of course material and for text based interaction. The DisCo-system provides a website for each course, one of its components being the core object for this paper, namely the Discussion Board. - A primitive web-based conference, where discussion topics are divided into threads presented on the screen with indents that indicates the structure of the discussions. Each entry is presented with a hyperlinked title, a date/time-stamp and the signature of the author. The threads are sorted in descending time order with respect to the first entry of each thread. An entry is displayed in full text by clicking on the title, it is then possible to choose to post a follow up to the entry. In addition to text (with html-tags if so desired) the author of an entry can choose to submit a picture, a URL and or an email address. Each entry should be signed with a name or a pseudonym by the author. A new discussion-thread is started in the same manner.

Laurillard (1993) classifies the debate board to be a discursive media. Using her conversational framework she claims that discursive media addresses interaction at the level of description and reflection upon actions, feedback and goals. Long & Baecker (1997) emphasizes the conversational style of a debate board, allowing for conversation among groups where each person can respond to all others, having the complete dialog-history displayed.

3 Research Approach

In a previous study the email and discussion-board entries of the course in Mathematics and Statistics have been analyzed using a method designed by Orlikowski and Yates (1994). This method uses the concept of Genre to detect patterns in the electronic interaction. Orlikowski and Yates defines a genre to be a:

Typified communicative act having a socially defined and recognized communicative purpose with regard to its audience.

The Genre concept accounts for both the substance and the form of the interaction. Substance refers to the topics and the discursive structure of the interaction, and form has three sub-dimensions: structural features, communication medium and language. The concept of a Genre Repertoire (ibid.) refers to a set of genres providing a social template for communication within a community. The audience or community in this case is of course the group of students and staff (teachers, course-administrators) interacting through the DisCo-system. The result indicated a genre repertoire consisting of three distinct genres appearing both on the debate board and in the email to teachers. The genres were labeled Query, Feedback and Smalltalk (See Svensson 1998b for a thorough discussion).

The Query genre was characterized by having the primary purpose of discussing exercises and aspects of the course literature. The purpose of the Smalltalk-entries is to entertain, and socialize even though the content is often related to some course activity. Social activities like this are often reported in distance learning projects, (see Fjuk 1998), and serves an important role in building and maintaining the learning community. These entries can to some extent be a substitute for the sublime feedback signaling the mood of the students discussed in the first section. However the focus in this paper is more directly linked to the Feedback genre which constitutes the foundation for the analysis reported in this paper.

4 Data collection and analysis:

The aim of this explorative study is to present as rich a picture as possible of the nature of the evaluative discourses that took place on the discussion-boards. The primary unit of analysis is the discussion-thread. All threads with an evaluative content are included in the study. The threads were classified with respect to the feedback-topic(s) being discussed (see table 1). Secondly each debate-board entry was analyzed with respect to the nature of the feedback. Inspired by the classification of different types of feedback a teacher can give a student presented by Draper (1997b), the following scheme was adopted. The entries were classified into one or more of these feedback types. Some simple quantitative measures such as number of entries, the number of follow up levels and the time-span between first and last entry was recorded in order to give complementary

information on the nature of the debate. In addition to analyzing the debate-entries the log-files containing data on all visits to the debate boards were analyzed.

Topic	Description
Course-Context	Comments on administrative issues, student-facilities or service
Course-Content	Assignments, Course-Material, Topics of study, literature etc.
Learning Technology	Comments on Videoconference or issues related to DisCo (tech problems, features etc.)
Teacher performance	Comments on lectures and tutoring
Debate Climate	Comments on the form or style of other debaters.

Table 1: Classification of threads

Feedback types
1. Agree/Disagree with other debater
2. Success/Failure: Debater stating that something is bad (or good)
3. Behavior recipe: Debater presenting a suggestion for change
4. Explanation: Elaboration on why something is wrong (or right)

Table 2: The different natures of feedback

5 Result

The log-file data shows that the discussion-boards have been frequently visited. A total of over 12 000 visits over a 40 week period. This resulted in 223 threads with 563 entries. (One out of 20 readers posted to the board). 50% percent of the threads (60 % of the entries) were classified as feedback-threads and therefor included in the study. The topic-analyses revealed that a majority of the evaluative threads focused on one and sometimes two topic-categories. (see table 3)

Topic of feedback	Math/Stat	Comp.Science	Bus.Admin	Finance	Programming
Context	4	1	7	3	6
Content	4	10	6	1	2
Technology	16	9	9	1	2
Teacher	5	1	1	3	0
Discussion	1	2	3	1	1

Disc/Content	0	1	0	0	0
Teach/Content	2	4	2	0	0
Teach/Tech	0	4	0	0	0
TOTAL	32	32	28	9	11

Table 3: Number of entries per feedback-topic and course

Comparing the courses shows that the debate-frequency is fairly equal in the first three courses, and dropping slightly in the last two. Also the length of the threads drops from an average of 3-4 in the first 30 weeks, till no more than 2 in the last ten weeks. The fact that the 5-week courses tend to be more intense could be one possible explanation. Another explanation could be that the fact that issues related to the DisCo-system were frequently debated in the first courses (, but gradually the system has become more and more transparent to the student's and is therefore not an interesting topic to debate. In the latter courses the technology threads relates to how it is operated by teachers and integrated with course content. The short threads and solo entries could be found in all categories, but dominated in Learning technology and Debate climate. The longest discussions are concerned with the context or the content of the courses.

The lifetime of most discussions were very short (1 or 2 days). Only three threads have a span of more than a week between the first and the last entry. One explanation to this could perhaps be found in the graphical interface of the debate board. Since the complete dialog history is presented on the screen, the threads disappear from the start-screen of the board after 15 – 20 entries have been made. Then the scroll-bars must be used in order to read the entries or post a follow up. There were some examples where debaters chose to start a new thread continuing the debate on an existing topic, instead of adding to the original thread.

In table 4, the entries are divided with respect to the nature of feedback. It is worth noticing that an elaborate explanation or a suggestion for changes is included in 53 percent of the entries, leaving only 47 percent with short-answer-like reports on success or failure or commenting someone else's opinion.

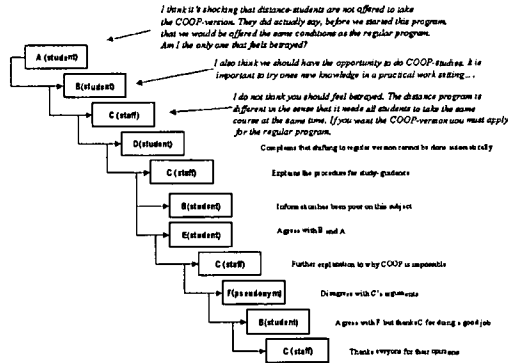

Cat	Description	Math	Comp.Sci	Bus. Admin	Finance	Programming	Total
1	Agree/Disagree (A/D)	17	13	24	4	5	63 (18%)
2	Success/Failure (S/F):	34	30	21	8	9	102 (29 %)
3	Behaviour recipe (BR):	5	5	14	1	3	28 (8 %)
4	Explanation (Exp)	15	18	17	4	10	64 (18 %)
1 & 3	A/D with BR	1	1	2	0	0	4 (1 %)
1 & 4	A/D with Exp	3	6	10	0	1	20 (6 %)
2 & 3	S/F with BR	4	9	4	0	0	17 (5 %)
2 & 4	S/F with Exp	9	8	3	1	1	22 (6 %)
3 & 4	BR with Exp	1	3	2	0	1	7 (2 %)

-	Others	1	4	11	1	3	20 (6%)
---	--------	---	---	----	---	---	---------

Table 4: Number of entries per feedback-type and course

In order to visualize the debate, two examples of threads are presented below. The first example deals with the debate climate of the second course as well as the use of outdated software. The second thread is from the computer-science course and deals with a course-context issue. The header of the first entry was “Why not COOP??”, referring to the fact that students on the distance education program did not have the opportunity to integrate work-placements with their studies.

Descriptions in italics are translations from debate-board entries (in some cases, somewhat shortened)

6 Characterizing the Discursive Evaluation

It is important to emphasize that the opinions expressed by students on the debate-boards cannot be uncritically regarded as being representative for the whole community. Hall (1997) and Wheeler (1997) argue that studying computer-conference interaction can be biased by the fact that students tend to participate in the debate to a varying extent. Hall claims that technology-friendly students are quicker in adopting the media and will therefore be over-represented. Issues such as fear for lack of anonymity and reluctance to express ones opinion in writing could imply that some students hesitate to participate in the debate. The students in this study can however all be assumed to be reasonably positive in their attitude towards computer technology, since they are studying for a degree in System Analysis. Furthermore, the familiar and 'talk-like' language generally reported to be a characteristic of text based computer-interaction, (Sproull & Kiesler 1991, Ljungberg 1997), could enhance the wish to express written opinions compared to other evaluation techniques like open-ended questionnaires. In a distance educational setting when students and teachers seldom meet face-to-face, it can be difficult to keep track of students' attitudes (Hall 1997). The discursive nature of the debate board is very well suited for both discovering these perhaps diverse expectations, and even manage them by explaining and elaborating. Hall (1997) reaches similar viewpoints. She says that using the content of a computer-conference for evaluative

purposes could be prosperous when wanting to find personal, subjective opinions among students. The illuminating qualities of the debate, reported in this study, would serve as a good complement to a post-course questionnaire. Such questionnaires are perhaps more valid in terms of representing the attitudes of the whole community, but often suffer from short comments without elaborated explanations on complaints and suggestions.

There are several important properties of the debate board itself, which can separately as well as collectively contribute to the way it used. In addition to these qualities there are of course also other essential factors of the learning context that will effect the outcome.

(1) *The debate is Public*: The fact that all entries can be read by everyone in the community serves at least three essential purposes. Firstly, the risk of minority-opinions being overestimated is reduced since such entries is likely to be contradicted by others. Secondly it makes it more interesting for students to express an opinion when they know that it will be read by more people than the teacher. A third feature related to the public nature of the board is its social functions. The existence of the Smalltalk genre (Svensson 1998a, 1998b) points to the fact that students use the board for social purposes. It can not be ruled out that an evaluative entry to the board is more of a social action than a wish to give feedback.

(2) *The threads are Auto-structuring* ∴. The entries are automatically sorted into threads, making topic-oriented analysis easier for an evaluator or teacher. If the debate is regulated (i.e. suggested topics for discussion) the threads can still provide good structure with respect to sub-issues. However if the regulation is too strict, there is a risk of loosing the discursive structure supported by the threads. At a point it will become arbitrary whether a new entry should start a new thread or add to an existing one.

(3) *The medium is Asynchronous*: Laurillard (1993) argues that the asynchronous nature of discursive media can contribute to students making entries more carefully thought trough and 'well formulated', reducing the risk for misunderstandings in analyzing the content. Draper (1997a) argues that reflecting on ones own writing, is a form of 'self-feedback' that promotes learning. In the same way, taking time to reflect on other debater's viewpoints can induce a similar intellectual process.

(4) *The discussion is Continuous and Online*: Draper et al (1996) says that an important constraint in evaluation is not to overload students. On the debate board they only express their opinion when the want to do so. This is not the case in traditional post-course evaluations where many issues worth giving comments on are long since forgotten. Furthermore, the possibility that suggested changes could be implemented and reported errors could be dealt with is likely to enhance students' willingness to give constructive feedback.

7 Conclusions

The key qualities of the board all contribute to form the nature of the discussions. The results from the case study show discussions in many course-related topics, rich on constructive suggestions and argumentation. This feedback could be a valuable input for teachers, but perhaps even more important, it makes it possible to challenge and influence students' attitudes and expectations. Especially in distance educational settings, where students and teachers seldom meet in person, it is important to identify ways of picking up sentiments and sources of irritation. A discursive media like the discussion board presented in this paper should not be perceived as a formal instrument for objectively evaluating a learning context. On the contrary, it is a forum for conversations and discussions for the learning community of students and teachers, perhaps to some extent compensating for the loss of informal communication-channels of the campus based education. Thereby making it possible for teachers to monitor students' opinions and influence them at the same time. What better way to change someone's opinion than to engage in a discussion.

Abstract: This paper reports our project on enhancing science and technology education. Curriculum development that integrates a pattern-based learning concept into the design of lesson plans and web deployable courseware will be described. This project serves as a vehicle for the "proof-of-concept" on the proposed pattern-based learning concept, and as a mechanism for evaluation and assessment of the learning concept. With the experience gained, pedagogy based on pattern-based learning is realized and serves as a blueprint for the development of web deployable courseware. The development of web deployable courseware for content materials specific to mathematically oriented science concepts will also be briefly described.

1. Introduction

This paper presents our experience on curriculum development and on introducing a conceptual learning tool for web-based courseware development to enhance science and technology education. This project is part of the effort on a program funded by the NSF DUE division for enhancing undergraduate science and technology education. There are two groups of targeted audience. The first group is the freshman and sophomore students who may be or have already been majoring in a science or technology discipline. The second group is the senior and graduate students in Computer Science.

There are three major components of the NSF ILI funded program. The first component consists of two parts. The first part is a course curriculum development. A new undergraduate introductory course CS86 --- Science Problem Solving using Computing Tools --- was developed and implemented in Fall/98. The second part is the curriculum enhancement on a graduate course CS762 ---Algorithms based on Probability Methods. The second component of the project is a "proof-of-concept" feasibility study on a conceptual learning tool that has been integrated into the course activities. The process of "proof-of-concept" has led to the development of a set of web-based courseware for CS86 and CS762. The third component of the project is the development of web-based courseware that can be accessed by students anywhere in the Internet with an ActiveX enabled Internet Explorer browser and the Mathcad OLE2 automation server [Mathsoft 1998][Simon 1997].

This paper will focus on the first two components of the project, while the third component will only be briefly described due to the page limit. In the next section we will first describe the profile of our institution and the backgrounds of our students, and the process leading to the development of the course CS86 and the course enhancement for CS762. We will then detail a conceptual learning tool that is based on the concept of patterns. An illustration will follow to demonstrate how various physics and mathematics concepts can be presented within the model of pattern-based learning. Finally, we will discuss our experience on the curriculum development and the student reactions on the courseware evolved from the concept of pattern-based learning.

2. Background

The City University of New York (CUNY) is comprised of seventeen colleges with a student population of about 200,000. Our college is one of these colleges with a student population of 18,000 in the undergraduate and graduate programs. Among them about 1500 are enrolled in the undergraduate science

BEST COPY AVAILABLE

1059

programs, and 40 are enrolled in the pre-engineering program. Within the Computer Science Department, there are about 500 undergraduate students and 200 graduate students. Since our college is a commuting college, many students are residents of the local community, and are the first generation immigrants who have been in this country for less than five years.

One of the highest priorities of our college is to improve the science programs to be more inclusive so that science student population reflects our diverse student population. Cross discipline collaboration is traditionally appealing within our college and viewed as a viable strategy to increase the likelihood of exposing students to science disciplines, even some of these students may not eventually be majoring in science but could still benefit tremendously from increased "science awareness".

Although there are efforts on cross discipline collaboration, most active collaborations often remain in faculty research with limited opportunities for students. We conclude an important first step to stimulate students excitement, and to prepare and engage students in science is the development of a science problem solving course that will offer students general science education and prepare them to participate in cross discipline collaborative science activities. Towards this end, we have developed a course "science problem solving using computing tools" (CS86) [Sy 1997] in which students were introduced to science problems that span cross disciplines and touch their daily life. For example, students will be guided to access the World Wide Web and download from the U.S. Census Bureau [Census Bureau] personal income survey data to determine through a simple statistical analysis on any possible correlation between the age and the personal income.

Another equally important group of student population we focus on is the senior and graduate students majoring in Computer Science. This group of students has been trained traditionally on solving computational problems through analytical algorithmic approach or experimental system approach. However, their exposure to applying learned approaches to solve practical problems may vary from individual to individual depending upon their backgrounds. For example, students may master a theoretical computational algorithm for string match problems, but lack the real world experience on applying it to, for example, promoter detection in DNA alignment problem in molecular biology [Clark and Russell 1997]. Towards this end, we have decided to enhance our course "Algorithms based on Probability Methods" by providing software tools for analyzing data from cross disciplines of science/technology. In order to bring the practical aspects of the analysis of algorithms, the tools just mentioned are web-based in the form of ActiveX components for statistical data analysis and for probability model discovery. These tools are located in the web site listed in [Sy 1998] and the details of access will be presented in the conference. An example of the course activities is the analysis of the interior-point optimization algorithm with a primal-dual formulation [Wright 1997]; where the analysis would be based on a practical application of the algorithm to discover an optimal model useful for reasoning about social patterns, or the molecular structure of musk.

Due to the diversities on cultural backgrounds and language proficiency among our student population, students often have different perspectives on a concept introduced to them. This is particularly evident when students engage in class discussions through topic-centered collaborative learning. In addition, we have observed various learning patterns among our diverse student population. For example, many students with oriental cultural background seem to take an approach that is mathematically oriented, and skill-based practice, leading up to the understanding of an abstract concept. On the other hand, students with English as their first language tend to take an approach that is "word-based reasoning" leading to a mental visualization of an abstract concept. Our observation on learning patterns among students is consistent with a recent report by Stigler [Stigler and Hiebert 1998] suggesting that teaching is a cultural activity.

3. Pattern-based Learning

Given the observation just mentioned, we ask two fundamental questions related to enhancing science and technology education for a student population with diverse backgrounds:

1. Within an instructional environment where a diverse student population may incline to different approaches for learning, what are the common characteristics among these different learning approaches?

In other words, from a learning-centered perspective, is it possible to have a unified learning model that can encompass and provide linkages among different learning approaches?

2. How do we develop instructional techniques and teaching environment that can accommodate different learning approaches and are pedagogically sound? From an instruction-centered perspective, how do we develop courseware that would deliver effective learning, even the preferred learning approach of individuals may vary?

We hypothesize the concept of patterns may provide a linkage among various learning approaches. In our preliminary study, we will focus on one particular aspect of science and technology training --- modeling --- a process often involved in engineering design and scientific analysis.

Loosely defined, patterns may refer to regularities exhibited in a phenomenon, or the existence of certain structures in an entity of particular interest. For example, tornado and twister are weather phenomenon with a spiral rotating wind circulation. "DNA" is a polymer made up of a linear component of sub-units known as "nucleotides" --- composed of phosphate, sugar, and base [Clark and Russell 1997]; where there are four bases: A (Adenine), T (Thymine), G (Guanine), and C (Cytosine).

In our project, we elaborate on the concept of patterns [Grenander 1993 & 1996] to develop a pattern-based learning framework. Within our proposed pattern-based learning framework, the foundation of learning a science/technology concept is based on the discovery process for identifying a set of patterns that represents the concept. Various learning methodologies [Mestre 1995] have been proposed and studied for exploratory discovery process. We concentrate on the formalism of developing a mental model for a concept to be learned through the set of patterns resulted from the exploratory discovery process.

The essence of our proposed pattern-based learning lies on formalism that information coded in patterns can be explicitly represented as a mathematical structure, a visual model, or a graphical model. A mathematical structure could be simply a sequence such as a geometric series, a system of differential systems such as Lorenz equation for weather modeling, or a complex dynamical system for solving "traveling salesman problem" [Banzhaf 1989]. A visual model for representing information coded in patterns could be various kinds of simple plots such as simple 2D/3D scattered plots, surface contour plots, sophisticated Trellis graph or QQ-plot [Mathsoft 1997], or complex high dimensional scientific visualization [Nielson et al 1990]. Yet another useful representation of patterns is a graphical model of functional dependency. For example, projectile motion of a ground-to-air missile reveals a pattern that its (vertical and horizontal) displacement is functional dependent on the initial velocity and initial angle of projection. The functional relationship among the displacement(s), initial velocity, and initial angle can be shown in a dependency network that graphically displays the structure of the functional dependency among these parameters. We will show such a graphical model in the conference presentation via Internet access to one of our web-based courseware that represents a simplified version of functional dependence between aerodynamics and flight control.

An important aspect of the proposed pattern-based learning technique is the inter-relationship among the three different kinds of representation. A mathematical structure that captures the behavior of patterns is an abstraction of the corresponding concept (or physical phenomenon) in terms of functional expressions. Such functional expressions could be in an open form such as a Taylor series or a close form such as a formula for a geometric series [Grenander 1993 & 1996]. A visual model is an abstraction of the corresponding concept (or physical phenomenon) that is based on a data-driven approach to provide a visual perception of the behavior of a pattern [Miller 1986]. A graphical model is an abstraction process that attempts to capture the qualitative "causal" relationships among the parameters needed to describe a concept/phenomenon [Pearl 1988].

There are three processes associated with the proposed pattern-based learning technique: synthesis, analysis, and summary. Given a mathematical structure, one can synthesize data from the functional expressions. The data synthesized is a source for constructing a visual model that is based on data-driven approach. Given a visual model, a learner's task is to summarize the observed relationship in terms of qualitative causal or dependency relationships in a graphical network form. This concept is not unusual as evidenced by the notion of concept map in education community [Gange et al 1988] and belief network in AI

community [Pearl 1988]. In reverse, one can analyze a given set of data in an attempt to discover the functional expression. Or given a graphical dependency model, one can try to discover a mathematical model through which one can use the functional model to derive data for constructing a visual model.

4. Illustration

Projectile motion is a concept commonly used to illustrate the law of motion in Physics. The law of motion describes the inter-relationship among the displacement of an object in relation to its initial velocity, initial angle of projection, and acceleration. The change in the position of an object can be calculated using the equation that characterizes the law of motion. In particular, the vertical displacement at time t is $S_y(t) = ut \sin(A) - 0.5gt^2$; where u is the initial velocity, A is the initial angle of projection, g is the gravitational constant, and t is the time elapse. Similarly, the horizontal displacement at time t is $S_x(t) = ut \cos(A)$. The position of an object in projectile motion ($S_x(t)$, $S_y(t)$) can be computed using the mathematical equations just shown. These two equations are the functional expressions that underlie the mathematical structure of the projectile motion.

Using the functional expression of the projectile motion, one can generate a set of data $(x(t), y(t))$ that corresponds to the position of the object at time t , with $x(0)=y(0)=0$. If $(x(t), y(t))$ is plot one-at-a-time on a x - y axis, the animation of the plot shows the projectile motion. This animation presents a visual model of the projectile motion. The change in the maximum horizontal and vertical displacement can be observed when the initial velocity or the initial angle is changed. The dependency of the maximum horizontal and vertical displacement on the initial velocity and initial angle can be shown in a graphical network model similar to a Bayesian network [Pearl 1988].

In pattern-based learning, a learner may first make observations on the change of projectile motion in relation to the change of initial velocity and angle. This first step is to engage the learner in a discovery process to identify patterns of projectile motion and to develop a "mental visual model" of the projectile motion. The learner will hypothesize the relationship among the changes in displacement, initial velocity and angle. Then a graphical dependency model will be constructed to reveal the hypothesized relationship. At the same time, the learner may take measurements on the change of vertical and horizontal displacement over time for various fixed settings of initial velocity and initial angle. With the measurement data on hand, the learner can perform a reverse engineering process by deriving a functional expression for the horizontal displacement with time as the independent variable on a fixed initial velocity and angle, and similarly a functional expression for the vertical displacement.

The pattern-based learning process just described is an exploratory approach where a learner begins the learning process by making connection between his/her internal experience with the observations made for the external physical phenomenon. There are two end products of this step: a mental visual model and a graphical dependency model. The next step of the learning process is to discover the mathematical structure of the concept of the projectile motion. A point noteworthy is that these steps can be applied in a reverse order to engage a student in the pattern-based learning if the student prefers a more mathematically oriented approach on learning a new concept. Yet another point noteworthy is the built-in mechanism for assessing learning. Consider the case where a learner hypothesizes a positive linear relationship between the maximum vertical displacement and the initial angle by overlooking the critical turning point 45 degrees, a simulation based on synthesizing a visual model will reveal a discrepancy between the simulated and observed projectile motions. We will illustrate this point further during presentation using a web deployable courseware that runs on a PC with a Mathcad/Mathconnex automation server.

5. Web Courseware and Dissemination

The web deployable courseware of our project consists of three tasks: (1) content material development, (2) media presentation and application feature, and (3) dissemination. Currently we focus on developing courseware for content materials that involve mathematically oriented concepts, in particular,

those concepts that are difficult to our students; e.g., system equations for projectile motion in CS86, or the computational geometry of hyper-tetrahedron that encompasses all possible discrete multi-variant probability models.

As noted from our students, math and science understanding are often related to the ability to visualize. Therefore, an important consideration of our courseware development is the visualization feature for a student to explore visually the mathematical structure behind a difficult concept. Our approach is to adapt proven authoring tools such as the one by Mathsoft Inc. for courseware development. The courseware will be in a form of electronic books that provide 'live' formulas where the data can be manipulated, graphed, or even animated [Spiegel 1989] [Edminister 1995]. These electronic books are not just a textbook in an electronic form, but a new media providing new modalities for learning. Integrating new modalities with traditional text-based modality is particularly well suited for our proposed pattern-based learning approach, which is a significant and integral part of our project on enhancing science and technology education. Using these new modalities, students can apply the conceptual learning tool --- pattern-based learning --- to gain a greater insight into visual reasoning behind the numbers and their mathematical relationship.

Currently our dissemination strategy on the web is on a vertical scale. That is, we adapt one environment for authoring and accessing the courseware. Namely, our environment is on Microsoft operating systems (Windows 95, 98, or NT), and the web browser is ActiveX enabled Internet Explorer. Within this environment, the authoring and computing tools are Mathcad by Mathsoft Inc., the data exchange is mostly on Microsoft Office and Mathcad OLE automation servers, and the programming development environment is by Inprise (former Borland). This strategy works well within our local community since we involve in the planning and implementation phase of building the infrastructure to support dissemination to our students. This strategy, however, has yet to be found out its effectiveness beyond our local community. Below is a list of issues to be explored:

1. Our courseware is tied to pedagogy based on pattern-based learning that seems to work well with our students. How effective is our courseware on students in a different community, and perhaps even with different learning attitudes due to the cultural differences; e.g., foreign students as compared to students went to the high schools in the US, or students in different geographical localities?
2. Currently our courseware is deployed via the web, but require Mathcad OLE2 automation server, as well as Internet Explorer (IE) with ActiveX capability (i.e., IE 3.0 or above), and Microsoft Office OLE automation servers for data exchange. Is this requirement on the resources a reasonable expectation on the audience outside our college who can benefit from our courseware?
3. It is conceivable that different campuses may have their unique characteristics in terms of the choice of approaches and tools to best suit their students. What are the (additional) resources required for cross campus dissemination with respect to the support for courseware customization, media and technical support, as well as lesson plan development?

6. Conclusion

This paper presented the major components of our NSF project for enhancing science and technology education. We have discussed the curriculum development and enhancement of two courses to make our science programs more inclusive so that our science students reflect the diversity of our student population.

Due to the diversity of our student population, we noted that students generally take different approaches in learning a new concept. We have presented a learning approach based on the concept of patterns. It is our hope that this proposed pattern-based learning would serve as a linkage for bridging various learning approaches taken by students. A set of web deployable courseware has been developed to help students engaged in pattern-based learning. In our preliminary assessment, we found students responded favorably to our proposed pattern-based learning. This is in part due to the rich variety of representations that provide different perspectives for understanding concepts which may otherwise too difficult for students to grasp.

The favorable response from students is an indication of "proof-of-concept" for our proposed pattern-based learning. As a consequence, we plan to make our courseware accessible to not only just the audience

inside our college, but are currently exploring possible dissemination of our courseware (and its application to enable pattern-based learning) beyond our college through web deployment. Further details about our courseware development and dissemination will be reported in an upcoming workshop supported by the faculty development program of the Research Foundation of the City University of New York.

Student 2000: Net-based Learning for the Next Millenium

Kåre Synnes, Peter Parnes, Johnny Widén, Dick Schefström
Departement of Computer Science / Centre for Distance-spanning Technology
Luleå University of Technology, 971 87 Luleå, Sweden
{Kare.Synnes,Peter.Parnes,Johnny.Widen,Dick.Schefstrom}@cdt.luth.se

Abstract: Luleå University of Technology has for the last few years deployed a net-based learning environment, mStar, to distribute courses to students independent of time and geographic distance. The mStar enviroment gives remotely attending students equal possibilities as traditionally attending students to take an active part of a course, as well as enhancing the learning experience for all students. This is made possible through a novel combination of IP-multicast technology and the WWW. This paper reports on experiences gained over a few years of practice and depicts a vision of the next generation of the mStar environment.

1. Introduction

If the Internet is the next industrial revolution, then net-based learning may be the next educational revolution [Synnes et al. 1998]. The evidence of this is clearly present at most major universities and companies, where the WWW is used to distribute information to students. Many environments have been presented at past WWW conferences and we can today see that the technology is maturing as usage is increasing.

Some of the early educational uses of the WWW [Perron 1994][Goldberg et al. 1995][Ibrahim et al. 1995] and virtual classroom environments [Lai et al. 1995] have been a major influence for this educational revolution. The availability of course related information such as lecture notes, extra course material, exercises, and course schedules blended with the WWW's inherent qualities such as hyperlinks and accessibility have added much information to the classical structure of courses.

A common deficiency found in these early environments are the lack of support for spontaneous interaction between students and teachers. Additional functionality like real-time textual chat and video conferencing has enhanced communication, creating environments that are near to complete in functionality. The mStar environment [Parnes 1997a][Parnes et al. 1997b][Synnes et al. 1998] is a fully symmetric and distributed system for net-based learning that include the necessary support for spontanous interaction between students and teachers.

Although the mStar environment is functionally well equipped, the usage of it is still immature. Courses at Luleå University of Technology, LTU, are still given in the traditional way, with lectures and laborations, and students are not using the available possibilities of interaction.

This paper reports on experience gained from a wide use of the mStar environment for over three years and depicts a vision of the development of net-based learning using this environment in the next millenium. The paper consists of a brief background, a presentation of how the mStar environment is used at LTU today, and finally a discussion on how a future environment could be like.

1.1 Background

One of the major driving forces behind the Centre for Distance-spanning Technology, CDT, is to deploy net-based learning in the county of Norrbotten. The reasons for this is quite evident: a sparse population in a large geographical area, a decrease in funding while students increase in number, a higher demand from industry for post graduate studies, and the increasing problem of finding competent teachers.

Thus, many high-schools cannot gather the critical mass, funding and competence to offer the courses and subjects that are possible in the more densely populated areas. By giving multimedia- and WWW-based courses over the networks, a sufficient critical mass is generated, creating a county-wide virtual university with breadth and quality that might otherwise not be possible. This virtual university can also be used to guarantee life-long

learning aspects, where people continuously can take net-based courses that does not demand their full workday attention. This is becoming more important as people without a university level degree have increasing problems to find work, at the same time as it has become economically harder to complete a full university level education.

LTU have given a large number of distributed courses using the mStar environment, ranging from graduate-courses to full fledged under-graduate courses. The university has achieved a significant deployment and usage of distributed education over the Internet, not only internally but also to other companies and organisations in the county. Giving joint courses might help bridge the gap between local industry and the university.

This paper therefore presents the concrete results of a wide deployment effort of the mStar environment for distributed education where secondary schools, the university, local companies and communities are all active participants. We are now only starting to see the first social and cultural changes within the schools and companies involved. The paper also depicts the vision of the future use and continuation of the net-based learning efforts at LTU.

2. Net-based Learning Using the mStar Environment

The mStar environment is a collection of tools that span from preparation to presentation. The tools are flexible enough to be useable in many educational scenarios, from large scale lectures to small group activities.

Note that by combining the possibilities offered by available networks, the accessibility and ease of use of the WWW and the benefits of IP-multicast [Deering 1991], we have been able to make these scenarios a part of our everyday, real-life teaching experiences. We would like to stress that this is a working system in real use.

This chapter means to briefly describe the current use of these tools, as well as some lessons learned.

2.1 Large Scale Distributed Lectures

The traditional large scale lecture is currently an important part of the net-based learning efforts at LTU; not because it is the best form of education, but perhaps because it is most similar to ordinary education.

To conduct a distributed lecture the lecturer prepares HTML slides before the lecture, where additional content can be linked into the slides for in-depth information. The slides is then put on the WWW in advance of the lecture which give ambitious students the possibility to prepare for the lecture. They can also be used after the lecture for repetition or further in-depth study.

The lecture hall is equipped with computers, cameras, microphones and projectors. This enables projection of the HTML slides in the lecture hall as well as distribution of the slides to remote students attending from the net. In addition audio and video are distributed from the lecture hall, which gives the remote students an equal opportunity to take an active part in the lecture. The remote students can also send audio and video, which gives them the possibility to ask voice questions just as if they were in the lecture hall.

All-in-all the learning experience come near to something that is *better-than-being-there*. That is, the remotely attending student has an enhanced learning experience in comparison to the normally attending student. The remote student can in parallel to the lecture follow in-depth material, have side conversations with fellow students, and can even do secondary low attentive. Furthermore, remote students with disabilities have benefits that are not otherwise available, such as control of the slide presentation format (font sizes, colors etc) and a more undisturbed audio environment.

The mStar environment constitutes a set of tools based on IP-multicast. These tools and their respective use have previously been presented in detail [Parnes 1997a][Parnes et al. 1997b][Synnes et al. 1998], but here is a brief summary of the most used tools:

- mMOD - media-on-demand server for recording and playback of sessions
- Marratech Pro – fully symmetric media client, which consists of two parts:
 - mVideo (audio and video)
 - mViewer (slides, chat, whiteboard and session directory)

The lecturer announces a session for the lecture, then both lecturer and students launches Marratech Pro. All media are then presented locally in the lecture hall as well as distributed to the remotely attending students. The student can ask questions by either sending voice (mVideo), text (mViewer chat) or figures (mViewer whiteboard). Note that the students in the lecture hall can hear and see the remote students and the other way around.

The participants are 'submersed' in a fully symmetric environment that takes distance education a step further

from traditional HTML-based courses. The students are no longer passive receivers as they can interact in real-time, which is very important for promoting student participation and debates between class members.

Finally, the lecture can be recorded with mMOD and can then later be played back. A recorded session can for instance be played back into a live lecture, which enable reviewing and debating of related recorded material. The recordings also give students a possibility to rehearse before exams, and – more important – follow courses asynchronously. The latter is a major point for life-long-learning issues, where people that cannot attend during day-time or even follow a course full-time actually can take part of a course.

2.2 Virtual Student Community

The lectures mainly offers a one-to-many channel, since students often are too shy to ask questions – especially if the session is large. We have found that something complementary is needed, where students can cooperate and interact with each other. It is naturally very important, perhaps even vital, for remote students to have a continuous contact with the teachers and fellow students.

Creating such a community, as described in [Lai et al. 1995], can also lessen the workload for both students and teachers. Today students themselves are sources of information, the teachers are no more the sole information source, which means that collaboration and sharing of information is vital to make large distributed courses a success.

However, most of the courses currently given using the mStar environment at LTU are *normal* university courses. This means that the incentive to establish a virtual student community is weak, since there is a physical community to fall back on. It is always possible to knock on the teachers door. The result is also that the current virtual student communities are sparsely populated. This would change if most students were *real* remote students, and the physical community was not available.

2.2.1 Virtual Teachers Room

The virtual teachers room is basically a Marratech Pro session where the teachers of a course are available to answer questions or chair discussions. This could also be a session where a group of teachers are available – thus not necessary linked to a specific group, but as a general resource. The latter case might be important for the feeling of continuity for remote students, since they change courses every tenth week and need a fixed point in their studies.

2.2.2 Virtual Group Room

A Marratech Pro session can be used by a group of students, forming a virtual group room, to discuss course related issues, with or without a teacher attending. The virtual group room can also be used for project status presentations, where a subgroup of a larger class is attending.

This form of meetings may prove invaluable, as remote students need to overcome isolation by forming groups and socialize. It is therefore important that courses emphasize collaborative over individual learning, in order to stimulate use of this media.

2.2.3 Virtual Billboards

The value of asynchronous communication should not be underestimated, as many students choose to follow courses entirely or partly asynchronously. Systems that support asynchronous communication are numerous, ranging from simple mailing lists to advanced WWW-based boardsystems. LTU has recently deployed a system developed internally, W3Cs, which enables students and teachers to communicate via a bulletin board. W3Cs also offer basic support for course management, a task earlier handled by homemade scripts individual to each teacher and course, as well as support for document publication.

One observation made is that usually silent students also contribute to asynchronous communication, maybe because they have more time to formulate their meaning or since the interaction is more abstract. This is more noticeable if a electronic group is maintained over time, creating a virtual community of students where the

students *feel like home*. The virtual community must however have an active leadership (introducing new members and excluding misbehaving members) and clearly defined boundaries (limiting what should be discussed).

2.2.4 Lessons Learned

The statistics from our mMOD server logs show that many students prefer to watch lectures during evenings, or even late at night. The possibility to watch recordings is clearly useful for students having overloaded daytime schedules. Using the playback facilities offers another clear advantage; it enables students to take pauses, to either read additionally related information or to consult the course literature. Unfortunately, these students can not be part of the spontaneous discussions during lectures. Having multiple participants active in the playback environment might remedy this to an extent, but this is clearly an area to be improved.

We have noticed that other social protocols have been established when using the environment for presentations and education. Foremost are the sub-discussions that take place using the chat tool, where a set of the participants either discuss the presenters material or something completely uncorrelated. This kind of discussions and sharing of information enhances the learning experience, since attending a lecture physically normally disallows side conversation in the audience.

By encouraging the use of different means of communicating electronically, such as email or WWW-based discussion media, we have found that students tend to help each other. This form of social clustering, is most interesting. It lessens the traditional burden of a teacher, where students with additional knowledge often share it with the rest of the class and the teacher. The fact that students are able to share this knowledge with the group is an enormous advantage to more traditional teaching, where students seems to rarely form groups with more than five members.

A downside is that lectures distributed with the mStar environment tend to become more static than classical (i.e. non electronic) lectures. Experienced teachers are most often those who can improvise and dynamically alter the course of a lecture. These teachers usually do not need to prepare presentation material, as their lectures often take the shape of a normal conversation. With mStar, teachers are easily *caught* in the flow of their pre-made electronic material. It is therefore very important to still allow the teacher to improvise, perhaps by making use of an electronic whiteboard or a sketchboard.

3. Net-based Learning for the Next Millenium

The experience gained over the last years allows us to draw conclusions about how a future system for net-based learning could look like. This chapter therefore aims to present our vision and to give initial answers to some of the questions we have found important.

3.1 Questions

Who will the future student be? Students will range from persons reading a single course to persons following a complete fixed program, but the typical student will have a individualized program (where they select course themselves). They may also have varying study paces and learning styles, as well as different needs for learning support. A conclusion is that the future students will be a very inhomogenous group, especially if we take life-long learning into consideration. This means that courses must be modularized to a larger content than today, so that it is easy to customize a course for an individual depending on the knowledge level of that individual. Required background information and in-depth material should therefore be easily accessible to give individuals an optimal learning experience.

Where and when will the student study? The possibility to study independently of time and geographical location is increasingly important. The idea that a university is for everyone is otherwise hard to attain, atleast in Europe. People that are limited to study on evenings or that is resident far from a university are dependending on this possibility.

Will the university offer social training? The student used to be a passive individual that is fed information; this is something we need to change. The industry needs persons that can communicate easily and work effectively in groups, which means that we need to better prepare the student for the professional life after

graduation. The traditional lectures must be complemented by group discussions and projects where students work in groups. Again this might be a European phenomenon, but is generally important. It is naturally extra important for net-based learning scenarios, where the remotely attending students otherwise easily can get socially isolated.

Will there be a local university? The role of the present universities will not change initially, even if much of the competence will reside on the outside. There are however several efforts to create virtual universities, where top competence is gathered to one virtual location. This means that the physical location for studies will be less important in the future, even if it for obvious reasons always will remain (lab equipment etc). The most extreme is that the university only will be the *quality brand* of an educational program. It might also be so that the currently ongoing competence concentration around cities with universities will slow down, where the less densely populated areas also can take part of higher education and prosper.

3.2 The Vision of the Student Year 2000

Our belief is that students will not be much different than today, but that they will have increased possibilities to take part of university level education. No longer are large geographical distances or time limitations ruling out where and when education can be offered. The student year 2000 can be everything from a full-time student attending lectures physically on the university, to a part-time student following courses from his home at evenings and weekends. It might even be cheap, both from economical and time perspectives. By giving courses for a larger number of students, they will become cheaper per student. Remotely attending students will also need to travel less, which further lowers the cost as well as the time spent. The student in the next millenium will certainly have demands on cost and time efficient education.

By combining large scale distributed lectures with group projects and personal assignments, well balanced distributed courses is attainable. The lectures should contain invited speakers from the industry or other research organisations, to complement the traditional academic content and to better prepare students for what is required after graduation. The group projects leads to early training of social skills, while personal assignments remain important for grading reasons. However, when courses are attended by a large number of students, it will be increasingly important to establish personal tutors or advisors. Personal relations to teachers are important for the overall learning experience, students simply need someone to ask questions.

The future of net-based learning include equal parts of freedom and responsibility. We can clearly see that the old way of spoon-feeding students with information is coming to an end, and a more collaborative shared learning experience is forthgrowing. This however needs students with high self-motivation, discipline and commitment. It also put higher demand on the courses, on content as well as pedagogics. The new net-based courses must apply specially developed content, following the old tracks simply do not work, and new ways of teaching is also required, which emphasize collaborative learning.

4. Summary and Conclusions

This paper describes a novel multimedia environment for net-based learning which tightly integrate the WWW in a close relationship with IP-multicast technologies. The variety of usage experiences and the successful county-wide deployment clearly demonstrates that the mStar environment is scalable from small informal presentations to complete university courses.

We have argued this from a variety of perspectives, all showing that this environment offers extended support for interactivity, better help through the use of a *virtual student community*, as well as on-line availability of all course media. The goal is to create an educational environment that can be qualified as better-than-being-there, bringing everyday situations such as interacting, learning and collaboration to the Internet.

5. Future work

Today the different tools are simple and intuitive to use, and the technology is rapidly becoming stable. There is however a long way to perfection, especially considering the pedagogic aspects. Large scale lectures is still far too common, which in turn are too limited when distributed over the network. Using only HTML slides is too limiting, and using the mouse to draw in the electronic whiteboard is too unprecise. Work is currently proceeding

to install a pen-based electronic whiteboard (synchronised with the mViewer Whiteboard) in the lecture hall, to better support spontaneity.

Although the remote students have a very good environment for following lectures, the physically attending students have a less than perfect environment. This is due to bad hardware, where the LCD projector available in LTUs lecture hall is both too noisy and weak. Together with limited spontaneity, this creates a *tiredsome* setting for the locally attending students. Hopefully new funding can sponsor a better equipped hall.

As a last issue, the general pedagogic and social issues in our net-based learning environment needs to be studied. How good are distributed courses in comparison to traditional courses, and how does the results of remotely and physically attending students compare? Our belief is that we have a strong technology, but that we are weak on pedagogy. Hopefully, the new Center for Net-based Learning at LTU, CNL, will help us bring clarity to the remaining pedagogical issues.

Abstract: In rural states such as Vermont, it is often difficult to find needed resources in a single community. New educational concepts, new technology, and new subject content require collaboration among those who carry some experience in at least one of these new areas. With the advent of the World Wide Web and the recent technological ease of digitizing images, sounds, movement and text, these collaborations can occur at a distance. In 1995 the US Department of Education provided funds to Vermont schools via the WEB Project, <http://www.webproject.org>, to build an innovative online network of students, teachers, artists, and community organizations working together to help improve student performance in the arts, humanities, and social sciences. Online Arts Mentoring in music composition (Vermont MIDI Project) and visual arts (Art Responding Through Technology - ARTT) formed the first two groups.

High expectations and new standards placed on rural areas with limited resources can stress a system to collapse, or they can provide the conditions needed to spark ingenuity. Arts teachers in Vermont have chosen ingenuity over collapse and throughout the course of the last five years they have built an online system for support of these new standards that remains true to the artistic process and inspires the students, mentors, and teachers who participate. By selecting a few key learning goals in critique, problem solving, communication, and personal development, an online arts mentoring system has been built to address many national and state standards. This paper tells the history of the network's development and shows the importance of technology in meeting those goals.

First Exchanges -- E-Mail and Attached Files

In 1994 the state of Vermont, like many other states, offered monies to schools so that they could build a technological infrastructure and create models for effective distance learning. While most schools were thinking of hubs and routers, a small group of music teachers were worrying about meeting a new standard for music

composition. Because few of the group members had ever been taught to compose, they faced many of the same concerns that teachers in other disciplines face: how can I teach something I don't know myself? The distance learning grant provided the initial computers and keyboards necessary to begin an exploration of this question together. With accounts from America Online, teachers sent e-mail and attached MIDI files to each other and to the network coordinator. Like many other early initiatives across the country, there were more discussions about what to do and how to do it than there were actual compositions exchanged. Measurement of success was counted in terms of numbers and types of messages, with an assumption that a reduction in technology related questions and an increase in actual music exchanges would show improvement. Other national projects (quote Judi Harris work) analyzed their beginning exchanges in a similar manner.

During the initial phase of the project, January - June 1995, the only guideline established was that people would send messages. Lots of messages were sent and the quality of student compositions was understandably low, with rare exception.

That the Vermont MIDI Project had begun something cherishable dawned on participants at both ends of a telephone line in 1995. The story below describes this event (MacLeod 1998):

"In the spring of 1995 I waited with a 9 year old student in southeastern Vermont who was sending a composition to students in northwestern Vermont as part of a tech fair demonstration about a new project in MIDI Distance Learning begun the previous January. Will waited patiently while 6 adults tried to restore the school's dial-up connection so that he could mail his music. He paced quietly for the next hour while the students in Essex Junction read and responded to his composition. Will was asking them what worked well and what they thought needed improvement in his piece.

A response from Essex finally came.

Thanks for sending your piece. Good luck at the Tech Fair. A fifth grade class at Founders Memorial School listened and sends you these comments: Erin wants to know if you play the piano. How did you know what notes to choose? Jo liked the way it climbs and falls and likes how the rhythm keeps on rolling.... Joanna thought it was very creative it had a good beat and interesting notes... Lindsey wonders if it is finished because it doesn't sound like the end. She sang a pattern that would sound good as an ending....

Will responded with relief and a wry smile, "How did Lindsey know my piece wasn't finished?? I have been trying really hard to figure out the ending. I tried 10 things that didn't work. I can really use this." He left quite excited that someone he didn't even know had recognized his dilemma. Will wrote back again, asking for Lindsey to send him the patterns that she had made up. Even though he didn't use the exact patterns that Lindsey sent, she had given him the inspiration to finish his composition.

Beginning a Structure

An unstructured exchange continued until winter of 1996 when the network participants gathered in person for a meeting to discuss what was working and what needed improvement. Student enthusiasm for music composition using MIDI tools boosted the desire to continue the network. High on the list of priorities for improvement, however, was the demand for consistency in level of response (participants who were spending time giving detailed feedback to students in other schools were getting their feelings hurt when they received cursory response to their own work) and a request for help in teaching composition. These two desires provided a basis for the original structure of what would become Online Arts Mentoring. Guidelines for feedback were drawn up in the form of a three-point scale for reflection and critique:

Generic Rubric for Assessing Student Responses

Level 3: Accurately describes the area being discussed. Gives detailed examples, references, connections or responses to general insights. Uses arts vocabulary.

Level 2: Accurately describes the area being discussed. Uses a mix of arts vocabulary and general terms.

Level 1: Gives general comments that could apply to other situations as well as the one under discussion.

A plan to incorporate artists-in-residence into the network was also designed. A concern on the part of the coordinator that the e-mail exchanges were not resulting in any noticeable improvement to the network as a whole,

but seemed isolated to those who were receiving paired responses, was put on hold until the communications technology itself improved.

Formalizing the Structure in an Online Conferencing System

In the spring of 1996, the MIDI network gathered in person once more to discuss whether or not the suggested improvements were taking hold. By this point, teachers realized that the students cared deeply about the compositions and took their e-mail responses seriously, again providing the impetus to continue. Together, they articulated the need for a description of what the students were trying to do and a request for specific types of feedback so that the level of response could be at Level 2 or Level 3 on the scale designed previously.

By this point in time, the World Wide Web was becoming accessible and early Web based conferencing systems were on the market that could be adapted for the MIDI network's purpose with some additional cgi scripting and the development of a relational database. Funding for this particular effort and a broader extension to improve student learning in the Arts, Humanities, and Social Sciences came from the United States Department of Education, Technology Innovation Challenge Grants program with the funding of the WEB Project. Federal funds and a local match gave the system the resources it needed to prototype and develop ideas that were not yet available on the open market, and the WEB Project provided a link to learning in other content areas.

Design specifications were built so that the site would deliver a web-based system that would support the learning goals of the network, provide a system of assessment of the work, and create a database for future analysis.

Support the learning goals

Using a web based conferencing system meant that computerized forms could reinforce three of the emerging network agreements:

1) Describe in detail what you are trying to do.

Rich descriptions help the viewer understand the intent of the creator. It is helpful to know the assignment that the student is working on. Supplying this information gives the responders a context from which to comment. It is also helpful to know the stage of the work such as just getting started, in the process or completed.

2) Request feedback, but be open to more than what is asked for.

Saying what it is that you would like to have input about helps the responder to focus and give comments that are useful. That being said, a responder may also wish to give comments about some aspect of a piece that have not been specifically requested. High school students, especially, have asked that mentors use their expertise to help them stretch their imaginations and the possibilities offered.

3) Give specific and detailed comments that are based on helping a person reach his /her intent.

The goal of the online critique process is to develop multiple suggestions for how a student can go further with his or her work. That means that those giving responses need to listen to what is trying to be accomplished rather than responding solely from personal opinions, beliefs, or taste.

These agreements translated into a form with required fields for description of work and requested feedback and provided a link to an upload form for comments. All of the comments could be viewed as running text so that students could easily review the various, and sometimes opposing, ideas of others as they chose to use specific input to refine their compositions.

Provide a system of assessment

The MIDI network had already established a scoring system for levels of response. A third level of password security was built into the web design so that, should the network desire, scorers could assess the level of response of each comment. Allowances were also made to score the compositions themselves, even though a scoring system had yet to be built in 1996. To build in rater reliability, the WWW design called for three scores of a single piece of work. If all three scores agreed, then the file was to be placed into a "scored" archive. If all three scores did not agree, then the file would be placed into a "disputed" category so that agreement could be reached or the file discarded from analysis as "unscorable."

Create a Database for Future Analysis

If the online arts mentoring system remained as dynamic as the initial activity suggested, then it would be important to gather other data during the uploading which could be used later. Fields to measure classroom behavior over time (group work and locus of control), grade level indicators, and location were added to the form. A compromise between amount of data needed for research versus the desire for unobtrusive measurements resulted in the development of radio buttons and pulldown screens for these items. Questionnaires were also developed and the results are stored in an online database. Together with the data from assessment, the information gathered from the site forms and surveys can be used to make direct statements about student learning as a result of the conferencing system. A research project concerning the development of quality in the MIDI Project is currently underway.

Extending the System to Visual Arts

As the music educators and composers showed what was possible when students, artists, and mentors collaborated, their network attracted the attention of art educators who decided to adapt the music composition model to online visual arts in 1997. Thus, another initiative in Online Arts Mentoring was born (Art Responding to Technology -- ARTT), using a similar pattern of reflection and critique of student work-in-progress.

From: Lee

Organization: VT Elementary School

My name is Lee , I am a sixth grade student . I need help on my pencil drawing, I have no clue what I should do next. Do you think you could give me some help? I like this drawing alot.

Requested feedback: What can I do to the background? What should I do with the bird's chest? How can I make the values show more than they do?

Comment Excerpt From: Joan Curtis, Artist

The strength of your picture so far, I believe, is the interesting composition. The way you have arranged the close-up eagle within the picture's edges is quite powerful.... I would like to see a little more description of the feathers you are seeing.... Is it possible to be more specific with your pencil?...

Comment Excerpt From: Ken Leslie, Johnson State College Visual Arts Center

....You asked about "background." This is the place where you can add information that will tell a bit of a story. Imagine how different this same drawing would be if there were tree branches and leaves in the background, or hunters with guns, or zoo cage bars. Not one line of the eagle has changed, yet the meaning of the drawing is completely different for each of those backgrounds....

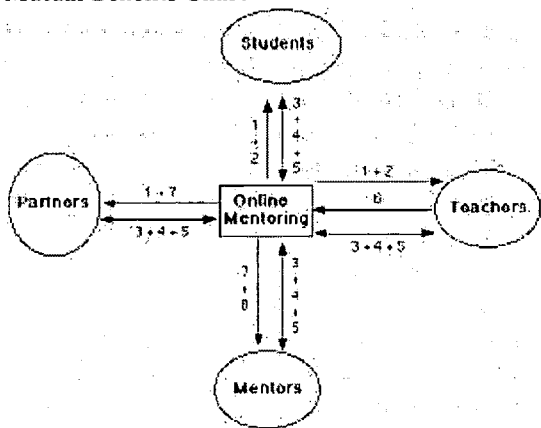

From: Lee

Thank you so much for all of your remarks. What I ended up doing is I put bars in the back so it looks like it is in a cage in the zoo.

Building on Research to Inform Practice

As the Online Arts Mentoring system was being developed, similar trials were occurring across the United States in other content areas, some of which were based on dialog as well. A literature search (Sherry in press) reveals that this process follows closely what Jenlink and Carr (1996) name "design conversations" and that the processes used to organically develop the online learning community embody the qualities of active learning articulated by the REAL Project (Rich Environments for Active Learning), especially that of cognitive apprenticeship (Grabinger 1996). A WEB Project survey taken in 1998 confirms that the Online Arts Mentoring system cultivates an environment where all participants are learning from the experience.

Mutual Benefits Chart

1. Improving their work
2. Getting affirmation
3. Seeing range of examples
4. giving critical feedback
5. Learning to use technology
6. Giving curriculum examples
7. Better understanding the educational system
8. Learning more about students

Teacher researchers have been developing systems to decrease the learning time that has been involved in addressing new standards, higher expectations, and the use of telecommunications to improve student learning. Through a University of Vermont course on Action Research, the current MIDI coordinator has designed a professional development process for music (MacLeod et. al 1998) which has also been transferred to the visual arts

(Tavalin et. al 1999). The characteristics of these processes include a mix which balances skill development, critical input on work in progress, and a learning environment in which all participants contribute and learn from each other.

Looking Toward the Future

With the advent of Online Arts Mentoring, Vermont's teachers and students are given a portal through which they find access not only to each other, but to working artists and community arts organizations where professional collaborations and even personal friendships can blossom and grow. The use of asynchronous threaded discussions for critique of student work online has provided teachers with a resource that is there when they need it, while community organizations and mentors, <http://www.vaae.org/studios.html>, have gained contact with young artists starting their explorations of the field, and access to new technologies which would have been out of reach financially for them to invest in individually. During the 1999 spring gathering, network participants listed what is currently working well in the Online Arts Mentoring and what needs improvement.

What is working:

- A developing sense of community among the teachers, students and artists/mentors
- A high level of enthusiasm amongst students
- A high level of exchanges about the postings. Students increasingly use arts vocabulary with precision to communicate abstract ideas
- Behind-the-scenes and online discussions about possibilities, planning, actions, problems
- System addresses creation as a process: 'The creative process,' rather than creation as an event

What needs improvement:

- A commitment that students reply once they have received comments
- Increased feedback to mentors about the usefulness of their comments
- A method for better management of time
- Increased participation of pre-service teachers

Having begun as an innovation, Online Arts Mentoring is entering a phase of institutional adoption, with agency sponsorship from the Vermont Arts Council which should lead to long term sustainability. As the process of online mentoring evolves and new members are introduced, it remains essential that they continue the conversation about what is working, how well it is working, and how to improve.

Abstract: Using the example of Taking a Stand in Cyberspace, we articulate issues confronting school, community, and higher education groups as they create online discussions geared to deepen the level of student discourse about literature. Through a collaboration between the Vermont Center for the Book, the WEB Project, and six Vermont schools, students read and discussed three books while teachers maintained an online discussion about the student conversations and the degree to which the student discussions showed evidence of reaching selected learning goals. The experiences resulting from Taking a Stand, along with earlier initiatives, indicate that an evaluation of the opportunity to use and exhibit critical reading skills is as crucial to the improvement of student learning as an assessment of an individual student's attainment.

Introduction

In schools throughout Vermont, educators are faced with the enormous challenge of helping all students move well beyond basic reading skills towards deeper understanding, critical analysis and interpretation of text. Building on the research and lessons learned through online art exchanges among students, teachers and professional artist mentors, The Vermont Center for the Book and The Web Project sponsored Taking a Stand, (<http://www.vermontbook.org>) an online book discussion series among middle school students from six Vermont schools. Students read and discussed, in class and online, three novels dealing with young people who intentionally or inadvertently take a stand on an issue.

To establish a common focus and address previously identified concerns about reading comprehension, three standards from the Vermont Framework were selected: 1. Students read for meaning, demonstrating both an initial understanding and personal response to what is read; 2. Students make informed decisions; 3. Students respond to literary text and public documents using interpretive, critical, and evaluative processes. Generic scoring systems, keyed to state evidence for these standards, were provided as guidelines for quality.

To facilitate the educational goals, a web-based conferencing system was carefully selected that supported group collaboration and the easy ability to see discussions in list and running text formats. The software interface was essential to building dialog between participants in that it provided a common, reliable space with access to whole conversations and a robust search engine.

Evolution of the Online Experience -- One Classroom View

At Walden School, eighth graders typically spent literacy classes two weeks prior to their time online reading and participating in small-group, Great Books-style discussions, forming and responding to interpretive questions and referring to passages in the text to explain or underscore thoughts, back up opinions, and frame questions. They related issues in the books to their own lives and, in some cases, built background knowledge to

gain a greater understanding of the book's context. At the end of that preparatory period, they worked with other students in small groups to select an idea or post a question, based on their class discussions and writing.

As a prelude to their online book discussions, students at the six schools got acquainted through personal introduction threads. This was initially very awkward for Walden students as they sought a way to present themselves in cyberspace to unknown others. This was particularly challenging before students had fully conceptualized the experience of online discussion, confirming what Brent Wilson articulates as he describes some of the dilemmas of engaging students in online learning communities (Wilson 1998). Prior to *Taking a Stand*, some Walden students had used e-mail, some had done chats, most imagined that communication would be relatively immediate. Few, if any, had experienced asynchronous, threaded discussions and were somewhat taken aback by the time delays. Once students received responses or read other postings, however, their interest and eagerness soared.

Students initially discussed *Nothing But the Truth*. Each school distributed groups of students among three discussion forums so that the volume of responses would be manageable and students would have opportunities to dialogue with small groups of students from each of the other schools. Even with this precautionary organizational structure in place, floods of questions, rudimentary responses, and only occasional examples of complete cycles of dialog characterized the first discussion.

As students reflected on the first book discussion, they recognized the importance of thoughtful responses and sustained dialogue. Informed by their early experiences, many students approached the second book, *Beyond Safe Boundaries*, with greater focus and understanding. These qualitative improvements were also promoted by the students' feelings of indignation and outrage about the injustices experienced by many of the characters in this book about young South Africans taking a stand against apartheid. This helped fuel passion for participating in the discussion as students were personally moved and had a stronger desire to write about the issues raised. A less overwhelming volume of responses online, generally greater focus, and more sustained dialogue resulted.

For the third book, *The Chocolate Wars*, schools were paired for discussions. This restructuring made threads even more manageable, although it left sites more vulnerable to the peculiarities of a single partner-school's computer and Internet access quirks, class trips, and scheduling conflicts. As students participated in their third discussion, incomplete cycles of online communication reduced and students increased their critical responses to other postings. The development of critical response over time stresses the importance of conducting a series of discussions rather than structuring online discussions on a book by book basis.

Results of Teacher Research and Online Discourse

Teacher online discussion remained at a functional level throughout *Taking a Stand*. Questions such as "How can we structure this experience so that it works well within our disparate classrooms?" took precedence over questions related to student learning. Despite previous experiences with online communication for some *Taking a Stand* teachers, most students and many teachers operated at the novice level in online discussions. Thus, retrospective written analyses based on transcripts of the three book discussions, a review of RMC Denver evaluation survey results, and an in-person exchange provided greater insights than did online teacher discourse as *Taking a Stand* progressed.

One university paper (Kruse and Quinn 1999 p.5-7) summarizes the flow of discourse from the classroom vantage:

"Although there are overarching factors affecting the flow of a discussion that are related to students' level of experience, teachers observed some patterns during discussions of each of the three books:

- In class, good level of involvement in early discussions.
- First few days of online discussion seems like a "make or break" time. If students find another student's posting interesting, or if they receive what they consider to be a thoughtful or relevant response, there is motivation to continue.
- Somewhere just past the midway point of a two-week cycle, interest and activity peaked as there was a variety of conversations happening and students chose ones to respond to.
- Often, as discussions just got going, the flow was not as smooth as it might otherwise have been, due to factors such as trips, residencies, illnesses and general scheduling. The flow was then very dependent on the quality and quantity of responses; if there was too much lag time or if responses didn't feel thorough or apropos, students felt frustrated and began to lose interest.
- In some cases participating schools posted and disappeared, leaving students at the other school only able to respond to each other.

• As the window closed, some discussions had come to a natural conclusion, while others abruptly ended. It would have been possible to continue, but schedules did not seem to coincide and students were then on to the next book. The need for closure became critical; as one student mentioned, 'The ending of some discussions was like falling off a cliff.' ”

Relationship between Standards, Assessment and Community Facilitation

Three standards with accompanying generic scoring guides provided a predetermined tool of analysis for student discussions online. An example from “Students make informed decisions” follows:

Level 3: Seeks information and bases decisions on evidence from reliable sources; describes and explains decisions based on evidence; differentiates between decisions based on fact and those based on opinions; recognizes others' points of view and assess decisions from others' perspectives; and analyzes and considers alternative decisions;

Level 2: Seeks information and bases decisions on evidence from reliable sources; describes and explains decisions based on evidence;

Level 1: States opinions and thoughts. Little reference to specific facts.

Scoring student discussions against this rubric showed that the students in the 3 classrooms, which supported an inquiry, based approach from the outset scored consistently at Level 1 or Level 2 while students from the other 3 classrooms scored consistently at Level 1. Growth over time from Level 1 to Level 2 was seen in four of the six participating schools.

Subject: reply

Yes. Archie plays on people's fears. Fears that have already been bred into them by The Vigils and Brother Leon. Archie enhances their fears with his own "above it-all" attitude and his power with the assignments (see pg 177, the line right above the bottom when he clearly implies that he believes he is above everyone else). Archie would rather con or blackmail someone for something rather than stand up for them. Archie needs people behind him for support. Jerry went on his own to do what he believed in.

(http://209.213.98.1/forums/index.cfm?CFAApp=30&Message_ID=207455)

Example of a Level 2 Comment

Scoring of individual posts does not serve as an exclusive indicator that online discussions have been successful. For instance, even though the above example “meets the standard” (Level 2) at an individual level, an examination of the entire thread reveals a single question followed by a single response. Hence, dialog has not occurred. Instead, this online episode mimics a typical “question and test response” approach to reading and discussion.

In reading and reviewing transcripts, it became apparent that genuine discourse unfolded online over a series of postings as students talked their way through an engaging question. Each new entry added evidence that the dialog as a whole was approaching the agreed upon criteria for critical reading. Looking at episodes of dialog

such as the one on the following page reveals that through successive posts, other pieces of evidence from the selected learning goals, such as showing different points of view and multiple interpretations of text, emerge. Moreover, this dialog example comes closer to fulfilling established definitions of learning communities, especially those depicted by Jenlink and Carr as they differentiate between "discussion conversation" and dialogue conversation" and Bereiter who writes about "progressive discourse." (Sherry, in press).

The perspectives of individual performance (single posts) and ensemble activity (dialog episode) provide a system for monitoring a discussion as it progresses so that participants and facilitators can examine whether or not the opportunity to engage in critical conversations about literature has been provided. Then, follow-up presentations or essays can be used to determine if individual students have improved upon their abilities to read critically.

Example of a Dialog Episode

I think the reason for Jerry not selling the chocolates is because he was called a square by the hippy near the bus stop on page 20. This got Jerry thinking about following what people are saying, and I think that is why he decided not to follow what other people were telling him to say.

Date: March 31, 1999 12:24 PM

Subject: reply

I do think you are right, but I think he didn't sell chocolates for a different reason. I think he didn't sell the chocolates because Brother Leon was always the most powerful and nobody had stood up for themselves, so Jerry was the only one who was strong enough to actually do something about it.

Subject: Reply to Ty (ler)

I agree that the hippie on page 20 had to do with his decision, but I don't think calling him a "square" really made a difference. I think it was his talking about living in a pattern that affected him; his stand was a way to interrupt the pattern and not become the same as everyone else.

Subject: Reply

I think that you are right. I also think that Jerry was just trying to stand up for himself, and in the beginning it was just something the Vigils wanted him to do and then I think he wanted to show that he wasn't just going to do whatever people wanted him to do. I also think that he was sick of Brother Leon being on the top of everything and running what they do and how they do it.

Subject: Reply to Nicky

I agree, I think he was just sticking up for himself and wanted to show the vigils that he wasn't scared of them and that he didn't want to be bossed around. Like when they were calling him Gay or fag.

Lessons for Further Improvement

The lessons that emerged from Taking a Stand point toward some simple next steps both for the participating schools and the facilitating community organization. From a teacher's point of view, student individual postings can be monitored through a simple assessment instrument while the co-facilitating organization, in this case Vermont Center for the Book, looks at the overall dialog for opportunities that explicate the learning goals. In order to assess whether or not the opportunity to learn has indeed resulted in actual student learning, essay exams or similar types of traditional assessments can be administered once the online discussions have been finished. To ensure that this cycle leads to the desired results of the network, we emphasize the following lessons:

1080

1. Begin with common learning goals AND common methods of teaching. Selecting standards is only part of ensuring a common focus; a common approach to teaching is also necessary. In this case, inquiry based learning led to progress toward desired results faster than a traditional “test question/response” approach. Furthermore, an inquiry based approach to discussions is directly aligned with the learning results and assessment systems that have been established by the network.

2. Model the common approach in-person and online. Site analysis reveals that most questions from Taking a Stand fit into the “test question” category, rather than resulting from genuine inquiry. Thus, essential to model for teachers and students what genuine inquiry looks like. Initially, this may take the shape of learned forms of interaction so that students are taught directly how to hold meaningful inquiry.

3. Assess individual and group performance both in-progress and with a final product. In-progress measures include opportunities to learn (monitored by Vermont Center for the Book) and substantive dialog. Specifics of this system are currently under development.

Abstract: There is an increasing need in organisations to store, provide and manage information using Internet based information systems. Today's Internet information systems allow easy access to huge amounts of information which are available on the Web. However, existing systems share one drawback: the lack of capabilities that allow users to customize and personalize the systems and their content to their personal needs. This paper presents a metadata based approach for customization and personalization on the Web. The paper starts with an architectural description, which is then followed by a technical design on which the current prototype implementation is based. The functionality of the prototype is presented by several examples.

1. Introduction

There is an increasing need in organisations to store, provide and manage information using Internet based information systems. Catalogs are an effective means to support users in accessing information made available by such systems. Traditional cataloging schemes, such as USMarc (US version of machine readable cataloging) are extensively developed. They provide a large number of different metadata (i.e. data about data) fields for sufficiently describing information resources. In addition, there are often hundreds of fields which are reserved for user extensions. Due to historical reasons, these metadata schemes are ill equipped to describe resources in all detail (e.g., down to the article level in journals). One solution to overcome this drawback is to add new appropriate fields to the original ones. This however affects the standardized metadata schemes and compliance between different catalog systems cannot be guaranteed any more. Another solution is to provide customization of the cataloging schemes without affecting the original scheme. As a result, information resources recorded in catalog systems can be accessed using personalised descriptions. This in turn makes it more attractive for users to work with such personalized systems.

The importance of user customization capabilities has often been noted in the literature. Nürnberg et. al. identify the need to allow easy personalization of the information accessed by web client applications [Nürnberg et. al. 1995]. Additionally they point out that the new digital processes that will characterize future information systems will require customization support. Marshall notes the importance of supporting personal annotations in the digital library [Marshall 1997]. According to Roescheisen, value can be added to an information space through the process of personalization [Roescheisen et. al. 1995].

Important though it may be, the user customization and personalization process is currently not well supported for Internet based information resources. In the development of most systems that are currently used to serve and access information on the Internet, emphasis has primarily been placed on providing access to information. The very limited or non existent personalization capabilities of existing systems is not entirely surprising or unexpected. The Internet presents a difficult environment in which to support the information customization process. Most systems that are accessible over the Internet typically have a very large if not unlimited user base, a characteristic that compounds the difficult issues associated with supporting object customization. Also, many of these systems provide access to information without charge. Overall, the developers of these systems have had limited incentive and resources to support the user personalization of data items. This paper presents a metadata based approach to support customization and personalization on the Web. To do that, the remainder of the paper is structured as follows:

Section 2 describes a metadata approach for supporting customization. The next section then presents a software architecture based on the approach and the current prototype implementation. Section 4 examines related literature and the paper closes in Section 5 with a brief look at future work.

2. An Architecture for Customization and Personalization on the Web

The primary characteristic of the approach described in this paper for supporting the customization and personalization process is that it is metadata based. The use of metadata to support customization was motivated by one its primary characteristics: the ability of metadata to exist and be maintained completely independent of the data to which it refers [Tochtermann et al. 1997]. For example, consider a digital catalog system. The information described in a digital catalog might exist locally (with respect to the catalog itself), it could be managed by a remote system of some kind, or indeed it might not even be available in digital form. In any case, it is possible for the descriptions contained in the catalog to be defined and maintained separately from the information they refer to. The approach described here exploits this characteristic of metadata to enable the customization of data objects in a way that places no restrictions on where the objects are stored or by which system they are managed. Similarly, write or update access to the data objects being customized is not assumed or required.

To achieve this, a strategy is employed in which metadata is used to represent the customizations that are made to data objects. However, instead of using metadata in its more traditional role, to create widely applicable or universal descriptions of objects, such as those found in digital catalog systems, it is used to support much finer grained and individualized descriptions of data objects. These adaptations to the conventional use of metadata enable the approach to support the individual user level customization and personalization of an object independent of the object itself.

The central component responsible for supporting customization in the approach described here is the Customization MetaData Manager (CMDM). As illustrated in Figure 1, the CMDM is a server process positioned between an information supplier (on the right) and an information consumer (on the left).

Figure 1: Architecture for metadata based customization

In general, in response to client application requests, the CMDM creates and updates metadata information representing customizations that are made to data objects. The metadata corresponding to data object customizations is maintained by the CMDM in a customization metadata store. Note, however, the customization metadata store does not contain the actual data objects themselves. They continue to be managed by the system where they were originally located ("Remote Data Resources" in Figure 1). Only the metadata information that represents changes that have been made to data objects as part of the customization process are contained in the metadata store. When the CMDM receives a request by an application to retrieve a data object, it first retrieves the data object from the system where it is located; next consults the customization metadata store for any changes that have been defined for the data object; applies any changes that are found; and then returns the data object to the requesting application. More in depth information is provided in [Hicks et al. 1999a].

3. Description of the PADDLE prototype

The architecture presented in the previous section serves as a basis for our prototype system PADDLE (Personalizable Adaptable Digital Library Environment).

3.1 Technical Implementation

Figure 2 depicts the technical architecture of the current prototype implementation which is based on the architecture presented in the previous section.

The CMDM is based upon Netscape's Fastrack Web server and provides a Java Servlet [Servlet, 1999]. For each client the Servlet initializes a CMDM request processor which handles all requests coming from the respective client. For example, this includes the coordination of all processes needed to retrieve data objects from a remote information resource or to connect to the customized metadata store.

One challenge was to keep the system as open as possible to heterogeneous remote data resources while at the same time the same basic functionality should be provided for the communication between the CMDM and the remote data resources. For that reason the interface between the CMDM request processor and the remote data resource is implemented as an abstract Java class which provides the basic communication functionality (e.g. abstract methods for retrieving data objects). This interface can be instantiated according to the remote data resource to be connected to the CMDM. An instantiation of the interface defines via which protocol the remote data resource and the CMDM request processor communicate with each other. In addition, it can also implement further functionality which is specific to the respective remote data source. For example, Figure 2 shows two instantiations "Instance1" and "Instance2" using the RMI and the FTP protocol, respectively.

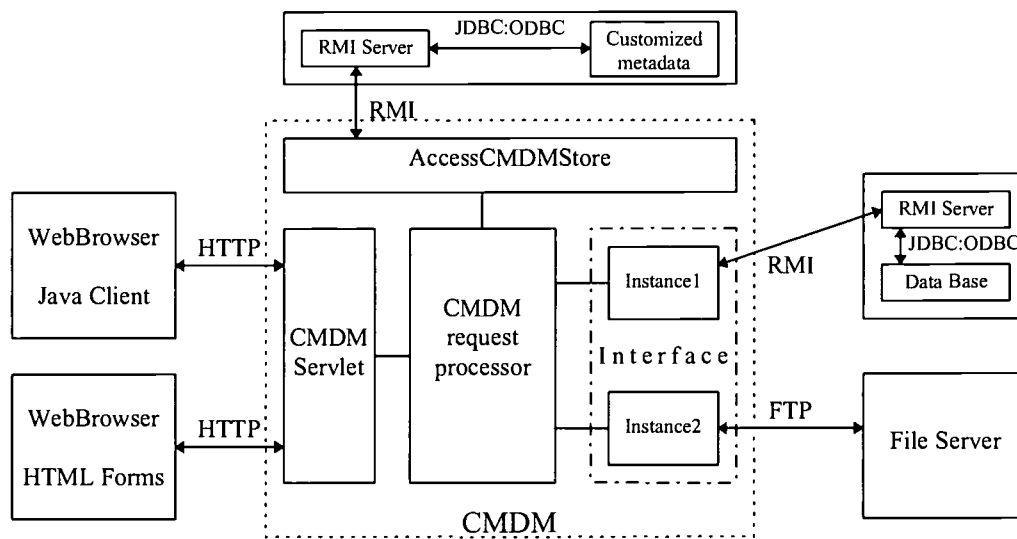

Figure 2: System architecture of the prototype

In the current prototype an exemplary remote data resource is provided by a Microsoft Access database. This database contains about 2000 documents and about 40 descriptive metadata fields for each of the documents. The customized metadata are stored in the CMDM store which comprises a Microsoft Access database for the storage of the customized metadata and an RMI server (remote method invocation) for communication purposes with the CMDM request processor. The communication between the RMI server [RMI, 1999] and the database for the customized metadata is based on SUN's JDBC-ODBC bridge which translates JDBC commands [JDBC, 1999] into ODBC commands. It is worth mentioning that with the JDBC-ODBC bridge it is only possible to run the CMDM request processor and the CMDM store on the same machine. To overcome this restriction and to better support a distributed digital library environment, we

decided to use the RMI server as part of the CMDM store. With this infrastructure the communication between the CMDM request processor and the CMDM store is as follows: The CMDM request processor always communicates directly with the RMI server. The RMI server translates all requests coming from the CMDM request processor to JDBC/ODBC commands and sends these commands to the customized metadata base. Results from this database are returned to the RMI server using the JDBC-ODBC bridge.

3.2 Current Prototype

The implementation has successfully been tested for remote data sources which are stored in an environmental database system. This database contains information which describes the state of the environment in Gemany [Hicks et al., 1999b].

The current prototype provides the following possibilities for customization: (a) add/remove metadata fields, (b) change the value of a metadata field, (c) design search forms according to the customized metadata. The following figure shows the form which is used to change the value of a metadata field. For example, the value of the third field "Semantic Relationship" was personalised which is also indicated by a preceding "changed". The fourth field "Temporal Relationship" was added by a user which is indicated by a preceding "new". In the upper left corner the prototype displays in a grey box those metadata fields which cannot be changed (e.g. the content provider of a remote data resource cannot be changed by individual users.)

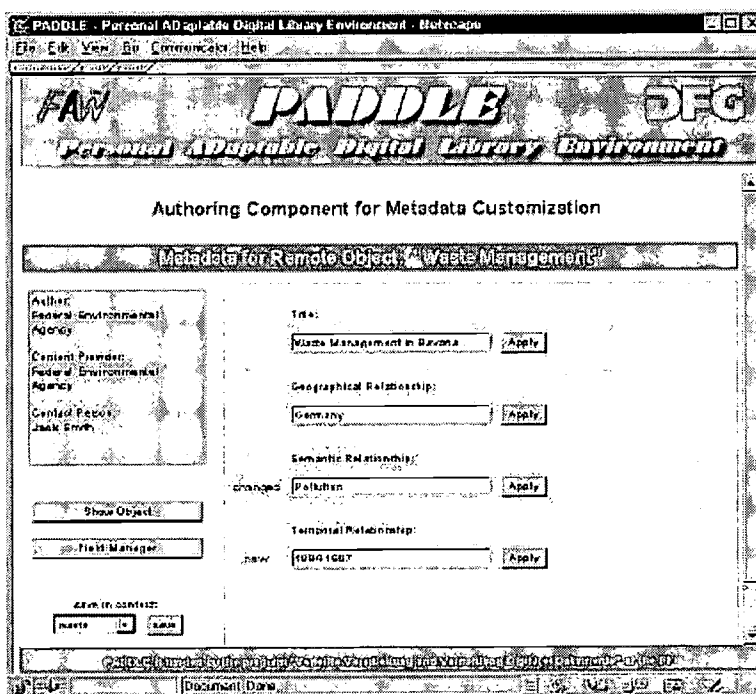

Figure 3: Authoring Component for Customization

Once a user has added new metadata fields he wants to use these fields for his search. This, however, requires that he defines his personal search forms which fit to his personalised metadata.

Figure 4 illustrates on the left the authoring component for the design of a personal search form. At the beginning the user starts with an empty search form. Using the "Add field" button (on the left) a user can add in accordance with his personalised metadata new metadata fields to the search form. To do that, the user simply types in the name of the individual metadata field (e.g. "Temporal Relationship" in figure 4). The search form on the left shows that a user has already added the metadata fields for "Geographical Relationship", "Abstract", "Title", and "Semantic Relationship" to the search form. The screenshot on the right of figure 4 displays the result of the personalization of a search form. For example, one can see the field for "Temporal

Relationship" was added to allow a search for this field which does not exist in the original metadata scheme but which was added to the metadata by the authoring component for metadata customization (c.f. figure 3).

Figure 4: Customization of Search Forms

4. Related literature

After the introduction of literature which calls for customization facilities at the beginning of the paper, this section briefly relates our approach to two recently published papers in that area.

In [Schatz 1999] the authors argue that in the 21st century, a billion repositories will be distributed over the world. The difference to the current situation will be that small communities will maintain collections of their own knowledge. Functionality which was first used by professionals will then be used by ordinary, less skilled people. Our approach presented in this paper can be considered as a first step in that direction. Capitalizing on existing catalogued data sources, users will utilize easy-to-use functionalities to adapt the existing repositories to their own needs. Also, with the ability of our approach to easily connect almost arbitrary systems to the CMDM the technical infrastructure exists to build up numbers of independent and small collections which can be maintained by small communities. The Stanford Digital Library Infobus [Paepcke et al. 1999] provides an infrastructure which is similar to the one used in our approach. Similar to the CMDM in our approach, the idea of the Infobus is to pull all components of a distributed digital library together. Library services built into the Infobus provide the necessary support functions, including query translation and metadata facilities. The main difference, however, is that the Infobus models documents stored in the remote data sources as objects while in our approach no abstraction of the original documents exists in the CMDM. Also, the Stanford Digital Library supports hierarchical metadata models while at present our approach allows flat metadata models only.

5. Future work

In future work, we want to investigate how many different and which types of data sources we can support. Our prototype implementation indicates that the approach works well for customizing metadata. A second step will be to apply our customization strategies to the data sources themselves. For example, a customization of a data source could change its layout in the way it is presented to the user. XML appears to be an appropriate

document description language for this purpose. Currently we have a flat metadata model only, but expect it to be worth exploring how structured metadata models could improve our approach [Paepcke et al. 1999]. Such structured metadata models could allow users to define individual metadata for a group of information sources rather than for single sources as is currently the case. Another important issue is the consistency maintenance that is to keep the CMDM store consistent with the remote data resources. Finally we are thinking about the implementation of the CMDM metadata store using a database, such as Oracle [Oracle 1999], for which JDBC drivers are available. Compared to our implementation the advantage would be that the SQL-Net protocol of Oracle allows direct communication (without an RMI server) between the CMDM metadata store and the CMDM request processor.
