ABSTRACT

The 1999 WebNet conference addressed research, new developments, and experiences related to the Internet and World Wide Web. The 394 contributions of WebNet 99 contained in this proceedings comprise the full and short papers accepted for presentation at the conference. Major topics covered include: commercial, business, professional, and community applications; educational applications; electronic publishing and digital libraries; ergonomic, interface, and cognitive issues; general Web tools and facilities; medical applications of the Web; personal applications and environments; societal issues, including legal, standards, and international issues; and Web technical facilities. An author index is included. Most papers contain references. (MES)

Preface

On behalf of the Program Committee and AACE, it is our pleasure to present to you the proceedings of the fourth WebNet conference – WebNet 99. This conference addresses research, new developments, and experience related to the Internet, Intranets, and Extranets.

The 394 contributions of WebNet 99 presented in this volume consist of the Full and Short Papers accepted for presentation at the conference from a collection of 912 submitted from 49 countries. All submissions were carefully reviewed by at least three members of the Program Committee and their recommendations used for selection. Borderline cases were reviewed at a special Program Committee meeting where appropriate decisions were made based on re-reviews.

Of the accepted contributions, 18 were considered outstanding based on reviewer's scores and comments. These outstanding papers represent the top 4.5% and are acknowledged in the table of contents. Authors of outstanding papers will be invited to submit extended versions of their papers to the *WebNet Journal*.

The coverage of the contributions is very wide, which is one of the features that distinguish the WebNet series of conferences from others that focus on more specific areas. Our intention has been to provide an application oriented conference - a meeting place of developers, researchers, practitioners, and users - as a forum wherein persons from disparate but related fields can meet and learn about new developments that impact their activities.

This volume contains position papers by leading experts in the field; descriptions of ideas that are on the borderline between an idea, a prototype, and products; reports on concrete applications of the Web and its impact on various aspects of life; and considerations as to how society might adjust and react to the resultant changes.

The major areas covered at the conference and presented in this volume include:

- Commercial, Business, Professional, and Community Applications
- Educational Applications
- Electronic Publishing and Digital Libraries
- Ergonomic, Interface, and Cognitive Issues
- General Web Tools and Facilities
- Personal Applications and Environments
- Societal Issues, Including Legal, Standards, and International Issues
- Web Technical Facilities.

These general areas have been divided into 56 more specialized topics.

In addition to the papers included in this volume, participants in the conference heard leading experts present Keynote and Invited lectures; participated in tutorials, workshops, small-group discussions, and poster sessions; and had a chance to see demonstrations of various items of interest. The conference was preceded by a minicourse and followed by two days of tutorials and workshops. This printed record cannot show all aspects of this highly interactive, media-rich Web meeting, but it does convey the depth and breadth of the conference.

Let us take the opportunity to urge you to plan now to attend WebNet 2000 in San Antonio, Texas, Oct. 30 - Nov. 4. To attend and observe the WebNet series is one of the best ways to stay current with the rapid and intriguing developments of the Web. Periodically check <http://www.aace.org/conf/webnet/> for information.

All of us realize that the Web is coming to have a major impact in international society. There is increasing confusion and concern on the part of many, in a wide variety of fields, as to what the implications and possibilities of the Web are. We all, as persons immersed in the topic, have a responsibility to explore, and clarify for others, the practical possibilities. We urge that you, and those with which you are in contact, consider these matters and reflect that thinking in your participation in WebNet 2000.

In closing, we would like to thank all authors for submitting their work, and all members of the Program Committee, listed on the following page, for their cooperation and time spent reviewing submissions. Special appreciation is extended to Gary Marks (AACE), who is one of the main driving forces behind this volume as well as the WebNet series of conferences, and the AACE staff who contributed so much to the success of the conference.

Invitation to Join

The Association for the Advancement of Computing in Education (AACE) is an international, non-profit educational organization. The Association's purpose is to advance the knowledge, theory, and quality of teaching and learning at all levels with information technology. This purpose is accomplished through the encouragement of scholarly inquiry related to technology in education and the dissemination of research results and their applications through AACE sponsored publications, conferences, and other opportunities for professional growth.

AACE members have the opportunity to participate in topical and regional divisions/societies/chapters, high-quality peer-reviewed publications, and conferences.

Join with fellow professionals from around the world to share knowledge and ideas on research, development, and applications in information technology and education. AACE's membership includes researchers, developers, and practitioners in schools, colleges, and universities; administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government with an interest in advancing knowledge and learning with information technology in education.

Membership Benefit Highlights

- Gain professional recognition by participating in AACE sponsored international conferences
- Enhance your knowledge and professional skills through interaction with colleagues from around the world
- Learn from colleagues' research and studies by receiving AACE's well-respected journals and books
- Receive a subscription to the Professional Member periodical Educational Technology Review
- Receive discounts on multiple journal subscriptions, conference registration fees, proceedings books & CD-ROMs

Advancing Knowledge and Learning with Information Technology

AAE Journals

Abstracts for all journal issues are available at www.aace.org/pubs

Educational Technology Review

International Forum on Educational Technology Issues & Applications (ETR)
ISSN# 1065-6901

AACE's member journal is the focal point for AACE members to exchange information between disciplines, educational levels, and information technologies. Its purpose is to stimulate the growth of ideas and practical solutions which can contribute toward the improvement of education through information technology. All AACE Professional and Student Members receive *ETR* as a benefit of membership.

WebNet Journal

Internet Technologies, Applications & Issues

ISSN# 1522-192X Quarterly

Focused on WWW, Internet, and Intranet-based technologies, applications, research, and issues, the *WebNet Journal* is an innovative collaboration between the top academic and corporate laboratory researchers, developers, and end-users. Columnists offer how-to articles and expert commentary on the latest developments.

Journal of Educational Multimedia and Hypermedia

(JEMH)
ISSN# 1055-8896 Quarterly

Designed to provide a multidisciplinary forum to present and discuss research, development and applications of multimedia and hypermedia in education. The main goal of the *Journal* is to contribute to the advancement of the theory and practice of learning and teaching using these powerful and promising technological tools that allow the integration of images, sound, text, and data.

Journal of Computers in Mathematics & Science Teaching

(JCMST)
ISSN# 0731-9258 Quarterly

JCMST is the only periodical devoted specifically to using information technology in the teaching of mathematics and science. The *Journal* offers an in-depth forum for the exchange of information in the fields of science, mathematics, and computer science.

Journal of Interactive Learning Research

(JILR)
ISSN# 1093-023X Quarterly

The *Journal's* published papers relate to the underlying theory, design, implementation, effectiveness, and impact on education and training of the following interactive learning environments: authoring systems, CALL, assessment systems, CBT, computer-mediated communications, collaborative learning, distributed learning environments, performance support systems, multimedia systems, simulations and games, intelligent agents on the Internet, intelligent tutoring systems, micro-worlds, and virtual reality based learning systems.

Journal of Technology and Teacher Education

(JTATE)
ISSN# 1059-7069 Quarterly

A forum for the exchange of knowledge about the use of information technology in teacher education. *Journal* content covers preservice and inservice teacher education, graduate programs in areas such as curriculum and instruction, educational administration, staff development, instructional technology, and educational computing.

International Journal of Educational Telecommunications

(IJET)
ISSN# 1077-9124 Quarterly

IJET serves as a forum to facilitate the international exchange of information on the current theory, research, development, and practice of telecommunications in education and training. This journal is designed for researchers, developers and practitioners in schools, colleges, and universities, administrators, policy decision-makers, professional trainers, adult educators, and other specialists in education, industry, and government.

Information Technology in Childhood Education Annual

(ITCE)
ISSN# 1043-1055

A primary information source and forum to report the research and applications for using information technology in the education of children—early childhood, preschool, and elementary. The annual is a valuable resource for all educators who use computers with children.

AACE Conferences

Details for conferences are available at www.aace.org/conf

The exchange of ideas and experiences is essential to the advancement of the field and the professional growth of AACE members. AACE sponsors conferences each year where members learn about research, developments, and applications in their fields, have an opportunity to participate in papers, panels, poster/demonstrations and workshops, and meet invited speakers.

ED-MEDIA 2000

World Conference on Educational Multimedia, Hypermedia & Telecommunications 

JUNE 26-JULY 1, 2000 • MONTRÉAL, CANADA
JUNE 25-30, 2001 • TAMPERE, FINLAND

ED-MEDIA - World Conference on Educational Multimedia, Hypermedia & Telecommunications

This annual conference serves as a multidisciplinary forum for the discussion of the latest research, developments, and applications of multimedia, hypermedia, and telecommunications for all levels of education.

WebNet 2000 **World Conference on the WWW and Internet**

OCT. 30-NOV. 4, 2000 • SAN ANTONIO, TX USA

WebNet - World Conference on the WWW & Internet

This annual conference facilitates the exchange of information in these major topics: Commercial, Business, Professional, and Community Applications; Education Applications; Electronic Publishing and Digital Libraries; Ergonomic, Interface, and Cognitive Issues; General Web Tools and Facilities; Personal Applications and Environments; Societal Issues, including Legal, Standards, and International Issues; and Web Technical Facilities.

MSET 2000 **MATHEMATICS/SCIENCE EDUCATION & TECHNOLOGY**

FEBRUARY 5-8, 2000 • SAN DIEGO, CA USA

M/SET - International Conference on Mathematics/ Science Education & Technology

The conference focuses upon information technology in mathematics, science and computer science education across all levels and settings, including elementary, secondary, college, and teacher education. Learn about the current research, development, classroom applications, issues, theory, and trends.

SOCIETY FOR INFORMATION TECHNOLOGY & TEACHER EDUCATION **2000** **11TH INTERNATIONAL CONFERENCE**

FEBRUARY 8-12, 2000 • SAN DIEGO, CA USA

SITE - Society for Information Technology and Teacher Education International Conference

This conference, held annually, offers opportunities to share ideas and expertise on all topics related to the use of information technology in teacher education and instruction about information technology for all disciplines in preservice, inservice, and graduate teacher education.

Co-Sponsored Conferences

ICCE - International Conference on Computers in Education

ICCE is an annual event focusing on a broad spectrum of interdisciplinary research topics concerned with theories, technologies and practices of applying computers in education. It provides a forum for interchange among educators, cognitive and computer scientists, and practitioners throughout the world, especially from the Asia-Pacific region.

NOVEMBER 4-7, 1999 • CHIBA, JAPAN

ICLS - International Conference on the Learning Sciences

ICLS, held biennially, is designed for researchers, developers, practitioners, consumers, and policy makers to share experiences and insights on fostering effective learning to serve real-world needs. Represented are a diverse group from the fields of cognitive science, multimedia, training, education, and artificial intelligence.

User Interface Requirements in Educational Multimedia	1261
Sue Fenley, King's College, UK	
Going on a WebQuest with 'At Risk' Adult Learners	1264
Lynn Fox, Mt. San Antonio College, USA	
A Document Model for Generating Adaptable Courseware Using Background Data	1266
Katrin Franze & Frank Wehner, University of Technology Dresden, Germany	
Large-Scale, Web-based Learning: Opportunities for Enterprise Modeling and Decision-Making	1268
Lesley A. Gardner, University of Auckland, New Zealand	
An Interactive Approach To Teaching Concrete Design	1271
Ashraf M. Ghaly & Linda G. Almstead, Union College, USA	
In[side]out: Art in Virtual Reality, the Museum in Virtual Space	1274
Nan Goggin & Joseph Squier, University of Illinois, USA	
Reaching Teachers Through Web-Based Distance Education	1276
Carmen L. Gonzales, New Mexico State University, USA; Laura Sujo de Montes, Northern Arizona University, USA	
Collaborative Learning in an Online Human Learning Course	1278
Candace L. Gunnarsson, Xavier University, USA; Daniel D. Wheeler, University of Cincinnati, USA	
Knowledge Transfer and Knowledge Discovery -New Improvements for the Corporate Decision	1280
Christian Gütl, Axel Jurak, Josef Moser, Dietmar Neussl & Maja Pivec, Graz University of Technology, Austria	
TEAM 21: A Framework for the Total Enterprise	1282
D. Charles Hair, Timothy Martin & Yanhe Jin, iBASEt, USA	
Demands On Virtual Teams And Virtual Leadership To Support Sustainable Learning Processes	1284
Henrik Hansson, Viktoria Institute, Sweden	
Design, Implementation and Operation of an Intranet-based University-Information-Management-System	1286
Franz Haselbacher, Isidor Kamrat, Andreas Passler & Boris Rohrbacher, Graz University of Technology, Austria	
WWW Hyperbooks Created for Teaching Electric Power Engineering	1288
Ilpo Havunen, Jari Isokorpi, Tommi Keikko & Leena Korpinen, Tampere University of Technology, Finland	

Bleeding on the Edge II: Instructing with Live Audio, Video, and Text over the Internet.....	1290
Jeffrey B. Hecht, Illinois State University, USA	
Web Pedagogy: Extended Seminars on the World Wide Web.....	1292
Pentti Hietala, University of Tampere, Finland	
Context-Sensitive Filtering for Browsing on Web Pages.....	1294
Tsukasa Hirashima, Kyushu Institute of Technology, Japan; Toyohiro Nomoto, Noriyuki Matsuda & Jun'ichi Toyoda, Osaka Univ., Japan	
Experiences with Real-time Streaming Audio/video in Delivering Web-based Courses.....	1296
Thomas I. M. Ho, Indiana University Purdue University, USA	
Innovative use of IT to support Competency Based Learning Paradigm – The Ngee Ann's Perspectives	1298
Tan Hock-Guan & Lua Seu-Kea, Computer Based Learning Centre, Singapore	
Where To Build A Tide Power Plant?- Cooperative Learning On The Web.....	1300
Ying-Shao Hsu & Hung-Jean Wu, National Taiwan Normal University, Taiwan; Chi-Chuan Chen, ARGIS Company, USA	
Modulo: Development and Evaluation of an Interactive Multimedia Education Concept for the Subject 'Fundamentals of Computer Science'.....	1302
AXEL HUNGER, STEFAN WERNER & FRANK SCHWARZ, Gerhard-Mercator University of Duisburg, Germany	
Creating a Web-Based Learning Community: CalState TEACH	1304
John C. Ittelson, Joan Hanor, Nada Mach, Kevin Cahill & Sam Wilkerson, CA State Univ., USA	
Design Of An Interactive Forum Environment Tailored For Distance Education	1306
Céline Joiron & Dominique Lecllet, Université de Picardie Jules Verne, France; Gérard Weidenfeld, Centre National Enseignement à Distance, France	
Enabling Inter-net Students to Enthusiastically Compare Cultural Values.....	1308
Masakazu Karita, Himeji Dokkyo University, Japan; Tetsuo Shimada, Wakayama University, Japan	
Formative Evaluation of an Evolving Web-Based Digital Archival System.....	1310
Ed Kazlauskas, University of Southern California, USA	
Multipoint Multimedia Chatting and Collaboration Service	1312
Young Sun Kim, Sang Gil Kim & Sang Taek Kim, Korea Telecom R&D Group Multimedia Technology Lab, Korea	
Creating Poetry For Cyberspace: A 3-D Haiku Experience.....	1314
Michael A. Kolitsky, Rowan University, USA	
Examination Registration and Course Feedback System for Students in the Intranet	1316
Leena Korpinen, Ilpo Havunen & Seppo Loimio, Tampere University of Technology, Finland	
How the Hypermodern Technology Assemblage Bites Back	1318
Larry W. Kreuger & Michael J. Kelly, University of Missouri-Columbia, USA; John J. Stretch, Saint Louis University, USA	
A Model For Web-Based Collaborative Project-Learning Languages At Work.....	1320
Leena Kuure & Maarit Saarenkunnas, University of Oulu, Finland; Peppi Taalas, University of Jyväskylä, Finland	
A Web Based Authoring And An Adaptive Tutoring System For teaching And Learning.....	1322
M. Laroussi & M. Ben Ahmed, Riadi Laboratory, Tunisia; M.C. Pettenati, O. Abou Khaled & C. Vanoirbeek, Swiss Federal Institute of Technology, Switzerland	
Comparison of Computer Science and Humanities Student Preferences Concerning Web-Based Supplemental Course Materials	1324
William F. Lawhead & Pamela B. Lawhead, University of Mississippi, USA	
New Technology In Information And Communication : A French Experience.....	1326
Dominique Lecllet, University of Picardy, France	
Web-based Instruction: A Study of the Effects of Self-Efficacy and Task Values on Students' Commitment and Achievement	1328
Chia-Jung Maigo Lin, Shih Hsin University, Taiwan; Edward Kazlauskas, University of Southern California, USA; Nay-Ching Nancy Tyan, National Taipei Teachers' College, Taiwan	
Interactive Images: Explorations with OpenPix	1330
Janet Little, Sarah Haynes, Jayne Woods & Irene Neilson, University of Liverpool, UK	

Web Based Instruction: Intellectual Property, Compensation, and Redefining Faculty Work	1332
William Lynch & Michael Corry, The George Washington University, USA	
A Web Interface to Facilitate Traditional and Distance Student Interaction in a Problem Based Learning Setting	1334
Elizabeth Mackenzie, Sherry Kitto, Lesa Griffiths & John Pesek Jr., University of Delaware, USA	
A Practical Approach to Authoring Hypermedia Composites Used for Web Applications	1336
Seid Maglajlic, Denis Helic & Nick Scerbackov, Graz University of Technology, Austria	
Overview Of Groupware And The Groupware Market.....	1338
Julie R. Mariga, Purdue University, USA	
Interactive Courseware Quiz Creator: An Adaptive Zero-Programming Content Development Tool for Students Learning and Testing via Intra/Internet	1340
Ryoji Matsuno, Prefectural University of Kumamoto, Japan; Yutaka Tsutsumi, Kyushu Teikyo Junior College, Japan; Kazuo Ushijima, Kyushu University, Japan	
Information Environment for School Leader Preparation: Web-Based Software for Preparing Reflective Educational Leaders	1342
Christine Mayer, Jane Howland & Dale Musser, University of Missouri-Columbia, USA	
ENiSpace: Evaluating Navigation in Information Spaces	1344
Rod McCall & David Benyon, School of Computing Napier University, UK	
Web Based Teaching: - Do Learning Styles Matter?.....	1346
Barbara McCartney & Robert Shannon, University of New England, Australia	
PsychExps: A Web-based Cognitive Psychology Laboratory.....	1348
Kenneth O. McGraw, John E. Williams & Mark D. Tew, University of Mississippi, USA	
A Web-based System to Coordinate Examination Processing.....	1350
David McIntyre, University of Auckland, New Zealand	
A Nexus of Resources, Tools and Content: Using 3-D Animation and a Digital Image Library	1352
Steve McNeil, University of California, USA	
A Conceptual Model For Utilizing The Internet For Social Development Research In Third World Countries	1354
Goutham Menon, University of South Carolina, USA	
Wireless Digital Vehicle Mapping and Tracking System.....	1356
Thomas W. Mertz, Paul W. Ross, Timothy M. Bailey, Nathan R. Fichthorn & Michael J. Fiorill, Millersville University, USA	
Privacy, the Workplace and the Internet.....	1358
Seumas Miller & John Weckert, Charles Sturt University, Australia	
GUI for Geometric Inference Engine on Internet.....	1360
Keiichi Mishima & Sachio Hirokawa, Kyushu University, Japan; Naoyuki Kato, Matsushita Electric Industrial Company, Japan	
Internet Customized Teaching/Learning Environments	1362
John Mugane, Ohio University, USA	
A Web-Based Interactive Shared Journal System	1364
Dale Musser, James Laffey & Thomas Tupper, University of Missouri-Columbia, USA	
A Web-Based Homework Notification System	1366
Dale Musser, James Laffey & Dana Huyler, University of Missouri-Columbia, USA; Mary Laffey & Judy Trujillo, Oakland Junior High School, USA	
The Internet As A Research Tool: Cheers Or Tears?.....	1368
Mikiko Nakata, Hiroshima International Gakuin University, Japan; Rowena Santiago, California State University San Bernardino, USA	
SIMULAB, Collaborative Tasks for Language Learning in the Web	1370
Graciela Nielsen, Norwegian State Center for Adult Education, Norway; Boo Hever, Majornas Vuxengymnasium, Sweden; Aase Steinmetz, Undervisningsministeriet, Denmark; Antonio Sánchez Sola, Universitat Autònoma de Barcelona, Spain	

Structures and Tools of a Virtual Campus for Life-Long Learning	1372
Andreas Ninck, Federico Flückiger & Lorenz Müller, NDIT/FPIT, Switzerland; Giovanni Coray & Christine Vanoirbeek, Swiss Federal Institute of Technology Lausanne, Switzerland; Antoine Delley & Philippe Joye, Ecole d'ingénieurs de Fribourg, Switzerland; Jean-Luc Gurtner, University of Fribourg, Switzerland	
CLASS™ - Using Innovative Technologies for Distance Education	1374
Kathy Northrop, University of Nebraska-Lincoln, USA	
On-line Learning 'Assumes' On-line Delivery Skills.....	1376
John O'Donoghue, University of Wolverhampton, UK	
Introducing the Electronic Library Image Service for Europe (ELISE).....	1379
Colleen O'Reilly & John Eyre, De Montfort University, England	
Effective Online Teaching/Learning: A Case Study	1381
Jaishree Odin, University of Hawai'i at Manoa, USA	
Development and Use of Interactive Websites K-12	1383
Helen M. Parke, Dionna Draper, & Nancy Evans, East Carolina University, USA; George W. Bright, The University of North Carolina at Greensboro, USA	
Transporting Environmental Communication Across International Boundaries	1385
Lea J. Parker, Northern Arizona University, USA	
An innovative use of the Internet to teach alcohol awareness to grade 7 and 8 Students	1387
Robert Pearson & David Connal, Performx Inc., Canada; Judy Roberts, Roberts and Associates/Associés, Canada; Henry Cowan, University of New Brunswick, Canada; Thomas LeBlanc, Université de Moncton, Canada	
Comparing Computer-based and Text-based Research Writing: A Course Model	1389
Michael Petracca, University of California at Santa Barbara, USA	
Reinventing Electronic Commerce with Multimedia: Early Experiences with MCADE.....	1391
Vincent Phuah, John Nicol, Chris Martin, James Paschetto, & Kimberly Rush, GTE Laboratories, USA	
The Evolution of Faculty Development and Course Design at the SUNY Learning Network	1393
Alexandra Pickett & Peter Shea, State University of New York, USA	
Answering the Needs of Rural Communities: The Virtual High School of Newfoundland and Labrador.....	1395
Terry Piper & Ken Stevens, Memorial University of Newfoundland, Canada; David Piper, Acadia University, Canada	
Evolving from Face-to-face to Online Teaching for Large Student Groups: Phase 3, Restructuring in a Computer Based Student/Subject Management System	1397
Anne Porter & Robert M. Corderoy, University of Wollongong, Australia	
Formalization and Integration of Scaffolding in a Web-Based Learning Environment	1399
Sadhana Puntambekar, University of Connecticut, USA	
A Web Site Does Not A Community Make	1401
Mimi Recker, Utah State University, USA; Kimberly Lawless, University of Illinois, USA	
We're Wired – Get Connected! A District Model for Web-Centric Educational Services.....	1403
Pat Ridge, Brussels District Superintendent's Office, Belgium	
Techniques for Promoting Participation and Ownership for Learning in Web-based Instruction among In-service Teachers	1405
Paul Rodes, Dennis Knapczyk, Carrie Chapman, & Haejin Chung, Indiana University, USA	
How Does Achievement Differ in Comparing Learning By Distance to Learning On-Campus: A Preliminary Analysis	1407
Jonathan L. Ross, The University of Calgary, Canada	
Normative Influence and Emotionality throughout Web based discussion.....	1409
Khaled Sakhel, Maastricht University, Netherlands	
Surfing in the Web: an Experience of the Use of Internet in Educational Process.....	1411
Nicoletta Sala, University of Italian Switzerland, Switzerland; Largo Bernasconi, Mendrisio, Switzerland	
Teacher Development, Educational Reform and The Web	1413
Marilyn Schaffer, University of Hartford, USA	

Moderating the Future: The new Challenge for Educators	1415
Friedrich Scheuermann, University of Innsbruck, Austria; Ken Larsson, Stockholm University/ KTH, Sweden; Roxanne Toto, The Pennsylvania State University, USA	
Are we Creating New Teaching Environments with Web Courseware Tools?	1417
Kathy Schmidt, The University of Texas, USA	
Online Robotics Education at NASA.GOV	1418
Stephanie Smith, NASA Information Technology Office, USA	
Developing Interactive Lecture Notes	1420
Janak Sodha, University of the West Indies, Barbados	
A Three-Dimension Structure to Learning Object Management	1422
William Song, SITI (Swedish Research Institute for Information Technology), Sweden	
A Component-based Framework for Description and Management of Learning Objects	1424
William W. Song & Mats B. Andersson, SITI, Sweden	
The Geek Shall Inherit the Earth – Designing a University for the Next Millennium	1426
Paul Stacey, Technical University of British Columbia, Canada	
Asynchronous Brainstorm: An Intranet Application for Creativity	1429
Dick Stenmark, Volvo Information Technology, Sweden; IT & Organisation, Göteborg University, Sweden	
Architectural Detailing at Random: An Interactive Artist-Made Book On-Line	1431
Starla Stensaas, Southern Illinois University, USA	
The Effect of Motive on Response Rates in Web-based Surveys: A Proposal based on the Heuristic-Systematic Processing Model	1433
Tracy L. Tuten, Longwood College, USA; Michael Bosnjak & Wolfgang Bandilla, Zentrum für Umfragen, Germany	
High-Tech Solutions in Low-Tech Settings: A Distance Learning Initiative for Developing World Health Care Providers	1435
Joanne Tzanis & Pamela Harper, AVSC International, USA	
Creating Multimedia Learning Environments for the World Wide Web Using SMIL Technology	1437
Sebastian Uijtdehaage & Anju Relan, UCLA School of Medicine, USA	
Tools for a Design, Development and Management of Multidisciplinary Multimedia Web-Based Courses	1439
Vladimir Uskov & Maria Uskova, University of Cincinnati, USA	
Integrating Administration with a Learning Environment on the Web – Case Study	1441
Jari Vanha-Eskola, Open University of Helsinki, Finland	
The CATCHUM Consortium: Developing a Cancer Prevention Curriculum using the World Wide Web	1443
Gita Varagoor, The University of Texas Health Science Center at Houston, USA; Bob Joyce, Trevor Burt, Billy Philips & Brandi Dyer, The University of Texas Medical Branch at Galveston, USA; Melissa deSantis, The University of Texas Health Science Center at	
Knowledge Management in Education	1445
M. Vernooy-Gerritsen, CPS, Netherlands	
Applying the Hexa-C Metamodel of Instructional Theory and Design to Educational Web Applications	1447
M.R. de Villiers, University of South Africa, South Africa	
Online Experiments - Considerations and Possibilities	1451
Morten Wagner, Allan M. Krebs, Christian Rothe, Lars Østrup Petersen & Jørgen Bøegh, DELTA Danish Electronics, Denmark	
Busy City - On the Design of a Collaborative Learning Environment	1453
Erik Wallin, Lund University, Sweden	
Using Online Collaborative Workspaces to Design Technology Integrated Instruction for Supporting K-12 Historical Thinking and Understanding	1455
Beth Wellman, Maya Creedman & Jana Flores, UCLA, USA	
Remote Manipulation of A Robot Arm Via The World Wide Web: Recycling Old Technology	1457
Dawn E. Wilkins & Pamela B. Lawhead, The University of Mississippi, USA	

Global Team Teaching Using the WWW and Internet	1459
Barbara Williams, North Hennepin Community College, USA; Josef Kolar, Tomas Macek & Bozena Mannova, Czech Technical University, Czech	
Clash of the Titans: Managing Conflict Online among Adult Distance Learners	1461
Shahron Williams van Rooij, University of Phoenix Online Campus, USA	
Surviving Your First Web-Based Distance Education Course.....	1463
Shahron Williams van Rooij, Datatel, USA	
Using E-Designed Courses to Enhance Teaching and Learning.....	1465
Joan Wines & Julius Bianchi, California Lutheran University, USA	
Teaching Technology through Tradition: Native Access to Engineering at Concordia University.....	1467
Dawn Wiseman & Corinne Mount Pleasant - Jetté, Concordia University, Canada	
Incorporating Web-Based and Virtual Reality Instruction into a Distance Education Course Using the ADDIE Model of Instructional Design.....	1470
Kelly Ann Yamashiro, Jack Lee & Xun Ge, The Pennsylvania State University, USA	
WORK-IN-PROGRESS SHORT PAPERS	1472
Web Architectures for Database Access	1473
Nicola Aloia, Cesare Concordia & Vittorio Miori, Istituto del Consiglio Nazionale delle Ricerche, Italy	
WebQP : Web-based Teaching Assistant Quizzes Provider	1475
Hiroyuki Anzai, Takayuki Hirahara & Keisuke Mori, Kyushu Kyoritsu University, Japan	
Toward a Taxonomy of Risks to Human Subjects involved in Internet-based Research.....	1477
Melinda C. Bier, James S. McDonnell Foundation, USA; Stephen A. Sherblom, Penn State University, USA	
Establishment and Management of the Padua Astronomical Observatory Web Site.....	1478
Caterina Boccato, Astronomical Observatory of Padua, Italy	
Information Retrieval on the WWW: A Method Adapted to Trainers' Features in Distance Education	1480
Angélique Boitel & Dominique Lecllet, Université de Picardie Jules Verne, France	
The Journal of High Energy Physics: Scientific Publishing on the Web	1482
Simona Cerrato, Fabio Asnicar, Paolo Dall'Aglio, Amanda de Felice, Massimo Di Fant, Marco Mizzaro & Fabrizio Nesti, International School for Advanced Studies, Italy; Marina Candusso & Marino Miculan, National Institute for Nuclear Physics, Italy	
Mechanisms for Video Integration and Navigation on the Web	1484
Teresa Chambel & Nuno Guimarães, DI-FCUL, Portugal	
Learning in the Information Age	1486
Lih-Juan ChanLin, Fu-Jen Catholic University, Taiwan	
MedExpert/WWW: A Medical Knowledge Base Server	1488

Keynote Speakers

Utopia, Oblivion, or Muddled Compromise? Fantasies and Realities about the Coming Global Society (POWERPOINT SLIDES)

Nathaniel S. Borenstein
University of Michigan
USA

Utopia, Oblivion, or Muddled Compromise: The Coming Global Society and the Value of Info-Wilderness

We're all sick of pundits, but...

Internet pundits only say a few things anyway!

2 main Utopias, 2 dystopias

And a very muddy middle ground:

-- Probably most "right"

-- Certainly most pragmatic

-- Virtually inevitable

The real action is behind the scenes

We are not alone.

At least, not usually.

The new endangered species:

Independent, disconnected humanity

Preserve info-wilderness

(spaces free of the Group Mind)

My Life in the Group Mind

**I believe I have been living the future.
Almost never a day off-net, 1980-1998.
Email peaked at >1000 in 1994-95
Lived in "wilderness" with family & modem
Now struggling for identity off-net.
Not everyone will have that luxury.**

Where will the Internet take us?

Two Pipe dreams

Paradise 1: Libertarian Anarchy (LA)

We've all heard the story
(with many variants)
A tough neo-Darwinism is helpful.

Paradise 2: Centralized Democracy (CD)

Seemed semi-plausible not so long ago.
First-generation Cybernetic Utopia

Each Utopia Conceals a Dark Fear

CD --> Centralized totalitarianism

Consider the 20th century
"1984" imagined in 1948
Consequent fear long-since internalized.

Each Utopia Conceals a Dark Fear

LA --> Mercantile oligopoly

Any worms in the apple?
Q: "good" == "wealth-maximizing"?

A troubling example: "free market" in content restrictions may promote ethical systems of wealthy elites.

The Evolving Middle ground

Power coalitions limit oligopoly, a little.

Weak center limits totalitarian prospects

80/20 international governance

G7 -> "Binding Triad" hegemony?

Centrality required for certain purposes

War crimes, Trade rules Environmental law....

The weaker the better, in most peoples' eyes

Extreme example: ICANN.

-- STILL need to diffuse power.

A Deeper Illusion: Human Control

Individual humans have limited control.

Something more fundamental is changing.

Collectivized nexus of planning

The new conventional wisdom:

-- BRANDING IS EVERYTHING

-- Eyeballs are gold.

Esther Dyson wins if the name ICANN survives w/authority.

How did this happen?

Branding CW is true, but...

It didn't always used to be like this!

Branding as 20th century phenomenon.

Internet accelerates its importance.

Why the change? What's different now?

Why does money flow to "eyeballs"?

Intelligence is collective (c.f. insects).

Human group mind long-emerging

(Earliest mechanism: myths)

(w/books: Jung, Campbell, etc.)

Modern info-tech makes it efficient

Internet is most extreme, but TV, radio, etc. are a big part of it.

The power of branding:

Enlist small individual power into a branded (economically-directed) vision for the group mind.

Is this good? We may never know.

What's an Individual Human to Do?

Primarily: struggle for existence.

Don't worry about the future of the net. Worry about your mortal soul.

Let the group mind plan its own future.

The group mind needs us to flourish.

We can be stewards of the material world.

-- and --

We can preserve our individuality.

Preserve Individuality by

Preserving Information Wilderness

Keep a part of yourself off-net.

Declare independence from the group mind

Be conscious that it exists.

Take time off for yourself.

You're in Hawaii, but...

How isolated are you?

How independent?

How free?

Some good starting points

Ban modems in wilderness areas.

Create Internet/media-free zones

in your community.

in your home.

in your life.

Be conscious of yourself:

off net: as an individual

on net: as part of a group mind

Both aspects of yourself

are different.

are valid/useful.

have specific needs.

The Bottom Lines

For me:

-- Two decades on the net is plenty.

-- Currently off-net 4-5 days/week.

For society:

-- Individual impact is minimal. (guru to crackpot overnight)

-- Group action can be effective (temporary issue-oriented coalitions)

For you, now:

-- The world's most isolated islands!

-- Get unplugged. You might like it.

Human Communication and the Design of the Modern Web Architecture

Roy T. Fielding, University of California, USA

A software architecture determines how system elements are identified and allocated, how the elements interact to form a system, the amount and granularity of communication needed for interaction, and the interface protocols used for communication. Software engineers often find the inspiration for architectural designs within natural systems. For example, life is frequently compared to a distributed object system, since biological systems are composed of components with individual identity and behavior, communicating through changes in the body chemistry. A similar analogy can be used to describe the modern Web architecture.

Human communication can be thought of as a distributed hypermedia system. The mind's intellect, voice+gestures, five senses, and imagination are all components in the system of human communication. A person thinks of what they wish to communicate, translates that into a representation which they believe will be understood by the intended audience, exchanges that representation using their voice, gestures, and reference to other representations, and then hopes that each person receiving the representation will interpret what was transferred in the same way as the originator. Using this analogy, we can explore the design of the modern Web architecture as it has evolved to meet the needs of resource identification, intermediate processing, large scale caching, content negotiation, and more efficient use of the network infrastructure.

All's WELL That Ends: The Origins and Future of Online Community

Steve Jones, University of Illinois at Chicago

This presentation is focused on the connections between online community and commerce/economics, particularly the rhetoric of community as it has been taken up by those in e-commerce endeavors. It makes the case that the most influential symbol for online community, the WELL (Whole Earth 'Lectronic Link) should be examined in light of sociocultural trends apart from Internet-related ones, most importantly those that began to shape the social mores of the Baby Boom generation in the late 1960s. Of particular importance is the borrowing of language and ideas from Sixties literature and song in subsequent structuring of community discourse. Examining the rhetoric of online community in this context will add a missing link to ongoing debates about the construction of online community. The presentation will conclude with a discussion of the consequences of telepresence and immersive technologies for online community.

Escaping Entropy Death: Why The Web Works For Business

Simon Phipps, IBM UK Laboratories, UK

The world of computing is being revolutionised by the Web, Java and XML. This talk explains why. Expect clear ideas, interesting examples, humour and energy.

A new paradigm is breaking on the shores of the computing industry. Using agreed standards to complement rather than replace existing technologies, networked computing offers both businesses and casual computer users a new freedom to create effective computing solutions without damaging existing systems or creating future support liabilities. Based on technologies commonly associated with the internet (TCP/IP and web browsers), it is the Java software model that allows true power and flexibility to be delivered to solve business problems and increasingly to create interactive Web content. This presentation traces the history of the new paradigm, explains the truth about Java and the principles that make it the right model for business computing, and looks into the future of computing including connected devices and XML. The presentation is suitable for a general audience although technical questions are welcome.

Invited Speakers

Taking Hypertext Seriously: Scholarship and Storytelling

Mark Bernstein
Eastgate Systems, Inc.
134 Main Street Watertown MA 02472 USA
bernstein@eastgate.com

Abstract: The artifactual form of books and journals undergoes continual change and refinement, as technologies and tastes change from generation to generation. As serious writing migrates from the printed page to the screen, the development of hypertext and of the World Wide Web has made these changes unusually clear and has often evoked an emotional, rather than a critical, response.

1. Form: Beyond the Shell

Chieko Yoshimura is not enjoying her first professional conference. The papers are fascinating, and travel is exciting. But the contents of her purse vanished sometime during the first day, and with it her passport, plane tickets, and credit cards.

Chieko Yoshimura arrived at the conference with a new degree and a new job. Her new job is at a new company, in a new industry. Her dad came from the Old World, her mom from the Third World, she lives in the New World. Chieko is really a very conservative young woman.

This morning, a speaker was discussing genre, style, and the evolution of the Web. She'd already started to copy down a slide about Chieko Yoshimura's remarkably frank and revealing memoir when two things occurred to her:

- 1) Chieko Yoshimura was a fairly unusual name, and the URL on the slide was all too familiar.
- 2) She hadn't actually done anything to her Web site in weeks, when she'd added a picture of her kitten. There was nothing frank or revealing, or even interesting, on her Web site.

She wondered how on earth she'd get net access, in Europe, without a credit card. Or a passport. Or a ticket home.

She rather hoped her dad hadn't figured out how to use WebTV yet, after all.

Our protagonist has lost an important codex book, her passport, but this *precipitating incident* [Laurel, 1991] need not cause irreparable harm. She is not a stateless refugee, and the artifact can be replaced. The distinction between serious writing and its artifactual form has been blurred by critics who confound a taste for literature with book collecting [Birkerts, 1994].

The relationship between serious writing and its outward form or *shell* merits closer study [Rau, 1999]. Unfortunately, much attention has been focused on debating whether hypertext is illuminated [Landow, 1997] or corrupted [Miller, 1998] by postmodernism (or, arguably, modernism [Aarseth, 1997]).

The hijacking of her home page raises a host of interesting issues. The convention that the putative author of a work is identical to an actual person evolved from protracted scholarly debates and contravened longstanding customs [Johns, 1998]. Rhetorical [Lanham, 1993] and stylistic [Furuta, 1995] customs are conventions, not natural law.

2. Beyond Usability

Jan, the speaker who described Chieko's home page, did not know she was in the audience, and his purpose was not merely to tell the audience that this particular literary object was a desirable commodity. Neither criticism and scholarship are merely consumer reports.

Much discussion of hypertext and of Web page design focuses narrowly on access and usability — on the needs of new, novice, or casual readers. The assumptions that transparency is the ultimate aspiration of nonfiction writing (Rosenfeld and Morville 1998) (but see (Lanham 1993)), and that immersion is the natural goal of storytelling (Murray 1997) (but see (Gaggi 1997)), are so common that they often become invisible.

But Jan had not set out to discover a Web page written by a young Asian-American businesswoman that stirred his soul and made him see the world a little differently. These were not the terms he had supplied to the search engine; he couldn't search for it, because he didn't know he wanted to. Similarly, had the page been clearly and sincerely labelled, he would have dismissed it instantly as irrelevant; only by artful disorientation, by cleverly playing upon (and subverting) his expectations, could the author successfully make her point (Landow 1995) (Bernstein 1998).

The slide Jan used in his talk, while embarrassing to our protagonist, illustrates one of the common (but specious) objections to serious hypertextual literature. The *Bolter Test* [Bolter, 1991] objects that electronic books will be poorly suited to reading in bed or the bathtub, a concern that would be more pertinent if damp and sleepy readers were the aspiration of literature. Other common but ill-founded objections include eye strain from reading screens, format impermanence, loss of the sensual experience of ink and leather, and resemblance of computers to television [Moulthrop, 1989] [Miller, 1998] [Birkerts, 1994].

3. Literature and Economics

Jan's talk was recorded by several people in the audience, including Ted, one of the youngest attendees. Ted records everything; she routinely carries a video recorder, a digital camera, a minidisc audio deck, and a laptop computer. This record-making is not merely an archival gesture toward literary survival, as old age is not Ted's immediate concern. Rather, she uses the tools to change perspective, as a means of *remediation* (Bolter and Grusin 1999).

Ted, like many writers and scholars, creates primarily for herself. Rewards that accrue from publication may not be the motivation for discovery or creation, but literature and scholarship (like everything else) are bound in the pervasive network of relationships we call economics. If serious writing is payment-free, how will writers and scholars buy groceries? Dependence on the sponsorship of the state or the charity of the rich may resolve short-term funding problems, but only at the cost of restoring literature's medieval dependence on the patronage of princes and prelates. Confounding a free press and a press outside the economy is ahistorical and unsound [Columbia, 1996].

4. This is not a hypertext

This is not a hypertext, nor is it a story. These are some sketches, fragments of stories and of arguments that might be. Nothing is resolved yet, but resolution is possible: by suggesting a dramatic problem, we imply its solution.

Skeptics sometimes assert that hypertext is incompatible with narrative or with coherent argumentation, believing that stories naturally begin at the beginning and that arguments proceed from premises to conclusions. Inspection of actual narratives and real arguments, however, reveals a much richer variety of structural patterns. Clarity often demands that we forego strict chronology to make causes and effects clear, or that we anticipate a conclusion in order to motivate an argument. Coherence is not merely sequence (Kolb 1994) (Kolb 1997).

Understanding hypertext requires thoughtful criticism of actual hypertexts, not merely to make purchase recommendations or to award tenure, but rather to understand how hypertexts communicate (Walker 1999) (Tosca 1999) (Joyce 1997) (Bernstein 1998). *A priori* reasoning about what hypertext might become, necessary and useful as this was in the era before actual hypertexts were available (Nelson 1982), can no longer substitute for examining the data.

UK, Finland

Swiss Criminal Law Art 144bis

US Federal Law

18 USC Sec 1030 (a) (5) (A): „Whoever knowingly causes the transmission of a program, information, code, or command, and as a result of such conduct, intentionally causes damage without authorization, to a protected computer...“ („Computer Fraud and Abuse Act“ 1984, amended in 1986 and 1994)

Californian Penal Code Sec 502

(c) Except ... any person who commits any of the following acts is guilty of a public offense:

...

(8) Knowingly introduces any computer contaminant into any computer, computer system, or computer network.

Swiss Criminal Code Art 144bis

1. Wer unbefugt elektronisch ... gespeicherte oder übermittelte Daten verändert, löscht oder unbrauchbar macht, wird, auf Antrag, ... bestraft.

2. Wer Programme, von denen er weiss oder annehmen muss, dass sie zu den in Ziffer 1 genannten Zwecken verwendet werden sollen, herstellt, einführt, in Verkehr bringt, anpreist, anbietet oder sonstwie zugänglich macht oder zu ihrer Herstellung Anleitung gibt, wird ... bestraft.

Comparison to other Threats: Poisons, Real Virus

Is development forbidden? - in most states no

How would you legally develop medical treatments without the poison or virus?

Is production forbidden? - in most states no, even not in case of drugs (depending on quantity)

Is dissemination forbidden - yes, even without intent (e.g. Austria: § 169 StGB Fahrlässige Gemeingefährdung)

Problems of Criminal Investigation and Procedure

International Distribution

International Collaboration

Hearsay Evidence Rule

Who is obliged to help the authorities?

Experts

Suspect

Witnesses

Producers e.g. by including logging, tracing and GUID into their products

Prevention

Persuade authorities to build up adequate knowledge

Dissuade producers of internet-relevant systems to make virus programming easy (e.g. by procurement rules, advertising, ...)

Persuade providers to provide their services with adequate security

Persuade users to think over security (e.g. use edp-systems with access control, make boot sectors, template-files, etc readonly)

3D Inhabited Virtual Worlds

Interactivity and interaction between avatars, autonomous agents, and users

Jens F. Jensen,
InterMedia-Aalborg & Department of Communication, Aalborg University, Denmark
jensf@hum.auc.dk

Abstract: This paper addresses some of the central questions currently related to 3-dimensional Inhabited Virtual Worlds (3D-IVWs), their virtual interactions and communication. First, 3D-IVWs – seen as a new and unique form of multimedia – are introduced and the social construction of the 3D-IVW technology is briefly discussed. Second, a selection of the basic concepts and identifiable entities in 3D-IVWs is defined and commented upon. Third, some of the strange digital creatures, which currently inhabit 3D-IVWs in the form of cyber-hybrids, are outlined. Fourth, modes of interactivity and (virtual) interactions between users, avatars, bots, etc. in the new Virtual Worlds are briefly presented and typologized. Finally, the changing Internet and the virtual futures of 3D-IVWs are reflected on.

Three-Dimensional Inhabited Virtual Worlds (3D-IVWs) are currently becoming a reality. They first appeared in computer games and stand-alone multimedia applications, but are increasingly appearing in networked-based systems, e.g. the Internet, intranets, and the World Wide Web. Considered as new media, they can be characterized by the following traits:

- 3D-IVWs are generated from software, drawn as interactive computer graphics in 3 space dimensions (plus a 4th dimension in time), i.e. they exist only in cyberspace: in the digital domain of the computers and the computer networks.
- 3D-IVWs are represented on a two dimensional screen, i.e., 3D graphics in this context are understood as a way of representing 3D data in 2D so that it can be viewed on a computer monitor or a TV screen.
- 3D-IVWs usually contain computer-generated representations of their users – *inter alia*, so that other users can see them – in the form of so-called 'avatars'. In other words, this software is inhabited – inhabited by its users, designers and developers.
- These avatars can be moved around as movable computer graphics on the 3D scene and the movement is controlled interactively by the user.
- An avatar has a viewpoint that is fixed relative to the avatar.
- Consequently, as the user moves the avatar around, its viewpoint also moves. Because the background is animated, as well as the objects in the scene, the user can see the whole scene move relative to the figure. In short, the user can interactively control the viewpoint relative to the 3D space or scene.

One might call these environments '3D Inhabited Virtual Worlds'. However, they have other names as well, such as '3D Cyberspace', 'distributed virtual reality', 'Shared Spaces' [Bradley et al. 96], '3D Internet' [Wilcox 98], '3D Web', '3D chat', 'inhabited digital spaces' [Damer 95], 'Avatar Cyberspace' [Damer et al. 98b], 'avatar virtual worlds' [Damer 98a] etc. These 3D worlds are currently enjoying rapid growth. Fully implemented, existing virtual worlds include: Active Worlds, WorldsAway, Biota's Nerve Garden, Blaxxun, Traveler, The Palace, Oz, Worlds Chat etc. – and even more 3D-IVWs are under construction at the moment. Some of these 3D-IVWs are (re)constructions of large 3 dimensional 'cities' with buildings, streets etc., others are marketplaces, stages, TV programs, space stations, still others are strange places that have no similarity, whatsoever, with anything in the non-virtual world [cf. Jensen 98, 99a]. The majority of these worlds are accessible from the WWW.

Thus, while the Internet has [cf. Jensen 96], until now, primarily been a set of sites, which could be visited, a pile of two-dimensional documents that could be surfed, it is slowly turning into a three dimensional space with a virtual volume – thereby, for the first time, giving the term 'space' in 'cyberspace' a literal meaning – i.e., an entirely digital environment that can be lived in and populated and in which the users can move around, communicate, and interact. In these Virtual Worlds, it is possible to meet and have (mediated) social interactions and communication with other users on the network in real time. Via these simulated interactions, a new type of virtual social practice and virtual social structure or culture is being created. In other words, the Internet is changing from a dead and flat library, to a social and communicative space: a web of human relationships – a community. And the users are transforming themselves as well from 'surfers' to 'settlers' [cf. Bradley et al. 96].

It is these 3D Inhabited Virtual Worlds and their virtual interactions and communication that are the primary objects of this study.

Hypotheses and Theory

The paper is based on the following hypotheses (all in accordance with semiotic theory and media studies):

- That interactive multimedia systems and, more specifically, 3D-IVWs, like other media, develop a set of signs, codes and conventions, i.e., they develop a formal language specific to that medium just as theater has developed a dramaturgy, film a film language, television a television language, etc.
- That through theoretical work and empirical analysis it is possible to identify and describe the formal language and functionalities of 3D-IVWs.

- And that knowledge of older media can be helpful in the process of identifying and analyzing the new language and new aesthetics of 3D-IVWs. Presenting themselves as 3D-IVWs with artifacts and actors (avatars, autonomous agents etc.) it is the assumption of the paper that this new medium can be informed by theater and film theory in particular [cf. Jensen 99b].

On the other hand, although interactive multimedia in general, and 3D-IVWs in particular, are informed by existing representational conventions from film and theater (such as the relationship between stage and actors in theater, or the function and representation of point-of-view and 3D-perspective in film), they also break with the traditional functional and aesthetic conventions of these art forms. The most obvious examples are the user's ability to control movement and point-of-view in the Virtual World, the users mutual interaction represented by avatars, or users and avatars interaction with autonomous agents. In these aspects there are clearly no immediate parallels in the worlds of film and theater or other traditional (mass) media. Consequently, we have to supplement the first three hypotheses with the following (all in accordance with sociology and interaction analysis):

- That the signs, codes and conventions of the 3D-IVWs create a framework for and influence the interactivity (user/system) and the virtual interaction (user/user, user/environment, etc.) within the 3D-IVWs.
- That through theoretical work and empirical analysis it is possible to identify and describe the interactivity and (virtual) interaction.
- And that knowledge of interaction in non-virtual settings can be helpful in analyzing interactivity and virtual interaction within 3D-IVWs.

In regard to theory and methodology, the paper draws from sociology, interaction analysis, interpersonal communication, semiotics, cultural studies, and media studies.

The Background and the Social Construction of the Technology

3D-IVWs have a complicated background and consist of the convergence of a number of very different media and areas. Sue Ki Wilcox points out no less than five fields, which are said to have inspired 3D graphics. The first fields are: computing, the Internet, science fiction and theater. Fields which are said to have contributed the following characteristics: "Computing supplies the power to make desktop virtual reality happen; the Internet provides the space and freedom in which to develop; science fiction introduces the idea of cyberspace; and theater teaches the concepts of actors and role-playing" [Wilcox 98]. A bit earlier she also involves the social aspect as an important element. "Currently, the social aspect of the World Wide Web is just beginning to emerge from the newsgroups and e-mail stage... and the more lifelike it becomes, the more people want to be involved. Avatars promise to be even more engaging..." [Wilcox 98].

Bruce Damer identifies – slightly more modestly – Virtual Worlds as the children of two humble parent technologies: 'text-based virtual community' and 'computer games' [Damer 98a, Damer et al. 98a]. The aforementioned contributed in the form of communities built up around text systems and simple text messaging such as conference systems like the WELL, MUDs, MOOs, UseNET, IRC, chat rooms in on-line services and on the WWW, as well as some early text-based virtual communities expanded with graphic interfaces, where users are represented by avatars (such as Habitat, mid1980s), which is said to have contributed the sense of community built up around common interests. Computer games primarily contributed realistic 3D graphics and effects, especially "the power of existing 3D rendering engines developed for gaming applications such as Doom and Quake" [Damer et al. 1998a], which demonstrated that 3D graphics and virtual worlds could be fast and effective using minimal computer hardware like a regular personal computer. In other contexts, Damer includes a third predecessor: "The whole infrastructure of Internet Protocol and the World Wide Web" [Damer 96].

In this context, 3D-IVWs will be considered as consisting of four basic elements or building blocks: Virtual Worlds, 3D-graphics, Artificial Life, and Virtual Communities:

- The term 'world' refers to the all-encompassing context for the totality of human activities and experiences and the term 'Virtual World' refers to "computer programs that implement digital worlds with their own 'physical' and 'biological' laws... VW is concerned with the simulation of worlds and the synthesis of digital universes" [cf. Heudin 98, cf. below].
- '3D-graphics' refers to a way of representing three-dimensional data or 3D graphical spaces in two dimensions so that it can be viewed on a screen or a computer monitor.
- 'ALife' or 'artificial life' refers to digital simulations of living systems, which incorporate metaphors from biology, i.e., biologically inspired, synthetic organisms.
- And 'Virtual Communities' refers to human social communities that form in and around digital virtual worlds, often in the form of a group of people communicating with each other through computer networks.

These four elements are brought together and integrated within 3D-IVWs, which are generally constituted around computer simulations of whole worlds or digital universes with artificial life forms and social communities. The following will expand upon this attempt to define and discuss some of the key concepts in relation to 3D-IVWs.

Virtual Worlds – basic concepts

Representation. The concept of representation refers to all aspects of the appearance of virtual worlds including the appearance of avatars, bots, objects and other elements of the virtual world. Representation is related to the concept of sign. A sign is "something which stands for something else to somebody" [cf. Peirce 31-58]. In other words, a sign is a manifest, perceivable entity (whether it is a thing, an element of behavior, a form of appearance, etc.) which is received by the sense organs of an interpretative, mental apparatus and is interpreted as referring to something else (an item, phenomenon, feeling, event in the real or virtual world, etc.). The interpretative, mental apparatus establishes a relationship or a 'link' between the entity, which represents and

that, which is represented. The actual sign is then finally constituted as a relationship between these three entities: the representation, the entity that is represented, and the mental apparatus that interprets the first by linking it to the second [cf. Jensen 93]. In this way, signs can be seen as quite a distinctive class of phenomena, since they have meanings: they stand for or refer to other objects or events. The concepts of sign and representation naturally play a key role in this context of what are, in a certain sense, purely symbolic worlds; worlds which are exclusively constituted by representations, by signs. There are several types of representations or identifiable entities in 3D-IVWs, which will be considered and commented upon in the following.

Virtual World. The concept 'Virtual World' covers the total virtual environment, i.e., the whole 3-dimensional scene or 3D-space with its set of various objects and with all its special characteristics. The terms 'Virtual World', 'scene' and 'space' are here more or less synonymous. This 'virtual 3D space' has a number of general characteristics:

- It is coordinate-based, i.e., every position in the space can be identified by a set of 3 coordinates.
- It is geometrically finite, i.e., it makes up a 'bounded', 'delimited' world.
- It is continuously navigable, i.e., the user can move seamlessly through the world without transition of any kind. The space itself, however, can be made up of several linked files, as long as they appear to the user to be seamless.
- It is defined by a set of 'physical', 'biological', 'social', etc. rules. These rules have an affinity to physics-based laws like laws of nature, i.e. they define how one may move, interact, communicate, etc. in the space, except that in this case it is the designer, the creator of the world, who has established the rules.
- Each world represents a specific vision of what a virtual world can be and which experiences it can offer its inhabitants and users. Virtual worlds thus have their own ontology since all conceivable forms of existence seem to be possible within them, or more precisely: the nature of being is here only limited by the current technology and imagination.

In these virtual worlds or 3D-spaces there may be various types of interiors or elements, which can roughly be divided into objects and actors, differentiated by whether or not their primary function is to carry out an action.

Objects. An object can be defined as a limited, relatively autonomous part of the world. Examples of objects are trees, billboards, windows, doors, posters, etc. including props, i.e., the accessories or attributes of an avatar such as: a hat, a bike, a cane, etc. Objects typically consist of two basic components: 1) a model that determines what the object looks like, its size, etc. and 2) some characteristics that determine where it is placed, which actions it can carry out, etc. Objects can also be assigned actions, therefore, drawing a precise border between objects and actors, especially 'bots' (cf. below) can, in some cases, be difficult.

Actors. 3D-IVWs are not, however, solely composed of a space and objects; this space is also inhabited. Actors are entities that inhabit the virtual worlds and whose primary function is to carry out actions. They have two main forms, which will be described – for the moment – as relatively sharply differentiable polar opposites. This is done based on questions such as: who is controlling the actors? 'who is doing the driving'? On the one hand there are actors that react independently of the user, but which are controlled by software or AI, the so-called 'autonomous agents' or 'bots' (short for robots). On the other hand, there are agents, which directly represent and are controlled by users, the so-called 'avatars'.

Bots or autonomous agents. A bot or an autonomous agent is a bit of software, which is not directly or interactively controlled by a human user, but runs on its own, controlled either by a program or by some form of built in intelligence. In real life (RL), robots are often physically manifested as machines. On the Internet or the Web bots are often invisible or are only represented in a visible mode in the interface during input or output situations. The special thing about bots in 3D-IVWs is that they (most often) are represented as visible, that is, they have a sensory representation in the virtual world. In many cases, bots are similar to other users (i.e. avatars) and appear as a kind of automated or virtual avatar. Similarly, they may have some degree of built in AI, independence, self-motivation, personality, etc. Often bots are given specific assignments. In 3D-IVWs, they are usually used to inhabit sparsely populated spaces and thereby to provide the user or the avatar with company (automated conversational agents), to show the way or to guide tours, to answer questions, to entertain by asking riddles or offer clues to puzzles, to provide information on present users, the present scene, etc.

Avatars. At the pole directly opposite the bot or the autonomous agent is the avatar. Even though avatar technology is relatively new, the term 'avatar' is paradoxically quite old. It comes from Sanskrit and means something like 'the embodiment of a spirit in the flesh'. In its modern, digital, virtual incarnation an 'avatar' is defined in many different ways. Wilcox defines an avatar as "an electronic representation of a person in cyberspace", "[a] virtual expression of yourself, wearing your wardrobe of virtual clothes" or "an electronic version of the human form designed to let you enter cyberspace" [Wilcox 98]. And Damer defines it as "a digital body you can see", "a virtual personality in a 3-dimensional world" [Damer 98a] or "animated 3D models of users" [Damer et al. 98b]. An avatar is, in other words, a representation of the human actor or user in the virtual universe which can be manipulated and controlled by the user in real time, even if the representation is, at the same time, bound by the limitation and laws of the virtual world in question. In this particular sense, avatars are – as Wilcox also formulates it – "extensions of ourselves". So if Marshall McLuhan's old catch-phrase "media and technology are extensions of ourselves" has ever been relevant it must be now, in relation to 3D-IVWs, where the slogan has been given a most concrete incarnation in avatar technology.

The avatar serves several functions. It is necessary in order for the user to be visible to others and thereby to have a 'presence' in and interact with others in the virtual world. It is necessary for the user to have a position in the form of a set of 3 coordinates and thereby a viewpoint and a sense of 'presence' in the 3-dimensional world. And it is generally necessary in order for the user to enter, move around in and experience the virtual space as well as to become a member of the virtual community. In 3D-IVWs then, avatars are used (virtually) to meet new people, have new experiences, visit new places, learn, play, etc.

An avatar has two important aspects: appearance and functionality. One important thing about an avatar is naturally its appearance, what it looks like, because it is synonymous with the way the user presents himself in cyberspace. Another important thing is functionality, since an avatar can have many different functions. It can be equipped with animation, behavior patterns (where 'behavior' here refers to a sequence of animations), it can show emotion via facial expression, carry objects, belongings

or props or be able to prove identity in connection with financial transactions and, if desired, also give gifts and have pets. As far as special behavior patterns go, the components of animations and behavior – like avatars themselves – are often selected from galleries and then personalized. Specific animations and behaviors can then be released or triggered by different factors such as: user behavior (a click of the mouse and the like), a time factor, collision detection, proximity to other objects or avatars, the appearance of an object, a touch sensor, etc. Although by definition avatars are under the control of the user, the degree of control can vary in practice quite a bit. In certain cases the user can completely control all of the avatar's movements and communicative actions down to the smallest detail. In other cases, the user can only determine actions, behavior patterns, gestures, moods, manipulation of objects, etc. on a more general level. This behavior is then carried out by a pre-programmed automatic system. In yet other cases, parts of the avatar's behavior can be controlled by the user, while other parts are controlled by a system or a more or less intelligent program.

Within the avatar category there are both *user-in-avatar*, which is a representation of the human user in the 3D Virtual World and *designer-in-avatar*, which is a representation of the designer, developer or creator of the 3D world (sometimes called 'God'). 3D Virtual Worlds are then the only type of software, where one can actually meet and speak with the author of the application – within the application itself.

Human Actor. Finally, there is the human actor or user of the 3D system or world, who actually controls the avatar and/or the viewpoint of the world.

Cyber-Hybrids

Although there is then, in principle, a differentiation, in terms of definition, between bots and avatars, both concepts cover a relatively wide spectrum of very different types of phenomena with differing degrees of control. There also seems to be a tendency toward the appearance of more and more hybrids – we could call them 'cyber-hybrids' – combining avatars and bots. Furthermore, these hybrid forms are in many ways the most interesting and most promising in the virtual worlds at the moment. Rather than considering avatars and bots as polar opposites, it may therefore be more productive to consider them as the outer points along a continuum, between which can be found all sorts of combinations or hybrids. The following will briefly outline a typology of these strange new hybrid creatures, which currently populate this continuum in the virtual worlds [cf. Wilcox 98].

Alife/Digital Biota. Along the continuum between autonomous agents and avatars, Alife (Artificial Life) or digital biota is closely related to the former. Alife and digital biota are artificial or 'alien' life forms, i.e., biologically inspired, synthetic organisms in the form of quasi-autonomous software. Thus, Alife is the virtual world's counterpart to the real world's plants and primitive animal life forms. Jean-Claude Heudin describes the vision of ALife in Virtual Worlds in the following way: "Imagine a virtual world with digital creatures that looks like real life, sounds like real life, and even feel like real life ... This virtual world could be familiar, reproducing some parts of our reality, or unfamiliar, with strange 'physical' laws and artificial life forms" [Heudin 98]. Alife as a general area of research deals with artificial living systems and the general principles of the living state. *Alife online* describes the field and its background context in the following way: "Artificial Life – literally 'life made by Man rather than by Nature'. Artificial Life ('AL' or 'Alife') is the name given to a new discipline that studies 'natural' life by attempting to recreate biological phenomena from scratch within computers and other 'artificial media'... By extending the horizons of empirical research in biology beyond the territory currently circumscribed by life-as-we-know-it, the study of Artificial Life gives us access to the domain of life-as-it-could-be..." [Alife online 98]. With regard to the definition of 'digital biota' and their boundary surfaces to creatures such as bots, agents, AI, etc., Biota.org writes: "Digital Biota are a class of self-replicating autonomous software objects which includes computer viruses, artificial life programs, some cellular automata and some genetic algorithms. Once released they live or die by their own decisions as they interact with their environment. They are usually capable of reproduction – if they also have the ability to mutate and be affected by the force of natural selection to some degree then they can evolve. Biota shade out into the region of semi-autonomous objects which includes artificial intelligence, software agents and bots. These generally have only limited control of their own functionality, operate according to outside goals, and do not reproduce... The increase in avatar inhabited virtual environments on the Internet is one potential breeding ground for such digital biota" [Wilcox 99]. As can be seen here, there is not only a continuum between agents and avatars, the continuum stretches across the whole field of actors and objects: from avatars, to biota and Alife, to agents, AI, bots and (semiautonomous) objects.

The best known examples of Alife and digital Biota are probably: Tom Ray's *Tierra*, a digital ecosystem that produces synthetic organisms based on a computer metaphor for organic life; Karl Sim's 3D virtual creatures; and Biota's *Nerve Garden*, a biologically-inspired multi-user collaborative 3D virtual garden hosted on the Internet – i.e., a public terrarium in cyberspace – where visitors can plant a seed and watch it grow.

Characters using genetic algorithms. A bit closer to humans on the continuum between the artificial and the human are characters, which use genetic algorithms. In other words, these characters have a built-in ability to learn from the interactions they participate in, to learn from experience, and thus continuously change their characteristics and functionality. They often have a relatively independent existence in the given virtual world where they can live out their own life. Among the best known examples are perhaps *CyberLife's* popular game *Creatures*, where the user is supposed to raise the creatures from the egg stage, and the Japanese *Tomogatchi*.

Game Characters. In the middle of the continuum, but perhaps closest to the autonomous agents, are Game Characters. They are, as the name indicates, often related to games and can be regular autonomous agents with an independent existence and functionality in the universe of the game. At any given time, however, a user can take over control of a game character – for example

as a tool for getting into a game, in order to learn the rules of a game or under particularly exciting and critical passages in the action – in which case the Game Character's status is temporarily transformed into an avatar.

Mask Characters. Closer to avatars are Mask Characters. Mask Characters are avatars which – aside from the usual physical form and functionality of an avatar – also have a character that can control, guide or inspire the user, who is using it. For example, the character can tell the user, which high-level directions make sense in a given situation, and then given the user's choice, improvise a course of behavior [cf. Hayes-Roth et al. 97]. In other words, it is a 'smart' avatar with an independent mental life, a consciousness or a will. As such, Mask Characters are used in e-commerce, learning, and entertainment as well as to teach users to play certain roles in the virtual environment. Examples are Hayes-Roth's and Extempo's 'Imp Characters' which are guided by their roles, their personalities, their moods, as well as real-time directions from the user or other software.

Virtual Humans. Virtual Humans are 'naturalistic' copies or stand-ins for humans, where the main principle is to create the most convincing, realistic or perfect simulation of the human form and function (while normal avatars and agents may look like just about anything). Emphasis can be placed either on form (appearance) or functionality or both at once. Virtual humans are used primarily in simulations and in the testing of products and environments, but also in games and movies. Along the continuum between autonomous agents and avatars they, in reality, cover the whole stretch. In the bot-incarnation they may appear as pure dummies which make up simple pre-programmed, animated figures in a 3D model or they may be autonomous agents, which are controlled to some degree by artificial intelligence. In the avatar-incarnation they may be directly and interactively controlled by a human actor, e.g. in the form of 'ergonomic avatars' in connection with virtual trials of products, processes or environments by way of simulations in cases where Real Life trials may be inexpedient. The same virtual human can in fact change between being a bot and an avatar. The most prominent examples in this category are perhaps the computer-generated – but very realistic – Japanese pop star and personality Kyoko Date, made up of 40,000 polygons, and the work done on realistic avatars and virtual humans at MIRALab, Geneva.

Avatar/Agent. Furthermore, there are more and more examples of actors in virtual worlds being able to instantly switch, so to speak, from the avatar-mode to the bot-mode. One example is 3D Planets 3D-assistant, a 3D representation that can both function as an agent controlled by a program and be used as an avatar, depending on the situation encountered and the programs being run. The assistant functions in principle as an interface between the program that is actually running and the user, sometimes controlled by the program and sometimes controlled by the user. In this way, the 3D-assistant perhaps gives us a taste of what a so-called 'assistant interface' might look like in the future. Or one might imagine a user who participates in a communicative community represented by an avatar, but whose avatar lives on – even *after* the user has left the world and the computer – switched to some kind of 'automatic pilot', continuing to interact and communicate with other agents and avatars (perhaps also running in an automatic mode). In this mode the automatic avatar might either follow pre-determined parameters or pre-programmed behaviors, follow some form of artificial intelligence, or even simulate or mimic what it has learned from the particular user.

Interactivity, Interaction & Virtual Interaction

An area of particular interest in connection with 3D-IVWs obviously involves the new possibilities for interaction and interactivity that arise, partly seen in relation to RL-interaction, and partly in relation to interaction and interactivity [cf. Jensen 97] in more conventional media and computer applications.

Interaction. In sociology the word 'interaction' refers to the actions of two or more individuals which can be observed to be mutually interdependent, i.e., interaction can be said to occur when each of at least two participants is aware of the presence of the other and each has reason to believe the other is similarly aware, in this way establishing a state of reciprocal awareness. In other words, interaction is the relationship between two or more individuals who, in a given situation, mutually adapt their behavior and actions to each other. Important aspects here are that limited, clear-cut social systems and specific situations are involved, where the partners in the interaction are located in the same time and space – i.e., are in close physical proximity – and 'symbolic interaction' is also involved, that is, a mutual exchange and negotiation regarding meaning takes place between partners who find themselves in the same social context. A phenomenon which communication and media studies would call communication, or more precisely – since the partners in the interaction are situated in the same context – face-to-face communication or interpersonal communication.

Virtual interaction. In relation to this general definition, *virtual interaction* takes on a number of special traits. Once again interaction is connected to a concrete situation and a limited and clear-cut (though here virtual) social system and once again we can speak of symbolic interaction between the participating partners. However, the special thing about interaction in virtual worlds is that the interacting partners are situated in the same time (in terms of real time systems), but not within the same space. On the contrary, the interacting partners – understood as the human actors – are physically distributed without any immediate physical proximity, i.e., the interaction itself is mediated and only the interactors' representations share this physical proximity. The concept of 'virtual interaction' refers, in this context, to the relationship between virtual representatives of human actors situated in the same time and virtual space – i.e., in a form of virtual proximity – within a limited (virtual) social system; virtual representatives who mutually adapt their behavior and actions to each other and which mutually exchange and negotiate meaning and create a 'symbolic interaction'. Consequently, there is no face-to-face communication. On the contrary, there is a new form of face-to-interface or interface-to-interface communication. Only the avatars practice (virtual) face-to-face communication. One of the unique traits of virtual worlds as a medium is then, that they allow for the possibility of practicing face-to-face communication with all that that implies with regard to facial expression, gestures, body language, etc. – in a mediated and virtual form. Thus, in Inhabited Virtual Worlds, interpersonal communication and the knowledge that this discipline represents becomes, for the first time, relevant to the computer world. Moreover, since there is a sliding scale from representations of human users – ava-

tars – to bots, animated objects, etc., the concept of virtual interaction also covers the mutual relationship between avatars, bots, objects and other elements within the virtual world.

There are several different types of virtual interactions and simulated communication of interest in 3D-IVWs. If, to begin with, for the sake of clarity, we disregard the entire population of cyber-hybrids and only examine avatars and autonomous agents as relatively pure forms, these virtual interactions can be represented by the following matrix [cf. Fig. 1] where the redundant combinations have been eliminated.

	Actor (human)	Designer-in-Avatar	User-in-Avatar	Bot	Object	Virtual World
Actor (human)	Ac / Ac					
Designer-in-Avatar	D-in-A / Ac	D-in-A/D-in-A				
User-in-Avatar	U-in-A / Ac	U-in-A/D-in-A	U-in-A/U-in-A			
Bot	Bot / Ac	Bot / D-in-A	Bot / U-in-A	Bot / Bot		
Object	Ob / Ac	Ob / D-in-A	Ob / U-in-A	Ob / Bot	Ob / Ob	
Virtual World	VW / Ac	VW / D-in-A	VW / U-in-A	VW / Bot	VW / Ob	VW / VW

Figure 1: Matrix of types of interactions in 3D-IVWs

Due to limited space, only some of these types of virtual interactions will be described and discussed below.

Human Actor/Avatar. Interaction between a human actor and an avatar consists of the user controlling the avatar and communicating and interacting through the avatar. This depends, among other things, on how the avatar is controlled: via keyboard, mouse, joystick or some form of motion capture. Thus, this area corresponds to a certain degree, to the traditional area of Human Computer Interaction, or what is called interactivity [cf. Jensen 97] in conventional computer systems. The interaction is, however, mutual since the user must also adapt to the avatar's specific movements (e.g. its degrees of freedom) and abilities, its repertoire of expressions, as well as its built-in limitations. It is, for example, quite important whether the given avatar can express itself in written language, only in spoken language, or only through body language and facial expressions. The relationship between human actors and avatars also touches on the pivotal question of identity. A question, which in virtual worlds, more than being a philosophical or existential issue is primarily a question of relationships between an avatar and a person in RL. The question of identity concerns e.g. whether a person in RL can have several alternative virtual identities, the question of techniques for validating identity, visual appearance as a key to identity, etc. Identity in virtual worlds, then, concerns how it can be verified, stored, communicated, transmitted, etc.

Human actor/Object. Controlling an avatar is one thing, manipulating an object in a virtual world is quite another. How does one f. ex. throw a ball or catch something? This form of interaction deals with how one interacts with a virtual object-world via the computer's traditional input-output devices, but it also deals with how users implement objects in real time.

User-in-Avatar/User-in-avatar. Mutual interaction between avatars is perhaps the most interesting part of interaction forms in Virtual Worlds. It deals with how avatars communicate or exchange information between each other – through written text, voice, gestures, facial expressions, etc. – and how they exchange objects including HTML documents, business cards, props or other 3D objects. However, it also deals with how changes in the position of the avatars, movements and communication are tracked and how these changes are communicated to the rest of the surrounding world. Likewise, it deals with how avatars document their identity in relation to one another, f. ex. in connection with financial transactions.

User-in-Avatar/World. Interaction between a user-in-avatar and world primarily concerns the physical, biological and social 'rules' that are established for the world in question and the possibilities and limitations they set for the ways in which the avatar can navigate, maneuver through space, communicate, interact, etc. within that world. It also, however, concerns the 'rights', i.e., the range of permitted actions, that the avatar have within that world: the right to chat on certain channels, the right to enter but not to change the world, the right to make changes in the world and to what extent. For example: is the avatar allowed to move objects? leave graffiti tags on the walls? carry out vandalism? and will these changes endure when the avatar leaves the world? But avatar vs. world interaction also concerns which types of avatars the given world permits. Is it possible, f. ex., for the user to bring along his own tailor-made avatar designed independently and therefore new to the world? how complex is this avatar allowed to be in terms of polygons, considering the amount of calculation time that is needed for its representation? alternatively, are only avatars designed especially for the world in question permitted or is there a specific avatar file format? It also concerns how avatars arrive in the world (is there a pre-determined arrival spot?) and which objects can be brought into the world (does the world accept avatar props such as hats, bikes, dogs, etc. or is it necessary to leave them outside the world?). This type of interaction is not just about what avatars can do in relation to the world, but also about what the surroundings can do in relation to the avatar, e.g. what does the world look like from the avatar's position? does the world address – e.g. speak directly to – the user-in-avatar (or human actor)?

User-in-avatar/Bot. Interaction between user-in-avatar and bots concerns what bots are programmed to do and whether there are characteristics of avatar behavior that trigger agent actions and vice versa: collision detection, proximity, visibility, touch, etc. It also concerns whether agents are equipped with some form of artificial intelligence, originality, or self-motivation. Bots are often used in 3D-IVWs to carry out standard functions such as greeting avatars to the new world, giving guided tours or simulating interaction and communication with real avatars when no others are present.

BEST COPY AVAILABLE

User-in-avatar/Object. Similarly, interaction between user-in-avatar and objects typically consists of avatars being affected by the object (f.ex. stopped by it) or in some way being able to handle it (pick it up, carry it, move it). Or conversely, that an object reacts to the proximity of an avatar (becomes visible, rotates, blinks, makes a sound, etc.). Also in this case various types of triggers for action such as collision detection, closeness, visibility, touch etc. play an important role.

Virtual World/Bot. The relationship between Virtual Worlds and bots concerns things like which bots the given world allows, and which rights they are given from the world creator. This type of interaction may deal with protecting the world from being changed or destroyed by invading bots. Examples: can a virtual dog dig a hole in a lawn? can virtual weeds in the form of biota spread throughout a garden? can virtual termites chew holes in the furniture?

Virtual World/Object. The relationship between Virtual World and objects deals with which types of objects the virtual world accepts and which actions can be connected to those objects. It also concerns whether or not objects are persistent. This last instance can allow a user to place an object in a virtual world, to give a virtual gift, etc., which remains in the world even after the user/avatar has left it.

Virtual World/Virtual World. Finally, interaction or relationships between Virtual Worlds concerns whether or not it is possible to jump from one virtual world to another, as well as *how* these jumps can be carried out. In other words, it concerns the technical specifications for the various network-connected worlds. From the most general perspective it therefore also deals with whether development is moving toward universal cyberspace, where virtual worlds are compatible and interconnected, or whether there will be a multitude of incompatible, isolated islands of virtual worlds. The World-to-World relationship can also concern more specific problems regarding world's relationships to each other. What happens f.ex. if an object is thrown over the border of a world? Could it turn up in a nearby world, which may run on another server? Could it cause damage in the new world when it lands? And could it be retrieved from that world beyond?

The Virtual Futures of 3D-IVWs

3D-IVWs are not just being met with pure positivity and great expectations. There are also researchers who criticize the whole idea of 3D interfaces. "2D is better than 3D" was, for example the headline on Jakob Nielsen's Alertbox about a year ago "...because people are not frogs", he explained [Nielsen 98]. And he continued: "If we *had* been frogs with eyes sitting on the sides of the head, the story might have been different, but humans have their *eyes smack in the front of their face*, looking straight out". In arguing that 2D is more natural and intuitive than 3D, Nielsen digs up one of the world's oldest arguments – the evolutionary or perceptual aspect: "Evolution optimized *homo sapiens* for wandering the savannah – moving around a plane – and not swinging through the trees ... 2D navigation (on the ground) vs. 3D navigation (in the air)". A strange argument in itself, especially when Nielsen continues: "I do maintain that we are more capable of moving around a flat surface and that we spend most of our time doing just that". Strange, because moving around the surface of the earth is not moving in 2D since we do not find ourselves *in* the plane or surface of the earth, but *on* it. Contrary to Nielsen, it could be claimed that the fact that our eyes are placed in the front of our heads and that we are equipped with stereoscopic vision means that we have the ability to estimate distance and to see in depth, i.e. to see in 3 dimensions. Even 2-dimensional realities such as paintings, photography, film, etc. have developed a whole series of techniques to construct or fake a 3D effect [cf. Jensen 99], and correspondingly human perception has a built-in ability, as well as a tendency, to read 3-dimensionality into such 2D-representations. 3 dimensionality, depth, and perspective are as such extremely important for everyday perception and ordinary orientation. And, at this point, there is no reason to believe that the computer as a medium will not take advantage of this perceptual bias as well.

On the other hand, there is a long *de facto* list of important critical notes about the use of 3D on computers, some of which Nielsen correctly points out. Notes, which all primarily refer to today's state-of-the-art computer technology: devices such as the screen and the mouse, and current interaction techniques such as scroll, drag, drop etc., are all intended and designed for 2D interaction, not interaction in 3D. Navigation in a 3D space is often so confusing and difficult that users get lost. The 3D aspect means, among other things, that the user must also think about the 'behind' factor, i.e. what is behind him, are distant objects hidden by closer objects, smaller objects hidden by larger ones etc.? Besides, since the user must exert extra energy and attention in order to control and navigate the 3D view there is often a tendency to produce 'navigational overhead'. Poor screen resolution makes distant objects unrecognizable and text placed in the background illegible, and so on.

Some of these problems will, in time, be solved, some of them will not. So, many of the critical notes will still be pertinent within the foreseeable future. Consequently, there is no reason to believe, as it has been prophesied, that the 3D interface built around the metaphor of a space will, during the next few years thoroughly replace the current 2D interface based on the classic windows and icons desktop metaphors. 3D Virtual Worlds will most likely establish themselves as a medium or a type of interface among other media and interfaces. Certain applications and domains will be suitable for 3D and implemented as 3D Worlds, other applications and domains will not be suitable for 3D and thus be implemented, f. ex., as some sort of 2D media.

In many ways, Virtual Worlds are still a medium in search of an application. However, in the foreseeable future, the most important and dominant applications of 3D-Virtual Worlds will probably be a new galaxy of entertainment spaces offering action, (multi-player) games, adventures and exotic experiences; inhabited TV where viewers transmute into users and participants – in quiz shows, games and issue forums; virtual spaces for communication and interaction from family rooms to international political discussions; collaborative, community building environments; collaborative workspaces (GroupWare); shopping and transaction spaces; virtual class-rooms where students can learn together and from each other (at a distance); virtual meetings and events (virtual conferences, cyber-tradeshows, virtual exhibitions etc.); visualization spaces for physical objects that need to be understood in their solid forms (architectural sketches, design, molecular form etc.) and the like. And, just as likely, cyber-hybrids, combining avatars and agents will be used as: advanced visible message machines always available for access in a vir-

tual world; stand-in communicators, taking some of the information load off the user; multidimensional tools to collect data, negotiate, and act as guides in virtual environments, etc.

Conclusion

The most interesting aspects of any given new medium are always its unique characteristics, the characteristics that differentiate it from all the other known media. To summarize, the unique and essential qualities of 3D-IVWs in relation to existing media are primarily.

- The medium makes it possible to move your personal representation interactively and thereby to (interactively) control your represented viewpoint in the 3D Virtual World.
- The medium makes it possible to interact and communicate with other users via representation and hereby also to interact and communicate visually and bodily with sign systems such as (virtual) body language, non-verbal signs, facial expressions, etc. For the first time in the history of the computer, the whole range of interpersonal communication, face-to-face communication, non-verbal communication, etc. is therefore relevant and of interest to computer science.
- The media both makes it possible to communicate in a (very flexible) context and to personalize communication and interaction.
- And the encounter with the computer is transformed from an experience of a two-dimensional interface, which can be clicked on, to the experience of a space in which the user feels a presence and a community with other people; and correspondingly, that the encounter with the Internet tends to change from an experience of a web of linked 2D-documents, to an experience of a galaxy of interconnected 3-dimensional Virtual Worlds. A true cyber-space where – as Pavel Curtis once put it – “people are the killer app”.

Abstract: Research in information retrieval has traditionally concentrated on making assumptions about the content of documents based on very shallow semantic analysis through word occurrence statistics of various kinds.

But texts are more than bags of words, and the semantic analysis information retrieval systems typically used is overly simple. There is ample reason to try to broaden the view of what text is and why.

Better content analysis alone will not be enough. Texts are more than their meaning. Texts have structure, they have context, they are written in a style conformant or discordant to a genre they are to be understood in, they may be carefully written or hastily thrown together, they are written by various types of agent for various reasons. Besides information to be found in the text or from the author, texts are used by readers of various backgrounds, for various reasons, and with varying degree of satisfaction.

This paper outlines a framework within which to find more knowledge from texts than an approximation of their topic, and gives examples of how to use this knowledge to design useful tools for information access.

What is in a Document?

Arguably, the most important characteristic of a document is what it is about. The topic of a document is the most important criterion for selecting it from a collection. How to model the topic of documents in a collection effectively is the most obvious goal for most research in information retrieval.

But researchers in the field are keenly aware of the fact that the interaction of information seeking users and the tools to access information sources is important in itself. Information can be sought for various reasons and with various ideas of how to determine what documents or other information bearing units are relevant. Indeed, no interactive information access system can disregard the requirements posed by users -- and this is most often understood to allow users to request documents from the collection with a minimum of complexity, by modeling document and query topic concisely and succinctly, and to have systems respond rapidly with their inner workings transparent and understandable.

More Than Topic

Given that documents, besides topic, have internal structure, textual style, and usage context - not independently of topic, but highly dependent on it - the question is if this sort of fairly vague and informal variation can be used for information access purposes.

Most systems today put considerable effort in neutralizing and hiding this sort of spurious variation from the user.

But this information could be retained, just as easily. Modeling document variation along any number of vague dimensions can be done through none too complex analysis.

This is a first step towards new knowledge sources: less focussed than the obvious ones but knowledge sources just the same, and important situational factors in manual text categorization.

Text Usage: Collaborative Search

One of the most obvious characteristics of a document, besides its content, is its usage: documents have *context*, or *ecology*: texts are actually used by people for whom they are important [Walker, 1981].

The knowledge that documents are used differently and for different purposes can be used for better design of interfaces, to support various different access strategies [e.g. Belkin, 1994] - or by explicitly categorizing documents by the company they keep, by the other documents retrieved together with it [e.g. Karlgren, 1990; Resnick *et al* 1994; Hill, Maes]. The latter type of information can be used directly in retrieval. By gathering information about document usage or by asking users to list documents they appreciate a system will be able to *recommend* other similar documents - irrespective of topic.

This sort of systematic study of text usage rests on two observations. Firstly, users often have a fair idea of what they have read, and they can relate their query to their own readership history; the situation and the request in information retrieval situations can often be formulated as a form of "I read *A Good Book* - I want more of the same" posed to a librarian or a colleague, or to a number of them.

Secondly, an ordinarily unorganized bookcase may self-organize - somewhat unsystematically - based on users' behavior. Interesting documents may be found next to each other. They are interesting because someone placed or left them there, and they are placed there because they have some relation to the original document. In fact, in a library or a bookstore, people around an interesting bookcase tend to be interesting people. You tend to be able to get good reading tips from them. Similarly, a good librarian will remember that a certain book tends to be read by a certain set of people, and another book by the same set of people, and that there may be a similarity between the books, even though they may not be catalogized together - as of course, they often will not be. Anyone who has tried to organize a bookcase by topic knows how many cases of unexpected category conflict one encounters.

Text Style, Text Genre, and Text Structure

To a text reader, an obvious important dimension of textual variation is that of *style*. Stylistic variation between texts of the same topic is often at least as noticeable as the topical variation between texts of different topic but same genre or variety; style is, broadly defined, the difference between two ways of saying the same thing.

Stylistic variation in a given text, given the liberal definition above, can occur in many ways and on many linguistic levels: lexical choice, choice of syntactic structures, choice of cohesion markers on a textual level, and so forth.

Some choices are constrained by the intended audience and discourse ecology the text is produced in; some are left to be entirely determined by the author's preferences, personal idiosyncracies, and other qualitative factors of writing and editing. The former form the basis for distinguishing *genres* or *functional styles* that can be found in texts: newspapers, legal text, fictional prose, poetry; the latter, variation based on *individual style* [e.g. Vachek, 1975]. Stylistic variation is not orthogonal to or independent of variation that relates directly to content and topic, but is mainly along other dimensions. Naturally, there is covariance. Texts about certain topics may only occur in certain genres, and texts in certain genres may only treat certain topics; most topics do, however, occur in several genres.

Stylistic variation is easy to detect using surface cues in the text. Douglas Biber, for instance, has investigated what general dimensions of variation can be found in texts, and found that texts, across languages, speech and text, and genres can all be understood to vary along a small number of dimensions [1988, 1989, 1995].

Further experiments with simple stylistic cues, such as can be computed using readily available linguistic analysis tools show positive results. Even simple measures of terminological complexity - e.g. word length, relative

frequency of long words, type/token ratios, relative frequency of various indicative lexical items - paired with measures of syntactic complexity - e.g. clause length, number of complex conjunctions give enough purchase to allow the analysis and recognition of text genres through their individual characteristics with relative ease [Karlgrén and Cutting, 1994].

The measures were based on approximations of syntactic complexity – a dimension which exhibits considerable variation between genres [Losee, 1996; Menshikov, 1962]. Indeed, most stylistic measures heretofore have been attempts to find shortcuts for measuring syntactic complexity along with lexical complexity as measured by word lengths and occurrence frequencies of various sorts.

Besides the microstructure of text and its lexical items, *text structure* in itself is an important cue for manual categorization of texts. The subtopic structure of texts can be identified without too much complex computational machinery [e.g. Hearst and Plaunt, 1993; Hearst, 1997; Salton and Allan, 1994], by measuring the appearance and gradual disappearance of content bearing words throughout the length of the text.

In summary, text has easily distinguishable *form* in addition to *content* and *context*.

How can we use knowledge of document variation?

The types of variation mentioned above can be applied to the design and implementation of information access systems in several ways. Judgments or measures of documents based on new information could be added to today's relevance-based systems; alternatively the information can be used to categorize documents for presentation to the user.

Improving the Concept of Relevance

Information retrieval typically present results as ranked lists of documents, sorted after so-called system-determined of likely *relevance* to a search query. Given that we know more of documents today, adding this knowledge to a typical bare-bones retrieval system is not a trivial design task. If we know of a document that it may be of an interesting topic, it is a newspaper item, its style of writing seems to be personal and subjective, and that its quality seems to be rather low – how will we be able to convert all this information into a single dimensional ranking?

In fact, experiments have shown that stylistic and structural analysis can be implemented as filters for relevance judgments [Karlgrén, 1996; Strzalkowski *et al* 1996]. Depending on the collection at hand, certain types of document often can be discarded from retrieved sets - in a web context, very short documents containing the words “can not be found” usually are less useful than others. This form of information can be encoded in some way to be combined with probabilistic ranking retrieval systems.

Many or most knowledge based systems combine information from different sources by *weighting*, typically combining them in a linear combination of scores. But there is no reason to assume that variables engage in a relationship of a type that is suitable for linear combination. Some might be binary: “If singular first person pronouns are present, a text is not a legal text.” or the relationship may be more complex: “If there are numerous tense shifts and a relatively high incidence of personal pronouns the text may be an interview.” which could contrast with “If there are plenty of pronouns in the text it may be fiction”. Better ways of combining evidence, through decision trees or preferably a combination of decision trees, general pattern matching techniques, and algebraic techniques are absolutely necessary to be able to make use of and understand linguistic data.

And in any case, ranked lists give users little help in understanding and utilizing document variation: a richer representation of retrieval results to match a richer understanding of documents on the part of the system is a more fruitful approach.

Presenting Vague Categories

If we want to present users with information on e.g. document style or genre, we must (i) identify suitable categories or dimensions such as genres, (ii) choose criteria to cluster texts of the same category with usefully predictable results, and (iii) make use of these categories in an information access situation.

In the case of stylistic variation, useful genres must be based on differences known and recognized by readers. These differences mean different things to users, and may be difficult to recognize automatically. Naming them must be done judiciously to create and present a palette of genres both reasonably consistent with what users expect and conveniently computable using the measures of stylistic variation available to us [Dewe *et al.*, 1998]. (At this point we need to understand that *vagueness* is a desirable property in human language. If we want to present the user with categories based on notions of “quality” or “subjectivity” we are better off using abstract suitably vague terms to describe the document sets such as “Commercial text” and “Personal text” rather than try force decisions based on very concrete and well-defined terminology.) As but one example of such presentations, our prototype system combines stylistic analysis with topical clustering to broaden the ranking of a probabilistic background system into a matrix presentation of topical cluster by genre [Bretan *et al.*, 1998].

Style, Relevance, and Quality

In interviews with experienced internet users we found that from the users' point of view, it is very likely that an information retrieval or filtering problem is framed as a problem of low *quality* of information, not of low *topicality*. Although an information stream such as a mailing list or a Netnews conference is an interesting medium with occasional nuggets of interesting information, most of the material is irrelevant, uninteresting, and, simply put, of low quality. Quality is a many-faceted quality, and cannot be addressed with simple metrics - which brings us back to the problem of combining evidence addressed above.

Open Research Questions

Besides all computationally generally interesting questions and questions related to statistics and machine learning specifically there are important questions to address specifically related to information access.

Typical bare bones term-based information retrieval have weak points. The information flow between user and system is poor, and text can yield more information than the word statistics utilized by systems today.

The main hindrance to understanding text better is not faulty statistics or processing constraints, but faulty understanding of what text is and why.

A first step to understanding text better are experiments in stylistic and structural analysis of texts. They show that it is possible to extract non-topical information from texts with comparatively little bother. While it is true you get what you pay for, even shoddy analysis is informative: texts can be categorized in genres, provided the genres in question are well chosen. And this type of information can be used and has been used for both better presentation of information retrieval results and for reranking the output of probabilistic systems.

This is but a start. We need a better understanding of the small and vague clues readers use to pass judgments on texts.

Adapting Web Information to Disabled and Elderly Users

Alfred Kobsa

GMD FIT – German National Research Center for Information Technology

Abstract: Substantial research and standardization efforts already exist to make it easier for people with physical impairments to perceive and interact with web pages. This paper describes work aimed at catering the *content* of web pages to the needs of different users, including elderly people and users with vision and motor impairments. The AVANTI system and related efforts in the AVANTI project will be discussed and experiences reported.

1. Introduction

The World Wide Web is currently the most frequently visited electronic resource and is likely to become the access ramp to the electronic information highway of the next millennium. Web access should therefore ideally be available to everyone in order not to create yet another informational, and hence economical and social, disparity in society. Special efforts must be put into making the access to the web available to those who so far have been at a disadvantage, including people with disabilities and elderly people who until recently were only minority users of information technology. The terms “Design for All” and “Universal Access” have been coined to denote a design methodology for computer interfaces that does not automatically preclude users with special needs from using the system, as it often used to be the case with software developed to date.

In this context, increasing efforts are currently being made to render the web accessible to users with sensoric deficiencies. This primarily includes users with visual impairments [WAI, BrailleNet, Morley et al. 1998] and to some extent also users with motor impairments [Hermsdorf 1998, Hermsdorf et al. 1998]. Adaptations that are being researched include alternate input and output modalities (e.g., speech instead of text), adjustable behavior of user interface elements (e.g., toolbars with rotating cursor), and abridged non-visual navigation within and across web pages.

However, making the interface and the interaction with the interface universally accessible does not yet render a web site fully accessible. Users do not only have different needs with respect to perception and interaction, but also with respect to the information that is conveyed through the web. Users with certain disabilities often have specific information needs that are not shared by other users (e.g., information on wheelchair accessibility for motor-impaired people). Likewise, they are not very interested in certain information that may be important to other users (e.g., information about musical events for deaf users).

The amount of additional or different information required by certain user groups is sometimes quite sizeable. It would be a burden for all other users if this information were presented to everybody. This paper discusses principles to also apply a user-friendly design-for-all principle to the information that is being presented on the WWW, in addition to applying it to the interface and the interaction with the interface. The approach taken consists in the adaptation of the information to the individual information needs of each user, as expressed in a user model of each user. Research in the AVANTI project [Fink et al. 1999] will be described that developed the prototype of a comprehensive tourist information system for a wide range of users, including people with disabilities and elderly users.

2. Special Information Needs

In the area of tourism, a wide variety of different information needs can be observed. They stem from different interests, knowledge, preferences and physical abilities of each individual user. A user needs analysis that was carried out in the context of AVANTI revealed the following special information needs, among many others [Bini 1996].

Mobility-impaired people require substantially more information than able-bodied users and any other disability group. (This information is mostly redundant for these other users and should be omitted when presenting information to them). For wheelchair-bound users, detailed information concerning the accessibility of buildings (e.g., the existence and the dimensions of ramps and elevators, the type and width of doors, the type of floor covering) is important and should therefore be automatically provided. They should also be warned unsolicitedly when routes present insurmountable obstacles (like steps and slopes with a gradient of over 15% lengthwise and over 2% sideways) or when routes are very difficult to master (e.g., routes with a gradient between 8% and 15%, or routes with plenty of traffic).

For blind users, not only the modality of the presented information must be changed to tactile and/or audio output; in addition, supplementary orientation and navigation aids, like an additional table of content containing all internal and external links on a hypermedia page, are helpful [Kennel et al. 1996]. They should also be automatically warned of the presence of mobile obstacles, acoustic pollution, and long distances that need to be conquered without tactile or acoustic clues, since these are the main mobility barriers for this user group.

Elderly users are sometimes included in categories of serious handicap due to age and health conditions and should receive the respective special information. They should also be automatically warned of the presence of narrow or spiral staircases, slippery surfaces unaided by hand rails, and long distances that need to be conquered without rest or relief points. Escalators, elevators and restrooms should be particularly marked out.

The need for specialized information however does not only stem from disability needs. In any information system, the following distinctions between users should be made, among many others:

- Users who are interested in a specific subject area should automatically receive more detailed information on it than users who lack this interest.
- For computer novices, usage instructions should be augmented by an explanation. This is normally not necessary for experienced computer users.
- For users with low-bandwidth network access (e.g., via a slow modem), information with high data volume (e.g., videos and high-resolution pictures) should be replaced by less demanding, but nevertheless appropriate equivalents, in order to reduce download times. The response time of a hypermedia system is extremely critical from a usability point of view [Nielsen 1990].

In order to cater to these different information needs of users, techniques from the area of adaptive hypertext and hypermedia systems [Brusilovsky et al. 1998] have proven to be very useful. These systems dynamically generate hypermedia pages based on constantly updated assumptions about the user that are stored in a user model [Kobsa 1993].

3. Overview of the AVANTI System

AVANTI is a WWW-based tourist information system that adapts web pages to each user's individual needs before presenting them to the user. The system provides hypermedia information about a metropolitan area (e.g., about public services, transportation, buildings) for a variety of users (e.g., tourists, citizens, travel agency clerks, elderly people, blind persons, wheelchair-bound people, and users with slight forms of dystrophy¹) with different interests, knowledge, and abilities. The system can be accessed from people's homes, from travel agencies, public information kiosks and on the go. Users' hardware platforms, software environments, network speeds, and environmental surroundings thus vary widely. In order to cater to the different user needs and usage environments, AVANTI exploits methods and tools developed in the context of adaptive and adaptable systems [Oppermann 1994], user modeling [Kobsa 1993] and adaptive hypertext and hypermedia systems [Brusilovsky et al. 1998].

AVANTI consists of the following main components:

- Multimedia Databases with information about the AVANTI domain in different modalities (mostly text, images, and videos). They also include a restricted data model.
- The User Model Server which hosts models of all users. These models primarily contain information about users' abilities and to some extent assumptions about their interests.
- The Information Resource Control Structure (IRCS), a repository of mostly generic web pages that include links to database entries and rules for user-adaptation based on the current user model. IRCS pages are encoded in an extension to HTML.

[1] Dystrophy is a range of circa 40 neuromuscular diseases resulting in muscle weakness, paralysis, cramps, impaired muscle relaxation, etc.

- A Hyperstructure Adapter that generates user-adapted hypermedia document descriptions on the basis of the IRCS and the current user model.
- A User Interface that presents these hypermedia pages and performs necessary adaptations on the level of the user interface, particularly concerning the selection of appropriate modalities and interaction forms.

AVANTI acquires assumptions about the user based on the following sources of information:

- A short *initial interview* allows for the acquisition of primary assumptions [Pohl et al. 1995] about the user and is therefore a valuable source of information for initially assigning the user to certain user subgroups (see the “stereotypes” below).
- Basic information about users’ disabilities can be stored on a contactless *smartcard* that can be read from a distance of about 40-80 cm (15-30”), depending on the electromagnetic surroundings. Such a smartcard can record, e.g., information about users’ visual and manual disabilities, so that AVANTI can adapt the modality of and the interaction with the interface while the user is approaching the system. Fig. 1 shows an example: here the fact that the current user is mildly vision-impaired is stored on the smartcard and read with the antenna around the monitor. This information then automatically leads to screen magnification.
- Based on primary assumptions about the user and additional information about the application domain, the system can draw *inferences* in order to acquire further assumptions about the user. For instance, if the user requests more than once detailed information on the history of some churches, he/she can be assumed to be interested in churches, and this detailed information will henceforth be automatically provided.
- *Stereotypes* [Rich 1979] contain assumptions about interesting characteristics of user subgroups (e.g., the presumable knowledge of domain experts or the presumable interests of wheelchair-bound users). If certain preconditions are met, a stereotype can be activated for a specific user, which means that the assumptions contained in the stereotype become assigned to the user.

Figure 1: Automatic screen magnification for a mildly vision-impaired user after reading the user profile on the smartcard from a distance

4. An Example of Adaptability in AVANTI

The web page depicted in Fig. 2 informs about the services, facilities and amenities that are available in “jolly hotel excelsior” in Siena, Italy. The page can be separated into three areas. The left column with the brick-pattern background contains mostly the main menu. The central area contains the “real” information (e.g., the services offered by a hotel), and the right column includes menu buttons that point to other relevant information.

In its present form, the page is tailored to a user who is experienced in using both computers and the AVANTI system and needs special information for wheelchair-bound and dystrophic people (information about these needs would come from an initial questionnaire or a contactless smartcard). For instance, the optional navigation path displayed in the upper left corner is only available to experienced web users since its use requires at least a coarse mental model of the hypermedia space at hand. This path is therefore left out for web novices and their navigation tools restricted to the hierarchical Siena menu on the left-hand side since such users may be confused by alternative navigation elements on a hypermedia page. The hand icon pointing to “restaurants” and the link “nearest restaurants” in the lower right corner are pointing to information that is presumably interesting for the current user. Such an assumption is acquired by the system through inference mechanisms based on the navigation history. For instance, if the user requests more than once detailed information on the cooking style of some restaurant, she/he can be assumed to be interested in restaurants.

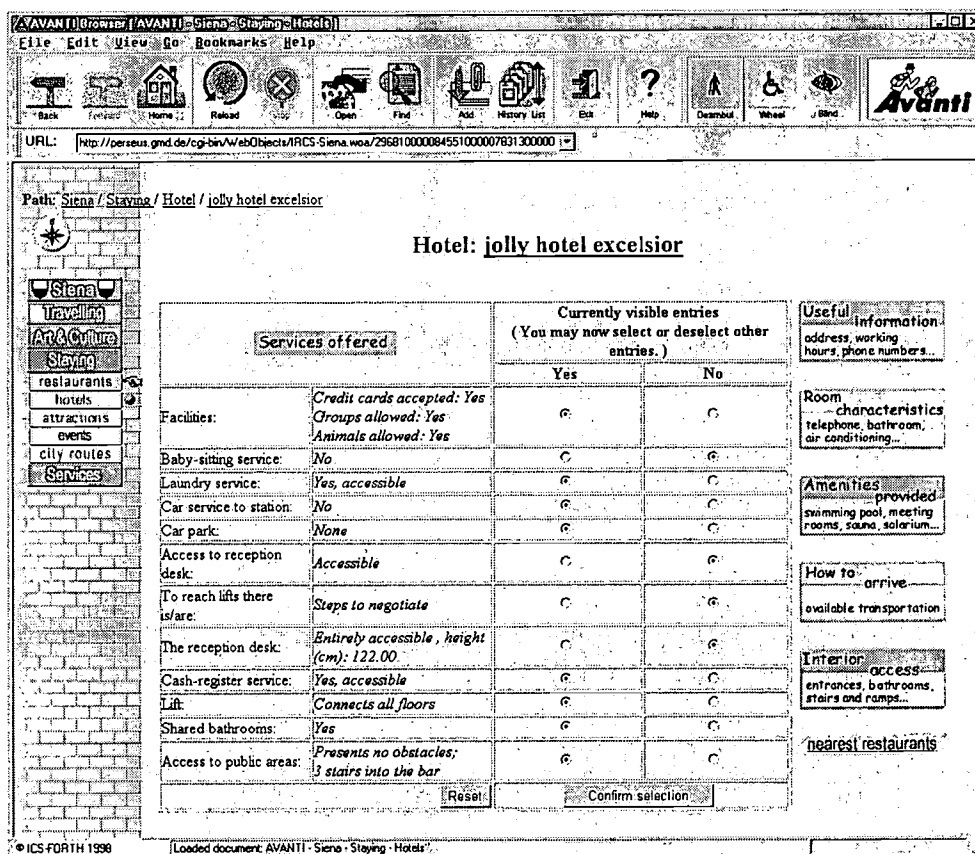

Figure 2: Example of Adaptive and Adaptable Elements in an AVANTI web page

Other optional elements are the so-called *role-taking buttons* in the toolbar of the AVANTI browser. The upper right corner contains the role-taking buttons “Deambul” for deambulation (walking around), “Wheel” for wheelchair, and “Blind”². The availability of these buttons is also contingent on the AVANTI expertise of the user. If one or more of these buttons are pressed (e.g., “Deambul” and “Wheel” in Fig. 2), the user automatically obtains additional information for the selected user groups (e.g., additional information for dystrophic people with difficulties walking around and wheelchair-bound persons, respectively). These buttons were designed for people

[2] These buttons, as well as the “Exit” and “Help” buttons, are part of the page descriptions coming from the HSA. They are included in the AVANTI browser while its HTML parser is processing the page. Since the HSA behaves like a “normal” web server, it is also possible to access the HSA with any commercial browser. The extra buttons will then remain in the HTML page.

BEST COPY AVAILABLE

who look for information on behalf of disabled persons. For instance, travel agency clerks can “take the role” of a wheelchair-bound customer while working with the AVANTI system. From a technical point of view, the role-taking buttons can be used to activate or deactivate certain stereotypes (i.e., “Dystrophic User”, “Wheelchair User” and “Blind User”).

In AVANTI, tables presented to the user contain those attributes only which the system deems to be relevant for him/her according to the current user model. The user is able to modify the system-initiated attribute selection by requesting an adaptable version of the table that includes all available attributes. Fig. 2 shows such an adaptable version where the user has de-selected “Baby-sitting service” and some other attributes and subsequently confirms his/her de-selection.

5. Experiences with AVANTI

The AVANTI system has been subject to extensive summative evaluations at three different cities in three different scenarios with a total of 180 subjects [AVANTI CD-ROM, Andreadis et al. 1998]. Users were tourists, business travelers, citizens, travel agency clerks, and users with vision and motor impairments. The common question shared by all experiments was whether the developed system is beneficial for users, and specifically whether it is technically feasible and useful for end users to introduce adaptability and adaptivity in the information content and user interfaces of hypermedia information systems.

Users were subject to usability tests to determine the system’s learnability, efficiency of use and memorizability, users’ error-proneness, satisfaction and overall attitude, and the specific contribution of adaptability and adaptivity. Data were collected through observation, interviews, questionnaires and the analysis of log files. The results allow one to conclude that AVANTI’s adaptation features were generally well understood, used, and appreciated (some of them were not self-explanatory though) and that the benefit for information systems probably lies more in user satisfaction than in efficiency gain or error reduction.

A general finding was that experienced users are more inclined to take advantage of adaptability features than users with less experience. While adaptability features have been recognized and understood by most users, they have been more frequently used by AVANTI experts (namely adaptive tables), and computer and web experts (namely the path navigation tool). Travel agency clerks liked the possibility to create their own shortcuts.

Travel agents also appreciated very much the role-taking buttons. These buttons were generally well recognized, correctly understood, and frequently used.

Motion-impaired users were generally more satisfied with the information provided by the system and had a better attitude towards AVANTI than able-bodied users. They found the system properly designed for them and the information on accessibility very clear and useful for mobility. They also appreciated very much the level of detail reached by the system, and many of them praised the system enthusiastically. In contrast, able-bodied users did not easily find information for their purposes (and often this information was not present in the system). It also seems that their concept of mobility differs from that of impaired users in several ways, and was not properly reflected in the system.

Introduction

When doing eCommerce on the Internet the various country-specific legislations are often a potential risk to companies that want to leverage the global aspect of the Internet and new markets. Especially data protection and copyright represent two of the main hurdles - just by comparing the US situation to the European situation one can see the legal difficulties emerging out of real global eCommerce.

The data protection directive 95/46/EC that is effective since 24th October 1998 has an enormous impact on multinational companies and such companies that operate globally but process their data outside of the European Union. The directive restricts process of of data from EU citizens outside the European Union if the country/specific organization that would like to process the data does not have adequate laws or guidelines embodied. International copyright issues have always represented another obstacle especially when trying to protect a product that can be downloaded from the Internet and modified easily.

Another interesting aspect is based on the different views about offers on the Internet. When doing eCommerce in Europe an offer on the Internet has not the same meaning and legal enforcements in the back than an Internet offer would have in the US. Digital signatures represent a way to settle contracts on the Internet and enhance security, however their legal basis varies tremendously throughout the world aligned with different liabilities - a truly international question addresses acknowledging and accepting different country-specific certificates.

Partly because of the legal difficulties but also because of the uncertainties in association with the Internet, trust is a big concern when doing eCommerce. A variety of trustmarks for different areas has been evolving lately, however the approaches are different and not often of the same quality.

The biggest challenge for secure eCommerce is going to be the unification of legal aspects, their enforcements and increasing the trust on the Net.

Data Protection and the Internet

Privacy and data protection always has been a big concern for individuals, especially in countries without a proper legislation. While the business for „information brokers“ booms in the US, the European Union (EU) enhances individual and corporate data protection. The data protection directive 95/46/EC which came into effect in October 1998 was not seen as a threat to most European companies, as they already had strong country-specific legislation on data protection. However, it was big threat for US based multinational companies (MNC) that processed EU-data outside of the EU.

Article 1 - Object of the Directive - already states that the directive is aimed to protect the fundamental rights and freedoms of natural persons, and in particular their right to privacy with respect to the processing of personal data. This article changed already many European country specific legislations as it refers to „natural“

persons, which means individuals as well as companies with an own legal entity. Usually the former data protection laws mostly covered the rights of individuals, but not companies with an own legal entity.

In Article 6 that belongs to Section I - Principles relating to Data Quality - obligations for the Member States are listed that explicitly state points such as fairly and lawfully processing of data, collecting of data for specified, explicit and legitimate purposes and not further processing in a way incompatible with those purposes, accuracy of data (when necessary kept up to date) and time limitation on data usage. This Article alone raises questions on its application when doing eCommerce on the Internet. Most of the times you see an Internet Webpage, you are not told upon the purpose of data collection, or how the data is kept accurate or processed fairly.

Article 7 states the criteria for making data processing legitimate, whereas the very first objective is that the data subject „has unambiguously given his consent“, or „processing is necessary for the performance of a contract to which the data subject is party or in order to take steps at the request of the data subject prior to entering into a contract“. Article 7 states more criteria, however these two are essential for eCommerce. It is already critical if e.g. an US company puts a questionnaire on the Internet and an EU-citizen fills out this questionnaire as part of a purchasing process, however the questionnaire asks for information that cannot be directly related to the purchase order. It is an unresolved issue whether just pressing the „submit“-button can be interpreted as giving consent unambiguously.

Completely new is Article 8 of the data protection directive that states a very special sort of data. The article says „Member States shall prohibit the processing of personal data revealing racial or ethnic origin, political opinions, religious or philosophical beliefs, trade-union membership, and the processing of data concerning health or sex life“. Of course, if an individual gives his explicit consent, one may process the data (if not definitely prohibited by the Member State anyway), also under certain other conditions that are stated in paragraph 2 of Article 8, but the essential thing starts when data is being joined in that area. Here comes a little example: An Austrian pharmacy wants to do eBusiness and offers pre-order of medicine on the Internet. All the customer has to do is pick up the medicine with the according perscription. Just this information is harmless, but if you link the certain disease to the medicine to the customer it already looks different. Just thinking of unauthorized disclosure of this data might lead to significant impact in insurance (the customer is probably only offered a high insurance) and other areas of life. In Europe this is no problem, as current country-specific data protection usually prohibits linking of data, but when the data gets outside the us, this might cause problems.

Especially of interest for companies are Article 16 and 17 upon Confidentiality and Security of Processing. Article 17 states „Member States shall provide that the controller must implement appropriate technical and organizational measures to protect personal data against accidental or unlawful destruction or accidental loss, alteration, unauthorized disclosure or access, in particular where the processing involves the transmission of data over a network, and against all other unlawful forms of processing. This certainly impacts the organization

of many European companies and global MNCs as it implies that the organization has to provide sufficient logical and physical access security, efficient monitoring and documentation of data processes, auditing features, a well-defined backup system, business continuity planning, etc. Many European companies, especially in the Central European area, are currently still lacking of this functionality. In many cases a business continuity plan is only referred to as disaster recovery for the IT-system, backup-tapes are stored within the server room (which might reduced usefulness in case of a fire...), physical access of the server rooms are not sufficient, logical access models are just based on departments within the company but not on the roles of an individual (which might lead to insufficient access control), auditing functions of operating systems, etc. are not enabled, documentation is done rarely and monitoring of IT-system security is not always efficient enough. Unfortunately not many companies see these points as critical to their success, so a company with well defined IT-guidelines for IT-system security and especially data protection is more the exception than the rule (especially in Central Europe).

Chapter IV - Transfer of Personal data to Third Countries has the biggest impact when talking about global eCommerce. The transfer of data to a third country - undergoing processing or where it is intended for processing - is only permitted if the third country ensures an adequate level of protection as the EU directive (Article 25). It is possible to transfer the data without this adequate level of protection if the data subject has given his consent unambiguously to the proposed transfer, or the transfer is necessary for a contract between the data subject and the controller, or reasons such as public interest or interest of the data subject. The permission can also be given when a certain company has adequate level of protection as the EU directive.

Especially in the US-region Privacy Policies have evolved due to the lack of adequate data protection regulation. However, these Privacy Policies differ highly in quality as well as enforcement. Non-profit organizations such as trusts aim to embody standards for Privacy Policies for WebPages, but so far there is still a lot of work to do to find a common, global framework and standard for privacy protection.

International Copyright Issues in eCommerce

Copyright issues have been a hot topic recently when doing business on the Internet. „Copyright“ can be defined as an exclusive right that embraces aspects of moral rights and property rights. It guarantees the creator and the producer of a work control over and participation in the commercial exploitation of the protected work and subject matter. The Internet offers a big source for downloading or copying protected work and subject matter without spending much money and without any timely loss or quality decrease.

Currently there is no such a thing as a global copyright law, and it probably will not exist in the near future. However as the Internet is related to a global aspect the country-specific-legislation problem is increasing.

Copyright is an immaterial right and represents the right to which the creator of a literary, scientific or artistic work is entitled in his or her immaterial work. There is nothing easier than downloading or copying a picture

All rights reserved.

Page 4

from somebody else's WebSite and reproducing it. The act of reproduction is governed by the law of the country in which the reproduction takes place. There is a difference between making work in digital form off-line available or on-line. If it is made available on-line we have the problem of the dispute which right is applicable in case of e.g. the Internet. One theory is called the „theory of country of emission“ and it states that the law of the country should apply where the work was made available on-line, and all laws of the receiving countries remain unimportant. Another theory is called the „country-of-reception theory“ and states that the entire process of a cross-frontier availability should satisfy the copyright law not only of the broadcasting state but also the copyright laws of all receiving countries.

The EU issued the Directive for the Legal Protection of Databases in 1996 where it states that databases attract copyright protection with respect to their originality of their selection or arrangement. Again this Directive was aimed to embody a unified approach within the Member States to copyright issues and databases. A sui generis right was created against unauthorized extraction and/or re-utilization of the whole or of a substantial part of a database, where the preparation of the database required „a substantial investment“.

Another copyright issue is the management of Internet names and addresses. Only a short time ago, the World Intellectual Property Organization (WIPO) issued a paper called the „WIPO Internet Domain Name Process“¹. Domain-name-grabbing was a very popular „sport“ and could result in significant money. The domain names are defined as „human-friendly form of Internet addresses“ in the above mentioned WIPO report and they caused significant problems when the Internet and electronic commerce grew. A domain name can be registered within certain local companies and is completely under private control. However, Domain Names provide a link between the Internet and a trademark and other recognized rights. Currently it is still up to the country-specific legislations how to handle conflicts between trademark owners and domain name holders. The problem increases significantly when the domain name is in conflict with another company that is not in the same country. The WIPO states in Paragraph 132 of its paper: „Because a domain name gives rise to a global presence, the dispute may be multijurisdictional in several senses. The global presence may give rise to alleged infringements in several jurisdictions, with the consequence that several different national courts may assert jurisdiction, or that several independent actions must be brought because separate intellectual property titles in different jurisdictions are concerned“.

This is not the only problem as outlined by the paper. Another one may arise between generic top-level domains and country code top-level domains. Because of many of them exist and because each of them gives the same access to global presence, the same dispute as stated above may manifest itself in many of the top-level domains.

It should be noted that the economic value of damage that can be done as result of domain name registration or domain-name grabbing is far higher than just the cost of simply obtaining that domain name. As speed is key in the Internet the problem has to be solved, otherwise companies can lose significant money e.g. because of

destroying brand image. Currently, resolving a domain name dispute may be urgent, but still may not be done appropriately, slow and very expensive in various countries.

Court litigation is governed by the civil law of the different states.

Contractual issues and the impact of digital signatures

Most people have already heard about the case of David J. Loundy², an attorney and author. He unfortunately came in touch with the differences of contractual law in the US and Europe when he wanted to buy a CD at its listed price from his favourite rock group. The CD was listed on the Internet to another price as what Loundy got invoices due to a list-price-error on the Webpage. Within the European legislation (in this case: UK), there was no contract by ordering the CD via Internet, as the WebSites „offer“ was actually only an „invitation to treat“. The problem grew further when asking what legislation should be applied - the UK law or the place of the fulfilment of the „contract“ - Illinois, US.

The question of what legislation will apply within eCommerce is still unresolved. There is no definite answer as services offered and their fulfilment differ, and in mostly it depends on the case itself. In the EU a proposal for a European Parliament and Council Directive on certain legal aspects of electronic commerce in the internal market (1999/C 169/14) was issued in 1999. The aim of the directive as stated in the Official Journal of the European Communities (C169) from 16th June 1999 is „to promote the spread of electronic commerce by helping break down legal barriers to trade“. The proposed directive addresses five key areas to establish a coherent framework among its Member states³:

- Establishment of providers of information society services: Providers have to fulfil specific information requirements in order to ensure the transparency of their activities.
- Commercial communications such as advertising, direct marketing, etc: Commercial communications have to be clearly recognizable as such, and the parties on whose behalf they are made must be clearly identifiable.
- Contracts: Member States have to adjust their national legislation to the common platform in the EU. The proposal wants to remove legal uncertainties by clarifying in certain cases the moment at which a contract is deemed to be concluded. In Article 11 it states that to conclude a contract with legal effect, the service provider must issue an acknowledgement of receipt, which must be reconfirmed by the buyer. However, the term „offer“ is still not clearly defined enough as Member States still handle this issue differently (see above mentioned case with Mr. Loundy).

¹ Final Report of the WIPO Internet Domain Name Process, World Intellectual Property Organization, April 30, 1999
<<http://wipo2.wipo.int>>

² David Loundy's E-Law Web Page. <<http://206.54.248.130/>>

³ Official Journal of the European Communities, C169, 16.6.1999, pp. 36 - 42.

- Liability of intermediaries: Especially on-line service provider liability is part of this section, where transmitting and storing third party information is discussed.
- Implementation: Community-level codes of conduct and administrative cooperation between Member States has to be established.

A significant step into the right direction to solve contractual questions especially related to risks such as data integrity and authentication is the usage of digital signatures. Looking at this issue within a global perspective, one finds various different digital signature laws. Only by taking the USA as an example there are different digital signature laws in almost every state. To form a common platform for trade it is significant to have a unified understanding and a globally accepted standard for the usage of digital signatures and acceptance of digital certificates.

The EU has issued a proposal for a European Parliament and Council Directive on a common framework for electronic signatures⁴ which was submitted by the commission on 16 June 1998 and amended in January 1999. It establishes a set of criteria which form the basis for legal recognition of electronic signatures. The proposed Directive focuses particularly on certification services and sets a minimum standard for Certification Service Providers (CSP) and certificates to ensure cross-border recognition of signatures and certificates within the EU. The approach of the directive is technology neutral. The Directive is aimed to increase the level of security and trust among the Member States and the proposal introduces liability rules for the CSP. The biggest challenge for digital signatures within a global aspect is going to be global recognition and quality assurance of service as well as liability and enforcement. The current state shows already the hurdles and the long-term problems evolving starting from discrimination if e.g. a CSP offers his services only to related clients of his core services (e.g. banks as CSPs, insurance companies, etc.), minimum security standards, quality of work, certification of issuing the root certificate, etc. Different types of digital certificates are going to evolve that are related to certain strength when signing with a digital signature. It is essential to find a global platform for digital signatures to enhance electronic commerce and to make it more secure.

Trust on the Internet - the evolving trustmarks and their approaches

Electronic Commerce is associated with certain risks that can be classified in four broad categories:

- Authenticity: Is the business partner really the one he says he is?
- Integrity: Is the data I received/see still the one that was sent/originally created, or was the data modified?
- Non-repudiation: Can I claim the proof of shipment and/or receipt of data?
- Confidentiality: Is the data protected from unauthorized or unintended disclosure or observation?

All of these risks are by nature associated with financial loss if they occur. They serve as inherent part of the business risk, and if no controls are enforced within a company they increase the risk of financial damage.

⁴ Proposal for a European Parliament and Council Directive on a common framework for electronic signatures, Document 598PC0297, <http://europa.eu.int/eur-lex/com/dat/1998/en_5989PC0297.html>

Because of the various legal obstacles and the above mentioned risks within electronic commerce and the Internet, trust has become a critical success factor for ebusiness. Only those companies that are „trusted“ on the Internet can engage their customers in significant interaction which furthermore leads to competitive advantage.

Many companies have already seen this need for trust on the Internet and offer a variety of trustmarks aimed for different target groups.

The most famous trustmark in the privacy area is TRUSTe⁵, a non-profit organization that aims to increase data protection and privacy on the Net. The idea behind the trustmark was governed by two principles: (1) Users have the right to informed consent; and (2) No single privacy principle is adequate for all situations. These two principles are the building blocks for TRUSTe's privacy work. Currently TRUSTe offers three levels of privacy assurance:

- **No exchange** provides for user anonymity
- **1-to-1 exchange** provides that private data will be kept only by the WebSite for the use with that specific user
- **3rd party** states that the site will provide the information to third parties, beyond the site's influence.

By clicking on the trustmark one can reveal the site privacy policy the the TRUSTe site. Only a small percentage of sites will receive on-site auditing though.

Another approach is used by AICPA WebTrust which certifies business practice, transaction integrity and information protection. To gain this certificate an AICPA/CICA licensed CPA/CA serves as assurance provider. The company that wants to have this trustmark has to obtain an unqualified report from the assurance provider for the criteria in information protection, transaction integrity and business practices. Then the assurance provider contacts the seal manager (i.e. VeriSign) to issue the seal and provides the Java applet to the business. The seal has to be maintained through regular updates by the assurance provider whereas the intervals may be no less than 90 days.

A trustmark that was especially designed for security is the NCSA Web Certification Program. Therefore the company that wants to obtain such a seal has to complete a web certification field guide to prepare for evaluation. Then the NCSA evaluates the field guide to determine if the site meets the requirements for an adequate „security posture“. This is followed by an on-site verification by NCSA or a partner. If the site passes the test, it receives the seal and a report is issued. The certification is typically good for one year. NCSA/agents can perform random audits.

The Better Business Bureau (BBB) trustmark provides business practice certification. If a company has been in business for a minimum of one year (with limited exceptions) and if it has a satisfactory complaint handling

record with the BBB, it can get the trustmark issued. The trustmark is aimed for consumer care and consumer protection. The company needs to agree to participate in BBB's advertising self-regulation program and has to respond promptly to all consumer complaints. It has to agree to binding arbitration, at the consumer's request, for unresolved disputes involving consumer products or services advertised or promoted online.

These and other trustmarks are aimed for special niches of interest to end-consumers as well as other businesses, however the correct audit approach and maintenance are key factors for reliable trust. An eBusiness is most of the times very complex and the to-be-seen front-end online shop is only the top of the iceberg. To ensure a certain process the auditor has to cover not only the mega- but also the major- and sub-processes and evaluate built in controls. There is always a very high audit risk if the trustmark wants to deliver reliable trust, and not many companies are willing to take this risk. This determines often the quality of trust associated with a certain trustmark.

Conclusion

A variety of issues still has to be solved for successful and secure electronic commerce. The Internet is still the space for people and companies where they have to deal with legal obstacles, especially within a global aspect. The differences of recognition for the need of unified platforms on Internet related regulation can be seen clearly amongst the country-specific legislation. The EU tries to put minimum standards for electronic commerce in place to create a secure marketplace for its member states.

One can see various initiatives and action taking place as companies recognize the need for trust on the Internet and its direct relation to profitability. However, these initiatives should not only be profit based but also aimed to create a more reliable and trustworthy Internet where electronic commerce can take place.

Abstract. The era we are living in is often referred to as "the age of communication". The combination of new and rapidly developing interactive multimedia computers and applications with electronic networks will require a restructuring of our traditional approach to strategic planning and organizational structure. World-wide telecommunication networks (using satellites, cable) are now facilitating the global pooling of healthcare information and medical knowledge independent of location. The G7 Global Healthcare Applications Project aims at improving quality and cost efficiency of healthcare delivery through telematics (remote access) tools. From these ten sub-projects two sub-projects are presented. The development of multimedia information and communication systems demands cooperative working teams of authors, who are able to master several areas of medical knowledge as well as the presentation of these in different multimedia forms. The assemblage of telematics and services offers a base for multimedia applications, for example teleteaching, telelearning, telepublishing, teleconsulting, teleconferencing, telemedicine etc. The expansion of the internet will also lead to the formation of interdisciplinary "Global Education Networks". The theory and practice of education are undergoing dramatic changes. Lifelong learning and adaptation of medical practice to new knowledge and new techniques will be even more important in the future.

1. Using Multimedia Technologies for Education

The internet technology is rapidly emerging as the most powerful medium of mass communication. Its WWW (World Wide Web) service has become a very important media for providing medical knowledge. Printed publications are more and more supplemented by electronical methods of publishing. Unfortunately the kinds of knowledge presentation in electronical media are often very similar to the traditional "patterns" that are used in printed books and scientific journals and are often only supplemented by hyperlinks and multimedia elements. The development of multimedia information and communication systems therefore demands

cooperative working teams of authors, who are able to master several areas of medical knowledge as well as the presentation of these in different multimedia forms (text, graphics, images, audio, video). This way has opened up new possibilities and qualities for the training of medical students in universities and for further education of hospital physicians as well as for practicing professionals. The user's interaction with the information is made possible by visualization and simulation. Of significant importance are the possibilities of simulating diagnostic and therapeutic methods close to reality so that patients later can be treated more precisely by a perfectly prepared team. The learners can vary the parameters of experimental series of tests independently. In addition to internet services, the medical information is offered on CD/DVD-ROM and can be used in multimedia PCs. Such offline-media does not cause a pressure of time by the user and allows repetitions whenever necessary.

Often electronic publishing groups offer medical information systems online as Web based multimedia communication systems (for instance the Health Online Service multimedia [www.multimedia.de], Physicians Online [www.po.com], Virtual Hospital at the University of Iowa [www.vh.org]). Such systems contain knowledge from renowned experts. Special support for diagnostic and therapeutic strategies are available. These Web applications are useful for distance education and training of practicing physicians, specialists of all fields in practice and clinical environments, students as well as providing health news for patients and consumers.

2. Teleconsultation Using PC Based Video-Conferencing Equipment

Telematics services are becoming essential parts of health care strategies. The increasing demand for rapid transmission of medical visual information for purposes of telepathology and education poses difficult challenges in image compression techniques. Under consideration of international standards (H.320, H.323) for PC video-conferencing equipment, online teleconsultations with remote medical experts for cooperative discussion and interactive handling of medical data and pictures/images/frames are made possible. Pictures that can be used can include still images such as frozen sections or x-ray images as well as moving frames such as ultrasound. Figure 1 shows a cooperative discussion using Microsoft Netmeeting's Whiteboard between the Institute of Neuropathology of the Hannover Medical School (Germany) and the National Cancer Research Institute in Tokyo. A discussion using a remote ultrasound image is shown in figure 2.

Figure 1: Teleconsultation using Whiteboard

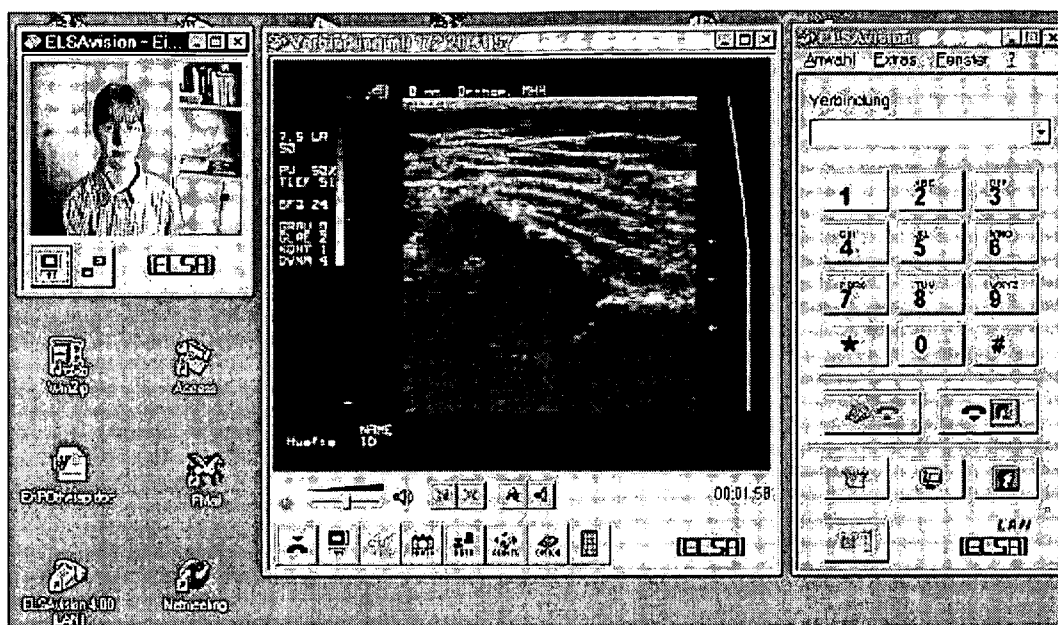

Figure 2: PC based video conference with remote ultrasound (live)

The main application of telematics in telepathology is the use of telemicroscopy. This will become more important since pathological expertise is not always available locally, and - in a worldwide sense - is extremely unevenly distributed. A first successful study at the Hannover Medical School was aimed to investigate the possibilities of teleneuropathology in a routine clinical setting [Matthies et al. 1998].

3. The G7 Global Healthcare Applications Project (GHAP)

The G7 is an informal forum of the seven major industrialized democracies. Ministers met in Brussels in 1995 and identified 11 pilot project areas for international co-operation, one is the GHAP. The G7 GHAP aims at improving quality and cost efficiency of healthcare delivery through telematics tools. It has ten sub-projects [www.gip.int]. Because this paper is only about education support possibilities we will only present the last two sub-projects

- Medical Image Reference Center (MEDIREC)
- IOA – International Online Academy (Special interactive TV and multimedia programs for professionals and public in dentistry and oral medicine).

4. The G7 GHAP Sub-Project MEDIREC

The objectives of this sub-project are to support clinical activities, contribute to medical education and training, and facilitate medical research. The proposed reference centers would include clinical and pathological images (still and moving) and typical, rare and difficult to diagnose cases. The G7 sub-project MEDIREC is co-ordinated by Japan [www.medirec.ncc.go.jp]. English language Medical Image Reference Centers are developed at the

- National Cancer Center Research Institute in Tokyo
MEDIREC / Images of Cancer
- National Cardiovascular Center in Osaka

MEDIREC / Images of Cardiovascular Diseases

- University of Regensburg
MEDIREC / Images of Dermatology
- Hannover Medical School
MEDIREC / Images of Neurological and Neuromuscular Diseases

Accessing such image databases via internet is possible. Data collection mechanisms, online publishing, and organization (including regional co-ordination centers), for example, have been proposed. A technical group will ensure interoperability with other image databases and will develop an information security management for file and image transfer.

In co-operation with the research centers specified above, a multilingual "MEDIREC / Images of Neurological and Neuromuscular Diseases" is being developed at the Hannover Medical School [Matthies et al. 1999a]. Efficient Web based database access to the MEDIREC at the Hannover Medical School is made possible via an Oracle Application Server that uses Java-based programs to answer requests, i.e. all authorized internet users may access the data using a standard web browser (e.g. Netscape, Microsoft Internet Explorer). An editorial board is responsible for the quality assurance of contents. The case examples for the MEDIREC in Hannover were prepared by the Institute of Neuropathology as well as the Medical Computing Center. The search masks and appropriate search results (fig. 3) can be displayed in several languages (WHO recommendation).

Figure 3: Query mask and query results in different languages

5. The G7 GHAP Sub-Project IOA

The expansion of the Internet will also lead to the formation of interdisciplinary "Global Education Networks". Such an exemplary network (fig. 5) will be realized in the G7 GHAP sub-project "MEDlive/IOA". The aim of the interactive "MEDlive" is to promote the international knowledge and information exchange in dentistry and oral medicine with telecommunication services, e.g. digital broadcast and internet services. The "International Online Academy of Dentistry and Oral Medicine" (IOA) is part of "MEDlive" and provides means for high quality, structured and certified education and continuing education.

BEST COPY AVAILABLE

Figure 4: Video sequences for patient information

One day each week, video on-demand (fig. 4) is available as a test program via satellite television receivers (ASTRA) or television-based Web browsers. Project coordinator is the international Quintessence Publishing Group [quinline.globaldent.com] in Berlin. The aim of this engagement is to strengthen innovation, to assure the quality of content and to support the qualification and competence of the professionals on the road to the information society.

Figure 5: Link between MEDIREC and the G7 GHAP sub-project IOA

6. Results

Telematics is a combination of telecommunications and informatics resulting in the transfer of information across distances. High rates of data transmission are necessary for the efficient use of multimedia technologies. Modern telematics infrastructures allow for instance

- flexible possibilities for distance learning
- world wide access to certified knowledge bases and digital image archives
- as well as simulations of and training for surgical procedures
- flexible training for the support of diagnosis and therapy by using visualization and simulation
- decision support for diagnostics and therapy
- creation of digital video libraries of clinical treatments.

The new information and communication systems open up new forms of learning and make it possible to combine classroom instruction/lecture and multimedia applications. New educational technologies and course contents will be required. First experiences have shown that in addition to medical lectures, specific offers for further education are required in dealing with electronic information sources. Learners' motivation will be improved by the access to multimedially supported teaching materials and contents. Problem-oriented learning will thus be possible and the quality of education will increase in general.

Multimedia technologies simplify the access to information from databases and electronic libraries. Renowned experts can give online support for healthcare professionals and patients. Knowledge and research results can nowadays be published and offered much quicker by the available telematics infrastructures. In contrast to printed books or video tapes, multimedia applications can permanently and easily be activated.

The theory and practice of education are undergoing dramatic changes. An innovative education resource for professionals and patients is the interactive use of multimedia applications in telecommunication networks. Video on-demand via satellite television receivers or television-based Web browsers will play an important role as effective user interfaces for access to broad range of knowledge and information resources. Learning is independent of time and location. The expansion of the internet will also lead to the formation of interdisciplinary "Global Education Networks" that focus on learning, not teaching. The challenge is not only for academic staff to change their work habits, but also for students to accept a changing concept of university education. Lifelong learning and adaptation of medical practice to new knowledge and new techniques will be even more important in the future.

Introduction to the 5th Framework Programme

The European Commission's 5th Framework Programme for Research and Technological Development, 1998-2002¹ is divided into five thematic and three horizontal programmes. The Information Society Technologies (IST) programme² is the largest of the thematic research and development programmes with a global budget of 3600 million Euro.

The main focus of the IST programme (1999 work programme) is on enhancing the user-friendliness of the information society: improving the accessibility, relevance and quality of public-services especially for the disabled and elderly; empowering citizens as employees, entrepreneurs and customer; facilitating creativity and access to learning; helping to develop a multi-lingual and multi-cultural information society; ensuring universally available access and the intuitiveness of next-generation interfaces; and encouraging design-for-all.

Multimedia content finds a central role in the IST programme. The objective here is to confirm Europe as a leading force in this field and enable it to realise the potential of its creativity and culture.

The Information Society Technologies Programme

The IST Programme brings together and extends the ACTS³, Esprit⁴ and Telematics Applications⁵ programmes to provide a single and integrated programme that reflects the convergence of information processing, communications and media technologies. The 1999 IST work programme is mainly composed of action lines dedicated to four IST Key Actions, complementing each other in their overall objective to enhance the user-friendliness of the Information Society. The four Key Actions and their budgets for the 5-year programme are:

Key Action	Title	Budget (M euro)
I.	Systems and services for the citizen	646
II	New methods of work and electronic commerce	547
III.	Multimedia content and tools	564
IV	Essential technologies and infrastructures	1363

In this context the focus of this paper is on cultural heritage in Key Action III.⁶

Key Action III – Multimedia Content and Tools

This Key Action aims to improve the functionality, usability and acceptability of future information products and services, to enable linguistic and cultural diversity and contribute to the valorisation and

exploitation of Europe's cultural patrimony, to stimulate creativity, and to enhance education and training systems for lifelong learning. Work covers new models, methods, technologies and systems for creating, processing, managing, networking, accessing and exploiting digital content, including audio-visual content. This Action Line integrates both applications-oriented research, focusing on publishing, audio-visual, culture, education and training and generic research in language and content technologies for all applications areas.

Digital heritage and cultural content is one of the five main areas for research and technological development and the aim is to expand the contribution of libraries, museums and archives to the emerging culture economy, and thus encompasses all aspects of economic, scientific and technological development. It is co-ordinated by the European Commission's Cultural Heritage Applications unit, DG XIII-E2⁷, in Luxembourg.

A View of the Future

What is emerging as a focus for the future is to help create a European cultural information landscape by encouraging cultural memory organisations to participate in R&D actions providing innovative prototype networked services for both professional users and citizens. This future information landscape should be easy to identify, easy to access, and easy to navigate and should be extended to also encompass Europe's scientific and industrial heritage.

Equally tomorrow's cultural content will be produced by generating new forms of digital media. What this cultural content will be, and how it will be created, managed, distributed and preserved remains uncertain and a fertile ground for future research and experimentation.

The key participants in future cultural heritage projects must be Europe's memory institutions, both public and private, with a particular focus on new alliances with technical and content-related partners.

Research Priorities⁸

In translating this embryonic vision of the future three research priorities have been identified, namely:

- Ensuring integrated access to collections and materials held in libraries, museums and archives
- Improving the operational efficiency of large-scale content holdings by means of powerful interfacing and management techniques
- Preserving and accessing multimedia content of various types, including electronic materials and surrogates of physical objects.

The Annual Work Programmes

The IST programme is a flexible framework where focus is built within distinctive annual work plans. For the 1999 work plan⁹, the research priorities are taken up in two main action lines:

Key Action III, Action Line 2.3, Access to scientific and cultural heritage - call for proposals was launched on 19 March 1999, closed on 16 June 1999

Key Action III, Action Line 2.4, Digital preservation of cultural heritage - call for proposals scheduled for 15 September 1999.

Action Line III.2.4 Digital preservation of cultural heritage

Objective: To address new ways of representing, analysing, manipulating and managing different kinds of digital cultural objects from different media sources, with special attention given to surrogates of fragile physical objects. The work should focus on the sustainable development of valuable digital repositories in Europe's libraries, museums and archives. It should address the technical and organisational problems surrounding the viability of scaleable digital repositories, e.g. through test-bed creation for: long-term preservation and content management in distributed heterogeneous collections (e.g. provenance, authenticity, identification and links). Particular attention should be paid to long-term accessibility, both by citizens and for scientific analysis, and to quality, affordability and acceptability.

Client Design for Service Centric Architectures

Mark T. Smith

Hewlett Packard Laboratories, Visual Computing Department, Palo Alto, California USA
msmith@hpl.hp.com

Abstract: Next generation computing clients and appliances are components of systems and applications that are service centric, and the potential for economic growth of e-commerce and e-services that use such systems is immense. This paper will address the design of next generation clients considering new constraints and opportunities that result from this shift towards a service centric architecture. Designers need to consider factors that cut across both mobile and fixed client design and include aspects of networking, new hardware, data types, and operating systems. From a technology provider's viewpoint, the definition of a system or application is now more abstract, but also provides opportunities by creating ways to benefit both technology users and providers. The paper will also illustrate how some of these points are being addressed through work in next generation clients taking place at Hewlett Packard Laboratories, Palo Alto.

1. Introduction

Next generation computing architectures are increasingly service centric. This is characterized by a shift away from a box centric approach to system design towards ones that are specifically targeted to exploit network based goods and services. Such architectures are comprised of more loosely defined elements, largely dependant on and coupled together through communication networks. Evidence is strong that the growth of the internet, and the current expansion of on line resources and services lumped under the industry term e-commerce are responsible for this shift. In 1998 the United States generated \$301 billion USD in revenue from e-commerce, and it is predicted that by the year 2006 almost half of the work force in the United States will be employed by industries that produce information technology or are intensive users of it [Page 1999]. Coupled with this are new alternatives to the PC for how customers will consume and interact with e-commerce. As a means to access web based information, the PC will drop from 94% now to 64% by the year 2002. Information appliances are predicted to exceed PC sales by the year 2001 and by 2002 it is predicted that 56% of homes in the U.S. will be connected to the internet [Business Week 1999]. Other non-computer devices such as entertainment systems and classic home appliances will be connected to the internet to allow customers to obtain new types of support services further illustrate this shift. The box, or client device is just a means to exploit e-commerce. As the revenue generator, e-commerce becomes the real consumable.

The problem for client and system designers is how to design a next generation client. What makes this important is the realization that customers are now paying for services in a very literal sense. They want to consume the goods they select, and interact with the services they desire, and they have individual expectations for how these appear and function. Designers need to address how the definition of an application is changed when, from the user's viewpoint, the system focuses more on the services and less on the clients. New technology considerations will enter into the client design process for both mobile and fixed internet appliances and applications. Combined with this are new constraints, benefits and opportunities that can add new ways of generating revenue for technology providers. This paper address new technology considerations that should be made in the design of next generation clients used in service centric architectures.

2. Application Definition

To understand the impact of a service centric architecture on client design, it is useful to consider how applications are defined from the user's and technologist's viewpoints. From the technologist's viewpoint, a service based application is an aggregate of four abstractions; clients, transport, servers and services. Services represent the revenue

generating consumable, and can be associated with functionality such as information, productivity, entertainment and communication, and supporting resources such as electronic payment, user authentication and agent services. Servers are the physical entities that host the services. Transport refers to the means by which servers present services to clients, and can be realized in a variety of wired and wireless forms. The clients are the physical entities that users interact with to consume services. In a box centric architecture, all of these abstractions can be represented in a single device, for example a PDA with a data server process communicating using an inter-process communication protocol to a client process that can display information on a screen. In a service centric architecture, the abstractions are physically distributed, sometimes over large distances, and are linked by a data network. The aggregate that makes up an application can consist of multiple elements of each abstraction. An application may require multiple services from several vendors connected by different physical transport mechanisms. An application may require the participation of multiple individual clients, for example a future home entertainment system consisting of networked speakers, tuners, storage and displays. An application can be spatially large scale, such as an energy utilization service for an entire building deploying potentially hundreds of clients associated with lighting, heating, cooling and human presence detection. The grouping of all the components into an application can happen statically or dynamically, even allowing an application to add or remove components during utilization. In both cases application components need the ability to discover other components to form a complete aggregate. In some cases, multiple choices of equivalent functionality can be discovered, and a mechanism used to select one over others, for example user preference, cost, or service quality.

From the user's viewpoint, an application can only consist of two elements; the user, and the intended function, for example to listen to music, or look at a picture. Any logistical functions outside of these two elements such as connecting, configuring, or initializing something often are unanticipated requirements of the application that does nothing to enhance the value of the intended function from the user's point of view. If sufficient amounts of these logistical extras exist, their impact can outweigh the expected benefit of the anticipated function, resulting in the customer rejecting the technology. Works such as [Landauer 1996] discuss related issues in traditional computer applications. These issues apply equally to service centric applications, possibly more so given the potentially unbounded nature of internet services with respect to the components. New client technology must conceal logistical details from the user as much as practical. In addition, for a given application, different users will have internalized different expectations for the intended function, resulting in the need to personalize, or accommodate individual preferences in an application.

3. Design Aspects of Next Generation Clients

In work taking place in next generation client design for internet applications at Hewlett Packard Laboratories in Palo Alto, shifting technology considerations resulting from the need to meet the new requirements of service centric applications have been influential in client design. These considerations apply to both fixed and mobile clients, and affect both hardware and software. Among the most important that will be discussed are client power considerations, the effect of shrinking client size, internetworking, operating systems, dynamic persona and user privacy.

3.1 Client Power

In many portable devices, the biggest contributors to weight are batteries, housings and printed circuit boards [Funk 1999]. To design devices that are unconsciously portable requires a strong attention to power consumption in order to maximize battery life for a given weight. From the client designers view, there are three ways to address minimizing power consumption. They are to design and deploy low power circuits at the device and gate level, to design into the device support for dynamic power management, and to use algorithmic power optimization. Designing and using low power circuits is already something many designers do as it is desirable in most areas of circuit design. It is driven by environmental concerns as well as by practical necessities such as the maximum voltage ratings of small lithography processes, and the desire to balance battery size and weight with lifetime. To exploit low power circuits, designs from the start should use power as a metric reflected in specified performance. For example, processor requirements should be expressed in *MIPS/watt*, and memory systems should be expressed in *bytes/sec/watt*. When combined with cost, these metrics can become striking.

Dynamic power management is also an area that many designers take into consideration by designing entire subsystems that can be powered down when not needed. Software working with such hardware through a well defined

interface is a good way to provide a coherent, system integrated solution for controlling several separate subsystems. Operating system support for ACPI is a good example of this [Intel 1996].

With respect to next generation clients, algorithmic power optimization is a new tool methodology. In this approach, a cycle accurate model of the entire client is constructed, including models for all memory, I/O, processor, cache and other subsections. A simulator is configured to use these models and provide in addition to circuit behavior a cycle by cycle picture of where energy is expended. We have used this technique [Simunic 1999] to co-optimize the performance of prototype hardware and algorithms, in this case for MPEG image decompression, by exploring many different hardware and software architectures and finding the one that give the best performance expressed in decompressed *frames/sec/watt*. This technique is especially suited to clients for service centric architectures because in many cases such clients are designed for a specific application, such as multimedia or communication, making such hardware/software/power co-optimization very practical. For the user, this translates into *amount of service/watt*, which is expected to be maximized.

3.2 Effect of Client Size

Many emerging services will be targeted towards mobile, wearable and other clients where the physical size of such clients are expected to be very small. For example, size and weight are drivers in the Japanese handset market [Funk 1999] where devices weighing 68 to 85 grams are the current state of the art. While such size trends provide users with clients that are increasingly unconsciously portable, designers need to be concerned with maintaining or increasing functionality. Messaging services in Japan represent 40% of calls on PHS handsets, and other non-voice services such as restaurant locating, horoscope, sports and others are becoming popular. Services exploiting speech and audio are appearing everywhere, and video will follow. As streaming media services and higher bandwidth networks become available, allowing the proliferation of multimedia applications, designers will have to insure that although the size of mobile clients remain small, the interface to the user remains 'large'. The trend toward smaller mobile client size produces non-obvious new design considerations.

One of the most prominent is support for streaming audio and video. To support applications that require high resolution displays of 800x600 pixels and higher and still maintain small size, designers will have to implement emerging personal display technology such as foldable and wearable microdisplays. For such wearable displays, designs will have to take into account details such as field of view, vertical position, transparency, level of immersion and others [Gaddis 1999]. The display technology will determine the interface, which can be difficult to design and integrate while keeping power consumption reasonable. For example, a microdisplay having an interface utilizing sequential color loading will require a pixel drive rate triple the usual parallel RGB pixel rate. Binocular, stereo visual data will add more to this. Another consideration is interconnect. When a wearable microdisplay is combined with headphones, controlling the number of physical interconnection wires becomes difficult unless the use of high speed bit serial driver technology and data packet protocols that can contain both the video and audio data are considered. Interconnect of this kind will also be necessary as common devices such as wristwatches, wallets and eyeglasses increasingly become components of wearable clients distributed over the user. Designers need to establish standards for the physical interconnect and the data protocols that will go over them.

3.3 Communication and Internetworking

As with personal displays, the availability of streaming media will require designers to focus on support for communication protocols, and data formats. Obvious considerations include hardware to support chosen physical interconnect and data formats such as compression standards. Design decisions that are not obvious, especially in designs that will exploit wireless communication, are how to provide robustness to data errors and loss and how to accommodate data streams that are intermittent in nature, especially in wide area and electrically noisy environments. The ability of clients to handle broadcast and multicast data streams may require designs that can support transcoding of audio and video data to accommodate differing hardware capabilities. This uses special coding methods that can require hardware support especially for high resolutions and frame rates. Commonality at the physical layer in wireless environments may never be achieved, so internetworking with other devices that may be required to form a complete application presents a design challenge. The technology associated with wireless access points will also influence the choice of the physical interconnect. For them to be ubiquitous, access points must be very inexpensive, preferably cheaper than the cost to install them, and require no maintenance. For example, can access points be self powered?

Power requirements of radio subsystems will remain a problem for wide area systems where watts of transmitting power at times are required. For local area and home systems, radio subsystems need to migrate toward lower voltage, lower power designs. The design of the application and how it uses the communication channel also affects the hardware design. For example, applications that use mobile clients should design access points to beacon in search of clients to connect to, rather than requiring the battery operated client to beacon instead.

Designers will have to balance cost, power and quality of service. Meeting quality of service requirements is an active subject in the compression and networking communities. The client designer must still balance latency, and synchronization with a required quality of service for an application. This will be reflected in the processor, memory architecture and I/O chosen with an associated influence on power consumption. In [Qu 1999] a system synthesis methodology for multimedia applications is shown that attempts to minimize silicon area, including buffer memory requirements to support a desired quality of service. The synthesis system will identify a best choice of processor and caches, and once fixed will determine a task schedule with minimum storage requirements. When combined with power optimization, the designer can explore the cost, power and quality of service tradeoffs and converge on an optimal solution.

3.4 New Operating Systems

Clients used in service centric applications will be designed to support operating systems that focus on different functionality than the ones typically used now in PCs, PDAs and most embedded applications. As is the case now, no single operating system can be reasonably expected to satisfy the needs of all application spaces. Service centric spaces will emphasize support for distributed applications, and the necessary provisions for safety, security and communications that go with them. Aggressive power management is also a requirement, both from supporting dynamic power management, and by employing algorithmic power optimization on the operating system itself. In addition to the applications being distributed, new applications will emerge that use multiple client devices, which themselves are distributed. In this case there will be a need to coordinate the individual devices in an application dependant way, both with respect to individual functionality and as an aggregate. Finally the footprint of these operating systems should be kept as small as possible to allow the client designer another means to control cost, power and complexity. An example of an operating system that supports many of these goals is found in [Gabber 1999].

An experimental framework for organizing, constructing and deploying complex software called *Component OS* developed at Hewlett Packard Laboratories addresses these issues. Component OS creates systems that are collections of *component services*. Component services are code and data generated by the Component OS system that encapsulate a set of resources or functionality. These resources can be anything describable to the Component OS system, such as a hardware subsystem in a client like a communication interface, a software functional block like an IPC mechanism, or an entire client device like a speaker. The component services provide a mechanism for the resources to be structured and used. The integration of the components into a system is done by an abstraction called a *service interchange* which is responsible for directing operation requests to the appropriate place in the service code and for enforcing any protection requirements. There is no pre-determined list of component services that must be used when constructing a system. This means that a resulting operating system and program environment constructed by Component OS is precisely tailored to the specific resources that can be provided by a client device, and can be constructed and deployed on an application by application basis. By using a detailed model of the client hardware, algorithmic power optimization can be exploited to produce component services that are also optimal with respect to power consumption.

3.5 Dynamic Persona

The ability of a device to appear or function differently in a fixed application depending on who, where and under what conditions the application is being used is termed *Dynamic Persona*. People who purchase a client device, for example a digital camera, have a good idea of the desired application they want it to perform, in this case to take pictures. Different people will have very different ideas of exactly how they want it to perform, for example how the camera is configured, how the pictures should appear, and how they should be processed, stored and shared. This makes the ability to personalize a device or application very desirable from a technology provider's viewpoint. As applications become service centric, the ways that the application can be personalized potentially becomes very large. To support dynamic persona, a client device needs the ability to determine who is using the device, where it is being

used, and the environment it is being used in. Environment means data such as whether or not a device is still in a user's possession, if the user is moving or stationary, if moving is the user in a vehicle or walking, is the user alone or with others, is it light or dark, wet or dry, hot or cold and so forth. To do this, a client needs to be designed with sensor technology. Biometric sensors are used to determine user identity. GPS, specialized beacons or information about the access point or base station a client is connected to is used to determine a user's location. Environment data is obtained by using a variety of sensors to detect such things as sound, images, motion, position, humidity, electromagnetic fields and temperature. An example of such a client platform currently used at Hewlett Packard Laboratories that is capable of supporting dynamic persona is described in [Maguire 1998]. Sensors can be deployed and dynamic persona exploited in both fixed and mobile devices.

In addition to allowing a device and application to be personalized, knowing who, where and in what environment a device is being used offers other advantages. Devices can be self configuring or filter data based on location and environment. By knowing a user's identity passwords and PINs are unnecessary. New services can be dynamically offered to the user opportunistically based on surroundings and needs. Devices can reveal who is using them and how, resulting in new ways to support applications and products. New spaces for services are created in areas such as authentication and security, monitoring, agent correlation, business resource management, new user interfaces and marketing. One current example can be seen in [ISO 1999] where a proposed metadata standard for digital pictures can make use of such sensor data. The advantages to consumers are that now applications are tuned to match the expectations of each user, and that many of the logistical tasks required to use a device or application, such as passwords, connectivity or configuration no longer need be performed by the user. For the technology provider there are many advantages in new service and application opportunities.

3.6 Security and Privacy

Designers will need to accommodate the requirement that transactions between client devices and services be secure. Algorithms and possibly special hardware to facilitate encryption of all data communications are needed to protect both the user and the service provider. For clients that do not exhibit dynamic persona, and contain user data, the design should allow for the data to be rendered useless or unintelligible should the device be lost. The deployment of sensors to create user, location and environment aware clients creates new problems of privacy that go beyond those that can be solved by encryption. There is a significant amount of public confusion over the issue, and this will challenge the client designer because technology alone will not resolve the issue, and will require aspects of sociology, legislation and litigation.

From the designers viewpoint, the need to accommodate user privacy will expand the definition of a trusted system. Not only is it trusted to provide secure and authentic data and resources, but it is also one that protects privacy interests. With respect to applications on next generation service centric architectures, privacy issues will likely be resolved application by application. The user must be allowed to decide the tradeoff between the perceived benefit of an application and the perceived privacy risk. Client designs must support the user's right to dynamically choose from no protection of privacy to full protection even for the same application used under different conditions. This is consistent with the idea of dynamic persona in that it allows an application to also behave with respect to privacy according to the user's expectations. Dynamic persona may be of use in other aspects as well, for example by possibly combining elements of augmented reality with biometrics thus allowing a single individual to have multiple logical identities, each one different for each different application. Privacy with respect to technology is a rapidly expanding field of study, and much more work will be needed.

4. Conclusions

The trend favoring the growing number of goods and services appearing from networked sources illustrates the shift towards future computing architectures that are service centric. Future clients used in these architectures become components of the system and are used in potentially new roles. The shift towards server centric architectures introduces new technology considerations in client design that the designer needs to account for. Areas where these new considerations particularly stand out are in design for low power including algorithmic power optimization, the effect of shrinking size on other parts of the client design and new requirements introduced in connectivity and internetworking, especially those that are the result of the emergence of digital multimedia services. New operating systems that focuses on the requirements of distributed services and clients, the use of sensor technology to personalize

both services and devices and allow for dynamic persona, security and privacy issues are also new technologies for the designer to consider. The benefits of these emerging service centric architectures and the next generation clients that support them are shared by the technology providers and the users. For technology providers, the benefits are to enable new businesses, services, marketing and support that will be major revenue generators. For users, the benefits are that applications will be personalized, and will more closely provide the functionality the user expects while removing from the user many of the logistical concerns of using the application. The future will involve the evolution of new supporting services and standards, such as those for electronic payment, encryption and authentication, and services that support dynamic persona. These will in turn present further new technology requirements for client designers. Support for privacy protection is one such area that will drive designs of the future.

Abstract: Through its grants, the National Science Foundation sponsors workshops that inform faculty of current topics in Computer Science. Such a workshop, entitled, "Developing Multimedia-based Interactive Laboratory Modules for Computer Science", was given July 27 - August 6, 1998, at Illinois State University in Normal, Illinois. Each participant was expected to design and implement a small part of a laboratory module. This paper describes what some of the faculty members who participated in the workshop have done with the knowledge obtained from the workshop.

1. Introduction

The five authors met at an 11-day multimedia workshop sponsored by the National Science Foundation and hosted by Dr. Dean Sanders and Dr. Janet Hartman of the Computer Science Department at Illinois State University in Normal, during summer of 1998. After participating in intensive all day classes together, we spent the evenings in the multimedia lab applying what we learned each day. We also ate breakfast, lunch and dinner together, and checked out Normal, Illinois together during the weekend, all the time exchanging ideas, arguing and laughing together. Having shared a wonderful learning experience, we made a pact to meet again to share the results our attempts to apply our newly acquired knowledge to courses that we teach in and to new course development. Devoting 100 percent of our time to discover what multimedia [Vaughan 1996] was all about with interested faculty was an ideal way to learn about multimedia [Walsh 1995].

2. Ahmad Nasri

Recursive Subdivision is receiving a great deal of attention in Computer Graphics for modeling and animation. It is also becoming an important component in courses such as computer-aided geometric design (CAGD). The nature and the diversity of these techniques require the development of illustrative tools that help students to digest the ideas, interactively manipulate shapes and even explore new techniques. Such a technique is defined by a set of rules that takes in a configuration and generates another subdivided one. Inspired by the NSF multimedia workshop,

we have begun implementing a multimedia course in computer-aided geometric design, which we expect to be an essential tool in our CAGD course. Students will be able to use the system in various ways such as:

- Visualize how a set of rules leads to a limit curve or a surface.
- Exploring ways to alter the subsequent subdivided configurations to deform the limiting shape.
- Interrogating subdivision curves or surfaces such as surface/surface intersection.
- Visualize how to compute moments such as volumes, center of mass and inertia tensors for physically based animation. Several tools are developed using Visual C++ which are added to the Multimedia parts for interactive use.

3. Anne-Louise Radimsky

Many students have difficulty with the abstract concepts associated with data structures. I have always believed that concrete analogies and visualization of the algorithms involved would help those students understand better the ideas presented. In particular, computer animation is a powerful tool to display in a clear manner the effects of the execution of a piece of code on the representation of a structure. Several attempts at having graduate students develop such animations have met with mixed results.

During the workshop we were presented with two powerful systems designed to produce animation: Asymetrix Toolbook and Macromedia Director. They use different paradigms. The first relies on an approach similar to that of Microsoft Powerpoint., the second is based on the concept of "actors" which can be brought into a scene at different times to create a scene in a play. I chose ToolBook, both because it seemed better suited for the text-based animation I had in mind, and also because it was available on my campus.

I first created a prototype using Powerpoint. This allowed me to determine the screens sequence and the visual components needed. It proved very useful. It was easy to produce and allowed the instructors to offer suggestions on the flow of the presentation and the screens design. My goal was to illustrate the insertion of a new element in a linked list implemented with simulated pointers (i.e. using an array of nodes). As the code is executed the changes to the array are displayed.

I have added some additional operations and, with the precious help of a member of the campus media department, greatly improved the presentation. Although this individual does not have the background required to understand the substance of the algorithm, his input and experience has been invaluable in improving the appearance of the system.

My plans are to continue to develop modules for additional operations and other list representations. Ultimately, I plan to provide this material on the web for students to use in self-paced mode. Judging by the number of sites providing various kinds of multi-media resources for teaching computer science there is clearly a strong interest in many quarters for such educational material. The California State University system is also strongly encouraging the use of web-based multimedia systems to support delivery of instruction.

4. Bon K. Sy

In the last few years we have explored the possibility of employing multi-media technology to enhance teaching and learning science and technology. This is a result of the NSF Scientific Visualization workshop (1997) in Atlanta, Georgia, and the NSF Multimedia technology workshop (1998) in Bloomington/Normal, Illinois. Our focus is on using multi-media to support instructional activities. Learning based on multi-sensory channels will be an integral part of our curriculum in training students majoring in computer science and related science disciplines.

There are three major components of our project on employing multi-media technology to enhance science education. The first component is the development of a computer controlled instrumentation laboratory and curriculum enhancement under the support of a current NSF ILI grant. The focus is to introduce students with computer based instrumentation for automatic data acquisition and data analysis; e.g., using temperature and humidity sensors to collect weather data for predicting possible thunderstorm. Recently, a new course CS86 has been developed as a vehicle to implement the curriculum. Our goal is to use this vehicle to attract students to major in science and technology, as well as to retain them in the disciplines. This new course was offered the first time in the fall semester of 1998. Our initial success has led to the permission by the administration to offer the course again this coming fall semester.

The second component is our research on the learning methodologies for machine and human learners. We have investigated a pattern-based learning principle that integrates the rigor of mathematical based scientific analysis with abstract visualization of difficult science concepts. We are in the process of harnessing and integrating decision support tools developed from research laboratories with commercially available analytical tools. One specific component is the integration of a Bayesian decision support system developed by us using ActiveX technology with existing analytical tool S-PLUS.

Another component of the project is to create a scientific data depository based on Oracle server as the back-end, and to integrate it with the integrated analytical tools just mentioned. Further details can be found in another paper to be published in this conference proceeding [Sy, B.1999]. Several sets of courseware that implement the pattern-based learning principle have already been developed and will be demonstrated during the conference presentation.

The third component is the activities related to the two workshops mentioned earlier. The focus is to identify multi-media tools that will be effective for developing courseware for educational purposes, as well as Computer Based Training (CBT) packages, to support and enhance learning. Specific activities will include the development of CBT packages to illustrate the use of complex software systems effectively. A sample example developed in the NSF Multi-media technology workshop is available on the web via "<http://tweety.geol.qc.edu/nsf/courseware/>". We intend to use this component of the project as a vehicle to produce and prepare (electronic) documents for not only local distribution, but also wide dissemination over the Internet to other parties who may be interested in our projects.

Now we shall present our experience on the development of web deployable courseware for this project. The targeted audience of the courseware is the students of two courses: (a) Science Problem Solving using Computing Tools (CS86) --- a course for freshman and sophomore students in general science, and (b) Algorithms based on Probability Methods (CS762) --- a course for undergraduate senior and graduate students in Computer Science.

The development of web deployable courseware consists of three tasks: (a) content material development, (b) media presentation and application feature, and (c) dissemination. Currently we focus on developing courseware for content materials that involve mathematically oriented concepts, in particular, those concepts that are difficult for our students; e.g., system equations for projectile motion in CS86, or the computational geometry of hyper-tetrahedron that encompasses all possible discrete multi-variant probability models in CS762. An important consideration of our courseware development is the visualization feature for a student to explore visually the mathematical structure behind a difficult concept. Another important consideration is the transportability of the courseware for a wide dissemination beyond our local community.

In this project, the pedagogy behind the content material development is an integral part. Many science concepts are mathematically oriented; e.g., the fundamental principle in electromagnetic is stated in terms of Maxwell's equation [Paul et al. 1997], the behavior of an electron can be stated in terms of Dirac equation [Hawking 1993]. As a result, science concepts are often taught like mathematics, but with attached meanings as they are related to our physical reality. Yet for many students the details of mathematics, as opposed to the structure of a concept behind the mathematics, could be a distraction that hinders the comprehension of the concept. Thus the ability to visualize and formulate a structure mentally from the mathematical details is an important skill to understand many science concepts that are mathematically oriented.

As noted from our students, math and science understanding are often related to the ability to visualize. This often left out many students to engage in science and technology. Fortunately, new and better computer tools have become available for scientific computing and are widely used in industry [Johnson 1997], [Oppenheimer 1997]. Improvements are now at the point where these tools could be integrated into the undergraduate science curriculum. These new tools may help to ease that gap by being an aid to that visualization.

These new tools come with electronic books that provide 'live' formulas where the data can be manipulated, graphed, or even animated [Spiegel et al. 1998], [Nelson et al. 1995], and [Spiegel et al. 1989]. This is not just a textbook in an electronic form, but a new media providing new modalities for learning. Integrating new modalities with traditional text-based modality is particularly well suited for the pattern-based learning approach mentioned earlier [Sy, B.1999], which is a significant and integral part of our project on enhancing science and technology education. Using these new modalities, students can apply the conceptual learning tool --- pattern-based learning --- to gain a greater insight into visual reasoning behind the numbers and their mathematical relationship. By increasing the number of ways a student can learn scientific formulas, we can make science education more inclusive.

Many famous scientific publishers are producing learning materials in this new media. For example, Schaum's Interactive Outline Series based on Mathcad allows students to run the outlines electronically [Edminister 1994]. Students can access formulas with the click of their mouse, and interact with the formulas while grasping the subject

matter. In our project, we have developed an array of courseware using Mathcad, as well as courseware based on ActiveX technology.

Each courseware is web accessible in the Internet with the Mathcad/MathConnex plug-in that takes the advantage of OLE automation technology. Each courseware being developed is focused on a special topic/concept in either CS86 or CS762 mentioned earlier. A set of courseware already developed for our CS86 and CS762 can be found in our web site <http://tweety.geol.qc.edu/nsf/demo>. The details for accessing the courseware will be detailed during the conference presentation.

5. Richard Jou

My "Computer Graphics" class for the Spring Semester of 99 includes a multimedia project using some of the software tools that I was exposed to during the summer NSF multimedia workshop. This is a junior/senior class covering mainly geometric modeling and algorithm designs of the basic principle of computer graphics. The basic software tools used for this class include C, C++ and a graphics library.

I am also designing Web-based courses where most of the class materials, homework assignments, and project assignment are uploaded onto our Web server, where students can access them through a Web browsers and submit their homework through E-mail. Each semester allows me to re-evaluate my course content available on the Web through student successes/failures and feedback . I am currently updating my Web based teaching materials to improve them.

6. Sandra Honda Adams

At the workshop I was pleasantly surprised to see how easy it was to prepare multimedia slides using Powerpoint 98. We are presenting workshops in Powerpoint to the faculty here to show them how interactive, non-linear presentations can be created using this authoring tool. Buttons that trigger video, sound or music, and navigation to other slides can easily be incorporated into Powerpoint slides used for lectures. Director workshops will also be given to faculty at our institution and for area high school faculty. Five new projections units have been added to classrooms to help encourage the use of technology in the classroom.

The students are able to create multimedia animations [Gross et al. 1999] using Macromedia Director's embedded text and paint programs, and embellished their work with recorded sounds. Thanks to the NSF workshop I have added segments on video, photo [Sawyer & Pronk 1997] and audio capture [Seaman & Cline 1996] and manipulation to these classes by including additional segments on Photoshop [Quinn et al. 1997], CoolEdit and scanning to our existing multimedia courses. The video component will allow the student to modify a portion of a personal VCR tape, creating short segments to include in their multimedia productions. The scanning component will allow students to scan photographs [Aaland 1996] for PhotoShop manipulations. CoolEdit will allow students to record and manipulate speech and music. The added material will delight students as they deploy their Director movies for the web by preparing their movies for streaming shockwave. [Yeaman & Dawson 1996]

I have been spending my time learning other software to develop new classes for our non-major courses and for our Info Tech major. We have many employers who are calling for Web and multimedia developers and designers [Fromm 1995]. Their requirements are constantly growing and students wanting these positions need to know other Web based software. We have developed and are constantly re-designing our Web Design course [Siegel 1997], [Lemay 1997]. We are also planning to add Authorware [Roberts 1997], Flash [Plant 1998], and Dreamweaver to our Multimedia and Web Design Courses.

We are experiencing an increase in the number of students enrolling in our new Information Technology MS program. Graduates of other programs are also interested in learning more about Information Technology. They are very interested in joining startup companies that are developing e-commerce or companies that are developing or maintaining Internet or Intranet sites.

7. Conclusions

Each faculty member has utilized some of the tools that were presented and have implemented them in a variety of ways in their courses and curriculum. The NSF multimedia workshop was an excellent opportunity to learn something new and meet others who were curious about learning and using interactive multimedia and web technology in the classroom.

Web-CS: Infrastructure for Web-based Competitions

A.T.M. Aerts, P.F.M. Bierhoff, P.M.E. De Bra

Abstract: Most cooperative environments that have been developed for the Web are designed for groups of people with "equal rights" working together on a task, possibly supervised by a single level of administrative authority. We present a Web-based infrastructure for cooperation between many different parties. The infrastructure is designed for Web-based competitions, involving an editorial board, designers of assignments or events, evaluators, different organizational layers, and of course contestants.

Web-CS is entirely Web-based: all the communication between the cooperating parties is achieved through communicating Web-browsers and Web-servers (augmented with Java-applets on the client side and a database system on the server side). This paper presents the global architecture of Web-CS and its implementation, which is currently being tried out in Hungary and in The Netherlands.

1. Introduction

Internet and its most prominent application: World Wide Web are becoming a part of the daily life of a growing part of the population (in highly developed countries). More and more professional and social activities that are centered around knowledge, information, or both are being supported by Internet technology. Teleconferencing hard- and software (for an example application see [LFL]), shared workspaces, and other Internet-based CSCW tools [BSCW, DReSS] mostly aim at supporting small groups of people who are on the same level of an organization's hierarchy. There may be supervision by a single higher level of authority (the "boss" or the teacher [BKPW]), who in theory has more rights than his associates, but who often needs the help of a system administrator to actually use these rights. (Organizational rights often do not translate to information system rights.)

Applications or frameworks are still lacking for supporting activities in which many different parties are involved, each with different *rights*. Large *competitions* involve such a variety of parties. This paper presents a Web-based version of the Hungarian KöMaL competition. Competitions in different kinds of games, physical and intellectual sports, music and sciences are all organized in a similar way. The exact organization of KöMaL is described in Section 2. Generally speaking such competitions are organized according to the following scheme:

- There is an *editorial or supervisory board* that "organizes" the competition.
 - It decides which "organizations" may participate in the competition. Such organizations can be local game or sports clubs, schools, etc. Participating organizations are responsible for entering individual contestants into the competition.
 - It determines categories of contestants. It designs rules to determine in which category a contestant should be entered. The rules may use age, skill level, sex, etc.
 - It determines which "events" will take place, fixes dates or chooses assignments or quizzes, etc.
 - It may appoint referees (or judges).
 - It collects results and publishes overviews, on a daily, weekly, monthly or yearly basis.
 - It has the final authority to overrule questionable decisions of referees, or to change the rules of the competition.
- Participating organizations appoint *delegates* who enter contestants into the competition (or who approve applications of contestants). While this is not always visible in "real world" competitions, it is essential in a Web-based competition.
- *Designers or local organizers* propose *events* to the board. Examples of events are a chess or bridge tournament, or assignments and problems for a science competition. The board decides on the acceptance of such events.
- *Referees* (or judges or evaluators) determine the results of events. They are appointed by the board.

- *Interested third parties* (the press, the public) wish to view results.

Such a competition involves several layers of authority and responsibility. This hierarchical structure is the basis for keeping the whole competition *honest* and *fair*. If, for instance, contestants could enter themselves into the competition without going through an approval procedure, they might wish to enter into a "lower" category in order to have a better chance of winning.

The Web-based competition system presented in this paper is aimed at competitions that deal only with knowledge or information. The *events* are assignments or problems that are distributed through a Web-site. Contestants submit *solutions* to the editorial board who appoints *evaluators* to score these submissions.

The paper is organized as follows: Section 2 describes KöMaL, the paper-based competition that was brought on-line through our Web-based competition platform. Section 3 gives an overview of the architecture of Web-CS. It also describes some design details of essential components. Section 4 presents the current state of the project and its past and future developments.

2. The KöMaL competition: requirements for Web-CS

KöMaL stands for the Hungarian 'Középiskolai Matematikai és Fizikai Lapok'. It is a Mathematical and Physical Journal for Secondary Schools. It is published monthly by the János Bolyai Mathematical Society and the Loránd Eötvös Physical Society.

2.1 Current Competition

The competition is centered around *exercises* or *problems*. Exercises are invented by *designers*, who send them to the KöMaL *editorial board*. An exercise is awarded a *level*, indicating the level of the students (third year, fourth year) for whom the problem was designed. The board makes a selection from the available exercises and publishes them in the journal, together with the results of earlier competition rounds. Each month about 20 mathematics and 10 physics exercises are published. An exercise that appears in the journal has an associated deadline, before which solutions must be received by the editorial board.

The students read the journal and formulate answers to the problems. They submit their solutions to the KöMaL-office. There the solutions are sorted by problem and distributed over a number of *evaluators*. Evaluators can specify their preference for a particular problem to the editorial board. The evaluators check the solutions they get assigned for correctness, "correct" them and give a grade. The corrected solutions and grades are sent back to the editorial board, who check them, and who may change grades if deemed necessary. The grades are entered into a computerized information system. The corrected solutions are sent back to the students. The evaluators recommend the best solutions for publication in a later edition of the journal. At the end of the term for the monthly competition round, the results are printed out and published. The competition takes one school year (nine issues and sets of problems). The student with the highest total score wins the yearly competition (for his or her level).

There is a separate competition for mathematics and for physics. The published results contain scores per student and per school. These results are not only printed in the journal but also published on the KöMaL home-page, at <http://komal.elte.hu/>. It is possible to review the results of the previous competitions, and to see the exercises and assignments of the current competition round.

KöMaL has already entered the digital era: students are allowed to submit solutions by e-mail, in Microsoft Word, LaTeX, Postscript or plain ASCII format. The solutions are printed at the KöMaL office, and sent to evaluators through paper mail.

The competition at present comprises seven, not necessarily disjoint, groups of users:

- **students**: they subscribe to the competition (subject to approval by a teacher) and submit solutions to the problems that are published in the magazine.
- **evaluators** (or correctors): they subscribe to certain problems, obtain a set of solutions for those problems (shortly after the deadline for submission) and correct and grade the solutions before a certain date.
- **editorial board**: this board consists of the publishers of KöMaL, who are responsible for the correctness of the contents of the magazine. The board selects the exercises to be published from the proposals sent in by the designers (see below). Board members can check the work of the evaluators and have the right to alter the grades. The board keeps track of the competition results and publishes this information .
- **designers**: they submit proposals for exercises and assignments to the board.

- **schools:** a school requests to take part in the competition. The school delegates its rights to a number of teachers.
- **teachers:** a teacher approves the application of students to enter the competition. He or she ensures that students are entered at the appropriate level.
- **third parties:** everybody who takes an interest in the competition: the public and the government who sponsors the competition. This group is not actually involved in the competition itself, but is interested in information about it.

As can be seen from the description above, the information flow associated with the competition involves a fair number of parties, each with different rights and responsibilities.

2.2 Requirements for Web-CS.

The aim of Web-CS is to provide a *fool-proof* infrastructure for Web-based competitions. By this we mean that the interaction between all the different parties and the Web-CS system should be uniform and simple to install and to use. The reasons are:

- Some (maybe all) parties involved in a Web-competition may have limited experience with computers or Internet tools.
- The parties involved in a competition may overlap. Many designers are also evaluators, and some of them are also teachers. The user-interface for these parties should be very similar.

Students may be working on problems and interact with Web-CS at home or at school. Therefore:

- The system should not require participants to have a permanent Internet-connection or to be connected for long periods of time.
- The system should not depend on a user always connecting from the same computer. Thus, the well-known "Cookie" mechanism cannot be used.

A *generic* competition system should be suitable for problems and solutions that are in very different formats. A mathematics competition involves formulas in questions and answers; a physics or biology competition may involve pictures and drawings; a computer science competition may involve the submission of program code. As a result:

- The published assignments may need a presentation format that is richer than the plain HTML-with-images style of the Web. All participants need to have a viewer for the chosen presentation format(s).
- Students need to be able to use a powerful document creation tool for writing their solutions. (Plain text and images are not sufficient.)
- Evaluators need viewer(s) for every document format which students are allowed to use in their submissions.

Most of the board's work should be automated:

- Problems should have unique identifiers.
- Solutions should have unique identifiers as well as the identifier of the problem they address.
- The distribution of solutions over evaluators should be automatic.
- The approval (and possible modification) of grades by board members should be easy.
- Approved grades should be published automatically and the corrected assignments sent back to the students.
- The scores should be published automatically, both monthly (which is the frequency of publication of the KöMaL journal) and yearly.

Students are eager to win, sometimes at the expense of others. Therefore the system should offer a number of security features to avoid cheating:

- Each participant in the system should have a distinct username and password. (An exception is the "public" who needs no password for viewing publicized information such as assignments and scores.)
- Users must identify their "role" (e.g. teacher, designer, evaluator). Each role has associated *rights*. Users must not be able to perform tasks associated with a different role, or to select a role they are not allowed playing.
- Sensitive data, including passwords and solutions that are being submitted, should be communicated in encrypted form to prevent snooping attacks.
- The communication should be tamper-proof. A solution submitted by a student should arrive at the KöMaL site unaltered, and should also arrive at the evaluator's computer unaltered. Grades assigned by an evaluator should arrive at the KöMaL site unaltered.
- The KöMaL site should be well protected. Only board members should be able to access the database with grades directly, and be able to modify grades.
- Submission of (previously prepared) solutions should be possible without the solution being displayed on the student's computer screen.

The Web-CS software is intended for multiple applications.

- The presentation of the whole Web-site and the entire communication should be possible in the native language of the students. Since applications in Hungary and in The Netherlands were envisaged from the start, this means that the software must be language-independent.
- Some competitions may have a slightly different organization. The software needs to be adaptable to local situations. E.g., some organizations may require that students are entered into the competition by their teacher, while others may let students register themselves but ask teachers for approval afterwards.

A final requirement is availability.

- Web-CS should be able to handle a high volume of requests for assignments. It is expected that when new assignments are published many students will be eager to view and download the new assignments quickly.
- The submission and evaluation process is more spread out in time. Currently KöMaL receives and grades around 50.000 solutions (to about 300 problems) each year. Processing these data (and generating overviews) requires the use of a database system. The computing overhead in the evaluation of a solution is much higher than in delivering the problem to the student.

2.3 Comparable systems

Several Internet-based competitions already exist. However, none (of the ones we found) offer the functionality required for the KöMaL competition. Most non-commercial competitions we found are organized by North-American organizations.

- <http://www.gcschool.org/abacus.html> : This is the home page of the ABACUS International Math Challenge. This competition focuses on grades 4 to 8 and enables students to view the exercises (written as HTML pages) on the site. Solutions can be sent in by e-mail, after which they are corrected by the organizer of the competition. This competition has no automated system on its home page and is comparable to the current KöMaL-competition on the Internet.
- <http://mathcounts.org> : Mathcounts is the American National Mathematics coaching and competition program for seventh and eight grade students. On their home site a problem is published each week. For this problem no real competition exists. Mathcounts is a straightforward non-automated competition which has an interface to the World Wide Web for registering information, just as KöMaL already has. The actual competition is held at competition centers, where teams from schools physically gather on special competition days.
- <http://math.uwaterloo.ca/CMC/CMCHome.html> : The Canadian Mathematics Competition is a good example of a KöMaL-like competition which also has a home page to publish the answers and results of competition exercises. Again this competition is not an Internet based competition. The real competition is a tournament held in several cities in Canada.
- <http://olympiads.win.tue.nl/oi/> : Also the organization of the International Informatics Olympiad publishes the exercises used in their computing science competition, together with the solutions and other information via a WWW page. Again the real competition is held in annual tournaments in countries all over the world.

From these examples we see that Internet, and in particular World Wide Web, is used as an environment for publishing information concerning exercises, but that no integrated, automated support is offered for the organization of the competition. Existing environments for Web-workflow (e.g., Lotus Domino) and for CSCW [BSCW, DReSS] are not yet well suited for competitions because they lack the support for the many different roles that appear in competitions.

3 Web-CS architecture

To keep Web-CS simple, yet flexible, and to keep the client-part small as well, the system has been designed using off-the-shelf technology. The whole system consists of five parts:

- On the client-side the authentication and the execution of the user's *rights* are controlled by a trusted (signed) Java Applet. This applet communicates directly with a special KöMaL server.
- A standard Web-browser (at present this is Netscape Navigator) hosts the applet.
- A standard Web-server is used to serve information pages and the applet.
- A Java-based special-purpose server translates user requests to database queries and updates.

- All data about users, rights and grades are stored in a relational database. Web-CS uses the freely available PostgreSQL database system [PSQL]. This database system supports JDBC for the communication with the Java-based server part.

3.1 Basic module structure

The basic functionality of the system supports students, evaluators and other users in their typical activities. The requirement that no other software than a browser should be necessary to run the application suggests that each time a user starts the application, e.g. from the competition home page, sufficient software should be made available to enable him to interact with the rest of the system. This part, a Java Applet, is kept small in order to minimize download time. It is a *trusted* or *signed* applet to ensure that it has not been tampered with, and to enable it to access the user's file system.

The Web-CS applet offers a uniform interface for all users. When a user logs in (through the applet) the applet communicates with the database to verify the password and to determine the *rights* of this user. Depending on the role the user plays, different modules (rights) become available to the user. A user, who is unknown to the system, still can view the exercises and high scores, but has no other rights.

The applet is designed in an object-oriented way that corresponds to the different roles a user can play. Known (authorized) users can login directly. Students, who want to join the competition, and teachers are introduced to the system via the school. This introduction is subject to approval by a board member. Board members introduce users, playing other roles, such as designers and correctors. By adding (or removing) rights and some associated code, one can modify the system for competitions with a different organization.

3.2 Document formats and file-uploading

An important design decision for Web-CS is the choice of the document format(s) that can be used for problems and solutions. Because problems and solutions are somewhat similar documents (they deal with the same subject area) and because we want the user-interface to be very similar for all types of users we have opted to use one document format for problems and solutions. Two options were considered:

- It is possible to include a *special-purpose editor* in the Web-CS applet. This has the advantage that all users are automatically ensured to have the same editing environment. Unfortunately this option requires that a user is on-line in order to download and activate the editor from the Web-CS site. Developing a powerful editor-applet takes considerable effort, and the size of the applet would make downloads unacceptably long. For these reasons this option was not selected and implemented.
- A Web-browser can be told to execute a client-side application when receiving a document of a specific *MIME-type*. Web-CS provides one such special MIME-type for both assignments and solutions. All the users of the competition must configure their browser to activate a specific editor, chosen by the editorial board. For the Hungarian KöMaL competition Microsoft Word was chosen because all the secondary schools have PCs with this editor. Other competitions could opt for a different editor that is more suited for their particular audience.

Designers submit assignments to the editorial board. Students submit solutions to assignments. Evaluators submit corrected solutions and grades. To keep the user-interface uniform a single upload mechanism is needed. There are several options for implementing upload mechanisms:

- Use form-based uploading, as supported by most modern Web-browsers. This requires the Web-CS applet to send a request to the browser to first show an appropriate form. The upload is then performed beyond the control of the applet. (Whether the upload is "safe" depends on the use of a secure communication between the browser and Web-server in general. This is possible through SSL.)
- Use e-mail and attachments for uploading. This is not desirable because apart from the solution itself some control information needs to be submitted as well, including the identification of the assignment. Whether the communication is secure depends on the security of the used e-mail program. It is beyond the control of the rest of the Web-CS system.
- Use ftp upload to the server. This is not desirable because it requires duplication of the authorization mechanism. Ftp upload is also not supported by Web-browsers (only ftp download is). Thus, this would require a separate user-interface.

- Use special upload software on the client, which is activated through a special-purpose MIME-type, just like with the editor. This is not desirable because we do not wish to force users to install any software on their system.
- Implement a special upload protocol within the Web-CS applet. This solution was chosen because it makes it easy to realize a secure communication, which is under the complete control of the applet.

Regarding the security of the communication the current Web-CS architecture leaves two options:

- The Web-CS applet and the Java-based Web-CS server can use the JCE, the Java Cryptography Extension, for encrypting all messages that are exchanged between the applet and the server. This allows for *secure uploads*, but *not for secure downloads*. Indeed, when, e.g., a solution is downloaded by an evaluator, it is downloaded to the Web-browser, using a special MIME-type to activate the client-side editor (which in the case of KöMaL is MS-Word). The download does not pass through the applet, and can thus not be decrypted by it.
- The Web-CS applet can communicate with the Web-server instead of the Web-CS server. The Web-CS server can easily be embedded into the Web-server using Servlet technology. The communication (both ways) between the browser and server can be secured through the SSL protocol (supported by most modern browsers, and by some Web-servers).

The issue of encrypted communication in Web-CS is still under investigation.

4. Current status and Future work

The Web-CS competition system can be tried using Netscape at <http://wwwis.win.tue.nl/webcompetitie/>. In this prototype only schools can subscribe. The editorial board can perform their supervisory tasks. Students can submit solutions to assignments. Evaluators can get an overview of the solutions they have to correct. They can grade and correct solutions and submit them. The prototype does not yet use encryption. However, because the client-side is entirely based on Java applet technology, the modified client software will be downloaded automatically once it becomes available. The transition to encryption uploads will not be noticed by the existing users.

Two field trials are currently being prepared. In Hungary, the development of the completely Web-based version of the KöMaL competition is continuing. In The Netherlands we are working with the organizers of the International Informatica Olympiad to use Web-CS, e.g., for the pre-selection of candidates for the annual computing science tournaments. Based on feedback from the field trials the user-interface may be updated (probably to give it a more "sleek" look and feel). Also, more ways to generate overviews and reports will be added.

A full version of this paper can be found at <http://wwwis.win.tue.nl/webcompetitie/webnet99/>.

*Don't worry about your difficulties
in mathematics; I can ensure you
that mine are still greater.*

A. Einstein

1 A Motivating Question

We do not know if Albert Einstein's sentence could be useful to students for overcoming the wall of their ignorance in mathematics, or to face with the psychological block that prevents them from efficient learning. In this section, rather, we provide some basic motivation to use games for the learning of logic. A question arises: Why games?

A quick answer is on offer. Learning is a cognitive process, a "mental action," and it is well expressed by playing a game. Games involve competition, death and victory, deception and frustration, emotions—exactly as in real life. Games in logic, or logical games as a general case, are a natural learning environment, constructive situations, a "cognitive laboratory for studying deliberation, action, communication and information flow" [van Benthem, 1998], p.7. Besides more specific studies concerning the impact of emotions in the learning of mathematics, it is a fact that games are widely used in primary school teaching. As referred by [Hodges, 1998], Dienes and Golding relied on the funny side of games when they published the volume *Learning logic, logical games* for teaching logical notions to primary school children. For example, in one of their games a child has to stand up and try to list *things that he is not*. The other children listen to catch him out when he makes a mistake: the first child to spot a mistake takes over and has to list things that *she is not*. And so on.

We believe that there is a link between games and learning (of logic) that it is time to wake up to. At present, most of the education institutions involved in the teaching of logic encounter difficulties that sometimes grow with the students' age. At the same time, the use of games in teaching decreases with the student's age. To see an example, one can compare Dienes and Golding's book with the teaching material available today at the secondary and undergraduate levels.

As far as we know, the use of games in high school and undergraduate courses is not a very common experience. Nevertheless, there is a rich literature and some interesting tools on games as an explanation of concepts from logic, language and computation. For instance, [Doets, 1996, Hodges, 1997, Ebbinghaus and Flum, 1995] give three different ways to present Ehrenfeucht-Fraïssé games. These games are the main interest of this paper. Other games include semantic evaluation games (see for instance [Hintikka and Sandu, 1997] for a survey) and dialogue games for validity. For the semantic evaluation games, Tarski's World [<http://www.csli.stanford.edu/hp/Tarski2.html>] provides a simple game that students can use when a sentence evaluates in a way they did not expect. In dialogue games, the validity of some given formula is examined in terms of a two person, perfect information game. To the best of our knowledge, [van Benthem, 1998, Hodges, 1998] are the only lecture notes available at present that use games in logic and language as a unified perspective; [Abramsky, 1997] does the same for computation.

BEST COPY AVAILABLE

Figure 1: Example 1.

In this paper, we focus on games to be used in teaching logic. As a main result, we provide a Java application for playing logic in Ehrenfeucht-Fraïssé games as defined on graphs. Our system is available on the Web at [<http://www.wins.uva.nl/aiellom/java/ef>].

2 EF Games

Ehrenfeucht-Fraïssé (*EF*) games are two player games. To fix intuitions, let us baptize the players in the game as Professor and Student—we call this paradigm the examination paradigm. Professor and Student play a game of some length on two structures, say \mathcal{A} and \mathcal{B} . Professor wants to test the ability of Student as being examined on the question: Do you know how to compare the structures \mathcal{A} and \mathcal{B} ? A slightly different paradigm is the problem solving paradigm, where Student is being examined by Professor in solving a problem and either ‘ \mathcal{A} is similar to \mathcal{B} ’ or ‘ \mathcal{A} differs from \mathcal{B} .’ Whatever paradigm one chooses it makes no difference here. Professor and Student play as follows. Professor and Student take turns to choose elements from the structures. At each turn, Professor moves first and chooses an element from either \mathcal{A} or \mathcal{B} . Student replies by choosing an element of the other structure. Student loses if the set of atomic formulas satisfied by the elements chosen so far from one structure differs from the set of formulas satisfied by those elements chosen in the other structure (regardless of which player chose which elements). We refer to [Doets, 1996] for a general discussion on Ehrenfeucht-Fraïssé games. What is essential to define, rather, is the notion of strategy. A *strategy* for a player in a game is a set of rules which tells the player how to move, depending on what has happened so far. A strategy is *winning* if the player that uses it wins every play of the game.

To generalize our discussion, in what follows we shall refer to Professor and Student to their well known names. Thus, Professor is for *Spoiler* and Student is for *Duplicator*.

2.1 Some Examples

Is it time to play? By now we know the rules and we know that we can gain from playing, so it appears to be the time for some real games.

Example 1. Suppose that the set $A = \{a, b, c, d\}$ equipped with a relation $R_A = \{(a, b), (b, c), (c, d), (d, a)\}$ and $B = \{a, b, c, d, e\}$ with $R_B = \{(a, b), (b, c), (c, d), (d, e), (e, a)\}$ are given (as shown in [Fig. 1]).

The resulting structures are different, but the question is: how much different? In other words, how many turns will *Spoiler* need to win?

A possible play would develop as follows:

1. *Spoiler* chooses a in A , *Duplicator* answers b in B . Nothing very interesting happened here, both players just chose an element. Intuitively, both players thought: “exists x ” in terms of the language, which holds of both sets A and B .
2. *Spoiler* chooses c in A , *Duplicator* answers d in B . Here *Spoiler* knows that $\forall x \exists y (x, y) \notin R$ is true in both structures. So, he can’t win yet, but he is preparing his victory.

- Spoiler chooses d in A , Duplicator has no good moves that leave a partial isomorphism. Spoiler's final win is justified by his thinking: "Well, the structure with domain A can be described by $\forall x \exists z (\exists y ((x, y) \in R \wedge (y, z) \in R) \wedge (\exists w ((z, w) \in R \wedge (w, x) \in R)))$, while the structure with domain B can not."

In the next section, we justify formally why Spoiler's way of thinking brought him to win.

Example 2. Suppose $A = \{1, 2, 3\}$, $B = \{8, 9, 10, 11\}$ and $<$ be the usual linear order. A possible play is the following:

- Spoiler chooses 2 in A , Duplicator answers 9 in B ;
- Spoiler chooses 11 in B , Duplicator answers 3 in A ;
- Spoiler chooses 10 in B , Duplicator has no moves.

Looking at this play and at the thoughts that drive Spoiler and Duplicator, it should give us hints of the underlying strategy they are using. The thoughts of the two players in this example are analogous to those highlighted in Example 1. One thing must be noticed though: the formula $\exists x \exists y \exists z \exists w : x < y < z < w$ does not describe the structure $\langle A, < \rangle$ but the structure $\langle B, < \rangle$. This formula is quite easy to write by looking at the picture of the two structures [Fig.2]; but one can do better and find more elegant formulas. Finding these formulas is a pedagogically good exercise. In this example, one is $\exists y \exists z : (y < z \wedge (\exists x : x < y \wedge \exists w : z < w))$. The elegance resides in the quantifier rank of the formula, notion that we define formally in the next section.

Example 2 is an instance of a more general game that can be played: the game on two structures having domains of different cardinality and equipped with linear ordering.

Example 3. A pedagogically interesting example is that of playing on the integers \mathbb{Z} and the rationals \mathbb{Q} equipped with the usual $<$ ordering relation.

As in the above example Spoiler has a winning strategy for all games of 3 or more moves. This is due to density, a property that \mathbb{Q} has, but \mathbb{Z} doesn't, and that can be expressed by the first order formula: $\forall x \forall y : (x < y \Rightarrow \exists z : x < z < y)$. Again, notice that the number of nested quantifier is 3, like the number of turns that Spoiler needs to win.

Example 4. Another appealing example of games on ordered sets is that playable on the rationals \mathbb{Q} and the reals \mathbb{R} equipped with the usual linear order $<$. It is a fact of model theory that their models $\langle \mathbb{Q}, < \rangle$ and $\langle \mathbb{R}, < \rangle$ cannot be distinguished in first order logic. This means that it is not possible to write a first order formula that is true in $\langle \mathbb{R}, < \rangle$ and false in $\langle \mathbb{Q}, < \rangle$. For instance, we can express that the rationals and the reals are dense. But there is no way to express, say, that between $314/100$ and $315/100$ there is a number representing the ratio between the circumference and its radius.

One can familiarize oneself quite easily with the notion of first order expressibility by playing an EF game on $\langle \mathbb{Q}, < \rangle$ and $\langle \mathbb{R}, < \rangle$ as follows: Spoiler tries his best in as many rounds as he wants; but if Duplicator knows how to play, Spoiler has no chance of winning. Thus, Duplicator has a winning strategy for every length of the game, which means that every first order formula which is true on the rationals is also true on the reals.

In terms of learning and getting feelings of model-theoretic concepts, it is useful to play a game on structures where the domain is a set of numbers. Moreover, making the moves for both Spoiler and Duplicator is a unique experience for the student that should be integrated with formal explanations.

2.2 The Adequacy Theorem

We have been educated to compare *sets*. Elementary school has first provided us for sets of sweets, big and small. A common question then was: "What is bigger?" More complex issues appear later. For instance, we have been trained by comparing mathematical objects as algebraic expressions and polynomials, and we meet equality. Moreover, Euclidean geometry told us more on comparison by providing new insight into equality of figures on a plane, or solids in the 3-dimension space. But we have not been well trained in comparing *structures*. For doing this, we introduce one well known and important concept in logic: *elementary equivalence*.

Elementary equivalence is a basic notion in model theory. We refer the reader to [Doets, 1996] for general terminology. Informally, elementary equivalence is the property that two structures have when they model the same

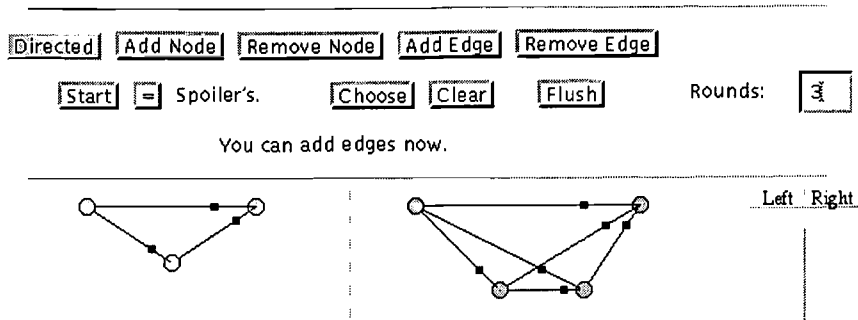

Figure 2: drawing the graphs.

set of sentences of a given language. Formally, we consider a language L and two structures that interpret L , that we call L -structures. We also stipulate the proviso that the vocabulary of L is fixed, finite, and contains only relation symbols and constants (no function symbols).

Definition 1 (Elementary equivalence) Let A and B be L -structures. We say that A and B are elementarily equivalent—in symbols: $A \equiv B$ —if and only if A and B satisfy the same sentences of L .

Definition 1 has a simple extension that accounts explicitly for the quantifier rank of the sentences of L . Recall that the *quantifier rank* $d(\varphi)$ of a formula φ is the number of nested quantifiers occurring in it (see for instance [Doets, 1996]).

Definition 2 (n -Equivalence) Let A and B be L -structures and n be a natural number. We say that A and B are n -elementarily equivalent—in symbols: $A \equiv_n B$ —if and only if A and B satisfy the same sentences of L of quantifier rank $\leq n$.

We are now ready to state the result by Ehrenfeucht (1961) which allows us to explain elementary equivalence in terms of games. We denote by $EF_n(A, B)$ the Ehrenfeucht-Fraïssé game of length n (with n a natural number) on the structures A and B .

Theorem 1 (Adequacy Theorem) For L -structures A, B and $n \geq 0$ the following are equivalent.

- (a) Spoiler has a winning strategy in $EF_n(A, B)$.
- (b) $\exists \varphi : d(\varphi) \leq n$ and $A \models \varphi$ and not $B \models \varphi$, i.e., A and B are not n -elementarily equivalent.

We have so far stressed the importance of EF games in the context of learning model theoretic notions. By the Adequacy Theorem we get what we hinted in the examples above, namely, the formal correlation between winning strategies and syntactic properties, such as the quantifier rank of a formula.

3 ...Via the Web

We now describe how we have brought these ideas into a Java applet—we called our application $ELgA$. We chose Java for its well known features of portability, integration in HTML documents and interface primitives. All these features allow $ELgA$ to be of potential interest for a wide audience as the WWW presently has. $ELgA$ provides a self-evaluating environment for students in the context of graphs, where both directed and undirected graphs can be played on. (Recall that a *graph* is a structure $\langle G, E \rangle$. The elements in G are called *nodes*; E is a binary relation on G whose elements are called *edges*. A graph is said *directed* if E is symmetric, and *undirected* if E is asymmetric.) Reflexive relations are also allowed: edges that start and end in the same node can be constructed.

BEST COPY AVAILABLE

Figure 3: beginning to play.

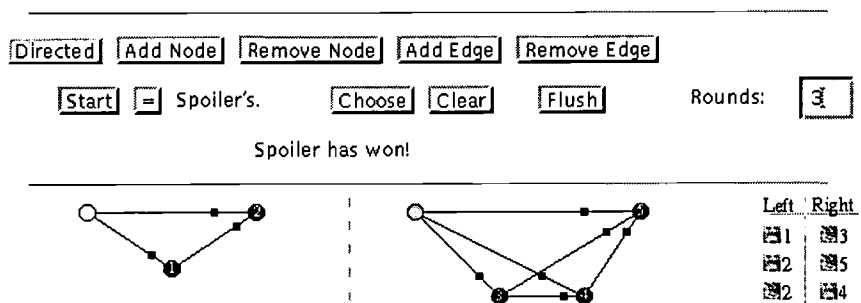

Figure 4: Spoiler has won.

3.1 Sessions

A session starts by choosing whether to have directed or undirected graphs. Then, thanks to a graphical editor it is possible to draw the two graphs.

The first move is granted to Spoiler. The node that he chooses is highlighted in black and a log of moves on the left side is updated. During a game it is possible to change the number of rounds, to decide whether playing with equality or not. A status bar always indicates who's winning, if a move is legal or not, and it helps students in their self-evaluation learning process.

Once a game is over, it is possible to play again on the same structures, eventually modifying some parameters like the number of rounds and the use of equality, or to change the game by drawing new graphs.

3.2 Example

Let us consider Example 2 above. To be able to play that game we have to input the structures. The relation $<$ is asymmetric, thus we play on directed graphs. We add 3 nodes to the left side and 4 to the right. We connect the nodes as shown in the [Fig. 2]. We are now ready to play. We set the number of rounds to 3. Spoiler can pick the central node on the left side (see [Fig. 3]). Then, Duplicator picks one of the two central nodes on the right side, and so on as in Example 2. The final situation is depicted in [Fig. 4].

4 Future Developments

The self-evaluating paradigm is not the only one from which a student can benefit. There are at least two further approaches that we plan to explore in the future.

- The possibility of playing against a *perfect opponent* should be investigated. The student that hasn't understood the game yet, should be able to play it against a perfect player. By losing the first games, a perfect

player will make the student eager to develop a new strategy and to play again, thus improving his/her understanding of the notion in the game. A client-server architecture would be the best solution, keeping the Java applet as the interface with the user on the client and implementing the perfect opponent as a running program on the server. Whenever the user makes a move, a request is sent to the central server (via a usual CGI architecture), that computes the best possible move.

Computing such move amounts to checking for partial isomorphisms between graphs. A heuristic should be devised if the player to automate is *Spoiler*. In fact, if the structures in the game are not isomorphic, *Spoiler* should pick his elements in such a way that he wins in the least possible amount of moves. On the other hand, it is easy for *Duplicator* to win in the case there is an isomorphism. He has to find the isomorphism and always play isomorphic elements.

The problem of computing moves is exponential in the dimension of the graphs on game. However, given the low number of nodes in each graph, the system would still give an output in a very short time. The server computing the moves for the automatic player could be easily implemented in Prolog or, to increase performance, in C++. The student would have the possibility to play against a perfect player and to switch sides while playing, or to look at the same game as being played between perfect players.

- Another paradigm to explore is that of having the student play against a *human expert*, say, a teacher. The teacher does not necessarily have to play the best move, and he/she can decide what to do in order to let the student learn. A space for written comments should then be available. The teacher could comment each move and explain what is going on to the student.

The implementation of these features could be obtained by the Java capabilities for establishing TCP/IP connections. The connection could be either one-one (teacher-student) or one-many (teacher-class).

Acknowledgments

The idea of implementing Ehrenfeucht-Fraïssé games came up while the second author was attending Johan van Benthem's course *Logic and Games*. We are grateful for his suggestions and the time spent to discuss the topic. We thank Johan van Benthem and Fausto Giunchiglia for useful feedback on previous versions of this article. This article was written while the first author was visiting the ILLC, Amsterdam. He thanks ILLC for his fruitful visit. The research of the second author is partially funded by CNR, borsa-203.07.27, 9/4/97.

Evaluation And Comparison Of Web-Based Testing Tools

Grigoris Baklavas, Anastasios A. Economides and Manos Roumeliotis
Applied Informatics Department, University of Macedonia
Thessaloniki, 54006, Greece
E-mail: grigoris@uom.gr, economid@uom.gr, manos@uom.gr

Abstract: In this paper, we evaluate popular Web-based tools for test design, implementation, delivery, automatic grading and result analysis. We compare these tools with respect to the variety of question types that support, the capabilities for multimedia use, the security, the easiness of development, maintenance and delivery of tests, the automatic grading and the statistical analysis of the results. Based on these criteria and practical experience with the tools, we concluded that the best ones were Cyber Exam and QuestionMark Perception.

1. Introduction

The growth of the Internet in the last decade has given rise to the demand for virtual classrooms and distant learning. The concept behind this was that, through the Intranet of a University or even the Internet, a group of people consisting of a teacher and his students can 'meet' and perform a lecture via their computers. Recently, significant progress has been made towards this direction. The integrated support of text, graphics, audio and video by the Web makes it an appropriate vehicle for learning and knowledge acquisition. The student is actively involved in the learning process using interactive tools and collaborating with the teachers and other students [Hall 97, Brooks 97, Khan 97, Economides 99, Economides 97, Mamoukaris 99].

An important parameter regarding distant learning is the taking of the examinations of a course via a computer network. To facilitate the teachers in authoring, delivering, grading and analyzing the exam tests, special software tools had to be designed. Recently many tools that facilitate the exam taking process have appeared. These tools can be installed in a server and then used by teachers and students, replacing the classical form of written examinations or helping the self-evaluation of the student progress.

Although all of them share a basic template, they have major differences in their characteristics. In this paper, we evaluate the most popular Web-based testing tools, which are:

- Question Mark Perception of Question Mark Corporation [QuestionMark Perception]
- Hot potatoes of Half-baked Software [Hot potatoes]
- Test Maestro and School Maestro Internet Publisher of Russ & Ryan EdWare [Test Maestro]
- Examiner and FastTEST of Assessment Systems Corporation [Examiner]
- LXR * TEST of Logic Extension Resources [LXR*TEST]
- WebCT of World Wide Web Course Tools [WebCT]
- Cyber Exam of Virtual Learning Technologies [Cyber Exam]
- C-Quest of Cogent Computing Corporation [C-Quest]

We compare these tools with respect to the following criteria:

- Variety of question types
- Multimedia use
- Security
- Easy development, maintenance and delivery of tests
- Grading
- Statistical analysis of results

In the following section, we briefly present each one of these software tools. In section 3, we compare them with respect to the most important criteria. Finally, in section 4, we conclude and suggest directions for improvement of these tools.

2. Testing Tools Presentation

In this section, we present the evaluated testing tools.

2.1 QuestionMark Perception:

This is the best product of QuestionMark Corporation, a company that specializes in the design of testing tools. It helps authors to create questions easily with no need for HTML knowledge. The author follows on-screen instructions or uses a question wizard for even easier question generation. The question types supported are: Multiple choice, Multiple response, Explanation, Numeric, Selection, Text Match. Every question or test can have a time limit. Multimedia use is quite easy, and therefore any type of file (graphics, pictures, diagrams) can be inserted in a particular question. These files should be in .gif or .jpg format. Students use unique usernames and (if needed) passwords to access the test.

Perception generates tables of the grades achieved by the students that took the test, with the percentages of their right or wrong answers. This feature is remarkably useful as it allows the instructor to justify the correctness of a test or even a particular question of the test.

A disadvantage of Perception is the lack of support for Unix, requiring Windows NT environment only.

Generally, Perception is one of the top testing tools, and scores high in all the major criteria. It combines easiness, security, variety and statistical analysis in a very satisfactory degree.

2.2 Hot Potatoes:

This program is a collection of six utilities, each generating a different type of question, namely JBC for multiple choice, JCloze for filling blanks in a text, JQuiz for text insertion, JCross for crossword generation, JMix for ordering mixed words of a phrase and JMatch for text match questions. All questions can be time-limited. Hot Potatoes constructs the question Web pages automatically, immediately after the instructor inserts the questions and answers. These pages can then be stored in any Web server in order to be used by the students.

The major disadvantages of Hot Potatoes stand in the statistical analysis and in the security of the tests. It does not provide any kind of access control. Hot Potatoes can be used in unofficial testing and student self-evaluation.

2.3 Test Maestro & School Maestro Internet Publisher:

Test Maestro and its complementary program have a major difference to the other packages. They generate written papers for exams and not Internet-based tests. Questions supported by Test Maestro are: True/False, Fill in Blanks, Multiple Choice, Short Answer and Text Matching.

It is fully compatible with MS Office programs, and therefore Excel plots, Word documents or even mathematical equations can be easily inserted in a question. The generation of a test is password protected and therefore access to the question bank is protected.

Statistical analysis as well as automatic grading is totally absent from Test Maestro. These functions are left for the instructor to perform, since the exams generated are in written form.

2.4 Examiner:

Examiner is generating tests from a bank of previously developed questions. It can provide instant feedback and explanations to the student after he answers a question. Examiner is very efficient in the use of multimedia, as video or audio files can be inserted in a question. So, the instructor can develop questions about the recognition of a sound or a word.

However, the instructor can only construct Multiple Choice questions, which may have a time limit. Furthermore, the program can show the result to the student, if required, or present a detailed analysis to the instructor. Then, it is possible to store the results in a database and produce critical statistical values as mean, median and standard deviation.

2.5 FastTEST:

The main feature of FastTEST is the development of a question bank from which the instructor can pick the ones needed for his test. The program supports word processor features (Bold, Italic, Underlined, Colored Text, variable font size, left, right, centered alignment) and is fully compatible with MS Office. Its questions can be Multiple Choice, True/False, and Open Answer.

Although FastTEST is quite efficient in the statistical analysis of the test grades, it does not produce any results automatically. It only provides windows for the instructor to insert the numbers of his personal analysis of the results. Access control is accomplished by passwords on the instructor end, but not on the student end.

The main disadvantage of the program is the limited use of multimedia. Only pictures of type .bmp and .wmf can be attached to a question.

FastTEST is designed mainly for generation of papers for written exams. Its supplement, FastTEST On-Line, can publish the tests on a server, and have them time-limited, but it can only record the answers without doing any extra analysis on them. Therefore, it is in a significantly lower level than the other competitors.

2.6 LXR*TEST:

This program is designed for both written and computer-based examinations and can be definitely regarded as one of the best programs of its kind as it is very efficient in almost all the aspects of interest. The question types supported are: Multiple Choice, True/False, Text Matching, Numeric and Open Answer. Time-limited questions are also allowed. A major advantage of LXR*TEST is the multimedia use. Apart from the typical file types that are supported, a user can attach QuickTime movies in a question, a feature only present in this program.

The instructor is again able to develop a test using a previously built question bank. The individual questions are set up in a word processor-like environment with all the advantages that such a function provides. It can provide special grading for each answer so that the instructor can give higher marks in some questions. Standard security is provided with passwords not only for the instructor but also for every individual student.

The LXR*TEST is one of the best in the statistical analysis of the results. The program can record and store all the answers in a database and automatically create a table with the grades of all participating students. Then, the instructor can inspect the answers in every question of a particular student. Also, LXR*TEST generates a printable list of the grades of all students that can be attached to a notice board.

2.7 WebCT:

WebCT is not just a test authoring tool, but a teaching environment with functions like storing of lecture notes, support of mailing list for students, discussion area, chat area, glossary, index, syllabus, timetable, on-line exams and much more. Specifically, the exam generation section of the program is quite simple and the instructor can easily develop tests. It supports the following question types: Multiple Choice, Text Matching, Short Answer and Paragraph, with a choice of time limits. WebCT's special feature is the ability of giving negative values to special answers in order for the students to lose points when selecting that particular answer. Multimedia use is supported very efficiently. Access control is achieved by unique usernames and passwords that are needed not only to access the exams but also to log on to the server where WebCT is stored. The student answers and grades are stored in a database for further analysis by the instructor.

Generally, WebCT provides a very efficient teaching environment but it is not specialized in testing.

2.8 Cyber Exam:

The Cyber Exam provides all characteristics of a testing tool at very high quality. Its working environment is a web browser like Netscape Navigator and MS Internet Explorer. It supports many question types: Multiple Choice, Multiple Response, True/False, Short Answer, Fill in Blanks, Text Matching and Essay. Time-limited questions are also present. Multimedia can be used very efficiently. Apart from the usual type of pictures, audio and video, JAVA applets are supported and can be easily inserted in a question. Security measures are standard, providing password protection in both the instructor and the student ends. It provides a very high quality of

statistical analysis. Immediately after a student completes a test, the program automatically grades it and is able to present the result, if wanted, to him. Cyber Exam also produces statistical reports, such as higher/lower grade, mean and standard deviation of all the grades. The results can be easily imported in a spreadsheet package like Excel or even a statistical package like SPSS. Cyber Exam can be easily regarded as one of the top programs in the area. It achieves a high level of functionality and quality for all criteria.

2.9 C-Quest:

This program is a collection of tools helping test authoring and development. These tools are: C-Quest db for the question database construction, C-Quest Test for the written examinations generation, C-Quest Web for computer-based exams, and C-quest Echo for exams via e-mail.

The questions types supported are: Multiple Choice, True/False and Multiple Response. Time limits are allowed for every type. Many multimedia file types can be inserted in the questions. These can be pictures (.gif or .jpg), sound (.wav or .mid) and video (.avi). Access control is password protected with the instructor giving the usernames of the students. After the completion of the test by a student, the results are transported to the C-Quest Web Administrator. There, the generated tables can be sorted, printed or even be exported to statistical and spreadsheet packages.

Generally, C-Quest is a nice test development program, but there is nothing special to it in order to be considered as one of the best. In all aspects, it scores about average.

3. Testing Tools Comparison

In this paper, we compare Web-based testing tools with respect to some criteria. Our experience has shown that they have major differences in almost every aspect we examined. On every criterion, there were tools that scored very high, while other performed below average. In this section, there is a complete description and scoring of the testing tools. This description is made separately for each criterion and is followed by a table that gathers the given information.

Regarding the criterion of the different Question Types supported by the tools, we remark that the standard number of types is five. However, Hot Potatoes and Cyber Exam support more types. Specifically, Hot Potatoes is the only program that can generate crosswords and sorting out a phrase from its words. Cyber Exam, apart from six basic question types, supports essays that have to be e-mailed to the professor for manual grading. Therefore, Cyber Exam has to be considered as top in this criterion. Examiner, FastTEST and C-Quest score the lowest.

The criterion of Multimedia Use can be a very decisive factor as there are major differences between the software tools in this area. LXR*TEST, WebCT and Cyber Exam can be considered as being the top under this criterion. In these packages, almost every type of multimedia file is supported. Test Maestro and FastTEST, can be considered unsatisfactory.

The criterion of Security is a very important issue for a test delivery tool, since the exams have to be accessed by a very special group of people, the instructor and the students of a particular course. Most of the tools set up their own security parameters. However, Hot Potatoes does not consider the security issue and leave it to the instructor to decide what to do. Therefore, it is considered of a lower standard than its counterparts.

Simplicity of test authoring and test taking is another criterion we examine. QuestionMark Perception, WebCT and Cyber Exam provide very user-friendly environment for test generation using wizards or web browser interfaces.

Automatic Grading with special values for particular answers is a criterion supported by half of these tools. Perception, Examiner, LXR*TEST, WebCT, Cyber Exam and C-Quest can be considered as top since different scores can be assigned to different questions.

Finally, Statistical Analysis is a criterion for which there are great differences between the evaluated tools. Some of them, like Hot Potatoes and Test Maestro have no or very limited support of statistics of the results. FastTEST, WebCT and C-Quest perform standard statistical analysis. Perception, Examiner, LXR*TEST and Cyber Exam are superior to the others providing advanced and detailed statistical analysis.

After extensive investigation and experimentation with these testing tools, we came out with the following comparison table. In this table, we score the performance of these tools with respect to important criteria.

	Q.M	H.P.	T.M.	EX.	F.T.	LXR	Web	C.E.	C-Q.
Question Types	5	6	5	1	3	5	5	7	3
Multimedia Use	B	B	-	B	C	A	A	A	B
Security	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Simplicity	A	B	B	B	B	B	A	A	B
Automatic Grading	Yes	No	No	Yes	No	Yes	Yes	Yes	Yes
Statistical Analysis	A	-	-	A	B	A	B	A	B
Cost in USD	neg.	Free	35	875	199	1199	neg.	neg.	db: 160 Test: 152 Web: 602

The shortcuts refer to the names of the testing tools and are the following:

Q.M.	QuestionMark Perception	LXR	LXR*Test
H.P.	Hot Potatoes	Web	WebCT
T.M.	Test Maestro	C.E	Cyber Exam
EX.	Examiner	C-Q.	C-Quest
F.T.	FastTEST		

We also use the following scores:

A= Excellent
B= Very Good
C= Good

The sign (neg.) means that the price is negotiable between the company and the buyer depending on the number of instructors/students that are going to use the software.

4. Conclusions

The analysis we made in the previous Section states clearly that, overall, Cyber Exam and QuestionMark Perception can be considered as the best choices for Web-based testing. They scored very high in all criteria and had no major drawbacks in every aspect. Therefore, Cyber Exam and QuestionMark Perception can be considered as an option.

On the other hand, Hot Potatoes can be used for easy creation of unofficial questions and tests. Test Maestro is better suited for the production of test papers for written examinations, while Examiner is a tool that scored well in almost every criterion except the one regarding the supported question types, which is a fact that makes it unattractive. FastTEST and C-Quest are considered to be of a lower standard than its counterparts and LXR*TEST can be marked as the third best choice after the two we mentioned above. Finally, WebCT is a great selection not only for creating Web-based tests, but also for the generation of complete university courses that are going to be taught using the Web instead of the classic lecture-based teaching.

The Evolution of Electronic Pedagogy in an Outcome Based Learning Environment: Learning, Teaching, and the Culture of Technology at California's Newest University- CSU Monterey Bay

Dr. George Baldwin, Professor
Director, Institute for Community Networking
Social and Behavioral Science Center
California State University Monterey Bay
george_baldwin@monterey.edu
<http://indian.monterey.edu/gbaldwin>

Abstract: CSU Monterey Bay is the newest university in the CSU system. CSUMB's vision statement distinguishes the institution from others in the system by promoting learning paradigms of Outcome Based Education (OBE) and communication technologies of distributed learning (DL). Faculty are committed to the experimental use of technologies as resources to people, catalysts for learning and providers of increased access and enriched quality learning. The university begins its fifth year in its commitment to create a culture of innovation in conceptual design and organization; embracing outcome based education and distributed learning paradigms. Baldwin's formative narrative of the institutions experiences concludes that: 1) CSUMB has had difficult to find faculty with sufficient pedagogical experience with multimedia teaching tools and outcome based education to move directly to the new paradigm, 2) the organizational structure of ULR Committees has mandated "assessment by courses" rather than a true OBE approach.

Acknowledgements: The author would like to acknowledge the input for this paper from Dr. Armando Arias, Dean and Dr. Juan Gutierrez at the Social and Behavioral Science Center, CSU Monterey Bay.

Introduction

In 1994, California State University Monterey Bay was among the first public universities to develop a technological infrastructure- from the ground up - to deliver an educational curriculum using a multimedia Intranet/Internet design. In conjunction with the technology, the university planning faculty began with a mandate to create an "outcome based" educational model of collaborative learning and teaching that would promote transdisciplinary learning. Our ability to do so was based on support from defense conversion funds from the military as well as funding from the CSU system. CSUMB was created on the site of the former military base Fort Ord and from the beginning we were viewed as a national model demonstrating how to convert a military base into an economic engine, mediating the negative impact of a military base closure on the tri-county region. During the past four years, CSUMB has explored how to fully utilize the computer-mediated multimedia technology that was installed as a distributed method for course delivery. As we move into our fifth year of operation, we are taking our first steps toward integrating our teaching technologies with outcome base learning, enrollment and assessment management systems. "Contact hours," "seat time", and "the virtual campus" are constantly part of our day to day dialog. CSUMB is on the forefront of the CSU system's expressed interest to develop an outcomes based educational system which would replace the traditional credit-based system of graduation. Those hopes, as well as our recognition of the dramatic demographic shifts in the California population are reflected in the institution's vision statement, found at <http://www.monterey.edu/general/vision.html>. This "transformation" has occurred under the watchful eye of the state of California during a political period in which affirmative action has been challenged in California and and rival on-line university systems are being created both nationally and globally. For these reasons, CSUMB is a fascinating experiment in the application of distributed learning technologies to the teaching and learning paradigm of OBE. All of this in a political atmosphere of multiculturalism and transdisciplinary training! We do not have traditional majors or departments.

Distributed Learning at CSUMB

Where distance learning is understood to be pedagogy that attempts to replicate the classroom ambiance across geographic space, distributed learning (DL) involves the acceleration of interactions between teachers, researchers and students using electronic networks to communicate. DL may use the technologies of distance learning, but the focus is not on providing "education at a distance", it is on providing learning on demand regardless of the student or teachers' location - on or off campus. When integrated into instruction, the technology encourages teachers and students to reevaluate the traditional role relationships that have existed in western education. We eliminate the temporal and spatial restrictions on the instructional process and blur the distinctions between "distance" and "campus-based" education, changing the way in which students gain knowledge and faculty teach. California has a state wide initiative that is intended to leverage institutions to weave outcome based learning and technology together. The OBE philosophy is embodied in the Cornerstone Report and the use of technology is a CSU initiative. *The goal of the CSU technology initiative, as we understand it, is to enable all to communicate with one another and to interact with information resources vital to teaching and learning from anyplace to anyplace at anytime.*

At CSUMB, learning and teaching incorporate traditional classroom faculty performances (face-to-face) with video-taped lectures, streaming audio and video (this fall) , and interactive multimedia web pages. Faculty create learning experiences that address the 13 University Learning Outcomes (ULR's) that have replaced the traditional general education requirements of sixty plus units of credit. Students graduate when assessed as competent, not just because they completed 124 units. Major Learning Outcomes (MLO's)- our the requirements for a degree in a major. Some of our majors have been quite successful in moving curriculum content onto our network, making the information typically transmitted during a class lecture or lab accessible to the student independent of the class or professor who teaches it. Such courseware will ultimately allow our students to study independent of faculty members or even school schedules. The objective of the faculty planners was to create a "smart campus" from the ground up, rather than patching together the technologies into an existing architecture. To that extent, we have been very successful in creating a campus with an information infrastructure supporting widespread integration of technology into the educational process. CSUMB faculty and staff have multimedia workstations, and each student has assured access to a computer. As part of CSUMB's assured access policy, approximately 80 per cent of students bring a computer to campus with them, or buy one through one of CSUMB's attractive purchase/lease plans. Computer labs are available in the Library, Media Learning Center and dorms for students who do not have their own computers. Classrooms, labs, offices and residence halls are networked. Each student has an email account, at least 10 Mbytes of private server storage, access to Internet and an area for publishing electronically on World Wide Web. Electronic mail serves as the primary form of communication, scheduling, and document distribution mechanism. The *FirstClass* server (computer-mediated conferencing software) links students to each other via email and chat room to faculty, and to drop boxes for submission of course materials.

Our library has 15 full-time staff and regional and national access to on-line reference materials. Learners have access to more than 4,000 full text on-line journals through Lexis-Nexis, EBSCO, Masterfile, Expanded Academic ASAP, Business and Company ASAP, Academic Press IDEAL, Project MUSE, Novosoft, and World Wide Web publications. Students may also order journals and books from inter-library loan electronically. Linkages to partner libraries permit shared materials. The library staff have produced custom web browser interfaces to many databases, making access to information very intuitive. In fact, access is so simple, the author is concerned that students may not be able to use traditional libraries when they graduate from our campus. Many faculty, encouraged by campus initiatives and tenure/promotion schemes are working to place their course syllabi and assignments on web servers. In fact, in some departments faculty have converted their desktop machines to web servers for the express purpose of curriculum design and delivery. The day of the desktop educator has appeared! Work is distributed electronically via campus servers and handed in automatically into write-only drop folders via electronic mail. It is becoming routine for students to produce artwork, do research, submit assignments, make appointments, and create and perform class presentations, all by computer. They

communicate among themselves and discuss work with their instructors on-line. They use collaborative document techniques to work together, use spreadsheets and charts to portray numerical information, and make multi-media portfolios used for the assessment of their work. They are skilled at using scanners, digital cameras, and projection equipment, and most can make Web pages. A server is dedicated to student work, and any student may create a home page and link it to CSUMB. Off course, this is not an electronic utopia.

Our studies show that the use of our campus network is varies dramatically when the ethnicity, gender and educational level of our students, aculty and staff. Universal access and use of our network has been a goal the we have not achieved. In fact, we are only beginning to understand the unintended impact of using our multimedia network to move curriculum to students. The effective use of the technology for teaching and learning varies widely from one major to another and there are remarkable differences between individual faculty in their ability to incorporate (much less embrace) the teaching philosophy promoted by DL and OBE. For students, barriers to using our network have been gender (women are less likely to use it) , length of exposure to computer technology (transferring students with no computer training suffer), and cultural factors that have not yet been examined and that we simply do not understand yet. Faculty barriers to access a two fold: 1) lack of training and exposure to multimedia networks has retarded the development of multimedia DL curriculum and 2) there are as yet no contracts defining faculty rights to the content they create or provide online. Frankly, if a faculty member can make all of their "courses" (or learning experiences) available on-line, it means that ALL courses can be offered EVERY semester! The ramifications of this for calculating faculty load and full-time equivalency (FTE) are just now being examined.

Outcome Based Education at CSUMB

Outcome based assessment is not well understood by most faculty in the United States, for the simple reason that we were not exposed to it. As teachers, we tend to use the same techniques and philosophies that were used to train us. Most of today's educators were products of traditional schools that graduated us based on the credits we accumulated by taking classes, listening to lectures, and taking tests. The closest that most college professors came to OBE was the preparation of the thesis or dissertation. You may complete your coursework in graduate school, but without a thesis, you can not graduation. OBE separates course completion from the satisfaction of educational requirements. In other words, it is not time in a seat and the accumulation of units that leads to degree completion, it is the independent assessment of student competency. Most of our planning faculty understood this: many of us visited universities that were experimenting with OBE in their curriculum and in turn, we have been visited by them. New faculty did not have this exposure and even today there are many of our professors at CSUMB who do not understand what OBE is and may not be fully committed to it. OBE functions as follows at CSUMB.

Under the guidance and supervision of faculty, students are required to develop an Individual Learning Plan (ILP) that defines the *pathways* to achieve the 13 required university learning requirements (ULRs) and major learning outcomes (MLO's) Like many of our practices, this varies from Center to Center or major to major. However, the flexible learning principle is fairly ingrained in our campus culture, and it forces greater emphasis on the learning process. Faculty attention is focused on developing their courses with student learning outcomes central to curriculum content, presentation and specified deliverables. Because the MLO's and ULR's are defined by the university, courses (or other learning experiences) that do not provide content and deliverables addressing them are not helpful for a student to graduate. The original idea behind our outcomes based model was that students could learn on their own, with others, and through many different experiences rather than a fixed number of required courses. Although courses offered by faculty would be useful for assisting students to become competent, our objective was to provide many different pathways for learning students. Students would become "active learners" and the role of faculty would increasingly be that of assessor of student achievement, rather than content deliverer. Students would become less dependent on the information and learning assignments provided by faculty in class and more dependent on their own initiative and judgment as learners.

Technology was to play an important part in the empowerment of the learner as well as influence the role of the teacher-as-assessor. This is still a distinct possibility, but as a critical reviewer will see in the discussion that follows, traditional pressures for majors (called Centers and Institutes) to capture FTE in order to boost Center budgets, has resulted in a large number of Institutes that now *require courses* for graduation, intentionally derailing the original idea of allowing students to gain mastery from a body of learning modules or outcomes shared across disciplines, specified as part of their Individual Learning Plan.

Planning faculty (the first dozen hired to operationalize our learning outcomes) viewed competency assessment as central to OBE. The ULR's and MLO's were not to be centralized in any one "course" - as they currently are -- the learning outcomes were to be embedded throughout the curriculum in a cross disciplinary fashion. Early proposals were for curriculum modules (computer assisted learning - CAL) to be developed by faculty - or purchased out right by the university from commercial firms - that addressed the ULRs. Such modules -- or faculty sponsored learning experiences -- would allow students to develop products that could be assessed *independent of the faculty who facilitated the students learning*. In removing assessment from the faculty member, we believed that we could end social promotion, grade inflation, and identify poor teachers. This has turned out to be one of the most controversial aspects of our teaching philosophy. Our original vision of assessment independent of faculty still exists, but competes weakly against faculty sponsored ULR Committees that have developed a procedure for approving class syllabi that are said to address the ULR's. For most students on our campus, they need only take a class and get a passing grade (C-) which the ULR Committee has *officially approved as meeting the ULR*. In summary, for the most part, students now take classes, must get passing grades, and faculty do the assessment. By requiring a fixed set of classes within a major (in the funding battle for FTE) not only have we moved away from a true OBE model, we are closing the door on transdisciplinary learning.

In this authors view, true OBE puts the emphasis on the student's demonstration of what s/he knows and is able to do, not on completing a pre-determined set of courses. The CSUMB model - as we originally envisioned it - required that professors state in advance of instruction the learning outcomes students were expected to achieve (as a result of their teaching) and it required that students understand that they must demonstrate proficiencies associated with those outcomes independent of college units and classes in order to graduate. Our website describes the required ULR's as "... (the system) works a little bit like getting your driver's license. To get a driver's license, you need to demonstrate that you know how to drive and that you know the rules of the road. You can learn these things in a variety of ways, for example, taking private lessons, doing trial and error, or some combination. When you do get your license, you are not held accountable for how you learned to drive, but rather for demonstrating that you are able to drive " (<http://www.monterey.edu/academic/ulr>). We operationalized the University Learning Requirements as 13 ULR's and each major operationalized their own specialized learning requirements as Major Learning Outcomes (MLO) - sometimes called ULO's and MLO's (where the "O" stands for outcomes). The 12 ULR's are: Community Participation, Creative Arts and Expression, Culture and Equity, Democratic Participation, English Communication, Ethics, Language, Literature and Popular Culture, Mathematics Communication, Science, Technology/Information, United States History, and Vibrancy. It is beyond the scope of a paper this size to address the evolution of each of our MLOs. However, four of the ULR's deserve critical review because unlike the other nine, these four are required for *all* students at the university, including transferring juniors. Three of those four will be addressed in this paper. The additional nine are required of those that enroll as freshmen or sophomores, as a replacement for the general education requirements at traditional CSU's. These four are: **Technology and Information, Foreign Language, Service Learning and Culture and Equity**. These "special status" ULR's require the closest evaluation and will serve as examples for how CSUMB has operationalized OBE within the DL environment. To satisfy a ULR or MLO, a student must write and proposing an Independent Learning Plan (ILP that selects one of the following three pathways for fulfilling the ULRs.

1. If a student does not already possess the knowledge and skills required by a ULR or MLO, then the student can register for one of the courses which have formally been designated as offering preparation and assessment for that ULR, and the student will be assessed by the instructor(s) right in the course.

- 2.If the student does not already possess the required knowledge and skills, but he or she has a plan to gain the required knowledge in some way other than taking one of the designated courses, then the student should work out that plan with her or his advisor. After the student has gained the required knowledge through this alternative means, then the student would register for an independent assessment of that ULR.
- 3.If the student believes that he or she already possess the knowledge and skills contained in a particular ULR, then the student should register for the appropriate independent assessment (ASMT) for that ULR. After registering for the ASMT section corresponding to the ULR, then the student should see the chair of that ULR Committee for instructions on how to prepare for the independent assessment.
(see: <http://www.monterey.edu/academic/ulr>)

The Technology and Information ULR- One Example

The requirements for this ULR are as follows:

Students must demonstrate comfort with technology and information search and discovery methods. Demonstrate the ability to use tools effectively for the discovery, acquisition, and evaluation of information as well as core computer tools for the manipulation and presentation of information in a creative and ethical manner. Students will demonstrate ability to: 1.use their computers to create, edit and produce attractive documents which conform to a set of given standards. 2.produce a clear, cogent representation of tabular data.3.create a what if analysis on a set of quantitative data, using a spreadsheet. 4.create a pictorial representation of a set of data, using charting or graphing software. 5.successfully use a variety of information resources and information search and discovery systems, such as the CSUMB Online Library Catalog, as well as citation, abstract, full-text databases, and the Internet. 6.understand the scholarly publication process and distinguish popular from scholarly treatments and primary from secondary resources. 7.effectively attribute sources according to existing standards and use software tools for the maintenance and construction of bibliographic information. 8.evaluate information by referring to indicators of quality and accuracy. 9.create an aesthetic electronic presentation which includes images and data. 10.participate in the CSUMB electronic community. This includes the computing environment, including servers, electronic conferences, and electronic mail. 11.use computers in the creation of an artistic product. 12. demonstrate an understanding of “netiquette”, intellectual property/copyright, and of ethical use of technological tools.

The success of the Technology ULR curriculum can be understood when we see how it was created. Consultants (later to become part time faculty or staff) developed this curriculum under contract. The curriculum was originally treated as public domain, but has recently been treated in a more proprietary manner. Developed under contract, the curriculum is not owned any single faculty member, thus part-time faculty are typically hired to administer it, at great savings to the university. As you might imagine, this model of OBE sets the stage for an institution is primarily composed of part time faculty, and indeed CSUMB is currently staffed at over 60% part time with the lowest number of tenured faculty in the CSU system! It is obvious to many of us that when we allow curriculum to be own by the university so that students can achieve learning outcomes independent of a faculty member, assessment becomes the primary activity of a teacher, not pedagogy!

Operationalizing the performance criteria of the Tec ULR was not a highly political process, given that the outcomes were for the most standard computer applications well understood by industry as relevant to the modern electronic office. The infusion of technology into much of our pedagogy as well as the culture of the institution has lead many students to choose assessment, rather than a class, for demonstrating competency. In summary, the Technology and Information ULR is our best example of independent competency assessment, fully operationalized and described on the supporting university web

site. The outcome has been easy to operationalize. Technology tutorials are readily available online and owned by the university, not faculty. Students are increasingly fulfilling this requirement by assessment.

Service Learning and Culture and Equity: A Second Example

Where the Tec ULR may be viewed as a relatively noncontroversial set of learning outcomes, Service Learning and Culture and Equity share the common characteristic that students must demonstrate an implicit set of *values as well as content mastery*. When we assess for Learning Outcomes that require students to demonstrate normative (non-academic) values, we engage in a highly controversial area of education. Within these two ULR's, "college literacy" has been defined to include the demonstration of approved values and social behaviors such as volunteerism for Community Participation and demonstrating a "commitment to work for social equity" in C&E. These values are deemed as necessary for students to be "literate citizens in a multicultural, global society" and represent perhaps the most controversial aspect of our learning requirements.

Service Learning has proven itself to function usefully in the curriculum. For the past three years the ULR has not been well understood - many faculty asked the question, "how is volunteerism expected to contribute to student literacy"? Outcomes in service learning have been operationalized as a) **Civic Participation and Self Efficacy**, b) **Career Preparedness** and c) **Academic Relevance**. These outcomes are assessed by the application of the Student Service Assessment Questionnaire. Pre-testing and post-testing of students with the "service learning scale" have demonstrated that students (after the SL experience) see contributing to the community as more important than before the experience and believe themselves to be more comfortable in such situations. They claim to be more prepared for the world of work, and their motivation to enroll in classes that have "real-life" applications and "hands on experience" (Service Learning Research Student, January 1999). On our campus, the Service Learning Outcome appears to be functioning quite well in the role of a traditional internship- that is to say, it provides "on the job training (OJT)" that is especially relevant to our younger students. Never-the-less, older students have been known to find this upper division requirement irrelevant to their study and seek alternative assessment based on life time experiences.

What We Have Learned- Recommendations

There are two points that one might conclude from the above discussion. First, CSUMB found it difficult in its search for faculty with sufficient pedagogical experience with multimedia teaching tools and OBE. Over 6,000 resumes were screened for the first appointments of thirty or so teaching faculty. We discovered that of those hired, few could actually meet the 13 ULRs proposed by the planning faculty! Traditional universities require faculty with advanced degrees, not competencies and our selection process netted well qualified traditional academicians. Thus faculty have needed extra time for course preparation, faced with learning to manage multimedia software and students with flexible learning plans. Faculty loads have not reflected the planning and development component of faculty teaching, and overwork has been the result.

Secondly, the ULR Committee structure, which was originally developed as an organizational strategy to promote interdisciplinary study in an OBE environment has slowly recreated the traditional "graduation by taking a course" framework we are all familiar with. Those committees now approve syllabi as meeting MLO's, thus getting a C- in a class fulfills a graduation competency. Centers seek to bolster FTE by requiring courses "within the major" to fulfill MLO's and students can not author ILP's that are transdisciplinary. In contrast, the CSU Chancellors office in its support for OBE, rejects course based assessment in favor of overall program outcomes, stating that "Each university will strengthen baccalaureate education through student learning outcomes and assessment...Each university will identify student learning outcomes for both General Education and degree program majors, focusing on the outcomes of overall programs rather than individual courses (Cornerstones Report, p. 1). With such a

mandate, the CSUMB leadership will soon need to address MLO Committees that are restructuring our vision of OBE to that of a more traditional CSU.

IMAGO - Web Based Mapping Solution for Business Processes Modelling

Dr. Claudio Barbero
CSELT S.p.A., Via G. Reiss Romoli, 274 - Torino, 10148 Italy
Tel. +39 011 2288077, Fax +39 011 2288212, E-mail: Claudio.Barbero@cse.lt.it

Abstract: This paper describes the experience gained by the Telecom Italia Network Direction with IMAGO (the Italian acronym for Multilevel Interface for Graphic Organizational Analysis), an application designed to ensure that knowledge about the organizational structure of operation processes and how they evolve can be put to profitable use at all levels. The IMAGO application's objective is to build up a "Process Library" to represent operation processes uniformly and with various levels of detail, to disseminate these processes promptly throughout the company's Intranet, and to monitor how management of each process evolves over time. Users may choose, in a dynamic way, different kind of graphical representation and have a "real-time" data adjustment. The maps are visualised through Autodesk MapGuide software, this is one complete solution to build, deploy, and access intelligent, map-driven Web sites.

1. Introduction and Motivation

The IMAGO application's objective is to build up a "Process Library" for the Telecom Italia Network Direction so that possible or plausible relationships that now govern the workflow of the activities for which the Direction is responsible or will govern it in the future can be identified.

The IMAGO application is designed to satisfy a range of needs: to represent operation processes uniformly and with various levels of detail, to disseminate these processes promptly throughout the company, and to monitor how management of each process evolves over time.

With the complexity of the operation process maps it is thought to consider them as one of the cartographic maps, and to search through the GIS tools a solution to supply dynamic and interactive maps to the IMAGO's users. In IMAGO, it's been inserted the Autodesk MapGuide suite. Autodesk MapGuide software is a complete solution comprised of all the tools to build, deploy, and access intelligent, map-driven Web sites.

2. IMAGO Methodology

IMAGO provides a methodological support for business process analysis and allows model's description and representation. To guarantee that the description of operation processes satisfies the company's quality targets and business needs, it is particularly effective to be able to use a uniform methodology for analysing and representing the processes.

The methodology shall use *an information representation standard*, which employs formal notation in order to reduce the risk of ambiguity, inaccuracies or incompleteness in the description of operation processes.

The purpose of a business model defined through IMAGO is to represent all or part of the Network Direction's operation processes and to highlight the functional and control aspects and the relationships between the processes themselves and the corporate dimensions (Services, Organisation, Technologies, Systems and Standards).

Figure 1: Different type of maps

The IMAGO methodology consists of different phases from which:

- **Processes functional analysis:** consists in capturing the basic aspects of the processes to identify both functional components and information flows among them; a multilevel model (Process's Maps) is built through iterative specialisation steps.
- **Activities control property analysis:** processes that make up the last representation level of the functional analysis are specialised in activities. The outcome of this phase portrays a most specialised description of the model, and catches on the process's control and behaviour aspects. The ensuing model (Activity's Maps) is built on more levels through iterative specialisation steps.
- **Company Co-ordinate application:** aimed to define relationships between processes or activities and the corporate dimensions: organisation, information systems, services, technologies, norms, etc...
- **Operative flows definition:** they are processes and/or activities sequences, which are event driven, and time dependent.

3. IMAGO Tools

IMAGO provides a family of tools to editing, managing, publishing and consulting the diagrams of activities, processes, operative flows and the organisation chart:

- **IMAGO Modelling:** to represent the company's business processes, showing its functional and control issues and relationships among processes and other corporate dimensions: organisation, information systems, services, technologies, standards, etc ... The Library for all this information can be of any standard RDBMS. Each team member can work on his or her piece of the project free from fear of clashes. With IMAGO Library, they can all work on the same project, using the methodology that works for the piece they're interested in.
- **IMAGO Web-Publisher:** is used for publishing all the information from IMAGO Library to IMAGO Web. The site structure is completely configurable.
- **IMAGO Web:** much more than a set of HTML pages, the site generated by IMAGO Web-Publisher makes it possible to consult the information contained in the Library dynamically on the Web and contains dynamic links between all the elements, even the maps.
- **IMAGO Feedback:** an IMAGO reader can send a feedback or a message to the process owners.

Figure 2: IMAGO Tools

An IMAGO Reader must easily individuate the operative flows in which it occupy's, through out selection filters on the company co-ordinates (e.g. setting his organisation unit). When it visualises the operative flow map, an IMAGO Reader must easily individuate the activities in which it occupy's. An operative flow can involve more than one hundred activities and different organisation units. So the operative flow map can result in great dimensions. It is necessary to have the functionality of zooming and panning. Also it is necessary to have a mechanism to point out the activities been relational with a particular company co-ordinated. Each activity must be selectable to be able to ask for the relative description form.

With the complexity of the operative flow maps it is thought to consider them as one of the cartographic maps, and to search through the GIS tools a solution to supply dynamic and interactive maps to the IMAGO's Readers. In IMAGO, it's been inserted the Autodesk MapGuide suite. Autodesk MapGuide software is a complete solution comprised of all the tools to build, deploy, and access intelligent, map-driven Web sites. It delivers live maps and linked databases directly to your desktop, via Intranet or the Internet.

Within a browser, it is possible from each office equipment (PC), to surf on dynamic data using tools, buttons, query (with bullets selection) and properties. IMAGO Readers may choose, in a dynamic way, different kind of graphical representation and have a "real-time" data adjustment.

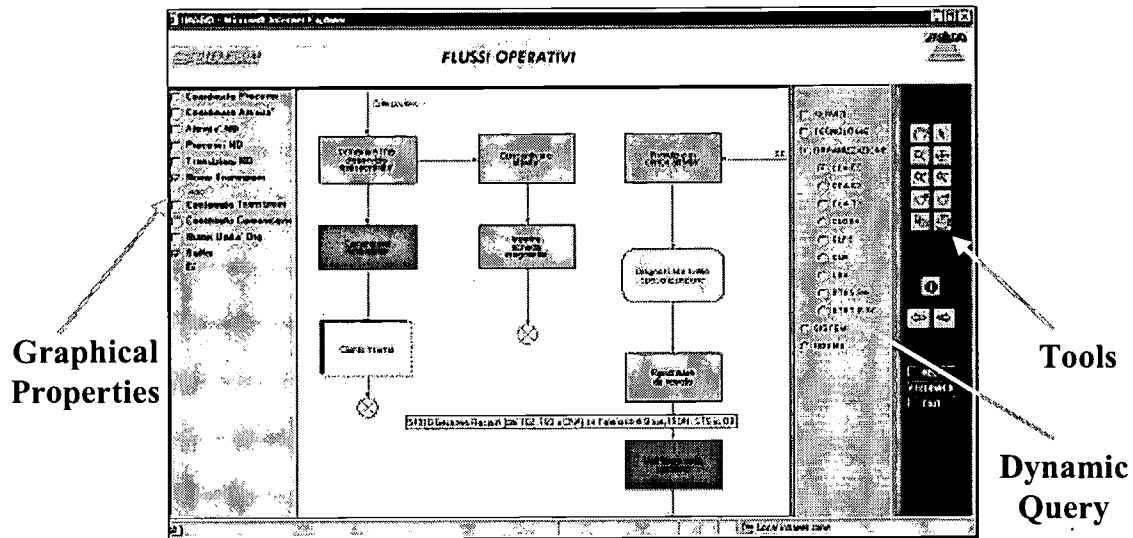

Figure 3: An example on graphical data navigation using an enterprise internet browser.

4. How Autodesk MapGuide Products Work Together

Autodesk MapGuide software is a complete solution, comprised of all the tools to build, deploy, and access intelligent, map-driven Web sites. The three main components are MapGuide Viewer, Author and Server.

Autodesk MapGuide Author stores maps as map window files (MWF). Each MWF file contains the specifications of the map window, including map extents, background color, data source information (SQL databases, spatial data files, and raster image files), layers of cartographic data (such as roads and countries), layer display information (such as attributes and visible scales), and map display configuration specifications (such as menus and legends).

To create a map, you use Autodesk MapGuide Author to combine resource data, such as spatial data (spatial data files and raster image files) and attribute data (SQL databases) into maps. The maps you publish using Autodesk MapGuide Author are saved as map window files (MWFs), which contain the complete specifications of the published map, including the boundaries of the map, background color, layers of cartographic data (such as roads and countries), layer display information (such as attributes and visible scales), and map display configuration specifications (such as menus and legends).

Autodesk MapGuide Author supports four types of vector map layers: point, text, polyline, and polygon. Each layer contains only one type of map object. You can create a layer and use it for a specific map, or save it as a separate map layer file (MLF) and use it in several different maps. A map can contain multiple layers of the same type, each of which can be set up independently of the others. Map layers are created from spatial data files (SDFs) or SQL databases. Layers created from SDF files can be linked to SQL database tables, allowing you to display data using display themes. For map layers built from an SQL data source, or SDF files linked to an SQL data source, specifies a valid SQL Where clause to restrict the map objects displayed on the map layer. The Where clause typically references a column from the Object Table.

Autodesk MapGuide Author draws layers in order of increasing priority. For instance, the program draws the layer with priority 0 first, then draws the layer with priority 1 next, on top of layer priority 0, and so on.

The end user who wants to view the published maps installs the Autodesk MapGuide viewer. The user's Web browser can then recognise the registered MWF file type as a map window file, so that when the user opens an

HTML page that contains an MWF file or clicks on a link to an MWF file, the Web browser automatically loads the Autodesk MapGuide viewer to display the map. The viewer reads the MWF file and displays the map according to the settings specified in Autodesk MapGuide Author. Whenever you use either Autodesk MapGuide Author to create a map or the Autodesk MapGuide viewer to view a map, a request is made to Autodesk MapGuide Server, which then provides the resource data in that map via the Internet, an intranet, or an extranet using the services of a Web server and a Web browser.

The Autodesk MapGuide Server software consists of three components:

- The Autodesk MapGuide Server Agent receives requests for map data from Autodesk MapGuide Author or the Autodesk MapGuide viewer via a Web server. The Agent queues the requests as they are received and distributes them to the Autodesk MapGuide map server.
- The Autodesk MapGuide map server receives and processes the requests for map data distributed by the Agent, formatting the data as requested by the map layer, and then sending the data back across the Web to Autodesk MapGuide Author or the viewer.
- The Autodesk MapGuide Server Admin gives you complete operational control over Autodesk MapGuide Server, allowing you to configure resource security, log file generation, data source directories and database access, integration with the HTTP server, and service start/stop.

Autodesk MapGuide Server is a scalable, fault-tolerant, 32-bit, multi-threaded software application that provides authored map data in response to requests from the Autodesk MapGuide viewer and Autodesk MapGuide Author. Using Netscape ® NSAPI interface to integrate with Netscape Web servers, the Microsoft ® ISAPI interface to integrate with Microsoft Web servers, or the standard CGI interface, the Autodesk MapGuide Server Agent can support an unlimited number of map servers by using remote procedure calls (RPCs). Autodesk MapGuide Server supports simultaneous connections to multiple geographic files and multiple relational databases resident either locally or under operating systems on workstations accessible on the network.

Figure 4: Autodesk MapGuide architecture

5. How IMAGO Server works

SDF files contain map objects, which are drawing objects such as points, polylines, and polygons that represent physical features on the map. SDF files can also contain polypolylines (multiple polylines grouped as a single map object), and polypolygons (multiple polygons grouped as a single map object). Each object definition describes the type of object, its name, unique key, and the number of points that are required to describe the object. Each of the points must be in latitude/longitude coordinates.

```
<ObjType>, <ObjName>, <ObjKey> [, <URLLink>], <NumPts>
<LatitudeValue1>, <LongitudeValue1>
...<LatitudeValueN>, <LongitudeValueN>
```

Each map object has a unique key (a string of characters that identifies the map object), which allows the map object to be linked to attribute data in a database. Each map object may also have an associated URL.

To use the data from an SDF file in a map, you use Autodesk MapGuide Author to link the SDF files to layers in an MWF file. Layers are like transparencies that, when overlaid, display as a single picture. Each layer displays one type of map objects only (points, lines, or polygons). The end user views the MWF files with the Autodesk MapGuide viewer, which sends requests to Autodesk MapGuide Server to provide the data from the SDFs.

In IMAGO for every type of map (context, processes, activities, operative flows and organisation) a MWF file is created. For every type of object that can be inserted into a map it has been defined one or more MLF file with the relative SDF file.

During the IMAGO Web Publisher publication for each object present in the map there is a record insertion in the relative SDF file setting the unique key `ObjKey="<MapID>-<ObjID>"`, where MapID and ObjID are the identifiers of the relative map and object in IMAGO Repository.

Every SDF file is linked with an appropriate IMAGO Repository table. This link is used during the consultation of the maps to visualise only the objects of the requested map. In fact when a reader asks for a map the relative MWF file is loaded and all the layers are set with the clause `Where="ObjKey like '<MapID>-*'"`, where MapID is the identifier of the requested map.

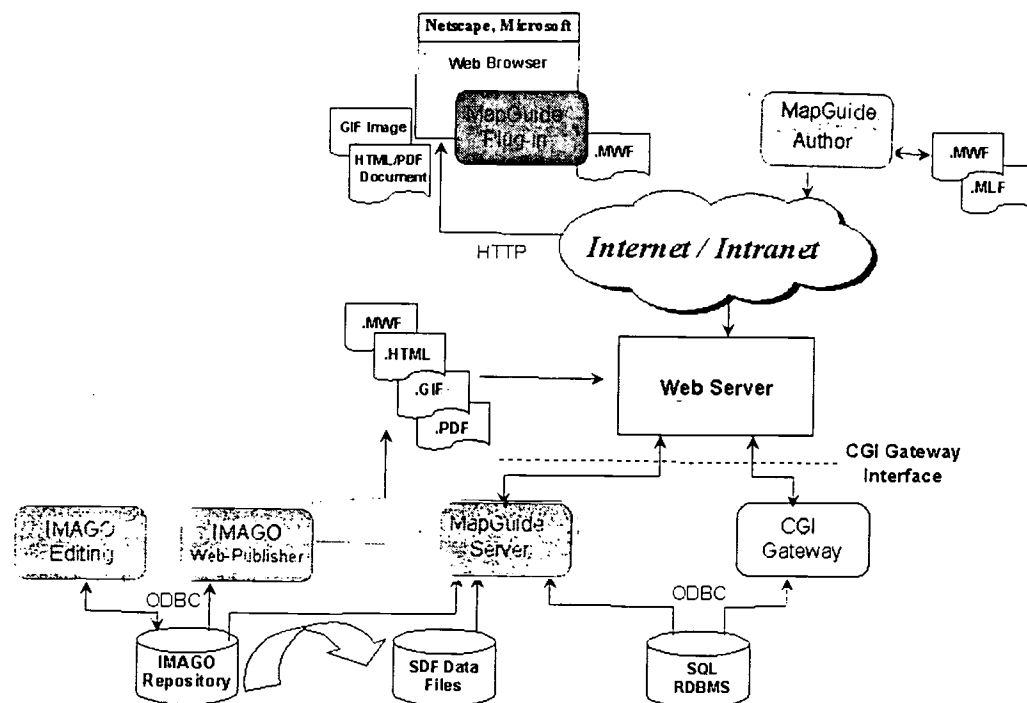

Figure 5: IMAGO architecture

6. Conclusions

It was shown that the design and the consultation of large operation processes have special needs requiring new concepts. The IMAGO project provides some powerful new ideas. It is an approach to editing, managing, publishing and consulting the diagrams of activities, processes, operative flows and the organisation chart. In Telecom Italia Network Direction many operation processes have been modelled successfully. We are currently re-engineering IMAGO Tools to improving the features.

A Study of Asynchronous and Synchronous Discussion on Cognitive Maps in a Distributed Learning Environment

Madhumita Bhattacharya
National Institute of Multimedia Education, Japan
Email: mita@nime.ac.jp

Abstract: A comparative study of use of asynchronous (bulletin board) and synchronous (chat) for discussion on three learning units based on the cognitive maps developed by the learners has been made. We have found that cognitive maps could be an effective tool for learners for discussion in a distributed learning environment. Cognitive maps provided learners to organize their understanding of the learning units. During the discussion session on the Internet the learners were able to exchange their ideas based on the cognitive maps. After the discussion learners modified their cognitive maps with regard to newer understanding of the text. The learners have preferred bulletin board as a discussion platform as it gave them better opportunity to concretize their thought before responding to the collaborating group members.

1. Introduction

There is a strong movement in education today toward a learner-centered model where the learning activities involve students in inquiry and problem solving, typically in a collaborative framework [Duffy, Dueber & Hawley 1997]. We are confident that a highly interactive, learner-centered environment is a worthy goal in higher education and training environment in terms of quality of the learning experience [Austin 1993; Johnson & Johnson 1993]. Interaction is valued as a vehicle for developing metacognitive, critical thinking and reflective thinking skills. In one of his recent publications David Jonassen [Jonassen 1996] explores collaboration as a function of knowledge construction.

Problem based learning (PBL) is perhaps the most widely applied approach to teaching in which the focus of learners' activity is collaborative inquiry and the teacher is a facilitator. We are presently involved in the development of a WWW based system for PBL [Madhumita & Akahori 1998]. We plan to implement bulletin board for on-line and off-line discussion among the members of a group. We also intend to introduce development of cognitive maps by individuals based on their understanding of various concepts and their relations during the self-study. Cognitive mapping is a process for representing concepts and their relationships in graphical form, providing teachers and students with a visually reach way to organize and communicate what they know. Use of cognitive maps during discussion sessions helps in focussing the discussion.

Cognitive maps or concept maps provide a flexible format for graphic representation of concepts and the relationships among them [Jonassen, Beissner & Yacci 1993; Novak & Gowin 1984]. Cognitive maps are hierarchical representations of concepts and propositions that reflect both the content and the structure of a person's knowledge in a given domain. We know that the knowledge content and structure may be different for different people (or change over time for the same person), cognitive maps may help us communicate with each other about what we know or think we know. Visual organizers, in general, can be defined as graphic representations of different kinds of thinking processes [Clarke 1991]. Cognitive maps are a form of visual organizer that, as Clarke has pointed out, supports both inductive and deductive thinking.

In the present experiments the learners summarized the given text material in the form of cognitive maps. In the process of summarization learners must read and understand new information and then transform that information in the form of a cognitive map. Cognitive mappings have been used as a visual organizing technique and were used as a tool for discussion.

2. The Study

The present experiment consists of three steps: 1. Construction of an initial cognitive map based on one's own understanding of the given text material and his/her previous knowledge regarding the concepts in the text, 2. Holding the discussion session using bulletin board and chat facilities over the Internet with the other group members and the teacher and 3. Refining the cognitive maps based on the newer understanding of the concepts.

Fifteen members from different organizations and institutions from different parts of the world have participated in the experiments. Most of the participants were professionals, mostly engineers, therefore, their background knowledge about different aspects of "The Theory of Learning" were same. The three articles chosen for the experiments were: Motivation and Goal Clarity, Learning on One's Own and The Role of Language in Learning. The subjects were supposed to read the given text material on "The Theory of Learning" [Cotton 1995], understand it and develop a cognitive map based on their understanding of the text. The cognitive maps were conceived and produced first on paper and then they were converted into Word or Power Point files. After completion of the individual cognitive maps these maps were sent to the author by fax or as email attachment. These cognitive maps were then delivered to each member of a group half an hour before the discussion session by using fax, as email attachment or as URL.

The subjects participated in the discussion session through the World Wide Web. There were six groups having three and two members using bulletin board and Internet chat respectively. One article was assigned to five participants where three of them discussed their cognitive maps using bulletin board and two used chat. In the discussion session subjects used nicknames in order to keep their original identity hidden such as name, sex and nationality.

The author (nickname: Mita) participated as the moderator in the discussion session. The cognitive maps were considered one by one for discussion in each group. Subjects were asked to explain certain features of their maps. The subjects concentrated on every aspect of a map. They discussed about the individual opinion of the collaborating partners on the given text material.

On an average discussion session lasted for one hour. The discussion took place by using Internet chat and bulletin board developed by the author. Excerpts from the discussion sessions using two different ways have been placed in figure 1 and 2. In order to make the discussions understandable, the cognitive maps produced by Celia and Sakura are given before [Fig. 1] and [Fig. 2] respectively.

Celia's Cognitive Map: Learning on One's Own

Ruth: while the article's title is learning on one's own, I think the author really didn't suggest any tips or ways to study on one's own.

mita: I am thinking about the Celia's map I would like to ask on what she meant by two different human figure

mita: celia do you agree with ruth that the article does not give any tips on learning on your own

Celia: about the figures, one is the learner and the other the teacher, there is an inter-relation, a feed back between

Ruth: For e.g., even in his tips to the instructors he says that either friends or groups are needed to learn . Recall "learning-to-learn work shop" in the text

mita: Actually this text is for teachers who should prepare the students for learning on their own this is my observation

Ruth: Mita! I think you are correct

Celia: One question, do you think these guidelines can be applied in learning at any level? I mean, university, high school, primary school?

mita: Celia in your fig. active transformation and gap filled by teacher etc the arrows pointing to the same box could you through some light on the same

mita: According to me this guidelines could be applied definitely in high school and higher education and with little modifications in primary education

mita: the last two sentences in your diagram convey something

Ruth: I thought these guide lines would be useful at higher levels, I mean in college or universities rather at primary and high school level

mita: yes definitely these are very useful for adult learners

mita: Celia some thing about last two sentences please

Celia: active transformation I think it is talking about the Piagetian words about assimilation and accommodation, what is necessary for learning from the learner and the square is indicating what the teacher can do, then it comes the relation between them. The two lines at the end are pointing that learning by one's own is not a solitary activity, it can't be so.

Sakura's Cognitive Map: Learning on One's Own

BEST COPY AVAILABLE

Hi members!

I must congratulate Sakura for making a lively pictorial presentation for the concept map.

I would like to make the following comments.

M1 I think after the 1st block one block should come. This block should tell the aim and objective because the learner should know what to study and to which extent(i.e., whether surface or deep approach in a time frame manner).

M2 The 3rd block should be little changed. Since this is a topic for Learning on One's own, the teacher need not to spoon-feed. Teacher should help only when the student request him/her to do so i.e. they need some guidance.

Merry

Hi Merry

your 1st comment on objectives is really valid because otherwise students are confused. Sakura has logged in she will contact soon. I am extremely sorry for the delay. I suppose learning on one's own could be successful if the approach is always deep otherwise strategic study is only for scoring marks.

Yes we call pro active (spoon feeding) and reactive (when desired by student) there are two categories. So teacher should be facilitator

Mita

Hi members!

Thank you very much for your clear pictorial view. Here I would like to answer regarding your points, these are as follows:

(1)Yes, the learner must have a particular aim and objective. The approach should not be superficial way, that is why I mentioned highest level of understanding and thinking should be achieved by the learner.

(2)Yes, learning by oneself should not be spoon-fed. But here by the strategy of study, I wanted to mean the proper way of collecting study materials (e.g. compiled brochure for proper library use should be given, important and interesting points on subject should be given to students for clear understanding)

Thank you very much for pointing out for the missing points.

regards,

sakura

Figure 2: Excerpts from Discussion Session (using bulletin board)

Participants using chat found it difficult to respond quickly as they got less time to think before responding. They were feeling some kind of mental pressure to respond immediately and so their responses were not involving much thought. The participants in the chat sessions were unable to gather comments and ideas in order to provide quick response. Therefore, the mental stress was accumulating.

After the discussions the participants modified their cognitive maps based on the newer understanding of the concepts particularly they modified the links among various concepts and added the missing concepts and links. An example of a before discussion cognitive map and after discussion cognitive maps are given in [Fig. 3] and [Fig. 4] respectively produced by the participant (nickname:Yang.)

At the end of the experiment the participants responded to a questionnaire. The responses to the questionnaire revealed that the participants liked the use of cognitive maps for discussion. They were able to focus and think critically with the help of the cognitive maps. Participants preferred the use of bulletin board as compared to Internet chat. They found that the quality of discussions are not very good in case of chat as participants hardly got time to think critically in order to respond.

Figure 3: Before Discussion Cognitive Map (based only on Self-Study)

Figure 4: After Discussion Cognitive Map (modified based on the discussion)

3. Discussion

In the exercise all the participants produced the cognitive maps based on their understanding of the given text material before the discussion session and all of them modified the maps after the discussion. All the subjects participated sincerely in the discussion. Some of the participants were reluctant to label relationships among ideas in their maps, and the first effort of these participants tended to present very less information regarding connection between concepts or ideas.

These differences in the cognitive maps may be explained by the amount of effort that participants put into their maps. As Corno and Mandinach's theory of self regulated learning suggests, learners adapt the level of effort and the ways in which they acquire (attending, rehearsing, monitoring, strategic planning) and transform (selecting, connecting, tactical planning) information to the situation [Corno & Mandinach 1983].

In the most involved mode of learning, comprehensive engagement, learners use all the learning processes and skills optimally. When learners are focused on a task, they emphasize transformation processes of selecting important information, connecting new information to already known, and making tactical plans to achieve the task. When learners are presented with situations that either encourage or force them to manage their resources, they expend effort in finding ways to avoid all or part of the effort (such as working with others to share work). When learners are in a passive position, such as a lecture situation, they receive information and avoid transforming processes. Therefore in this study participants modified their maps after the discussion session because sharing ideas made them identify the missing links and fill the gaps between ideas and concepts, reduce verbatim, etc. The modified maps were more complete. Cognitive mapping as a information manipulation strategy enhanced students' abilities to understand complex materials.

The asynchronous environment affords learners the time for thoughtful analysis, reflection, and composition as discussion of an issue evolves. Furthermore, the discussions are products that the teacher can review and grade and on which he/she can give feedback.

4. Conclusions

The individual cognitive maps produced after self-study could be a useful tool for discussion in a distributed learning situation. The learners could understand the text more thoroughly after the discussion session and modified their maps accordingly. Therefore, in this way cognitive mapping could be an effective organizing tactic in metacognitive and reflective thinking learning strategies.

Discussion in a distributed learning environment offers the potential for realizing the intellectual goals in higher education; to move beyond transmitting information and testing for facts and procedures. Issue-based or focused discussions provide opportunities for modeling of higher-order thinking skills and collaborating members provided cognitive scaffolding. As compared to synchronous discussion asynchronous discussion affords the opportunity for learners to engage in critical thinking. Database of asynchronous discussion affords the teacher to assess learners based on the quality of their thinking.

Schloss Birlinghoven, D-53754 Sankt Augustin

Abstract: In September and October 1998, GMD performed an evaluation of Content Management Systems (CMS) on behalf of one of its co-operation partners, a big German newspaper. These tools should enable interactive and collaborative production of a newspaper on the Web. This paper basically describes the test methodology and the framework for the tests together with the experiences made in running the evaluation. As the number of Content Management Systems is increasing with each new trade fair, the results for the systems under test can only be a snapshot. Therefore, the main purpose of the paper is to introduce the methodology and to give future evaluators valuable hints for their assessment of Content Management Systems.

Chapter 1: Introduction

Producing a newspaper today, on paper or on the Web, is done by work groups of people who are geographically dispersed, who may not share common working hours, and who in most of the cases have a completely different working style [European Commission 1998]. While this kind of freedom is very nice for the individual newspaper editor, certain rules, arrangements and deadlines have to be respected from the newspaper publisher's point of view. In order to keep the obstacles to work in a distributed editorial staff as small as possible, to guarantee a consistent state of the next newspaper edition, and to meet the deadlines imposed, the introduction of an editorship system is very usual and welcomed today.

For online journals and newspapers on the Web it is even more complicated to guarantee consistency as the production speed is much higher, as the number of Web pages to be maintained is growing fast, as topicality is a must to attract new audiences, and as it is technically possible to produce new newspaper editions hourly. A scenario where different editors work together on a common workplace called 'Unix file system' is not acceptable in most of the cases. A special class of Web site management tools are needed here, online editorship systems which we call 'Content Management Systems (CMS)' in this context.

Figure 1: Content Management System Architecture

Content Management Systems [Fig. 1] provide facilities for different members of the editorial staff to review and discuss drafts for Web pages and finally to publish them on the Web. The implementation of different roles is possible, be it author, editor, chief editor, contributor, reviser, Webmaster or publisher. The insertion and removal of Web pages is done semi-automatically while keeping link consistence, the changing of style sheets is simplified. As several products, commercial and with academic origin, are on the market to fulfil these needs [Reibold 1998], a situation analysis, an investigation and an evaluation has to take place before introducing a new system in the publishing work flow and process. In September and October 1998, GMD performed such an evaluation of Content Management Systems (CMS) on behalf of one of its co-operation partners, a big German newspaper [Bissel et al 1998]. The need for a CMS is not only for producing a newspaper, other non profit organizations like the German Government are also planning to produce their Web site with a database driven CMS.

Three steps have to be taken for the quality assessment of Content Management Systems (CMS). First, the quality characteristics, - objective and subjective -, have to be identified together with the customer. Then, the possible candidates for a CMS have to be figured out, again in perfect agreement with the customer. At last, the systems' quality has to be measured in a trial to identify the best fitting candidate [Haake 1997].

This paper is structured as follows: Chapter 2 presents the quality criteria identified in detail. Chapter 3 describes our method to find the candidates for our trial and our quality assessment procedure while chapter 4 introduces the systems under test. Our general findings in performing the trial and the final end results can be found in chapter 5. Chapter 6 concludes the paper with a self-assessment of our work and some hints for the future.

Chapter 2: Quality of Content Management Systems

With a Content Management System (CMS), content and layout components can be stored, retrieved, edited, updated, controlled, and output by a variety of different workers, such as authors, contributors, editors and Webmasters. Each user group has demanding expectations of a CMS with different priorities. Roughly spoken, the Webmaster sets up priorities in the data repository and in the provision of templates whereas the real users of a CMS need an intuitive user interface, beneficial editorial tools and well designed work flow schemes.

If the system will be accepted by the users the update process of an online newspaper will be more and more efficient and economic concerning time and costs. So the definition of the right goals for a CMS as outlined in the next chapter is the most important work during an evaluation of a CMS for an online newspaper or another company or organization. During our evaluation the following quality characteristic categories worked out to be decisive.

2.1 Functionality

Editorial tools: The users are comfortable with text editors, word processors and here and then Web editors (HTML editors). The ideal tool would be the direct change of the components within the Web page via a Web browser ('WYSIWYG'). The import of already existing texts and Web pages must be possible. The editors need to have a look at the structure of a Web page, but can take the content as focus: The tool will provide the correct output.

Data repository: A central part of a CMS is document management. It is important that the data repository consists of a database to facilitate the whole management of the content and the layout components. The underlying database must guarantee consistence and allow concurrent access as well as a backup mechanism. Commercial databases will be the best candidates and provide standard interfaces.

Work flow scheme: One of the main reasons to introduce a CMS is the participation of multiple authors, contributors or editors in producing online articles. Accordingly a well-designed work flow scheme is needed which keeps track of an articles' status, if it is still in work ('draft'), if it has been returned to the author or another reviser for re-work or if it has been accepted in its final form.

User interface: Authors, contributors, and editors are often pressed for time in producing an online newspaper. They will only use a CMS if it gains time. They should not change between a bunch of programs but benefit from one single user environment.

2.2 Management

The stability and reliability of a CMS implementation tips the scales. The amount of downtime and error messages and the average update time of storing and retrieving an article are stability features. They are decisive for the acceptance among the editorial staff.

2.3 System Requirements

Naturally, the CMS has to meet special hardware and software requirements and standards, according to the existing environment of the special customer. There are preferences for some operating systems, Web server or database products, and output utilities are needed for the exchange of data with other systems.

2.4 Costs

Even if the amount of costs for a CMS should not be the decisive aspect in such an evaluation, it has to be taken into account. It is important to distinguish between the costs for the software, for training, for the switch from the old software environment to a CMS and the ongoing costs i.e. maintenance costs.

2.5 References

It is very important that the winner of the evaluation has successful implementations within similar companies or organizations which can be interviewed or even visited.

These categories were the base for the single test sequences (as described in the next chapter) the different user groups had to walk through.

Chapter 3: A Test Methodology

3.1 How to find Candidates for a Content Management System

The business and the requirements of the special customer who wants to implement a CMS are in the focus of the test methodology. So what we did at the very beginning was to make an inquiry among the biggest German online newspapers with a daily update cycle to find out if they benefit from a CMS. The sobering result was that only a minority of the online newspapers use commercial Content Management Systems. Some of them have homebred solutions only fitting their specific criteria, but the biggest part of them use Web editors and their own scripts tailor-made for their daily work.

With a market survey we complemented this inquiry to a bunch of CMS out of which we identified together with our co-operation partner the first five as candidates for our evaluation study. We do not claim the list to be complete.

3.2 How to evaluate a Content Management System

When trying to find the most appropriate system, we were confronted with a multi-criterion decision problem. It is obvious that there is no single overall criterion that reflects the quality of such a complex system. The situation gets even more complicated when the different user demands towards a Content Management System are taken into account.

For this kind of decision problem, the use of a benefit value analysis can lead to the right system for one's needs [Zangemeister 1993]. The starting point for a benefit value analysis is to set up a hierarchical goal system. Each alternative's goal productions are then determined. All goal criteria have to be weighted, so the partial benefit values can be accumulated afterwards in order to build a single benefit value for each alternative.

The resulting preference score is demonstrable and can be subsequently screened. On the other hand, the subjective goal weights can be manipulated to get the desired preference score. To review the influence of varying goal weights on the decision made, a sensibility analysis should be performed. An important gain of a benefit value analysis is the clarification of the needs by setting up a goal system.

A weak point may lie in the way the accumulation of the partial benefit values is done, because it assumes that the partial benefit values can be measured cardinally and the criteria are benefit independent of each other. Done accordingly and with these restrictions in mind, the benefit value analysis is a valuable tool for solving multi-

criteria decision problems.

3.3 A Finite Test Plan

Due to time restrictions, - we had given only 4 weeks to perform the test -, a complete benefit value analysis could not be performed. However, our evaluation was partially based on its concepts to ensure transparency.

In co-operation with our partners, two lists of criteria were drawn up, one reflecting a system administrator's point of view, another the editor's. A single criterion was weighted as being 'crucial', 'nice to have', or being 'less important'. Each system had to be examined with regards to these criteria. This was done in descending order of preference by

- installing an evaluation version of the system and creating a demonstration project on which the work of an editorial office could be simulated.
- getting an account on a demo system supplied by the vendor.
- reviewing the available product documentation and investigating reference customers.

Though the most time consuming method, getting and installing an evaluation version of the software offers the most valuable experiences on ease of installation, system management needs, hardware requirements, performance, and stability. We jumped by ourselves into the different roles within a newspaper editorship.

Chapter 4: The Systems under Test

InfoOffice, StoryServer and NPS were the only systems out of the enumerated systems in chapter 3 that fulfilled the requirements of a Content Management System. We did not test the other systems according to the arrangements with our co-operation partner.

4.1 InfoOffice by InfoOffice

InfoOffice is designed for the management of middle-sized Web sites. It consists of different components to separate the content and the layout of a Web page. The template editor is the so-to-say layout tool that allows Webmasters to define the general structure of a Web page. The templates may contain different types of objects such as links, texts, graphics, database requests, or containers (which specify a special area of the Web page and again may contain another bunch of structural elements). Based on these templates the authors, contributors, and editors are able to fill the substitutes with the according content.

The InfoOffice Client gives the editors a limited view on the templates corresponding to their responsibilities and access rights. Access to a limited subset of the functions is also possible through Java Applets. The combination of the templates and their embedded objects with the Web pages is stored in a flat file database.

The construction of the final Web page is the task of the InfoOffice Generator which combines the layout and content components to a static Web page. This Web page may be exported via ftp to any Web server. The InfoOffice tools themselves can only be implemented in a Windows environment, but the Web Server could be any of the known Unix Web servers.

If the intention is to build up the Web pages dynamically i.e. via a database, the Web server and the database have to run in a Microsoft environment. The InfoOffice Manager is the central tool for user and access rights management.

4.2 NPS by infopark online service

NPS (network productivity system) is a Unix based Content Management System for medium-size Web sites. The system will export static Web pages which can be transferred to any Web server. The contents in form of HTML pages or generic documents are stored in the file system. All object attributes are stored in a relational SQL database. Link management, time-based publication and archiving of contents, indexing using predefined keywords, allocation of access rights, logging, job control system, definitions of work flow for the coordination of the online publishing, and user management are provided.

The contents are organized hierarchically in publications. Layout of contents can be based on templates or freely defined. Not only plain text or HTML documents but also other text or binary formats can be integrated (mif, rtf, gif, jpeg, etc.) or may be converted via an import interface.

Development and user management can be done via HTML forms. Besides this a more powerful TCL-interface is provided to automate tasks and by which extensibility is ensured.

Users only need a forms enabled Web browser to access the system. Different system views are provided and

can be customized. Several content attributes can be set, others are set by the system automatically.

4.3 StoryServer by Vignette

In contrast to the other systems in the evaluation, StoryServer is a dynamic solution. The content and layout templates are stored in a RDBMS, Web pages are dynamically generated on user request. To minimize the impact on system performance due to dynamic page generation, the caching of pages and frequently used page components is provided.

The layout of the Web pages is controlled via templates and completely separated from site content. In addition to content management, StoryServer provides application server functionality with database access and tools for Lifecycle Personalization. XML and the ICE (Information and Content Exchange) protocol are fully supported.

The system architecture consists of a content management server based on a database (RDBMS) to store content, templates and system configuration. Access to the content is achieved by application servers, one for development purposes and another to serve the live Web site.

The StoryServer tools are a suite of Java applications that allow content and project management, site development, user administration and overall system configuration and provide facilities related to personalization and log analysis.

Content entry and modification are done through HTML forms, contributors only need a Web browser. It is possible to define a work flow for the publishing process, so that chief editors are informed on new submissions and must review them prior to making them available on the live server. Articles can have both a launch and expiration date assigned that automatically controls the availability to site visitors.

Chapter 5: General Findings

5.1 User Interface most important

It is not possible to rate the different systems without having implemented them and tested them in practice with real editors. There are systems that impressed through a great fulfillment in the range of functionality but that were extremely complicated in the day-to-day operation. A simple Web user interface with intuitive functions is most important. Best case it must be possible to change a link or a text component without any special training.

5.2 No short-term Decision

The introduction of a Content Management System has effects on the management of data, on the work flow of the Web page production from scratch, and on the costs of an update process. Consequently the decision for a special CMS should be a long-term decision. A competitive and innovative Web Site with brand new contents should no longer be managed statically but dynamically, with all its layout and content components stored in a database and retrieved out of a database vice versa. The content should be XML tagged, in doing so the CMS should be able to interpret XML tags and retrieve special metadata information out of them.

The importance of such a long-term decision should be mirrored in the budget being available for the software and hardware requirements as well as for the training of the authors, contributors and editors. The costs for the upgrade and migration of data and the change of the work flow scheme of the production cycle must not be underestimated as well.

5.3 Benefits are obvious

„Some say that a CMS is a money pit where the spending continues for ever. That is true - but it is a positive thing, ...“ [Kartchner 1998]. The benefits of a CMS predominate the costs of a CMS. One large benefit is the same software environment for all workers, if they are part-time or full-time, newcomers or experienced ones. Additionally the amount of manual work will decrease more and more and consequently the costs of an update process too. Another great advantage is the availability of the content in a usable electronic form over years. With a return on investment model [Kartchner 1998] it has been shown that the reducing of costs with a CMS only begins in the second edition that means in the second year of a CMS in comparison with other publication methods.

5.4 Best Fit

From our evaluation candidates, we chose StoryServer by Vignette as the best forward-looking solution, in spite of its exaggerated costs. StoryServer does not fulfil all of the quality criteria which cannot be expected from any

system but most of them in comparison with InfoOffice and NPS. StoryServer is best suiting the management of large-sized Web sites where the biggest advantage is the storage and retrieval of all components within a database in a UNIX environment. The software and its documentation seem to be professional as well as its manufacturers, the user interface is a simple Web interface.

5.5 No general solution

Among web publishers, the need for a scalable, dynamic CMS is growing, the German Government for example, is also planning on basing their Web site on a database driven solution. StoryServer is not the best fit for all types of Web publishing due to its price tag and often unneeded functionality, especially for smaller or nonprofit Web sites.

DynaBase by Inso (<http://www.ebt.com/dynabase>) is a CMS we discovered after our evaluation. Unfortunately, although the product features look promising, we couldn't get a test installation or anything else from Inso, so we decided not to further consider DynaBase.

Our continued search has led to finding CoreMedia Content Publisher (COREM) by Higher-Order (<http://www.higher-order.de/Produkte/GOODNews/index.html>) with a better cost-benefit ratio. This modular system is built on open standards like CORBA and Java, based on a standard RDBMS and it is able to produce static as well as dynamic pages. Although COREM is a relatively new product that is missing some advanced features, these will be added during the next months by Higher-Order or can be developed by ourselves if needed to a nearly '100% solution'. Besides that, we will continue watching the market.

Chapter 6: Conclusion

The assessment of objective quality characteristics for Content Management Systems like performance or management (see chap. 2.2) relies on numbers to be measured. Once defined, the assessment can be automated by robots or intelligent agents and it can be repeated whenever the customer wants it.

Most of the quality characteristics however are subject to individual assessment and by that subjective like 'ease to use'. You really need a real-life user group here and you really have to go through the trails with them on and on. Depending on the people in the user group, you will get different assessment results. With respect to the time constraints given, - the test should be performed within 4 weeks -, we had no chance to work with a user group in our trial at all.

The understanding of Content Management Systems and their benefit value relationship at our contractor's side was only sharpened during the trial. The amount of resources needed to perform a successful test was underestimated. Particularly the lack of a goal system finally led to unpredictable results.

However, with our results we provide input for future evaluations and we started a discussion in the big German newspaper. The decision for the right Content Management System together with the introduction of a database management system will be made in 1999, months after our trial.

Abstract: This paper presents Scriba — a tool that facilitates the development of Java based Web applications. The tool allows the creation of script languages that can be embedded in HTML pages in order to process data dynamically. As well as the advantages of the use of Java technology, the structure in the tool's software components allows its users to redefine its functions, expanding or recreating its basic language. The AulaNet environment is an example of application developed with Scriba.

Introduction

The evolution of Java technology has made it possible for new approaches for the development of Web applications to appear. These applications possess diverse parts that may be organized in the form of software components, making the most of the potential offered by object oriented languages like Java. The software can be seen as a group of interconnected components that cooperate in order to promote the operation of the whole environment.

This paper presents Scriba, a tool that interprets commands for the fast development of Java based Web environments. Scriba makes the construction of Java based Web applications easier and quicker. Through specific markings in its language, Scriba enables data to be put on the pages in loading time. As well as possessing dynamic creation of pages with HTML templates, Scriba also makes the use of user defined script languages viable through expanding its language or substituting its command interpreter.

Scriba is being used in the development of a new version of AulaNet [Lucena et. al. 1999] an environment for creating and attending courses on the Web. The following sections give details of Scriba's own language and the way it operates.

Servlets and JDBC

The latest versions of Java incorporate two new language mechanisms used in the development of network and database applications known as servlets and JDBC. The new extension package for the Java Development Kit

1.1 (JDK 1.1) intended to be a Java substitute for CGI programs (Common Gateway Interface) is known as a servlet [Siyam and Weaver 1997]. With servlets, users can add new functions to HTTP servers.

HTTP servers that possess a servlet API provide an environment with all the resources that the servlets need to operate, and a model of security that maintains the integrity of the system. Servlets can contain any Java function or package that does not have graphic interface. They can read or write in files, process calculations, communicate with databases and create HTML files, functioning like a traditional CGI program, with the advantages of the Java language in terms of structuring in components and performance.

The latest versions of Java also incorporate JDBC [Hamilton, Cattell and Fisher 1997]. JDBC is an API for the execution of SQL statements on any relational database. The API of the JDBC allows users to write database applications using a purely Java interface. The JDBC carries out the following main operations: it establishes a connection with a database, sends SQL statements and processes the result. This solution is the one adopted by Scriba to communicate with users' databases.

Scriba

Scriba is a tool for creating dynamic HTML pages and defining Java classes to implement the processing of Web applications. Scriba offers a basic language that allows one to consult ODBC databases, exchange values stored and invoke user defined classes for the realization of functions specific to the application's domain.

Users who wish to implement Web applications using servlets and Java find the necessary elements in Scriba for the implementation of the whole application using HTML pages and Java classes. HTML pages can have the Scriba code embedded in them that carries out, among other things, data searches in any ODBC database. The Java user defined classes bring together the specific functions of the application in development. Scriba deals with all the control operations and creation of objects for the functioning of the servlets, communication with ODBC databases and operations referring to interpretation and execution of the commands of its language.

One of the main characteristics of Scriba is the possibility of configuring its functions through the user redefining its components. The structuring of Scriba in software components interrelated with well defined interfaces allows its users to rewrite most of its components. They can adapt Scriba to interpret any other language. There are two types of configuration of the Scriba functions: users can extend the basic language supplied through creating new commands in the interpreter or they can define a completely new interpreter for Scriba.

Scriba is made up of three basic components: a token divider, a command interpreter and a HTTP request receiver. Figure 1 shows the Scriba architecture and the classes that compose each of its components.

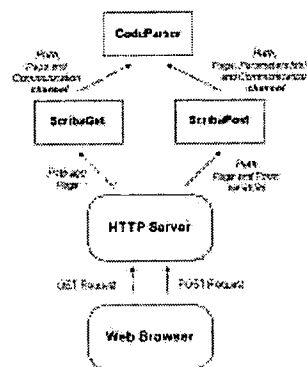

: Scriba components and classes.

The token divider is made up of two classes: *Parser* and *CodeParser*. This component is responsible for reading HTML templates and for checking the existence of the boundaries of its language. When a language token is found within the boundaries \$* and *\$ the divider passes this token to the interpreter so that the actions referring to the language command contained in the token may be taken.

The command interpreter is composed of the following classes: *InterpreterInterface*, *InterpreterException*, *Interpreter*, and *UserClassInterface*. So that the users write specific interpreters for their languages, the *InterpreterInterface* class supplies a pattern that a new class should follow in order to be defined as an interpreter in Scriba. The *Interpreter* class obeys the *InterpreterInterface* specifications through inheritance and implements the actions corresponding to each of the language commands. The *InterpreterException* class deals with all the errors created in the interpreter, standardizing the messages and explanations about the problems found in the interpretation of the commands. The last class of this component, *UserClassInterface*, defines the format that all the user defined classes for processing form values should present.

The HTTP request receiver receives the parameters passed by the HTTP server when a page is requested using the GET and POST methods. This component carries out all the necessary operations to implement the Java servlets and trigger the token divider to search the HTML template indicated looking for language tokens. This component is made up of the following classes: *ScribaGet* that deals with GET type of requests, and *ScribaPost* that deals with POST type of requests.

Figure 2 presents the execution flow provoked by the *ScribaGet* and *ScribaPost* classes for each request made to Scriba.

: *ScribaGet* and *ScribaPost* execution model.

After being created by the *ScribaGet* and *ScribaPost* classes, objects of the *CodeParser* class inspect the HTML template supplied and pass the tokens found to an object of the *Interpreter* class that will take the necessary action according to the language commands. The basic language commands defined to implement AulaNet will be presented in the next section.

Operational Details

In order to implement Web environments with dynamic pages, Scriba has a basic language conceived from the necessities found in the development of AulaNet. The Scriba language has commands that search for values in ODBC databases and create user defined classes. There is also a syntax so that the user can expand the language without having to redefine the interpreter completely.

The language embedded in the HTML files obeys the following general rules:

BEST COPY AVAILABLE

1. So that the code divider recognizes the existence of the commands embedded, it is necessary for them to be delimited by a marker at the beginning of commands (`<`) and one at the end of commands (`>`).
2. Scriba recognizes commands separated by `
` inside a HTML template. If it is necessary to define more than one command in the same place in a file, the user can use this construction: `<command1>
<command2> ... <commandN>` .
3. The command lines may be situated in different places in the file, however the argument and the command name can not be divided among various lines of text.

In order to construct Web applications Scriba has 8 commands as follows: *database.open*, *database.close*, *database.select*, *database.select.set*, *database.select.set.pattern*, *class.new*, *form.parameter*, *language.expand*.

The *database.open* command is responsible for creating a reference to an ODBC database. Its argument is made up of the name of the database registered in the ODBC (DSN). This command does not return values, it just prepares the database to receive SQL requests.

The *database.close* command closes a database previously opened by *database.open*. This command does not have arguments and does not return any value. Scriba uses a *DataManager* denominated class to provide the communication services with the database. This class brings together the calls to JDBC API that implement the JDBC-ODBC bridge.

The *database.select* command allows the execution of a SQL SELECT statement about the database previously opened by *database.open*. Its argument is the SELECT statement and its return value is composed of one unique field returned by this statement. If the return of the SELECT statement implied more than one field or line, the *database.select* command would only return the first field of the first line, ignoring the rest of the values returned. For example, if the command found were *database.select:=SELECT Name, Account FROM Users*, the return of the SELECT clause would possibly be made up of more than one register containing the name and number of each user's account. Even if the SELECT clause executed returned more than one register, Scriba would only inform the value of the Name of the first user register. In order to carry out clauses like the latter example, Scriba has a special syntax of the *database.select* command which is the *database.select.set* command.

The *database.select.set* command creates a table with the values returned by a SQL query statement internally in Scriba. This command does not have a return value and its argument is composed of the SELECT statement. In order to have access to the fields stored in the table the user should indicate which pattern is to be repeated changing the fields indicated by a value in the table. The syntax used to define the repetition pattern is the *database.select.set.pattern* command. Figure 4 shows how Scriba executes the *database.select.set* command.

The *database.select.set.pattern* command has as its argument any text that will be repeated for each line in the table of returned values. Within the argument of this command, the user can indicate to Scriba one of the fields to be changed dynamically by the values in the table through the *set.name_of_field* syntax. Returning to the previous example, the *database.select.set:=SELECT Name, Account FROM Users* command would be executed, creating a table with the returned values by the SELECT clause. The user could declare, for example, the command *database.select.set.pattern:=<tr><td>set.Name</td><td>set.Account</td></tr>* to create an HTML table with the returned values of the select clause.

The *class.new* command creates a class object whose name is indicated in its argument. The object is created dynamically by Scriba to carry out Java based user defined operations. With this command Scriba allow users to program sections of Java code to make specific processes with its application. The whole class created has access to the HTML form variables, allowing the implementation of programs that deal with data like the majority of languages do. For a user to create a class that can be declared in the *class.new* command he should define the class as child of the *UserClassInterface* class of the command interpreter component. When inheriting the characteristics of *UserClassInterface* through the IMPLEMENTS declaration in Java, the user will know which methods he must create and the parameters that he will receive in his class.

If a user wants to have access from his page to some variable declared on a previous form, he can use the *form.parameter* command. This command possesses as a argument the name of the variable that he wants to have access to and returns its value. With this command the user can pass values between different templates without having to retrieve these values on all the pages.

If it is necessary to expand the Scriba language, the user can use the *language.expand* command. This command allows users to create a class that implements the *InterpreterInterface* interface to interpret a proprietary language expanded in relation to the tool's original language. This class should have an action method that will receive a token and process it, identifying the command involved and carrying out the corresponding action. There is no limit to creating classes of this type.

Scriba allow users to rewrite the main parts of two of its components: the token divider and the command interpreter. In order to guarantee compatibility between the Scriba component parts and the parts created by the user, two classes are supplied: *Parser* and *InterpreterInterface*. The *Parser* class should be inherited by the user defined class that will substitute the *CodeParser* class. The *CodeParser* class is useful to break the HTML template tokens. If the type of template or the language markers of the user need to be changed, all that has to be done is to rewrite the *CodeParser* class according to its new definition, inheriting the characteristics of the *Parser* class.

: Scriba architecture and flexible points.

If the language to be interpreted is completely new, the user can define a new *Interpreter* class with the language commands and their respective actions. This new class should implement the *InterpreterInterface* class, inheriting its characteristics. The new interpreter should receive tokens from the *CodeParser* class and identify the statements of its language within these tokens, creating a convenient return value for each type of command interpreted. Figure 3 shows a view of the Scriba architecture, identifying its flexible points.

Scriba for AulaNet

Scriba was invented within the philosophy of the creation of Web based cooperative software environments that use databases to store their information. AulaNet is a case of the application of this technology. There are plans to modify the AulaNet architecture, using Scriba and Java, to restructure it in object oriented components that integrate to offer the services supplied by the environment.

AulaNet is an environment for creating and attending courses through the Web. Teachers in AulaNet can create courses by selecting a set of communication, cooperation and coordination mechanisms. After choosing the mechanisms for a course, teachers can input the content that will be seen by the students. The students can communicate and cooperate to construct knowledge and carry out activities in groups. As it facilitates the creation of courses through selecting mechanisms and inserting materials AulaNet is considered a high-level solution for low-end users.

AulaNet is made up of a group of HTML pages, CGI Lua scripts [Hester, Borges and Ierusalimschy 1998] and an MS Access database. The CGI Lua tool allows the creation of dynamic HTML pages and the processing of HTTP requests. CGI Lua possesses a library for communication with ODBC databases. AulaNet uses Microsoft

Access to store its data. Approximately 90% of the functionality of AulaNet is implemented using these components. The other 10% is made up of freeware software and two commercial softwares, offering the main part of the communication functions supplied by the environment.

The strategy adopted to substitute CGI Lua with Scriba will be guided to reduce the number of files in the software. The programs that would be executed in the templates to compose the page dynamically will be transformed into one or more Scriba commands, as they only use database functions. The Scriba functions map out the majority of the actions performed to search for data and exchange parameters in the templates.

The new version of AulaNet should benefit from some improvements brought about by the use of Java technology, like the portability of the programs developed. Another improvement brought about by the use of Scriba is the access to databases. As AulaNet uses the Access database, some concurrency problems were identified when various simultaneous accesses were performed in the database. The use of the JDBC to access the database reduces the problems of concurrency, as all the access methods used are synchronized by the monitor mechanism implemented by the Java language.

There are plans to create a software documentation pattern, benefiting from the reduction of files brought about by Scriba. The number of files in the Scriba based version of AulaNet should be approximately 50% less than the number of files in the current version, based on the experience of implementing 25% of the software already made until now.

Conclusion

Scriba, a tool for creating Web based applications, aims to simplify the creation and maintenance of Java based applications. Scriba adapts well to the types of applications that store information in ODBC databases. In order to implement its capabilities Scriba possesses a component structured architecture.

To facilitate creating dynamic pages Scriba has a language that executes SQL statements and creates user classes. The Scriba language also has the capability to recognize extended commands, allowing users to broaden the capabilities of its language without having to change the Scriba components. Another interesting characteristic of Scriba is the possibility to redefine the tool's components. Users can redefine the language to be interpreted and its markers through the redefinition of the classes responsible for the identification of language tokens and command interpretation.

Some improvements can already been identified for a future version of Scriba, according to the results obtained in its use:

- extension of the basic language;
- capacity to insert code directly in the script;
- a new approach for developing TCP/IP generic servers and clients by the definition of their communication protocol.

Finally we aim to develop Scriba so that it can possess a form of graphic representation of applications that allows the creation of a tool for the semi-automatic generation of programs. This will enable users to specify the application with graphics and create pages that compose it visually, avoiding contact with the code prematurely.

W3Gate - The Final Case Study

Manfred Bogen

GMD – German National Research Center for Information Technology,
Schloss Birlinghoven, D-53754 Sankt Augustin
Tel. +49-2241-142944, Fax: +49-2241-142095, E-mail: manfred.bogen@gmd.de

Abstract: This paper is the last paper about W3Gate, a gateway which allowed the access to the World Wide Web through electronic mail. It is about an approach to turn an academic project into a commercial one and about a marketing strategy which unfortunately failed. The purpose of the paper is to document and close the chapter W3Gate finally and to give software developers valuable hints for a successful marketing of their software.

1. Facts about W3Gate

W3Gate was a gateway between email and the World Wide Web (WWW) that enabled email users to retrieve multimedia objects in the Web. This could be done independently of the email protocol used, be it Internet or OSI mail, and asynchronously. An email sent to the address 'w3mail@gmd.de' requested WWW, FTP, WAIS, and Gopher documents. Even password-protected documents were retrieved by specifying the respective userid and password within their URLs [Berners-Lee et al. 1994]. Plain files (HTML, pictures, audio, video, ...) could be fetched through W3Gate and search requests at search engines like AltaVista, Lycos, or infoseek could be performed.

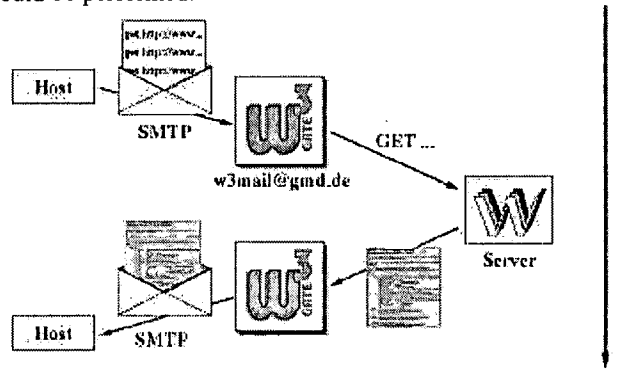

Figure 1: The W3Gate Functionality

W3Gate supported raw and formatted documents, encoding and compression, text and postscript versions, multiple documents, MIME, and partial messages. Files were accessed via *HTTP*, *FTP*, *GOPHER*, and *WAIS*. Users from more than 80 countries were using W3Gate regularly. They were from universities and schools but also from profit organizations. [Fig. 2] shows a typical user distribution among top level domains.

Figure 2: W3Gate Usage per Country

Since W3Gate started its work in May 1995 the number of transmitted files grew to 700.000 files a day. Simultaneously the traffic increased to 20 GB per month. Some declines in the usage-statistics were caused by operational problems and misuse. Finally, people used W3Gate in spite of our announcement about its end of service until the very end.

Figure 3: W3Gate Overall Traffic

Under the influence of these numbers, the statistics gathered, the service's success, and the demand of different organizations to have the software, it was finally decided to start a commercially oriented project based on W3Gate. The goal was to get additional funding for maintenance and further development.

This paper is structured as follows: [A Marketing Plan] reports our marketing strategy. [Marketing Activities] describes our attempts to make the W3Gate software distribution a success. [Marketing Results] outlines our achievements while [The End and Lessons Learned] describes the bitter end of the service and our general findings.

2. A Marketing Plan

A few questions had to be answered in defining a successful marketing plan:

1. Who buys the product and/or service and why?
2. Where are the competitors and what is their marketing strategy?
3. What is the best sales strategy in advertising and promotion?
4. What are the best dealerships and/ or distribution channels to get the product to the market?

2.1. Who and Why?

Studies of German publishers about the WWW usage had shown at that time that only in some cases (shopping, entertainment) a real interactive component was needed [Fig. 4]. The rest of the WWW usage was information or data retrieval which could be covered by asynchronous electronic mail requests perfectly.

Figure 4: General WWW Usage

We therefore saw several different potential customer groups to buy our software:

- Mail(box) service providers wanting a Web gateway as additional service for their customers.
- Content providers wanting W3Gate as integral part of their WWW information offer for the convenience of their readers.
- Companies with an Intranet providing their employees with a secure Web access via a gateway/proxy.
- Firewall manufacturers wanting W3Gate as proxy server for network security purposes.

2.2. The Competitors

There were almost no other competitors in the market. Other systems like the agora system [Secret 1994] had stopped their service in the meantime due to traffic load and resources consumption. We thus had a high-quality product or service with a strategic position in the market together with satisfied clients who trust in the product or the service, and reliable, enhanced, and sophisticated usage statistics.

2.3. A Sales Strategy

At first, we saw different possibilities to sell W3Gate:

- as public domain software,
- as shareware software,
- as a real licensed software product,
- as service in different gradations: a basic, limited service free of charge, and an advanced service for authentic customers,
- as basis for a co-operation with a potential partner where GMD should only be responsible for the technical enhancement of W3Gate,
- as regular, value-added service operated and billed by GMD, or
- as a regular, value-added service on behalf of a co-operation partner or funded by sponsors.

The first two alternatives meant no obligations for us at all but could not bring additional funding for further development. For a real, paid service however we had needed a performing accounting and billing mechanism, and a secure payment method which we definitely did not want to establish. Finally, we decided to follow two commercial paths: to sell software licenses to interested parties and to establish a service on behalf of a sponsoring third party, interested in W3Gate's feature to attach commercial information to the HTML documents originally requested.

2.4. Dealers and Distributors

As we were (and are) no marketing experts and as we wanted to concentrate on further developments we did not want to do the marketing for W3Gate by ourselves. We finally found a co-operation partner with promising contacts and experience willing to support us in following the W3Gate commercialization path.

3. Marketing Activities

A license agreement for the software sale and a co-operation agreement related to a sponsored third-party-service were signed. The distribution of tasks was rather straight forward: GMD was responsible for the W3Gate technology, our co-operation partner for the sale, the marketing, and the advertisement. W3Gate was integrated into the product offer of our marketing partner at once.

3.1. Licensing

We set up a licensing scheme with different service levels and different prices depending on functionality wanted and the size of a customer's company or organization (1-15, 16-50, 50-1000, > 1000 employees). The service levels started with the software package itself plus online documentation and ended in a package with the software, printed manuals, installation support, and hotline access.

3.2. Sponsoring

Sponsoring is a quite common business model within the Internet. Most of the Web indexes and search engines are funded this way. Sponsors want something in return for their financial engagement. So we implemented the ability to attach sponsor information to the documents requested through W3Gate.

The sponsors were planned to pay for the number of banner views per month. A banner was allowed to be 400*100 pixels (12 KB) and could include 4 lines of text with 80 characters each in order to avoid overloading the W3Gate replies. Apart from a fixed set-up fee for the service (ad-server)and the banner itself, we offered 4 different packages (containers) starting with 1000 electronic mail messages transporting the banner a month

and ending with 100.000 electronic mail messages containing the banner. The more banner views a sponsor was willing to buy, the cheaper the price for one single banner view should be.

3.3. Promotion

We promoted W3Gate from the very beginning and quite successfully [see Bogen et al 1996a]-[Bogen et al. 1997c]). It started with a poster during the WWW4 conference in Boston in 1995. After that we were present at all subject-related WWW/Internet conferences at that time like JENC7 in Budapest, JENC8 in Edinburgh, INET'97 in Kuala Lumpur, and finally WebNet97 in Toronto. Additionally we gave talks about W3Gate on national and international workshops and user group meetings (W3C, DECUS Munich). A few articles in computer-related German newspapers described the W3Gate functionality. Some books about electronic mail additionally also mentioned W3Gate as a good and performing example [Rudolph 1998].

While the papers and presentations mentioned were targeted to the scientific community and end users, we also tried to get in contact with real customers. We exhibited W3Gate at the Systems'97 in Munich [i.e. the 16th international trade fair for information technology and telecommunications], the OpenNet conference 1997 in Berlin, and at the CeBIT'98 in Hanover, which is the biggest trade fair for Office, Information, and Telecommunications in the world.

Our performances were accompanied and supported by the corresponding written marketing material like product sheets, price lists, posters, flyers, logos, contact sheets, and articles in the brochures of these trade fairs. It was sent in time to hundreds of addresses of potential customers especially in the computer and information technology industry. Information about W3Gate was offered to the editorial offices of journals and newspapers for publication and people were invited to visit the W3Gate stand booth. During those fairs, we actively tried to establish contacts to new customers by visiting their booths. Additionally, we offered special discounts for the duration of the trade fairs.

Our addresses of people/organizations interested in obtaining the W3Gate software collected over the years were used by our marketing partner for contacts and to ship latest information about the new order possibilities and our pricing scheme. News about W3Gate were published in GMD's monthly newsletter to about 2.000 service customers.

A WWW server 'www.w3gate.de' was maintained providing information about the functionality, the usage, and the licensing of W3Gate. W3Gate appeared on our companies homepage as central GMD service. We had separate e-mail contacts for sales and support and a frequently-asked-question file (FAQ) for the online visitors.

4. Marketing Results

We started a lot of activities, but our marketing plan did not work out.

4.1. Software Sale

Only a few numbers of contacts were made during the trade fairs. The contacts made to firewall suppliers were not very promising. Their initial interest disappeared very soon after the trade fairs. It turned out that our first pricing scheme was too high. As a result, the plan to attend Systems'98 in Munich and the idea to sell W3Gate to end users was completely dropped.

4.2. Sponsoring

We talked with the German Research Network Association (DFN), the IP Service Provider for the scientific community in Germany, about offering a W3Gate service together with other central value-added services. Unfortunately, it turned out that IP Service Providers (ISPs) prefer to invest into the backbone itself rather than funding a bypass for connectivity problems.

4.3. Ad Services

We made some tests with banners added to the W3Gate messages on behalf of a company selling banner views. Based on the usage statistics provided by us, W3Gate seemed to be a promising option for them. The results of the test were really disappointing. 100.000 mail messages were sent in the test period and they resulted in 100 clicks to the banner advertisement appended. This was completely unusable for advertisement. A percentage of 1-3% is normal. W3Gate users seem to concentrate on the information requested and filter the advertisement completely out.

5. The End and Lessons Learned

Finally, the author and 2 W3Gate developers left us for different reasons. Together with our failed marketing attempts this made us stop our service first and our commercialization activities next. We announced the end of the W3Gate service quite in time. Each document requested through W3Gate had this

information as additional body part/ attachment with it from August, 20th 1998 on. Additionally, we propagated this fact in our national monthly newsletter and we sent it to the people in the customer database. We still offered the possibility to buy the software for one's own purposes, but the reaction was minimal.

Figure 5: W3Gate usage per content

What went wrong? The high usage until the last day shows that lack of functionality was not our problem. By analyzing the statistic numbers we found out that W3Gate had been used for 'real' work and not for retrieving anonymously files with strange contents ('sex', 'girls', 'porno') [Fig. 5]. In principal, there should have been serious customers and chances to sell the software or to find a sponsoring co-operation partner.

5.1. No Plug-in Available

It would have been very convenient for end users to have W3Gate as a plug-in for a WWW browser. Each time they wanted to have an HTML page referred by an URL to be sent to them without waiting (asynchronously), they could have just pressed a button starting a job for W3Gate to fetch the referred document and send it to them through e-mail. Unfortunately we had no contact to the WWW browser industry (Netscape, Microsoft etc.) to discuss this possibility with them and somehow we additionally felt that these companies could develop a software like W3Gate much faster and better than us if they only wanted to.

5.2. A High-quality Service Free of Charge

There was really no need to buy the W3Gate software as long as there was a high-quality W3Gate service with almost no restrictions. We had an academic interest in the software and therefore wanted to have a testbed for further developments and new ideas. However, finally the service operation was counterproductive to the marketing and sales activities.

5.3. An Inappropriate License Model

An appropriate license model is the most important factor in a successful marketing strategy, sometimes even more important than the quality of the software itself. We had the wrong one. The right way to do successful marketing for a software package is:

- Maintain a public service for interested users free of charge (what we did).
- Give the software (binary code) away to the academic community free of charge to do research and development with it (download) and make it known by that and people used to it.
- Give test licenses to commercial users/customers free of charge who do not want to use the central service for whatever reasons (security!) and who want to install it in their premises (download). This should be done with restricted functionality only, where the restrictions may apply to the number of users at a time or to the time period for the trial. After the trial, licenses should be required.
- Make reasonable, small prices for the commercial users/customers wanting to buy (once) and keep (renewal) the software after their trials.

We underestimated the multiplication function of giving the software for free to the academic community for research and education purposes. So, the software was known only to a limited group of actual users of the central service. A customer reference list is very convincing for new customers. Nobody wants to be the beta tester. As we kept the software, we were not capable to build it up.

5.4. Starting Late

The major interest in W3Gate started in summer 1996 when the software was new and when a similar server had just collapsed. We waited too long and found our marketing partner too late, only in autumn of 97, to follow the contacts made. The marketing campaign started only in October 1997. Right Time, Wrong Place

As mentioned, we were present at several trade fairs to sell our W3Gate software package. At the CeBIT trade fair, the product presentation was embedded into the booth of our company which is a big research lab

and by that not a place where people expect to buy software. Therefore another hall for sellers and resellers would have been the better place for us.

5.5. A Marketing Partner

Our marketing partner was not as powerful and active as expected. W3Gate was just one of their products even with smaller earnings for them. Additionally, they had plans at that time to start a daughter company in the US which also took a big part of their concentration. Being a small, rather new company they were not experienced enough for the W3Gate exercise and they did not have the relevant contacts needed and expected to commercialize the W3Gate software.

5.6. National Publications Missing

With our publications about W3Gate we addressed an international scientific audience. We did not try to reach end users who normally read German newspapers, German semi-scientific journals, or manager magazines. An article about W3Gate here would have helped a lot.

5.7. Plain Old Mail

Electronic Mail is no hot topic any longer. World Wide Web, video communication, business TV, or digital audio broadcast are of interest today especially for marketing people. Compared to the World Wide Web, the number of bytes transported through e-mail is insignificantly small. Electronic mail services are taken for granted, they are as normal as the telephone today.

6. Conclusion

Together with our co-operation partners we put a lot of efforts and money into the marketing of W3Gate. Finally we were not experienced enough to succeed. We did not sell a single license of W3Gate and we did not earn a dime through advertisement, fees, or sponsoring. Maybe a spin-off company for W3Gate early enough could have been a better solution, but this is another risk to go.

Abstract: Computer and Internet based services are increasingly provided to users in our days. The users are also increasing exponentially and it is obvious that they are not experienced in the use of computers. This paper examines the problem of user friendly web based service interfaces and proposes a new kind of interface. This interface is called a Virtual Interface and is thoroughly presented. The Virtual Interface is compared to contemporary User Interfaces and the results of this comparison are also presented.

Introduction

In our days, it has become essential to be able to work with computers and communicate through them. In order to improve the efficiency of Human-Computer Interaction, computer and software manufacturers have developed friendly user interfaces. A User Interface (UI) in general is the medium between man and the computer that facilitates all human attempts to use the computer's potential in an easy way.

User interfaces have come a long way since their first introduction. They have been evolving ever since, trying to keep up with the computer technology evolution. Even so, during all the years of user interface evolution, the user environment that they presented remained very unfamiliar to the inexperienced user. Lately a new trend in computer user interfaces has arisen. This trend is the introduction of Virtual Use Interfaces and is becoming widely accepted by the computer industry.

User Interfaces for Web-based services

Definition of User Interface and its evolution

The term 'User Interface' is generally used to describe the methods and the devices that are used to accommodate interaction between machines and the humans that use them. Human-Computer Interaction consists of many kinds of interactions. A HCI takes place during the use of every computer-based system and environment such as a touch screen, an Operating System and most recently, the Web.

Human-Computer Interaction has been facilitated by UIs from the beginning of computer existence. At first the UIs were very simple and very difficult to understand. This was not strange though, since the users of almost all computers were the people who invented them. As time went by and computers became an integral part of everyday life, common people were becoming computer users. Due to this change UIs had to be improved in terms of the experience that was required from their users. Thus, the UIs were driven from the older text based interface to the Graphical User Interfaces (GUIs).

Figure 1 The evolution of User Interfaces

This family of UIs focuses on the needs of Human beings and in this way has reduced the training and experience that was considered necessary for a user to use a computer. In this paper the term 'User Interface' will be used to describe the software that facilitates the use of a Web based service and handles the interaction process between the computer and the user.

Definition of Web-based services and their User Interface requirements

In recent years the World Wide Web (WWW) is being used for all kinds of applications and communication. The wide spread use of this new means has made it very attractive to use as a platform for the implementation of existent and new services. A Web-based service is nothing more than the implementation and the provision of an already available contemporary service (such as the yellow pages) or a new service (such as a virtual library) through the WWW. The use of the WWW as a platform for the implementation of various services has many obvious advantages, such as the broadening of the range of the targeted users, but also has to face a very serious problem. This problem is the need to develop the UIs in order to help the inexperienced WWW users to understand and use the implemented web service, in other words the problem of designing easy to use Web User Interfaces (WUIs). Human-Computer Interaction is becoming Human-Web Interaction in our days and the WWW is being used really often, while its use is likely to expand even more. Thus, the need for the implementation of friendly and easy to use WUIs should be given a lot of attention by future developers.

What should a UI of a Web-based service contain

The two major characteristics of any UI that accommodates Web-based services (already mentioned as Web User Interface or WUI) must be user friendliness and user need facilitation. In other words a WUI must make the service easy to use and at the same time it must be able to attract new users. In our days, the profile of the Internet and Web user is getting closer to the profile of an every day person. Statistics show that almost one third of the citizens of the United States use the WWW and in Europe the WWW users' numbers are increasing rapidly. In order to address the user's needs, WUIs must be able to present the information required from and inserted into a Web-based service in a way that it resembles what users see and experience in the real world.

Contemporary user interfaces – An implementation instance

In order to distinguish between contemporary and virtual user interfaces, we present an implementation instance for each case. These implementation instances concern interfaces developed specifically for access to an existent Directory Service.

In the case of the contemporary user interface, a simple but functional interface was developed over the Directory Service. This interface was developed following all the existent conventions and methodologies for the deployment of WUIs. Thus, the user interface interaction cycle is [Rees 1996]:

- user clicks a command button
- browser sends state/contents of form elements to Web server
- Web server runs (CGI) script to generate new HTML page to transmit to browser
- browser displays new page

More specifically, the first page of the WUI designed contains a typical collection of Web-based form fields for the user to fill in. We reduced the amount of the information required from the user by eliminating the form fields that must be filled in. In this way, the WUI became as light as possible. Our aim was to lift the burden of the application from the user and impose it on the underlying service.

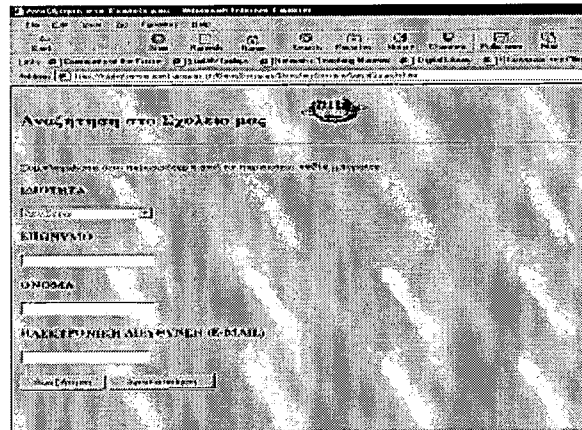

Figure 2 *The Contemporary User Interface*

We also tried to reduce the instructions towards the potential users as much as possible, as this may often be confusing and repulsive for those that are either inexperienced or in a hurry. Recent studies have shown that:

- Users don't like to read
- Text should be scannable
- Simple and informal writing is preferred
- Credibility is an important issue
- Users want to get their information quickly
- Text should be concise

Based on the above, the WUI designed retains its simplicity without compromising in terms of functionality.

The user has to fill in the forms presented to him in any way convenient to him. Keeping in mind that the WUI was developed for a Directory Service, the user can fill in the forms with either a part or the whole of the information he wants to search the Directory for. The underlying application is responsible for the error handling, thus protecting and facilitating the end user. Short and friendly error messages redirect the user to the correct position inside the WUI in order for him to re-impose his search query. When all the available information is inserted through the WUI into the service, the user has to press the submit button and wait for the interface to return the results of his search in a similarly comprehensible format.

From a technical point of view, the browser gives immediate feedback on the state of each individual interface element. Since effective user interface design requires interface elements to be tightly coupled, the selection in a drop-down menu may mean that other buttons/selections/fields should be disabled (grayed out or absent) since their existence is not appropriate for that selection. Furthermore, all information inserted before an error alert, except for the erroneous part, is preserved and reloaded in the new Web page presented to the user in order to re-submit his query. In this way, the WUI carries the responsibility for protecting the user from the redundant task of re-inserting all the necessary information, each time an error occurs.

Virtual user interfaces – An implementation instance

Designing Virtual user interfaces

The idea of a Virtual User Interface (VUI) lies on the potential to embed Web-based services into realistic three-dimensional Virtual Worlds (VWs) [Earnshaw 1995]. The developer of a VUI should initially conceive the 'Theme' of the VWs comprising it. By the term 'Theme' we refer to the instance of the real world that is virtually represented in the VUI. Examples stemming from actual implementations, include virtual representations of Exhibition Centers, Libraries, Schools etc. Consecutively, the developer has to design and implement the necessary VWs with respect to several constraints, some of which are described below. In [Schneiderman 1997] we are presented with three central concerns that all designers of VWs should have:

- The user must be able to imagine that the world portrayed is real, by the world's behavior
- The presentation of the virtual worlds should enrich the experience for participants, so that the VUIs will not become dull and emotionally flat
- Since the user has influence on the Virtual Worlds, the creator cannot plan the exact sequence of events. Therefore, all possible situations must be anticipated and predicted during the designing stage.

Apart from the artistic effect and outline of VWs, the developer must pay particular attention during the design phase to the potentials of his VWs, so that later on all functionalities provided by the underlying service will be able to correspond to actions in the VWs.

Important aspects concerning the design of VUIs include among others [Schneider 1996]:

- The VUIs must be productive as collaboration tools and enhancement factors for learning
- They should support multiple communication channels meeting the needs of different user groups
- They should support a large variety of media (é.g. text, graphics, sound, etc.)
- They must adapt to the users and not the other way round
- They must plan for change, growth and transformation
- They should contain objects that can be manipulated
- They can be enhanced with artificial agents or more generally can integrate Human-Computer Collaborative Learning Systems (HCCLS) with Computer-Supported Collaborative Learning Systems (CSCLS).
- They should have comprehensible and realistic navigation features
- At this point, the expansion of VWs to Distributed Virtual Worlds (DVWs) can be introduced.

DVWs allow multiple users to share the same VW, and so can be used for CSCW applications. This is so because the three dimensional nature of the shared workspace allows the policies used to manage communication and access to shared resources in traditional CSCW applications to be replaced by a more natural use of space and body language. Applications that are currently being explored include visualisation, teleconferencing, simulation, training, education and entertainment. These applications have widely varying requirements of the environment in which they are performed. According to the above, the designer of the VUI has to decide whether his product must support distributed use, based on its functionalities, and if so expand his VUI into a Distributed VUI (DVUI).

An important aspect in the process of designing DVUIs is user embodiment [Benford 1995]. By user embodiment the authors refer to the provision of the interfaces with appropriate body images representing each user in the DVUIs. Embodiment design issues include: presence, location, identity, activity, availability, history of activity, viewpoint, action point, gesture, physical properties, active bodies, time and change, truthfulness, efficiency and many more.

Description of a Virtual User Interface

Our implementation of a virtual user interface over an existent Directory Service involved the design and realization of a VW, which in our case was developed having as theme the teachers' office in a contemporary school. The VUI that we designed provides Directory Services to inexperienced users in such a way that only fundamental skills on the use of computers, such as navigating in a virtual world using the mouse movement, are required.

It consists of three unequal frames into which the Web-browser window is divided. The VW is shown in Frame 1. In Frame 2 constant text-based help to the user is provided, while Frame 3 is used for interaction between the VUI and the user. Through Frame 3 and the VW, the user enters information required from the underlying Directory Service and sees the results of his actions.

Figure 3 The Virtual User Interface

As the user enters the virtual room, he finds himself in front of a set of cabinets through which the Directory Service is mainly provided. The searching procedure to be followed is: click on the cabinet which holds the first letter (from A to Z) of the name of the entity to be found through the Directory Service, click on the appropriate name from the ones beginning with the specific letter, as they appear on a folder coming out of the cabinet and then receive information on the entity. This information is available in the form of a card (like a library card) coming out of the aforementioned folder. In the case of a human entity, the card consists of a photograph, information and several functionalities e.g. a button on which the user can click in order to send e-mail to the person presented. At any moment the user is able to recommence his trip in the VUI and initiate another search into the Directory Service.

Using frames in Web interfaces

The issue of using frames in web design is somewhat controversial. The most important problems are the following:

- The simplicity of the original “one page per time” web browsing may be lost in the complexity of frames
- The page may not be able to be bookmarked
- Browser URL’s do not comply with the information seen on the user’s screen but with the initial frameset
- Many users still use previous versions of browsers
- Print problems may occur
- Authoring problems may occur
- Search problems may occur
- Frames are against most of the users’ preferences

The problems that may occur by using frames and that were mentioned above can be surpassed by the frame implementation that we propose. The basic idea is to embed the fully-functional VWs in Frame 1 and use the other two frames as ‘aid-providing’ frames. Since VUI implementation is not very wide spread at the moment the idea of providing a service that would consist only of the VWs might prove to be quite hazardous. The environment that we propose is highly integrated and uses frames as cooperating modules.

Advantages and Disadvantages that come with the use of VUIs

There are many advantages in using VUIs instead of contemporary interfaces in the implementation of Web-Based services. The most important advantages are mentioned below:

- The VUI approaches the real world representation of the provided service. Thus, an inexperienced user may easily familiarize with the service provided through the VUI.
- The user doesn’t navigate for a long time and does not memorize some complex URL to use the service.

Create Online Learning for Where It's Going to Be, Not Where It's Been: An Online Pedagogy for 2006

Anne-Marie Brinsmead, French, Foreign Languages & Translation Studies, University of Toronto School of Continuing Studies, Canada, e-mail: abrinsmead@scs.utoronto.ca

Gregory M. Lang, Media & New Technology Studies, University of Toronto School of Continuing Studies, Canada, e-mail: glang@scs.utoronto.ca

Lee McTavish, Certification Studies & Later Life Learning, University of Toronto School of Continuing Studies, Canada, e-mail: lmctavish@scs.utoronto.ca

Content Abstract: The online distributed learning market is projected to be worth \$17 billion by 2006. If projections are realized and your organisation is prepared, a .01% share of this market would be worth \$1.7 million to you. Develop an online strategy that optimizes your ROI (Return on Investment) by evolving current business practices and needs into an online environment through the extension of your best pedagogical practices. Implement a distributed learning tactic, based on an evolutionary business model, which delivers immediate value to your organisation and its clients, while preparing you to share in the projected distributed learning market. Build an integrated online environment that derives its value by mitigating current business expenses, reducing the business risk of new product development and deployment and generating new revenue from the sale of micro-learning experiences. Explore with us the development of this leading edge, user-friendly, learner-centered environment and the power of its application.

The School of Continuing Studies at the University of Toronto has been in operation for over one hundred years, and has been providing distance learning opportunities for over fifty years. With the continuing evolution of technology and the changing demands of our customers, we recognized the need to 'think digital.' After a two year applied research project on on-line educational delivery, entitled The Carrier Pigeon Project, we concluded that we should enter this new market cautiously by continuing to evolve the services and products we traditionally provide. The Carrier Pigeon project highlighted many of the challenges that must be confronted in order to succeed online and was the genesis of our current online strategy. Our learning from Carrier Pigeon is best summarized by the second last paragraph of the Executive Summary of the report:

"However inspiring and seductive computer mediated interaction is, there continues to be the danger of limiting our concerns to the physical design; to be overly interested in the delivery mechanisms and interfaces while neglecting the content material to be learned. We understand on academic, business, and technical grounds, that for optimal learning to occur, it is the complex integration, not the simple balance, of interface and substance that will engage the learner at various cognitive and physical levels of interaction. And it will be the learners' ability to apply their learning that will engage their customers and corporations." Dr. Mary Cone Barrie - Director, School of Continuing Studies 1997.

The School of Continuing Studies has a strong tradition of responding to customer needs but intrinsic to those needs is our dedication to pedagogy. Within the context of both of these commitments we decided that we should continue to personalize and customize our products and services to meet the evolving needs of our customer community both off and online. The high capital investment required for online courses provided the framework for how we determined our next steps. After extensive strategic thinking and consideration we developed our online strategy and the tactical means: consolidate into an integrated whole the School of Continuing Studies' existing and future technology-delivered offerings, selected enhancements, customer service business processes, and the information technology components. In this paper, we present an online pedagogy for 2006, and highlight the optimal learning environment of the Web Forum by applying it to one course offering entitled Leadership Online.

- Statistics show that the Web users do not want to read a lot while visiting Web pages. A VUI minimizes the reading required in order to use a service since it is not text-based but graphic-based.
- Statistics have also shown that users do not like to scroll through long pages on the Web. The use of Virtual interfaces also eliminates this disadvantage of contemporary UIs.
- Another major advantage that comes with the use of VUIs is the added value that they provide to the implemented service. VUIs can be easily enriched at any moment with functionalities.
- The VUI can easily be customized to address specific user preferences.
- The future of many technologies is for them to be integrated. In our days we are looking at the attempt to integrate the WWW with television by creating a new medium called the Web TV.
- The use of VUIs facilitates the use of the WWW as an advertising and promotion medium.

Even though there are many advantages that come with the use of the VUIs, there are still certain disadvantages that derive from the fact that the technology is still new and not tested:

- The greatest disadvantage of the use of VUIs on the WWW as we know it today is imposed by bandwidth limitations. VUIs must be downloaded to the user's personal computer first, in order to be viewed.
- Most of the VUI implementations require a plug-in for the user's browser in order to be viewed. This makes the user download the plug-in before using the VUI, something that may also discourage him.
- There are no widely accepted standards in the field of VW implementation at the moment. This may discourage big companies to use the new technology.
- The technology is not supported by many older browser versions, that many users still use.

Conclusions and Future work

In this paper we have shown the potentials of the new Virtual Environments technology and a way that it may be integrated into a VUI. It is almost certain that this technology will mature and attract more attention in the future. Its use is a good solution to the uprising demand by WWW users around the world for more Web-based services. Our future work will focus on the subjects of linking databases and making them co-operate with the virtual environment [Bouras 1998] as well as creating educational Distributed Virtual Environments (DVEs). Both of the above will raise the functionalities of such environments to such a level that many established current technologies will become obsolete and be replaced. The next step in the way of further development of the proposed VUI is to make it customizable. As in all customer/user oriented WWW services the capability for customization is a key feature that must be supported.

We must note that we are convinced that VUIs may become a new means that will bring people from different parts of the world together and facilitate people with all the services that may have been formerly not accessible.

The Web Forum: An Online Business Strategy for 2006

The Online Strategy

To provide a personalized and customized learning experience to our community of learners.

The Web Forum:

The Web Forum is an online education management system that combines teaching and learning systems with management and administration systems. The Forum is comprised of a variety of integrated environments for the delivery of products and services that may be accessed in flexible combination, and includes:

Learning Experiences

Web Forum is an online environment in which appropriate course components are stored for sale-on-demand. A customer may access and complete the component parts of a course or training offering to meet their personal and immediate information and training needs. The School manages the customer's learning history to identify if and when s/he has successfully completed a significant portion of an existing course or a newly identified path of study. Once a match is made between the customer and the customer's specific requirements, the customer may register and take only specific information offerings or training modules, choosing whichever ones that will result in a customized experience.

Off-line Course Enhancement Environments

The Web Forum online environment is a repository which stores course enhancements and may include URLographies, reading lists, course outlines, weekly course updates, chat rooms, news groups, threaded discussions, educator/facilitator/mentor access, etc.

Dynamic Educational Links Database

The Web Forum is an online educational resource storage environment where links are indexed --by the School's program directors, by the instructors/educators/facilitators, and by the learners-- for quality and relevance. Course or learning module-developers may select appropriate links through keywords and references. Auto-check of link validity is a feature of this database. Access to this environment is available to learners or subscribers.

Course Environment

Web Forum is an online environment that hosts courses and learning offerings. It is also an environment where learners manage and/or complete their learning.

New Course / Instructor Environment

Web Forum is an online environment in which instructors may propose new courses and learning modules. Course or module proposals may be posted for marketability and need not be developed until interest is high.

New or Potential Learner Environment

Web Forum is an online environment in which potential learners may browse and sample courses and learning modules. They may peruse existing and potential course and module offerings, and identify what they would like to

learn, including the medium of delivery, the language of delivery, the timing, etc. This environment dynamically manages waiting lists by identifying growing interest in courses and learning modules through automatic notification to all stakeholders.

Instructor/Facilitator Development Environment

Web Forum is an online environment in which instructors/educators network with peers, and exchange tips and hints for managing adult learners' needs and learning style preferences. This environment is also the medium of delivery for instructor/educator/facilitator professional development.

A Summary of the Context in which a Course or Learning Offering May Be Integrated into the Web Forum

The critical success factors in the delivery of learning, in 2006 and beyond, will be the provision of personalized and customized learning experiences through the management of educational systems and the re-framing of the adult educator mindset. Learning organizations will be in the business of offering well-defined and parameter-driven personalized customer services to learners and will be managing the expectations of learners and the relations of learners and their adult educators.

Technology will provide us the opportunity to move us closer to achieving a pedagogical ideal. Online learning of the future will create a set of new assumptions about online learning delivery:

- ***Learner care.*** Technology provides us with the opportunity to finally meet an individual's education needs. Learning organizations that provide, with guidelines, personalized adult educator response, feedback and customer service will have higher online program completion rates, higher learner satisfaction ratings, and higher learner retention. Learning organizations will have a repository of learner data and learner-educator interactions so that fine-tuning of online education delivery is possible.
- ***Multiple touch points.*** Learning institutions will assure consistency and quality of educator-learner communications across the multiple touch points of telephony, i.e., e-mail, asynchronous and synchronous web-driven interactions as well as traditional communication channels.
- ***Personalize, personalize, personalize.*** Learning institutions and adult educators will devise flexible communication systems to manage learner expectations and achieve cost efficiencies while leveraging educator-learner contact, within parameters, to optimize the online learning experience.

Learners will come to expect and enjoy optimized learning experiences due to learner-educator interactions that will occur, with parameters and ground rules, across multiple touch points. Adult learning principles will be mined to serve professional education and continuing education learners and customers and will be applied in the form of personalized learning solutions and services offered in a communication system, the ground rules of which may vary from institution to institution, from adult educator to adult educator, and from offering to offering.

Adult learners will be treated as customers. The flexibility, customization and work with the adult learner "in the way that s/he prefers" will drive effective online pedagogy by 2006. The adult educator's attitude is key. Tremendous flexibility within the learning experience will be the international standard. With the customer service attitude of the adult educator as paramount, learning environments will evolve iteratively.

Learner-centered offerings will require adult educators to shift their priorities and their roles. The primary requirement to achieving effective online education will be that adult educators make this shift. Of equal importance, the roles and expectations of all stakeholders in the management and administration of this environment will require re-definition and alignment.

Towards a Pedagogical Ideal in 2006 – from the Online Learners' Perspective

We will present, from the on-line learner's perspective, where online learning has been, its shortcomings, and how we as adult educators may shift and move more fully toward a menu of pedagogical ideals, as facilitated by the solutions which Web Forum provides.

Shortcomings:

- There is a lack of personalized feedback from the adult educator to learners' queries, their assignments, their tests and exams. Outcomes: Even higher drop out rates for online courses in comparison with paper-based distance delivery. What is desired: personalized communication in order to progress in the learning process and maintain motivation to complete the program.
- There is a lack of multiple touch points (communication channels). No e-mail, fax or phone communication permitted between adult educator and learner. Where contact is permitted, technical complexity and difficulties have made the learning experience unfriendly.
- In first generation online courses, learners complain that they are simply lecture notes or a "text only" presentations thrown up on a website.
- There is a dearth of adult educators who have a passion and a desire to "deliver it right" online, or in other words, a desire for learner-centric delivery. (Both institutions and learners agree on this issue.)

Web Forum Solutions:

- With your adult educator and facilitator as personal guides, you will discover the subject matter in greater depth under the guidance of an expert adult educator and facilitator who will help you stay focussed.
- E-mail communications with your instructional team are strictly confidential, which means you can be comfortable raising sensitive issues in a confidential, secure environment. There will be an adult educator and a facilitator from within the institution as part of the learner support network that includes: technician, expert adult educator, facilitator, and peer communication support.

Shortcomings:

- Learning technology support requires reasonable parameters and funding to support the "help desk" infrastructure. The layering of help desk support is a key to the answer.

Web Forum Solutions:

- "Just-In-Time" help from your expert adult educator and facilitator responds to your particular needs and schedule, within reasonable timeframes. Contact your expert adult educator and facilitator by e-mail, phone or fax with questions about the content, or how to apply it as you learn, and you will receive answers and feedback in a timely fashion, usually within three to six working days. By having a learner support network, this will let you, the learner, understand and distinguish between the variety of your needs and will allow you to be discriminating in the selection of your support requests based on the communication network we offer. (Please see the Leadership Online example at end of this section.)

Shortcomings:

- Complaint: Educators are not paid for their web delivery time ("I'm checking for learners' e-mails at 2 am on Sunday mornings", etc.).

Web Forum Solutions:

- The learner will have better access to personalized feedback from adult educators, with reasonable parameters. Online communication does not mean instantaneous response. "It's not No, it's just NOT NOW." These include learners becoming familiar with the follow-up and response times arranged by the adult educators and the institution's support network. Learners' expectations will be managed and met by the communication network set in place by the institution.

Shortcomings:

- The following are types of required assignments and learning activities that have been known to fail with adult learners: required team chats, team projects & team assignments via email with attachments. In addition, first generation online courses are often packed with too many assignments (avg. 12+ hrs/wk/course) in comparison to the equivalent in-class program. Matching and branching processes are needed with respect to the type of program (i.e., hard skill or soft skill training) and the degree to which content will drive the degree of flexibility and choice of activity.

Web Forum Solutions:

- Complex, excessive “busy” work is out. Learning activities are doable and reasonable within the given timelines. You will be able to balance learning projects against the constraints of time, space, economic resources, and personal and professional relationships. Your online experience for assignment completion will be feasible with a moderate to high comfort level.
- Easy Access, Anywhere, Anytime: You mine the discovery hub and information repository of the Web Forum (as well as the Web) for your needs.
- Each educational skill area will be delivered through its own password-protected website containing carefully selected digitized learning materials, including access to a collection of vetted online resources.
- You’ll want to visit the identified online resources after your program has concluded, for continued learning.
- In Web Forum, the variety of online tools will include reading material and the website’s “discovery hub” of high quality, hot-linked URLs.
- The course website area within Web Forum will be the communication conduit for e-mail to your coach and peer networking. If you can connect with a web page, you can connect with the course.

Shortcomings:

- Intellectual property issues have not been sorted out. Several instances: For a brand new online course which adds to the department’s existing curriculum portfolio, the educator develops content, and is paid outright because the department purchases the intellectual rights to it. (“The professor takes the money and run.”) In these instances, the institution holds the copyright and does not expect to see its investment paid back within the next decade.

Web Forum Solutions:

- The Leadership Online course example within the Web Forum model is based on rights to intellectual property, not outright ownership of the course content. Access to these rights is due to a cooperation, not a competition model. Adult and professional education are differentiated markets from that of the University proper. The cooperation model was made possible by selecting an existing program designed for the corporate marketplace. With a view to cooperating in the expansion of market outreach to the general adult population, the intellectual property owner was attracted to the University’s ability to serve differentiated markets and thus was willing to sell rights to the program for online, paper-based distance and classroom use.

Shortcomings:

- Adult learners online identify an immediate need or work-related problem that is relevant within the context of the course, but solutions are time consuming or go beyond the immediate need and strictly defined course objectives. Learners have a variety of learning styles and needs and often find it nearly impossible to schedule an in-class distance learning, or online course.

Web Forum Solutions:

- The learning experiences environment provides Just-in-Time learning based solutions, which, when combined with other learning experiences, form a module or course and deliver pedagogical outcomes.
- This new and potential learner environment provides a dynamic waiting list segment allowing them to identify what, when, where, and how they prefer to learn.

Shortcomings:

Personal computers are subject to crashing and Internet connections cost most users money

Web Forum Solutions:

The strategic design of courses and learning experiences minimizes the time learners spend on-line by providing download options to work offline.

Shortcomings:

Learners have specific interests and needs arising from a course of study and would often enjoy access to and guidance from other resources on a specific topic.

Web Forum Solutions:

The dynamic educational links database environment provides learners with the opportunity to self-direct their study path moving beyond the boundaries of the traditional syllabus, and provides them with the opportunity to share their intelligence and experiences with others.

Conclusion

The Web Forum delivers optimal learning environments and value to the customer. It may be deployed without major investment and prepares the institution to benefit from the projected \$17 billion market in 2006 while delivering learner-centric education opportunities.

Using 3D to Support Awareness in Virtual Teams on the Web

GMD - FIT, E-mail: wolfgang.prinz@gmd.de

Abstract: During the last few years several Internet based 3D environments have been realized. Many of them provide a virtual environment for chatting, talking, and the representation of users by avatars. Such shared virtual worlds however, have not yet found their way into the daily office work. They are rather used for gaming or private meetings.

In this paper we will show how shared 3D environments can be used in an office environment. We will introduce a sample scenario based on our toolkit for shared virtual reality applications to demonstrate how such environments can successfully be used to support members of virtual teams.

1. Introduction

Internet based shared virtual environments have been around for some time now. Examples include ActiveWorlds [www 1], Blaxxun [www 2], or Sony's Community Place [Lea et al. 1997]. However we can observe that after the initial enthusiasm such environments often become less and less attractive to the users and finally grow lonely completely. People only return for particular events scheduled in advance. Most of the remaining time however, these worlds are sparsely populated. The reason for this development is not the quality of the software available or the design of the particular virtual worlds but rather the missing purpose of such worlds. Most of these worlds were created to provide a compelling and interesting environment for chatting and meeting people on the Internet. While this seemed to be a good idea on the first glance, long-ranging it did not seem to attract a significant number of users (especially when compared to classic chatting environments such as IRC). Due to improved support for 3D rendering on most computers today, graphics performance usually is no longer an issue. Nevertheless people enter a 3D world, navigate through the scene, and often already leave after a few seconds. People avoid such worlds, if there is no significant new information compared to their last visit. This situation is not really improved by providing the user a possibility to modify the world interactively as ActiveWorlds shows.

In contrast to these observations networked 3D games have recently become very popular. Some of them such as Ultima Online [www 3] attracted thousand and thousand of users over a period of several month. We can identify a number of reasons for this:

- each participant has to compete against other users
- the number of competing users is always rather high
- even if there are no other users in the same area of the virtual world, the environment is challenging for the participant
- the 3D environment is very dynamic - players visiting the world often and for a long time have advantages over users spending only a few minutes in the environment

Games however are used (or at least should only be used) in the user's spare time. They require one hundred percent of the user's attention. This also applies to existing Internet based virtual environments. This has a significant impact on the use of shared virtual environments within a regular office environment. One possibility would be to let the user switch between his regular working environment and the 3D environment. This method can be used for scheduled meetings only. Additionally the usability of the 3D environment is limited to a small set of applications which can take advantage of a 3D representation of objects or users. It can for instance be used to enhance the communication between distributed users without the high-bandwidth requirements of video confer-

ences by supporting the transmission and representation of the users' gestures and body language. The goal of this paper however, is to show how 3D worlds can be used in a non intrusive way to support regular office work.

In this paper we present our approach to use 3D for supporting mutual awareness in distributed teams on the Internet. In the second section of this paper we will give a brief introduction of the infrastructure our application scenario is built on. In the third part we will finally show how this infrastructure can be used to create a 3D environment to support virtual teams.

2. Technical Infrastructure

In this section we present the basic infrastructure we have realized to support the development of distributed virtual reality applications on the Internet as well as the mechanisms to achieve awareness of events. Our approach is based on following three basic technologies:

- a universal toolkit for creating shared virtual environments on the Internet
- a set of software and hardware sensors to create new interfaces to gather data about user and object states
- a basic awareness infrastructure used to process and filter the captured data and make it available to other applications

This infrastructure presents the basis for the application scenario created to support distributed virtual teams.

2.1. SmallTool

Our sample applications are based on our SmallTool multi-user VR toolkit [Broll 1998]. *SmallTool* consists of a set of libraries to minimize the effort required to create distributed virtual environments for the Internet. The toolkit supports the creation and maintenance of shared virtual worlds populated by users and animated characters.

The main parts of *SmallTool* include:

- EV - the extended VRML library
- DWTP - the distributed worlds transfer and communication protocol
- DIC1 - the device independent communication interface

These *SmallTool* libraries are currently available for Windows95/98/NT, Linux and some UNIX flavors (IRIX, SOLARIS). For performance reasons all libraries are realized entirely in C++. The rendering part of the extended VRML library is based on the OpenGL graphics interface available for all major platforms.

We have built some sample applications on top of the *SmallTool* libraries. Our main application is SmallView, a multi-user VRML browser. It allows us to share virtual worlds among several users and to represent users by avatars. Additionally it provides various input and application programming interfaces.

The *SmallTool* distributed VR toolkit supports VRML by its extended VRML library (EV). VRML'97 [Ames et al. 1997] is the ISO standard for 3D objects on the Internet. The extended VRML library can be used to read and write VRML files and to manipulate and render VRML objects. In addition to the features defined by the VRML standard it provides support for the representation of users by avatars and the synchronization of multiple scene data bases. The latter feature can be used to keep several distributed copies of a shared virtual world consistent. The synchronization events are generated automatically upon object changes and the VR application just has to sent them to the scene data base of other participants - either directly or via a central server. These mechanisms provide the basis for distributed multi-user virtual environments.

SmallTool uses DWTP - the distributed worlds transfer and communication protocol for all network communication specific to shared virtual environments. DWTP is an application layer Internet protocol - similar to HTTP or FTP - tailored to the needs of distributed multi-user virtual reality applications. In contrast to simple web pages, such applications usually require different types of data to be transmitted:

- files, containing the description of the scene or the avatars
- events and messages for updating and synchronizing distributed copies of shared worlds
- streams containing audio or video data

Additionally connection types between the participants are not limited to reliable one-to-one connection (as used for HTTP). One-to-one connections can be used along with one-to-many or many-to-many connections or both reliable and unreliable internet protocols. DWTP hides the underlying protocol from the VR application and provides a simple, high-level interface to transmit and receive data of the types listed before. In addition to its cli-

ent interface, it provides a number of services which can be used as daemons or within application servers to realize scalability, reliability and persistence for distributed VR applications.

The device independent communication interface (DICI) finally supports the easy connection of new innovative I/O devices via the Internet. Each I/O device is connected to a DICI server part, which makes the device available to all or selected hosts on the Internet. Applications which want to use these services (either receiving input data or sending output data) simply include the DICI client interface. The services can then be used by specifying the Internet address and the name of the requested service. We have realized DICI servers for 6DOF magnetic trackers and the MOVY tracking system [Henne 1999].

2.2. Collecting User Data from Sensors

A major requirement for the support of awareness in distributed teams is the possibility to collect data about the current activities of the individual user. Existing input devices such as mouse and keyboard are not sufficient for this purpose. In order not to disturb the user during his regular daily work, it is important to use non-intrusive methods for the collection of the user specific data.

2.2.1 Hardware Sensors

One hardware sensor used to detect user actions is the MOVY tracking system. MOVY is a wireless inertial tracker developed in our institute. Compared to magnetic tracking devices it has a wider operation area and is not influenced by metal or electric fields. Further more it does not require any fixed base installation in the environment.

Depending on the location of the sensor, different types of user actions can be tracked by MOVY:

- mounted on the user's forearm, gestures of the user can be detected
- located in the user's pocket or attached to his upper leg, basic body movements such as *walking, sitting, and standing* can easily be recognized
- mounted at the chair in a user's office, it may be used to detect whether the user is sitting on the chair and whether he is looking to the screen (depending on position and orientation of the chair).

Other hardware sensors currently used to gather information are

- light barriers mounted at doors of several rooms to register people entering or leaving the room
- noise sensors to register the activity level of people in a room
- web cams to identify the location of users

Hardware sensors can be both personal or anonymous. Which type of sensor to use and how to handle privacy issues depends very much on the people involved and the type of application.

2.2.2 Software Sensors

Software sensors can be used to detect the activity of user by monitoring his keyboard and mouse input, and observing the applications and files currently used. A background process continuously captures all input events (keyboard, mouse, switching focus, etc.). These events are then aggregated to receive an activity level for the user or the particular computer. For privacy reasons the data might be forwarded anonymously.

Beside the capture of general system information, events can be created by the individual applications. This does not necessarily require any modification of the original program, in a MS Word document for example, this can simple be done by using an appropriate macro which could be part of the standard document template.

The data captured by the various hardware and software sensors is always processed locally. It is made available either by a DICI server connected to the input driver or it is converted into events sent to the NESSIE environment.

2.3. The NESSIE Awareness Environment

The NESSIE - awareNESS environment [Prinz 1999] is a infrastructure for gathering, filtering, and distributing events. It can be used to achieve awareness on other users, web pages, or arbitrary other events. The interface to send events and to specify requests is based on simple HTTP requests, making it possible to access NESSIE from every application providing web access. Events are sent to a regular HTTP server which then forwards these messages to the NESSIE server. The NESSIE server saves, filters, and aggregates the event information and makes it available to applications upon request. Sample applications have been developed to create and to present NESSIE events. The content watcher application for example monitors web pages or specified parts of it and sends an event to the server, when the content has changed. The ticker tape application allows the user to visualize events received from the NESSIE server on their screen.

An often discussed awareness issue is the danger of misusing awareness information for control purposes. We address that problem by the introduction of event access rights and the disclosure of interest that others have registered in events that a user generates by the interaction with shared objects.

An event that is submitted to the NESSIE server can be protected against unauthorized access by the inclusion of an access control attribute. This attribute lists the ids of users or a group of users who are allowed to receive that event. This enables the server to perform an access validation on protected events. If the identified user is member of the access control list, a protected event is forwarded to the respective NESSIE client. With the introduction of access control for events the awareness environment ensures that activity information can be made visible to a restricted group only.

Although access rights are a suitable method to restrict access to awareness information, it can not guarantee to exclude misuse. An approach to address that problem is the provision of reciprocity. This is achieved by disclosing those users who have registered interest in an event to those users who produce the event - *when you see me I see you*. Whenever an event is submitted to the NESSIE server this information can be requested by inclusion of a special *observer* attribute into the parameter list. The return information lists those users who will receive that event instantly and those who are potential recipients.

This information is useful not only for the support of reciprocity. It further informs a user about the list of people who will become aware of the activity that is indicated by the event. This is important when a certain reaction is expected on the activity that raised the event.

3. Awareness for Distributed Teams

Before we introduce our approach to support distributed teams, let us have a short look on office work of teams. Usually members of a team meet from time to time to present their work, exchange results, discuss the future activities, and distribute new tasks. The co-workers then return to their work places, which are distributed over several rooms, floors, buildings, or even locations. Some colleagues may even work from home. In the time between the meetings people are usually not aware of the progress. One colleague could have updated or replaced a shared document, another one could have been hindered to finish a particular task. Some people could decide to have a spontaneous unscheduled meeting to discuss a particular aspect or problem in more detail. Most other team members will not become aware of such actions. They could be informed by their colleagues by telephone calls or by email. On the one hand this would produce a significant communication overhead and for that reason prevent spontaneous actions. On the other hand everybody would be flooded with information about activities of other team members, thus impairing his own work significantly.

The goal of our approach is to capture such actions and to make them available to the team members by addressing their peripheral awareness. Existing approaches to this problem send an email or pop up a window on the user's desktop. This however, seems to be too intrusive to achieve a peripheral awareness of the environment. In our opinion it is important to provide additional peripheral awareness similar to BT's Contact Space or Form Meeting Space [McGrath 1998].

3.1. Visualizing Activities and Team Members

Our approach therefore is based on a comprehensive virtual working group scenario including the representation of users by active avatars, appropriate visualizations of the users' real working environment (e.g. offices, coffee room) as well as virtual workspaces. These virtual workspaces may be used to represent sub-teams or subject related data.

Figure 1: Awareness for distributed working groups

Within these working group scenarios each member is represented by an animated avatar. The avatar's behavior represents the activity of its owner symbolically: If an employee opens a shared workspace and fetches a document, his avatar moves to the room representing this workspace, takes a paper out of a bookshelf, moves back into his office, sits down and modifies this document. If two users are talking in the coffee room, their avatars also move to the corresponding virtual counterpart.

In our prototype we use our VRML browser *SmallView* to visualize the activity of users in BSCW shared workspaces [Bentley et al. 1997]. Currently the system recognizes only a small set of user activities and maps them to symbolic actions of the corresponding avatar [Fig. 1]:

- an avatar moves between several rooms, depending on the current BSCW workspace the user is working on
- viewing a document (i.e. downloading it from the BSCW server) is represented by an avatar reading a book
- users working on documents are represented by a sitting and writing avatar
- an idle user is represented by a sleeping avatar

In order not to disturb the user during his regular work, in our sample scenario the 3D representation of the office environment is not displayed in a window on the user's desktop but on a separate screen. Another possibility would be to project it on the wall behind the user's monitor as a virtual 3D wallpaper. This however requires a high quality projection system usually not available in a regular office and especially not at home. This approach however allows the individual user to focus on his regular work, while always being aware of the overall situation in his working group.

To recognize the user activities the hardware and software sensors described earlier are used. Additionally software events can be generated out of the BSCW system, when users browse through different workspaces, download or upload a document, or modify other object properties. Editing a downloaded document can for instance be recognized via appropriate software sensors. To recognize whether the user is still working in his office, moving over the floor or is standing in the coffee room having a talk, the MOVY inertial tracker, web cams, and light barriers are used. For most sensor data, including the software events created by the BSCW system, we use the NESSIE awareness environment for collecting, aggregating and distributing the data. Raw MOVY data is transmitted directly to the *SmallView* browser using the DICI device interface.

The 3D-representation of the working environment allows remote users to achieve almost the same peripheral awareness as if working within the same office integrating them into their regular working team. Since the 3D worlds generated by this approach are diversified and expedient for the individual user, they do not leave this worlds after a short period. Nevertheless it is required to display the 3D environment on an additional screen or projector to ensure the user can still do her regular (2D) work on her regular desktop environment.

3.2. Privacy Issues

Applying the access control mechanisms provided by the NESSIE infrastructure, access to the 3D world is restricted to those users who share the displayed context. For that purpose all events that are generated by actions on

the BSCW workspace objects contain an access control attribute that lists all workspace members. This guarantees that only users who share a workspace are allowed to view the 3D world. However, although the access control mechanism restricts access it is still possible to observe a world by running the 3D client without participating in the world, i.e. without actually working in any of the visualized BSCW workspaces. We do not want to suppress that possibility, because users who share a context without being actually active, should still remain aware of ongoing activities. To address this issue, the reciprocity mechanism is used instead. This functionality of the awareness infrastructure provides information about those users who have currently registered interest in specific events. All users who view the NESSIE world, i.e. who have registered interest in the corresponding events, without being active in a shared context, are represented as lurking ghosts in the 3D world. Thus it is possible for everybody to recognize the presence of observers. This again realizes the principle *when you see me, I see you*.

4. Conclusions and Future Work

In this paper we presented our approach to support distributed working groups on the Internet. We showed how 3D environments can be used to enhance the daily office work of the distributed team members rather than providing an isolated meeting place.

In our future work we will include further work on more sophisticated hardware and software sensors to provide appropriate information on the user's activity. We will additionally enhance the representations of users and support new objects, such as a printer or coffee machine, to provide a richer information to the individual user. Beside these technical improvements, privacy issues require a further investigation.

“Don't Forget the Teachers!": Evaluating the Impact of IT Integration into a University Curriculum"

**Nigel Bruce [njbruce@hku.hk] & Pat Desloge [patrick@desloge.net]
English Centre, Hong Kong University, Pokfulam Road, Hong Kong**

Abstract

In this paper, we report on the findings of two surveys, one year apart, into the experiences and attitudes of teachers in a university English-teaching unit to the prospect of a curriculum increasingly mediated through information technology. The responses bear witness to the problems teachers experienced in attempting to computerise their pedagogical practices, and show how issues of technology, workload and support in the end can contribute to levels of anxiety and resistance in the workplace. By the end of the 2nd year, a few teachers remained skeptical that computers can enhance language teaching, but any remaining apprehension regarding IT tended to be focused on real administrative and logistical problems of implementation. The paper concludes with recommendations to institutions seeking to pursue the path of integrating IT into well-established curricular practices.

Introduction

The thesis of this paper is that, before they start throwing money at computerising their students' learning environment, educational institutions need to create the right pre-conditions –in terms of both technological and pedagogical support and staffing and hardware infrastructure. This paper discusses an initiative at the University of Hong Kong which involved the English Centre being funded to take a lead in integrating information technology (IT) into all of its first-year curricula. The rationale was that the English Centre alone had access to all 3,000 incoming students via its compulsory courses in English for academic and/or professional communication courses. Our own incentive was the opportunity to pursue the educational goals of providing richer, more individualised and more interactive language learning resources for our students. We were also providing a service the university was expressly asking us to provide, a novel situation which contrasted with the climate of under-appreciation we had been experiencing over the past few years.

Over the past two decades, CALL and CMC¹ have become accepted sub-disciplines of language teaching and applied linguistics. Much work has been done on strategies and techniques to harness technology to pedagogy, whether for program delivery or as ancillary resource: cf. Star Roxanne Hiltz' recent book on the Virtual Classroom (1994) and, in CALL/CMC specifically, earlier work by John Higgins (1988), and more recent American work by Mark Warschauer (1995) and Selfe and Hillgoss (1994). However, much of this work assumes an audience of teachers converted to the cause of CALL/CMC; any problems of implementation tend to be constructed as learner problems. Less common have been discussions of the problems of bringing a large body of teachers up to date with IT in institutional settings: problems of familiarisation, workload, training and back-up support resources – and of alienation. Those papers that have cautioned against the uncritical pursuit of computer-base learning and teaching have tended to focus on the students. Deming wrote of Word Processing “apprehension” back in 1987, and more recently (1994) Hiltz has used the term “*electronic anomie*”, but neither were identifying a problem that might afflict teachers. At the University of Illinois-Chicago's English Department, Sosnoski et al. (1997) were concerned about the effects of IT on teaching practices and the teacher-student relationship, and launched an investigation into the

¹ CALL = Computer-assisted language learning; CMC = Computer-mediated communication. CMC is now regarded as the more contemporary term, as CALL's notion of “assistance” is seen as too weak a term to describe the pervasive role of computers in modern communication.

possible implications for writing programs across the curriculum (the Tic-Toc Project ²). More recently still, Hara and Kling (1999) noted the absence of a social dimension to discussions of students' problems with computer-mediated education, and noted strong threads of frustration, notably at the lack of teacher response. Findings like these point to an underlying problem area equally under-researched: the practical and philosophical difficulties experienced by teachers.

In this paper, we report on the findings of two surveys, one year apart, into the experiences and attitudes of teachers in a university English-teaching unit to the prospect of a curriculum increasingly mediated through information technology. These surveys were conducted as part of a larger project, OACES, whose aim was to provide an environment and support for both teachers and students in the teaching and learning of academic communication skills. Specifically, this paper addresses the problems our teaching unit has experienced in attempting to computerise our pedagogical practices, and how issues of technology, workload and support in the end can contribute to levels of anxiety and resistance in the workplace.

Last year at Hong Kong University (HKU), the University administration decided to opt for a Laptop campus as a means of bringing curricular delivery into the 21st century. There were reference models in the USA – Wake Forest for one – but at HKU practically none of the University's curricular programmes were being delivered over the Internet (or Intranet). However, once institutional administrators begin looking at the economic advantages of switching to computer-based delivery of programmes, they can underestimate the resources needed to effect such wholesale changes in teaching practices – and the kind of affective fallout that can result. In effect, many teachers have seen in this development a pernicious extension of the automation of economic sectors to the field of education, a public service intended to yield long-term rather than short-term benefits for society. Already this institutional scale of the change being mooted has begun to produce a literature addressing the sociological and political implications and effects of such dramatic changes in our social and educational behaviour and environment (e.g. Leigh Star, 1995).

This study begins by describing HKU English Centre's attempt to integrate IT throughout its curricula. We saw an opportunity in this institutional imperative to help realise some of our own pedagogical goals, e.g. increasing the reliance on Word Processing, which we had made a requirement for students' assignments long before most other departments. We also felt we should take the opportunity to show the university that we could contribute significantly to the undergraduates' education, at a time when our funding was being pared down to the wire, and scheduled for more cuts over the following 2 years.

Background: Previous Initiatives and Pilot Experience

For early background, see the report of the 1st survey (at <http://ec.hku.hk/njbruce/OACESurvey.htm>). The emphasis from the beginning has been almost equally on both students and teachers, with interaction and feedback envisaged as being more important than delivery, with a sense that our teachers needed to be brought "on side" before we could concentrate on catering in any detail to our students' language learning needs. We decided to begin with areas which would be of help to our colleagues, rather than areas which might be seen as adding to their workload.

This original plan of action was overtaken by events in early 1998, when the University decided on its Laptop campus and IT-integration strategy. Some of us (the authors, David Nunan and Phil Benson,) put together a proposal to the University that emphasised our unique exposure to all 2,700 incoming students (the ones who would have the Laptops). We proposed that the "Integration of CMC into English Enhancement courses" project would focus on the following areas:

- Design and implementation of course and class web sites as a focal point for students' CMC work
- Design and implementation of CMC-based curriculum tasks and resources

We also recognized that integration of CMC into English Enhancement courses across the 1st-year program presupposed a degree of technical competence on the part of students and staff. Our development plans therefore needed to take account of an initial need for web-based support materials, ongoing consultation

² A report on their experience is viewable at <http://www.uic.edu/depts/engl/projects/tictoc/descript.htm>

for individual students and training and support for staff. The earlier-initiated OACES project continued to provide the infrastructural support for the English Centre's IT Integration [for an overview of this project's evolution and current focus, see URL: <http://ec.hku.hk/njbruce/oacetable.pdf>], but we were concerned that this latest development take account of the impact it would have on teachers' lives. Hence the concern to monitor teachers' reactions throughout this period.

The Pilot year: innovation and support

In September 1998 we embarked on the pilot year of IT integration, with two funded projects to help us in that endeavour: the IT Integration Project (ITIP) and the *WebRight* project. The IT Integration Project, funded by the University, began in early 1998, and provided technical and pedagogical staff to develop 2 web-based academic and a professional communication courses for 500 1st-year Arts faculty students. This project was mainly concerned with exploring new web authoring technology while putting together materials for up to 20 teachers, since a majority of teachers in the English Centre taught on one or both of these courses. The project also continued staff training in developing websites and authoring interactive tasks for the Web. The staff coordinating and training on this project excluded themselves from this survey.

The *WebRight* project, which we started in April 1999, was initiated in recognition that we lacked the resources to spread the efforts of the ITIP team to cover the other 24 courses that needed attention. For a range of reasons, we felt that a further bid for funding needed to be a modest one. Our solution to aiming for a low-cost, high-impact proposal was to budget for student research assistants. This also led us to realize the benefits for undergraduates of being trained to author websites. We proceeded to recruit 12 students to work as a team in collaborating with course coordinators and "IT reps" for the many courses, to develop websites for the 1999/2000 academic year. The 2nd questionnaire was circulated in the middle of this project, when many of the respondents were actively working with the student R.A.s to develop websites for their courses. We hope to be able to find further funding to continue each of these projects, as our regular funding barely covers the direct teaching we have to do.

Exploring Colleagues' Experience and Perceptions of IT Integration

In May 1998 and again in May 1999, we sent a Web-based survey questionnaire to all 34 teaching colleagues in the Centre, asking a range of questions about their experience of, and attitudes to, computers in education. The only difference between the questionnaires was that the final few questions of the follow-up survey necessarily asked for retrospective post-hoc feedback. Our first survey (May 1998) showed that for some teachers the proposed integration of IT presented an exciting prospect, while for others it loomed more threateningly. For a review of the findings of the 1st survey, and a copy of the questionnaire, see <http://ec.hku.hk/njbruce/OACESSurvey.htm>. In May 1999, we distributed a second follow-up survey, to find out how teachers had coped with the first full year of the demands of teaching in an IT-integrated curriculum (the year's teaching finished in April 1999).

Study and Findings from the 2nd survey (May 1999)

The same number of colleagues as last year, 18 (53%), responded. Up to half the respondents in the 2nd survey may not have completed the 1st survey, so comparisons need to take account of this variable. 6 respondents chose to submit anonymously, while 12 accepted the invitation to be contacted for follow-up interview. The 18 teachers had taught an average of 3.4 different courses over the year, from the full range of our pan-university activities: Engineering, Science, Social Sciences/Business/Economics, Arts, Law, Medics, Computer Science, Economics, Architecture and Dentistry.

We again elicited information about the length and nature of their experience using computers in EFL, and then their attitudes and perceptions regarding the benefits and problems. The data on experience held no surprises: as in 1998, colleagues had more experience with older forms of computer uses, like Word Processing and CALL authoring programmes, and over the trial year had inevitably gained experience with

more recent modes of delivery like the Web. The more interesting data – and what we shall focus on in this paper – came in the 2nd part of the survey, when we asked teachers about their attitudes to the role of IT in their curricula, on their confidence levels with various IT media, and about their views on the prospects for future developments.

In May 1998, confidence had been predictably higher with the more familiar, well-established forms of IT, with the exception of CALL programs which could range from technologically demanding programs to simple authoring packages. 5 of the 18 teachers interviewed expressed concern about their competence to handle Web authoring tasks, as this was being touted as the most high profile part of the IT Integration project. Interestingly, on a 1-5 scale, there was a fall in the mean among the 18 respondents in two significant areas. When asked about how confident they were that they would be able to handle classroom activities involving *authoring Web pages*, the mean fell from 2.8 prior to the pilot year to 2.4 at the end of it. *Using PowerPoint* also brought a drop in mean levels of evinced confidence, from 3.4 to 2.8. As noted, up to half the respondents in the 2nd survey may be different teachers, but the general trend indicates that anxiety levels were enhanced rather than assuaged during this pilot year. There are a number of possible explanations. One is that the wording of the question left it unclear whether the teachers were being asked if they were confident about teaching PowerPoint and Web authoring as IT skills, or just incorporating materials or student projects delivered via these media in their teaching. In the 1st survey there was some concern that IT-mediated teaching of English would not turn into teaching IT skills, and it is possible this remained a concern.

We then asked colleagues what benefits they perceived, personally and for the courses they coordinated or helped coordinate (all teachers are on at least one design team). The range of perceived benefits were predictable and similar to those nominated in the 1st, May 1998 survey, and were encouraging in their range and sophistication, given the relative novelty of IT in our practices. Perceived benefits for the courses were expressed largely in terms of curriculum-oriented benefits, but some addressed the possible impact on students. For a 2nd year, teachers nominated ease of access, range of choice, ease of communication, expansion of learning resources, individualization. In broader terms, many recognized the opportunity for professional development, keeping up to date, and projecting the right “progressive” image within the institution.

But it is at the level of perceived problems that the data become very interesting. In both surveys the teachers showed a sophisticated awareness of some of the fundamental problems with IT integration. This emerged on the issue of the threat of IT replacing teachers - via the administrator’s imperative to save money via another form of automation – and on that of workload, as the e-mail response and online marking proposals have clear implications for teachers’ time. After the pilot year skepticism remained high. A number of teachers used metaphors which suggested IT might be going through a transitory popularity phase. Teachers spoke of a “fad”, “*keeping up with the Joneses*”, a “gimmick”, and a “bandwagon”.

In May 1998, there had been a widespread expression of apprehension, amounting to outright fear and phobia in some cases. One teacher felt “uncertainty what to do when things go wrong & presenting myself as a “knower” & skilled user of the technology when I’m very much a learner; the capacity for demonstrating incompetence”. One year later, this tended to be replaced with either a greater comfort with the type of support they had come to enjoy or a skepticism that IT integration was really a positive new direction for language pedagogy. A number of interesting points were raised, and the following table picks out a representative range of positive and negative comments from the 2nd May 1999 survey.

Positive	Negative
<i>New skills</i> : “Learning a new and transferable skill”	<i>Time</i> : “very time-consuming”; “time it takes to master IT programs and training”
<i>Reliance</i> : “I have learnt that I don’t need to be a computer whiz myself – there are plenty of them around to help me”	<i>Apprehension</i> : Fear of computers taking over my teaching job”
<i>Project</i> : “The WebRighters’ help is crucial – I don’t think I could have worked on the course webs with the same level of	<i>Redundancy</i> : “If students know all the material is on the Web, they tend to feel they don’t have to show up in class”
	<i>Fashion</i> : “a gimmick we hide behind, hoping it’ll

<p>confidence if they had not been there to help with the technical side of the materials production”</p>	<p>solve our problems” <i>De-skilling:</i> “It potentially deskills some very fine classroom teachers ...not suited to this yet unproven bandwagon. <i>Infrastructure:</i> “Not enough ready-equipped classrooms; not many classrooms have sufficient facilities for us to conduct a lesson with IT”</p>
---	--

A few of the respondents were clearly skeptical, questioning the assumed logic of an increasing integration of IT in our curricula. One respondent ascribed a “*Talebanistic zeal*” to the more engaged proponents of IT integration, and appealed to them to “*engage us poor apostates in a lively critical dialogue*”, but then asked that this “*address issues such as how IT fits in with profoundly held beliefs*”. Another respondent pointed to a “*Them/us divide between computer literates/illiterates*” and the danger of a belief in IT as a panacea. Mostly, however, the kinds of problems identified were those that might obstruct the optimal application of web-based technology.

Discussion

The aim of these 2 questionnaire surveys has been to form a profile of teachers’ experiences, attitudes and values in relation to this IT integration initiative. Our intention is to use the resulting information to inform future IT integration policy in ways which take account of colleagues’ states of mind and concerns.

As we have noted, the problems identified tended to be framed as constraints on the potential benefits – e.g. “*We need ready-equipped classrooms. It is horrendous having to carry/wheel around/set up IT equipment*”. Only a few expressed misgivings about the potential of IT-mediated curricula. One respondent, aware of the return rate I was expecting, suggested the 50% non-respondents were likely to include those “*not that taken with the idea of integrating IT into the curricula*”. Whether this is related to actual commitment shown, or general attitude, is hard to say, but this was the only case of a respondent expressing a negative construction of colleagues’ attitudes to IT. Teachers were, however, concerned about how much would be expected of them as individual teachers with varying levels of computer literacy. There remained a degree of apprehension among our teachers, but one year later this took the form more of practical implications of excessive or unrealistic expectations regarding the authoring of Web materials, rather than the general anticipatory fear of the unknown expressed a year ago. Some respondents saw IT as a function that could be left to their less technologically-challenged colleagues. Most, though, tended to welcome the opportunity to be trained in the new technology, but expressed concern that too much would be expected of them. Fearing that our development funding would run out before the websites had reached fruition, one respondent asked if it was “*possible to organize a second WebRight project*”.

Conclusion and Recommendations

These surveys taken together offer encouraging evidence of a positive, if occasionally apprehensive, response to the prospect of having to integrate IT into our teaching practices. They have also revealed a sophisticated understanding of the issues and of the potential of IT in enhancing the learning environment we could provide for our students. Colleagues identified a number of problems with the pace of change, and with the lack of support for many aspects of that change, and these confirmed ideas we had already been considering. We can offer the following advice to organisations considering moving to computer-mediated practice:

From a technological viewpoint, advice to anyone attempting this scale of IT integration into their curricula would be to explore the technology before planning your budget, and to plan for the time and resources required to be able to adapt to changes in technology.

From a staff management and development viewpoint, we would make the following recommendations:

1. Involve teachers in planning this kind of integration project;
2. Find out what they want/need/fear, etc.;
3. Make the CALL/CMC agenda *supportive* of existing practices;
4. Provide a steady program of incrementally-staged workshops;
5. Provide continuous “pastoral” support; ensuring you have budgeted for this support;
6. Wherever possible, pursue funding options for training and development; we found undergraduates perfectly able to handle Web authoring projects.

Web-based Testing for Distance Education

Peter Brusilovsky and Philip Miller

Carnegie Technology Education, 4615 Forbes Avenue, Pittsburgh, PA 15213, USA,
Tel: +1-412-268-3537, Fax: +1-412-268-3505, E-mail: {plb | plm}@carnegietech.org

Abstract: The paper provides a technology-based review of Web-based testing technologies. It suggests an evaluation framework, which could be used by practitioners in Web-based education to understand and compare features available in various Web-based testing systems.

1. Introduction

Objective tests and quizzes are among the most widely used and well-developed tools in higher education. A classic test is a sequence of reasonably simple questions. Each question assumes a simple answer that could be formally checked and evaluated as correct, incorrect, or partly correct (for example, incomplete). Questions are usually classified into types by the type of expected answer. Classic types of questions includes yes/no questions, multiple-choice/single-answer (MC/SA) questions, multiple-choice/multiple-answer (MC/MA) questions, and fill-in questions with a string or numeric answer. More advanced types of questions include matching-pairs questions, ordering-questions, pointing-questions (the answer is one or several areas on a figure) and graphing-questions (the answer is a simple graph). Also, each subject area may have some specific types of questions.

Testing and quiz components were the first to be implemented and currently are the most well developed interactive components in Web-based education (WBE). Existing WBE systems differ in many aspects of dealing with tests and quizzes. When selecting a state-of-the-art technology for developing and delivering Web-based quizzes at Carnegie Technology Education we have created a multi-facet framework for comparing available systems. This paper provides a comprehensive review of features, which are important to evaluate current technologies for Web-based testing. Our framework could be used by practitioners in Web-based education to understand and compare features available in various Web-based testing systems.

2. Life cycle and anatomy of questions

To compare existing options we have analyzed the life cycle of a question in Web-based education (see Table 1). We divided the life cycle of a question into three stages: preparation (before active life), delivery (active life), and assessment (after active life). Each of these stages is further divided into smaller stages. For each of these stages we have investigated a set of possible support technologies.

Life of a question begins at *authoring* time. The role of WBE systems at the authoring stage is to support the author by providing a technology and a tool for question authoring. All authored questions (the content and the metadata) are *stored* in the system. The active life of a stored question starts when it is *selected for presentation* as a part of a test or quiz. This selection could be done statically by a teacher at course development time, or dynamically by a system at run time (by probability or according to some cognitive model).

Next, the system *delivers* a question: it presents the question, it provides an interface for the student to answer, it gets the answer for evaluation. At the *assessment* stage, the system should do the following things: evaluate the answer as correct, incorrect, or partly correct, deliver feedback to student, grade the question and to record student performance.

Existing WBE tools and systems differ significantly on the type and amount of support they provide on each of the stages mentioned above. Simple systems usually provide partial support for a subset of the stages. The cutting-edge systems provide comprehensive support at all the listed stages. The power of a system and the extent of provided support is seriously influenced by the level of technology used at each of the main stages - preparation, delivery and assessment. Below we will analyze the currently explored options.

Before	During	After
Preparation: <ul style="list-style-type: none">• Author• <u>Store</u>• Select	Delivery: <ul style="list-style-type: none">• Present• <u>Interact</u>• Get the answer	Assessment: <ul style="list-style-type: none">• Evaluate• <u>Grade and record</u>• Deliver feedback

Table 1. Life cycle stages of a test question.

3. Preparation stage

Questions are created by a human authors - teachers and content developers. A state-of-the-art question has the following components: the question itself (or *stem*), a set of possible answers, an indication which answers are correct, a type of the interface for presentation, question-level feedback that is presented to the student regardless of the answer, and specific feedback for each of the possible answers. In addition, an author may provide metadata such as topics assessed, keywords, the part of the course a test belongs to, question weight or complexity, allowed time, number of attempts, etc. This metadata could be used to select a particular question for presentation as well as for grading the answer.

The options for *authoring support* usually depends from the technology used for storing an individual question in the system. Currently, we could distinguish two different ways to store a question: *presentation format* and *internal format*. In WBE context, storing a question in presentation format means storing it as a piece of HTML code (usually, as an HTML form). Such questions could be also called static questions. They are “black boxes” for a WBE system: It can only present static questions “as is”. The authoring of this type of questions is often not supported by a WBE system. It could be done in any of HTML authoring tools.

Storing a question in an internal format usually means storing it in a database record where different parts of the question (*stem*, answers, and feedback) are stored in various fields of this record. A question as seen by a student is generated from the internal format at the delivery time. Internal format opens the way for more flexibility: the same question could be presented in different forms (for example, fill-in or multiple choice) or with different interface features (for example, radio buttons or selection list). Options in multiple choice questions could be shuffled [Carbone & Schendzielorz 1997]. It provides a higher level of individualization. This is pedagogically useful and decreases the possibility of cheating. There are two major ways for authoring questions in internal format: a form-based *graphical user interface* (GUI) or a special *question markup language* [Brown 1997; Campos Pimentel, dos Santos Junior & de Mattos Fortes 1998; Hubler & Assad 1995]. Each of these approaches has its benefits and drawbacks. Currently, a GUI approach is much more popular. It is used by all advanced commercial WBE systems such as [Blackboard 1998; Question Mark 1998; WBT Systems 1999; WebCT 1999]. Note, however, that some WBE systems use GUI authoring approach but do not store questions in internal format. Instead, these systems generate HTML questions “right away” and store them as static questions

The simplest option for *question storage* is a *static test or quiz*, i.e., a static sequence of questions. The quiz itself is usually represented in plain HTML form and authored with HTML-level authoring tools. Static tests and quizzes are usually “hardwired” into some particular place in a course. One problem with this simplest technology is that all students get the same questions at the same point in the course. Another problem is that each question hardwired into a test is not reusable. A better option for question storage is a *hand-maintained pool of questions*. The pool could be developed and maintained by a group of teachers of the same subject. Each question in a question pool is usually static, but the quizzes are more flexible. Simple pool management tools let the teacher re-use questions; all quizzes may be assembled and added to the course pages when it is required. This is what we call *authoring time flexibility*. The same course next year, a different version of the course, or sometimes even different groups within the same course may get different quizzes without the need to develop these quizzes from scratch.

An even better option is to turn a hand-maintained pool into a database of questions. A database adds what we call *delivery time flexibility*. Unlike a hand-maintained pool, a database is formally structured and is accessible by the delivery system. With a database of questions not only the teacher can assemble a “quiz-on-demand”, the system itself can generate a quiz from a set of questions. Naturally, the questions could be randomly selected and placed into a quiz in a random order [Asymetrix 1998; Brown 1997; Byrnes, Debreceeny & Gilmour 1995; Carbone & Schendzielorz 1997; Ni, Zhang & Cooley 1997; Radhakrishnan & Bailey 1997; WBT Systems 1999; WebCT 1999]. As a result, all students may get personalized quizzes (a thing that a teacher can not realistically provide manually) significantly decreasing the possibility of cheating. Note that implementation of a database of questions does not require the use of a commercial database management system. Advanced university systems like QuestWriter [Bogley et al. 1996] or Carnegie Mellon Online [Rehak 1997] and many commercial systems such as TopClass [WBT Systems 1999] or LearningSpace [Lotus 1999] use full-fledge databases such as ORACLE or Lotus Notes for storing their pools of question in internal format. However, there are systems which successfully imitate a database with the UNIX file system using specially structured directories and files [Byrnes, Debreceeny & Gilmour 1995; Gorp & Boysen 1996; Merat & Chung 1997].

A problem for all systems with computer-generated quizzes is how to ensure that these quizzes include a proper set of questions. The simplest way to achieve it is to organize a dedicated question database for each lesson. This approach, which is, for example, used in WebAssessor [ComputerPREP 1998], reduce question reusability between

lessons. More advanced systems like TopClass [WBT Systems 1999] can maintain multiple pools of and can use several pools for generating each quiz. With this level of support a teacher can organize a pool for each topic or each level of question complexity and specify the desired number of questions in a generated quiz to be taken from each pool.

A database of questions in internal format is currently a state-of-the-art storage technology. Research teams are trying to advance it in three main directions. One direction is related to *parameterized questions* as in CAPA [Kashy et al. 1997], EEAP282 [Merat & Chung 1997], or Mallard [Brown 1997; Graham, Swafford & Brown 1997]. This allows one to create an unlimited number of tests from the same set of questions and can practically eliminate cheating [Kashy et al. 1997]. The second direction of research is related to question metadata. If the system knows a little bit more *about* the question (for example, type, topics assessed, keywords, part of the course a test belongs to, weight or complexity) then the system can generate customized and individualized quizzes by author's or system's request. This means that the authors could specify various parameters for the quiz their student needs at some point of the course: total number of questions, proportion of questions of specific types or for specific topics, difficulty, etc., and the system will generate a customized quiz on demand (that is still randomized within the requirements) [Byrnes, Debreceeny & Gilmour 1995; Merat & Chung 1997; Rehak 1997; Rios, Pérez de la Cruz & Conejo 1998]. This option is definitely more powerful than simple randomized quizzes. Systems that make extensive use of metadata really "know" about the questions and their functionality. The third direction of research is the adaptive sequencing of questions. This functionality is based on an overlay student model which separately represents student knowledge of different concepts and the topics of the course. Intelligent systems such as ELM-ART [Weber & Specht 1997], Medtec [Eliot, Neiman & Lamar 1997], [Lee & Wang 1997], SIETTE [Rios, Pérez de la Cruz & Conejo 1998], Self-Learning Guide [Desmarais 1998] can generate challenging questions and tests adapted to the student level of knowledge as well as reduce the number of questions required to assess the students state of knowledge.

4. Delivery stage

The interaction technology used to get an answer from the student is one of the most important parameters of a WBE system. It determines all delivery options and influences authoring and evaluation. Currently, we distinguish five technologies: HTML links, HTML/CGI forms, scripting language, plug-in, and Java.

HTML links is a simple interaction technology that presents a set of possible answers as list of HTML links. Each link is connected to a particular feedback page. The problems here are that questions are hard to author (because question logic must be hardwired into course hypertext) and that it supports only yes/no and MC/SA questions. This technology was in use in the early days of WBE when more advanced interaction technologies like Common Gateway Interface (CGI), JavaScript or Java were not established [Holtz 1995].

The most well-established technology for Web testing which is used now in numerous commercial and university-grown systems is a combination of HTML forms and CGI-compliant evaluation scripts. HTML forms are very well suited for presenting main types of questions. Yes/no and MC/SA questions are represented by radio buttons, selection lists, pop-up menus, MC/MA questions are represented by multiple selection lists or checkboxes. Fill-in questions are implemented with input fields. More advanced questions such as matching pairs or ordering can also be implemented using forms. In addition, hidden fields can be successfully used to hold additional information about the test which a CGI script may need. There are multiple benefits of using server-side technology such as form/CGI technology and a similar server-side map technology that can be used for implementing graphical pointing questions. Test development is relatively simple and can even be done with HTML authoring tools. Sensitive information which is required for test evaluation (such as question parameters, answers, feedback) may be safely stored on the client side preventing students from stealing the question (the only external information which is required in a well-developed system to evaluate a test is the test ID and the student ID). Server-side evaluation makes all assessment time functions (such as recording results, grading, providing feedback) easy to implement. All these functions could be performed by the same server-side evaluation script. The main problem of server-side technology is its low expressive power. It is well suited only for presenting basic types of tests. More advanced types of tests as well as more interactive types of tests (for example, tests which involve drag-and-drop activities) can not be implemented with pure server-side technology. Authoring questions with server-side evaluation is tricky because a question's functionality is spread between its HTML presentation (either manually authored or generated) and a CGI evaluation script. Another serious problem is CGI-based questions do not work when a user's connection to the server is broken or very slow.

A newer technology for question delivery and evaluation is JavaScript [McKeever, McKeever & Elder 1997]. The interface provided by the JavaScript interaction technology is similar to the one of form/CGI technology. At the same time, JavaScript functionality supports more advanced, interactive questions, for example, selection of a

relevant fragment in a text. With pure JavaScript technology all data for question evaluation and feedback as well as evaluation program should be stored as a part of the question text. It means that a JavaScript question can work in standalone mode. It means that the question is self-sufficient: everything for presentation and evaluation is in the same file, and is a very attractive option for authoring. But it also means that students can access the source of the question and crack it. Also, with pure JavaScript evaluation technology there is no way for recording the results and grades. With all the above features JavaScript technology is a better choice for self-assessment tests than for assessments used in grading. We think the proper place for JavaScript in WBE is in a hybrid JavaScript/server technology. With this technology JavaScript can be used to present more types of questions, do it more interactively and with compelling user interfaces leaving evaluation and recording to be done by traditional CGI for reasons of security [ComputerPREP 1998; WebCT 1999].

A higher level of interface freedom can be achieved by using a plug-in technology.¹ The only example of serious use of this technology in education is the Shockwave plug-in [Macromedia 1998] which can run multimedia presentations prepared with several Macromedia authoring tools. Currently, Shockwave technology is used in WBE mainly for delivering “watch-only” animations, but this technology is more powerful. In fact, a variety of very attractive Shockwave-deliverable questions could be developed using Macromedia tools with relatively low effort. Some examples could be provided by Medtec [Eliot, Neiman & Lamar 1997]. The negative side is the same as with JavaScript: recording assessment results requires connection to the server. Until recently, Shockwave provided no Internet functionality and its users had to apply special techniques (e.g. saving evaluation results in a temporal file). Due to Shockwave communication problems, some teams that started with Shockwave migrated later to more powerful Java technology [Eliot, Neiman & Lamar 1997]. Still Shockwave still stands as a solid (and overlooked) platform for delivering various self-assessment questions.

The highest level technology for question delivery is provided by Java. An important advantage of Java is that it is a complete programming language designed to be integrated with browser functionality and the Internet. Java combines connectivity of form/CGI technology and the interactivity of Shockwave and JavaScript. Any question interface can be developed with Java, and, at the same time, Java-made questions can naturally communicate with the browser as well as with any Internet object (a server or a Java application). Examples of systems which heavily use Java-based questions are FLAX [Routen, Graves & Ryan 1997], NetTest [Ni, Zhang & Cooley 1997], Mallard [Graham & Trick 1997], and Medtec [Eliot, Neiman & Lamar 1997]. Developing question interfaces with Java is more complicated than with form/CGI technology and it is not surprising that all the examples mentioned above were produced by advanced teams of computer science professionals. However, the complexity will not stop this technology. Java is currently the way to implement a variety of question types non-implementable with form/CGI technology such as multiple pointing questions, graphing questions, and specialized types of questions. Developing Java-based questions can become suitable for ordinary authors with the appearance of Java based authoring systems [Ni, Zhang & Cooley 1997; Routen, Graves & Ryan 1997].

5. Assessment stage

As we noted, the choice of interaction technology significantly influences *evaluation* options. Evaluation is the time when an answer is judged as correct, incorrect, or partially correct (for example, incomplete). Usually, correct and incorrect answers are provided at authoring time, so evaluation is either hardwired into the question like in MC/SA questions, or performed by simple comparison (in fill-in questions). There are very few cases that require more advanced evaluation technology. In some domains correct answers may not be literally equal to a stored correct answer. Examples are a set of unordered words, a real number, a simple algebraic expression [Holtz 1995; Hubler & Assad 1995]. In this situation a simple comparison program is required. Some systems may apply special intelligent technologies for matching answers [Hubler & Assad 1995]. Finally, in some cases a “domain expert” such as the Lisp interpreter for Lisp programming as in the ELM-ART system [Brusilovsky, Schwarz & Weber 1996] or a computer algebra system for algebra domain [Pohjolainen, Multisilta & Antchev 1997] is required to evaluate the answer. The first two evaluation options are very simple and could be implemented with any interface technology - even JavaScript could be used to write a simple comparison program. If more advanced computation is required (as in the case of intelligent answer matching) the choice is limited to full-function programming with either Java or a server side program using a CGI interface. If a “domain expert” is required for evaluation, the only option currently is to run a domain expert on the server side with a CGI-compliant gateway. In fact, a number of “domain expert” systems (for example, Mathematica computer algebra system) have a CGI gateway.

¹ Plug-in technology enables independent vendors to extend the browser functionality by developing specially structured programs called *plug-ins*. At start-up time, a browser loads all plug-ins located in a special directory and they become parts of the browser code.

The usual options for the *feedback* include: simply telling if the answer is correct, not, or partially correct, giving correct answer, and providing some individual feedback. Individual feedback may communicate: what is right in the correct answer, what is bad in incorrect and partially incorrect answer, provide some motivational feedback, and provide information or links for remediation. All individual feedback is usually authored and stored with the question. A system that includes assessed concepts or topics as a part of question metadata can provide good remedial feedback without direct authoring since it “knows” what knowledge is missing and where it can be found. It means that the power of feedback is determined by authoring and storage technology. The amount of information presented as feedback is determined by the context. In self-assessment the student usually receives all possible feedback - the more the better. This feedback is a very important source of learning. In a strict assessment situation the student usually gets neither a correct answer, nor whether the answer is correct. The only feedback for the whole test might be the number of correctly answered questions in a test [Rehak 1997]. This greatly reduces the student’s chances for cheating and student’s chances to learn. To support learning, many existing WBE systems make assessment less strict and provide more feedback trying to fight cheating by other means. The only way to combine learning and strict assessment is to use more advanced technologies such as parameterized questions [Brown 1997; Hubler & Assad 1995; Kashy et al. 1997; Merat & Chung 1997] and knowledge based test generation [Eliot, Neiman & Lamar 1997; Weber & Specht 1997] which can generate an unlimited number of questions. In this situation a WBE system can provide full feedback without promoting cheating.

If a test is performed purely for self-assessment then generating feedback could be the last duty of a WBE system in the “after-testing” stage. The student is the only one who needs so see test results. In the assessment context the last duty of a WBE system in the process of testing is to *grade student performance on a test and to record these data* for future use. Grades and other test results are important for teachers, course administrators, and students themselves (a number of authors noted that the ability to see their grades online is the most student-appreciated feature of a WBE system). Early WBE systems provided very limited support for a teacher in test evaluation. Results were either sent to the teacher by e-mail or logged into a special file. In both cases a teacher was expected to complete grading and recording personally: to process test results and grade them, to record the grades, and to ensure that all involved parties get access to data according university policy. This option is easy to implement and it does not require that teachers learn any new technology. For the latter reason this technology is still used as an option in some more advanced systems [Carbone & Schendzielorz 1997]. However, a system that provides no other options for grading and recording is now below a state-of-the-art. A state-of-the-art WBE system should be able to grade a test automatically, recording test results in a database. It also should provide properly restricted access to the grades for students, teachers, and administrators. Restrictions are usually determined by university policies. For example, a student may not be allowed to see grades of other students or a teacher could be allowed to change the automatically assigned grades. Many university-level systems [Bogley et al. 1996; Brown 1997; Carbone & Schendzielorz 1997; Gorp & Boysen 1996; Hubler & Assad 1995; MacDougall 1997; Ni, Zhang & Cooley 1997; Rehak 1997] and almost all commercial level systems [Lotus 1999; WBT Systems 1999; WebCT 1999] provide this option in a more or less advanced way. Less advanced systems usually store the grades in structured files and provide limited viewing options. Advanced systems use database technology to store the grades and provide multiple options for viewing the grades and other test performance results such as time on a test or a number of efforts made. Database technology makes it easy to generate various test statistics involving results of many students on many course tests. In a Web classroom, where student-to-student and student-to-teacher communication is limited, comparing statistics is very important for both - teachers and students to get the “feeling” of the classroom. For example, by comparing class average with personal grades a student can determine class rank. By comparing class grades for different tests and questions a teacher can find too simple, too difficult, and even incorrectly authored questions.

Abstract

Higher education has begun transitioning from a traditional emphasis on the delivery of content (the Instructional Paradigm) to the more demanding goal of creating powerful learning environments that meet the needs of a diverse student community (the Learning Paradigm). However, most higher education faculty have been trained as researchers, not educators in the sense of the Learning Paradigm. We have used the development of interactive multimedia learning environments as a device to allow faculty to explore principles of the Learning Paradigm. In this regard, three pedagogical features of the technology resonated with many faculty and are identified below. In addition, we illustrate a simple taxonomy of four kinds of learning environments that our faculty have developed, ranging from highly structured environments to open-ended research simulations. Lastly, we explore assessment issues as they vary across this learning continuum.

Higher education has entered a transition from the Teaching Paradigm to the Learning Paradigm. This transition results from a variety of pressures that have created a climate of pedagogical self-examination during this "Decade of the Brain." Emerging from this process are powerful new teaching styles founded on principles of active-learning and improved insights on the cognitive development of learning. In science education, where this change has been late in arriving, the educational community has embraced the principle that we must provide high quality learning experiences for all students regardless of their learning styles. However, recognizing the need for change is simpler than achieving systematic change.

At the same time, educational technology is looming as a preeminent force in higher education. Of special interest to us are learning environments that exploit interactive multimedia. The educational potential of this technology closely parallels the pedagogical goals of the Learning Paradigm. However, the adoption of these powerful tools has not advanced as rapidly as its advocates have predicted. In part, this is because the pedagogical potential of the technology is subtle to faculty untrained to exploit it. Probably the learning potential of the technology is often

constrained by its mismatch with current practice. Faculty who operate within the confines of the traditional Instructional Paradigm are less likely to perceive and exploit the full learning potential of the technology. Also, the tremendous variety of learning environments seems to confuse many faculty. The pedagogical feature set of the technology is often not readily apparent and faculty frequently use the technology to "make a better lecture".

We would like to suggest a simple pedagogical feature set that resonates with many faculty and that can foster transition to the Learning Paradigm.

1. Interactivity fosters active learning,
2. The sensory-rich nature of this technology facilitates the engagement of additional powerful cognitive processes, and
3. Integration of assessment tools into the environment can provide students with feedback and encouragement, allow the collection of diagnostic clues about individual student learning needs, and enable the collection data to evaluate student learning outcomes.

We have used this tool in our own institution with such success that one half of the faculty have requested training in interactive multimedia authoring and one quarter of the faculty (74) have already undergone initial training. Subsequent surveys of faculty attitudes and technology use patterns indicate that faculty trained with an interactive multimedia authoring experience became much more optimistic about the ability of educational technology to improve student motivation and ability to learn. Although it may not be surprising that these faculty utilized interactive multimedia more in their teaching, they also used a much greater variety of educational technology with greater intensity after having had an authoring experience.

We will present examples of four kinds of learning environments developed in the Department of Biology of the University of Hartford to illustrate these principles:

1. Learning facts: "Cell Differentials". This system simulates a clinical experience in which students must classify 100 white blood cells and suggest what pathology might be indicated by this profile. This environment includes three kinds of assessment tools. To provide incentive to strive for competency, a quiz system is integrated. This grading system keeps a running mean of the last three performances, which encourages recurrent trials when necessary. Second, the instructor can enable a feedback function that informs students of the correct answer when they misidentify a cell type. Third, to provide diagnostic clues about individual student needs, two additional kinds of assessment are provided. A graphical display shows at a glance a matrix of cell type scores in the rows, with actual identities in the columns. The results are automatically saved for faculty review in a player application later. At the end of any 100 cell "lesson", a replay button can be clicked to call up a random review of all mistakes, so that the instructor and student can work closely on items with which the student may be struggling (Figure 1).

Figure 1. Practicing white blood cell identification before a wet lab.

This system is not intended to replace the wet lab. Rather it serves as a preface to even the playing field for people with different learning styles. In traditional wet labs, students examine real microscope slides in an individualistic environment (a microscope) that provides little feedback. Usually, only assertive students willing to call the instructor back again and again get substantial personal feedback.

2. Building concepts: "Eukaryotic Cell Divisions". The study of hierarchical systems, like those typical in biology, is often challenging to students because synthesis across levels of organization in a hierarchy is a demanding task. In this learning environment, content is chunked into short presentations followed immediately by assessment experiences that enable students to use the information incrementally as the content unfolds. Summary displays of student achievement are available for viewing and are automatically output to the instructor's server, as in the Cell Differentials system. Again, running means of the last three quiz grades encourage recurrent practice for those students who need it (Figure 2).

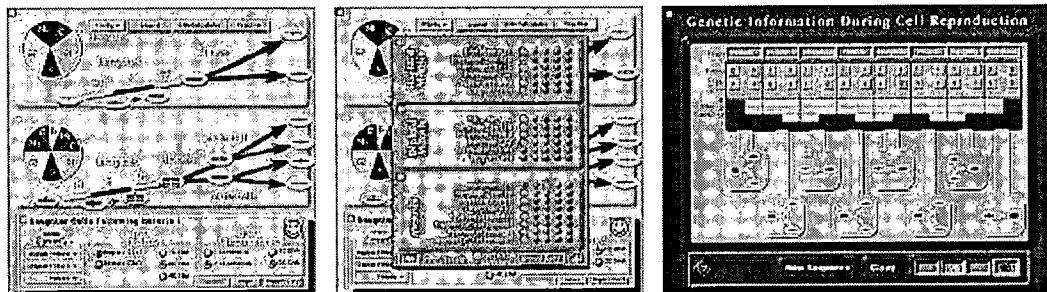

Figure 2. Exploring genetic changes in eukaryotic cell divisions to encourage students in concept-building: Assessment tools to collect diagnostic information about individual student learning needs.

This lesson was developed to give students practice in a demanding learning task. Early mean quiz grades have increased from the low 50s to the low 80s, with 90% of the students attaining a 90% proficiency within one week, compared to the mean 70% proficiency after two weeks with previous paper and pencil exercises. The effectiveness of this method has not only improved student learning outcomes dramatically, but it works so quickly that it has allowed the addition of additional course content, not the usual outcome of adopting more powerful pedagogies.

3. Experiencing Critical Inquiry: "The Search for the Hereditary Molecule". The previous two systems illustrate learning environments that are directed toward the mastery of foundational information.

Assessment tools can be developed with comparative ease for such structured learning goals. However, learning environments designed to foster the development of critical inquiry skills must be more open-ended. Students must be allowed to explore and to make mistakes more freely. Student interaction with the learning environment is of a higher order, but assessment is correspondingly more challenging.

In this research simulation, students are provided with the tools used in a famous experiment and also instructed what the basic research question was. The students are then invited to design a research program to resolve the question. We have taken two approaches to assessment. Limited structured assessment tools are provided to give students feedback about their understanding of foundational information necessary to design an insightful experiment. Assessment can assume a more reflective experience in active learning environments in which an effort is being made to transfer the authority of learning to the students. Therefore a different kind of assessment is employed to reinforce the learning experience of the more open-ended component of this system. The system actually includes several different sub-simulations that allow students to experience the inquiry in several different ways. Each of the three modules provides alternative insights about experimental design:

1. a virtual lab with emulated test tubes and petri dishes to manipulate,
2. a spreadsheet-like module that emphasizes an experimental design overview, and
3. a flow sheet in which the computer produces hypothetical realities that the student must interpret from experimental results (Figure 3).

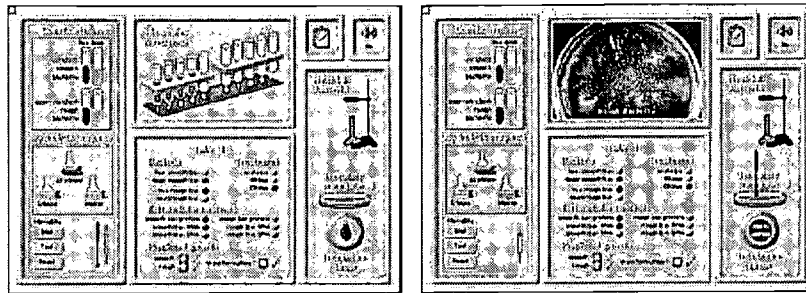

Figure 3. *The Search for the Hereditary Molecule*: A research simulation

4. Using interactive multimedia to foster student-originated research: "Developmental Selection". We have attempted to transition our introductory biology laboratory classes from traditional menus of demo-like experiences to real research experiences in which students are pursuing questions that they have originated. This is a challenging freshman experience. These young people usually lack the necessary foundational information required to originate questions. They usually have no previous research experience and can bring only superficial epistemological insights to bear in these inquiries.

We have developed several research simulations that elevate the preparation of most of our freshman students to participate successfully in this demanding program. These environments will be illustrated with our "Developmental Selection" research simulation. It includes three major modules. The first component allows students to alter system parameters with sliders, which allows them to develop their understanding of the foundational information required to study this phenomenon. The two remaining parts of the system focus the students experience on the differences between the initial "data collection" phase of the research experience and the "data analysis" phase of the investigation. Students often confuse these two processes.

Assessment in this open-ended learning experience assumes a new form. As students move from the simulation to experimental design with real field samples in mind, real life issues like sample sizes and subtleties of the data scoring of complicated phenomena come into focus. Rather than relying on faculty authority to answer these questions, students are encouraged to return to the simulations to probe specific issues themselves. They learn the value of models to test our assumptions and to evaluate complicated phenomena in relative painless ways.

Before the development of these research simulations, only our best students excelled in this experience. Many of our students seemed lost and revealed only limited learning outcomes from the experience. Introduction of these simulation prefaces has again evened the playing field for students with different levels of preparation for the experience (Figure 4).

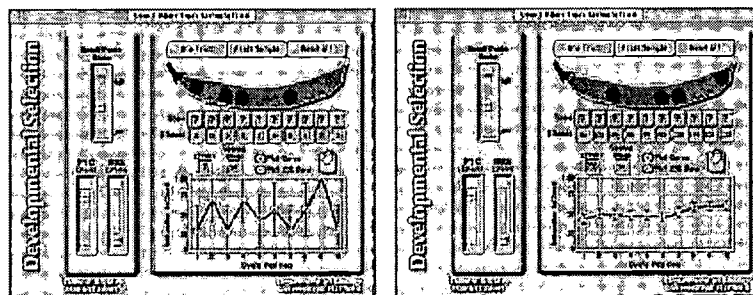

Figure 4. *Developmental Selection*: A simulation to foster student-originated research.

To summarize, the development of interactive multimedia learning environments by our faculty has allowed our faculty to teach things that we found difficult to teach before and we have been able to produce improved learning outcomes for other content that was pedagogically challenging. Moreover, authoring interactive multimedia learning

environments has allowed faculty to explore important principles of the learning paradigm that seemed much more daunting with traditional instructional methods. This technology has fostered the advancement of active-learning pedagogies in our teaching. It has improved our ability to exploit new insights about the cognitive development of learning. The utility of the computer to monitor student progress has encouraged us to think more carefully about assessment and to strive for the development of assessment tools that allow us to give our students more individual attention. Our authoring experiences have forced us to think more carefully about the appropriateness of different kinds of assessment tools for different kinds of learning experiences, especially new views of assessment that might better support open-ended learning experiences and active learning environments. Collectively, these features have allowed us to serve the varied learning styles of our students more carefully.

Abstract: A significant challenge facing educators today is how to accommodate students with different levels of preparedness. In many courses the gap between the most prepared and least prepared student is wide and growing. Our experience suggests that asynchronous online education can be part of the solution. In this paper we report on our experience teaching an introductory computer class over the Internet. We discuss how we are using Internet technologies to enhance the presentation of course material and information technologies to automate course management activities. Automating routine teaching and administrative activities has given us more time to work directly with students. This together with the asynchronous nature of the course has enabled us to successfully offer the course to an increasingly diverse student population.

1. Introduction

Three years ago it was becoming increasingly difficult to run our introductory computer class. In any one section it was not uncommon to have students with several years of computer experience sitting next to those who were just learning to use the mouse. Because it was an introductory computer class we couldn't assume any prior knowledge so instruction for everyone had to start at the beginning. Making matters worse, the opportunity for exposure to computers and the Internet was growing at an exponential rate so each semester the skill level of the best students kept getting better.

In response to this challenge (and for other reasons) we decided to put our introductory computer class online. More specifically we set out to:

1. Put all instruction and evaluation online in an asynchronous format. Students could work at their own pace and skip lessons on topics they already knew.
2. Use multiple media types and rich media types to accommodate different learning preferences.
3. Automate course administrative functions (collecting assignments, assigning grades, etc.) so staff could spend more time working with students.

In order to be successful we had to create an online experience that was as good as or better than the classroom experience. To accomplish this we had to identify features of the classroom experience that were important and find ways to achieve the same effect online.

We have been offering the course online for two years. By most measures our experiment has been a success. Today the course exists in 4 different versions and attracts students from around the United States. Enrollment has gone up 400% since the course was offered in a traditional classroom. Students report a high level of satisfaction with what they learn and with the method of delivery. The technical infrastructure has proven to be a valuable component of the overall course and is being incorporated into other online offerings.

In this paper we report on our experience. We think our most significant result is the demonstration of how online courseware and automation can be used to effectively manage students with a wide range of skills and abilities.

2. How the course works...

Probably the best way to understand how the course works is to follow the path of a typical student.

Step 1 – The student signs up for the course and we mail him/her an introductory letter. The introductory letter gives the student his/her user ID and password. The letter also explains two methods for getting started with the course:

- I. The student can access an online new student orientation, or
- II. The student can attend an “open lab” for a face-to-face orientation session.

About 77% of new students take the online new student orientation. Open labs are set times when an on campus lab is reserved and students can meet with a staff member to receive personalized help. A prerequisite for *remote* students is that they have enough skills to take the online orientation. There are no prerequisites for local students. Students that don't already have Internet skills can learn them during an open lab or during special face-to-face orientation sessions conducted during the first two weeks of class.

Step 2 – The student studies the online course content. Course content consists of text, pictures, video, audio, animations, and simulations.

Step 3 – The student works on and submits assignments.

There are two types of assignments. The first type is multiple choice true/false. These assignments are graded by the computer and returned to the student immediately. If a question is missed the correct answer is given and in some cases links back to relevant sections of the content are provided.

The second type of assignment requires the student to create a document (word processing, spreadsheet, etc.). Once the student has created the document he/she uploads the file to our server through a web page. Online submission allows us to efficiently receive and organize student assignments.

Through a faculty interface a staff member downloads and grades the assignment.

Step 4 – The student checks back in a few days to see his/her grade and any comments the grader had.

Step 5 – When the student is ready he/she attends an open lab and requests an exam. Remote students make arrangements to take exams from a testing center that is local to them.

In addition to the student and faculty interface, the course also has a proctor interface. Proctors at remote testing centers log on and download exams through the proctor interface. Proctors may also return student exams over the Internet.

Step 6 – We submit grades on semester boundaries. Students who have completed all assignments and all exams receive a grade. All other students receive an incomplete. If more than 9 months goes by and the student hasn't finished the course, that student is assigned a failing grade.

The faculty interface also contains a grading tool. This tool calculates and assigns a grade to everyone who has completed all of the course work. This end-to-end automation makes it very efficient to handle a large number of students or the rush times caused by allowing students to work at their own pace.

We now discuss the most significant features of the course in more detail.

3. Online Content

Having the content online in a digital form allows continuous update to both the content and the presentation of the content. When a student asks a question that is already answered online that is an indication the presentation might be insufficient. Because both the content and the presentation of the content can be continuously updated the quality of online content tends to be very high.

Much of our content is online in multiple forms. For example, students can learn a new word-processing command by reading about it or they can watch a short animation that shows the command being used.

The unique characteristics of the Internet allow for new and innovative types of online content. For example, some topics are presented with an AdaptiveLecture™. An AdaptiveLecture lecture works like this: Before the lecture the student takes a quiz. The lecture is then generated dynamically and includes only the content necessary to answer the questions that were missed. This is better than the student using his/her judgement about what topics to skip, because it directly links topics to competencies.

4. Asynchronous Content

When online content is designed to be asynchronous additional benefits can be realized. The most obvious benefit is students can work at their own pace. Another benefit is that since there are no scheduled class times there is never a schedule conflict with other classes.

Online asynchronous content is changing the definition of a semester. Because the content for our course is online and asynchronous students can start the course at any time. We also allow 9 months to complete the course rather than the 16 weeks of a regular semester. To accommodate the semester system at the University we assign an incomplete for every semester that goes by while the student is still working on the course.

One consequence of having all the instruction and evaluation online we didn't fully anticipate was that students tend to head for the assignments first and refer back to the content only as necessary to complete an assignment. In a traditional classroom instruction usually precedes assignments and students are motivated to concentrate on the instruction in order to prepare for *any* assignment. This made it important for us to design comprehensive assignments that would expose students to all instruction.

5. Time Management

Without a doubt the biggest challenge for us and students is time management. Students aren't accustomed to setting their own schedule for course completion. The tendency is for students to postpone work until the end of the semester and/or the end of the 9-month period in which they have to complete the course. This puts more pressure on students and staff toward the end of a semester.

To quantify this issue we ask incoming students if they plan to complete the course during the current semester. One semester 99% of the incoming students said they planned to complete the course during the current semester. In reality only 75% of the students completed the course by the end of the semester.

Our response to this issue has been to:

1. Encourage regular and steady progress
2. Automate assignment and exam grading to manage the end-of-semester rush that inevitably occurs.

To encourage regular and steady progress we warn students during the orientation lecture that they will be tempted to postpone working on the course. We also make it clear that it's not that there isn't a schedule for the course, but that *they* set the schedule for completing the course.

To capture some of the motivating influence present in a traditional classroom we provide an online class progress page. It shows for all students which assignments and exams they have completed. It doesn't show grades but it does show students how they are doing with respect to the rest of the class.

To help students schedule their time we formatted the course content to fit a 16-week schedule. We also provide a recommended schedule that includes a task list for each week. Students can print the recommended schedule and fill in for each week the expected and actual completion date for each activity.

On the lighter side we post a weekly puzzler to encourage students to visit the web site regularly. Each week we post a new puzzler and answer the puzzler from the previous week.

Because the course is online and asynchronous it attracts students that might not have time for a traditional classroom course. The consequence is that the course self-selects students that are likely to have trouble completing the course in one semester. However, even when you take this into account our experience suggests that the time management issue is one that needs more research.

6. Course Automation

The course incorporates two types of automation:

1. Content Automation, and
2. Infrastructure Automation

Content automation refers to technology that enhances the way content is presented. For example, AdaptiveLectures filter content in a way that personalizes the course to the needs of each student.

Infrastructure automation is the application of office automation techniques to the business of running a course. Infrastructure automation improves the productivity of the staff. Since the course was taught in the classroom enrollment has gone up 400% but staff size has increased by only 50%.

Technology moves fast. Recognizing we were working in a fast moving environment we choose to pick the best technologies and design around well-known interfaces. For example, we use CGI programs to deliver dynamic course content. In the short time we have been offering the online course the preferred technology for delivering dynamic content has changed twice (Perl → C++ → Java) but the interface remains the same. By designing around well-known interfaces we can take advantage of newer technologies without losing our initial investment.

Most of the automation tools used in the course have been design and build by work-study students from our computer science department. They get real-world project experience and we get custom tools built with state-of-the-art technologies.

7. Student Feedback

Incorporated into the course are various methods of obtaining feedback from students. Students complete a short survey on entrance and exit. Also, as part of one of the course assignments we solicit written comments from the students.

Overall students are satisfied with the course. The following graph summarizes the results of our surveys:

Not surprisingly, the issue of time management came up the most. The following quote from one student summarizes it best:

This course has taught me several things. I have learned many new skills on the computer, but most of all I have learned the importance of being responsible even when I am not being watched. With this course being strictly over the Internet it has been really easy to slip behind in the course work. As students I think that we are used to being in a structured classroom where our progress is closely monitored. This class allows the student freedom to complete work at their own pace while teaching them responsibility.

Not all comments were positive. Most of the negative comments dealt with the frustration of working in a public lab or the increased difficulty of learning from a computer as compared to learning in a classroom. The following comment by one student characterizes this latter sentiment:

I have not taken an Internet course before, and I probably won't again. It has been difficult to follow the lessons and toggle to Word to apply. I have found that in my computer experience, I learn better in a one on one situation.

What was not made clear to this student was that he or she could receive practically unlimited personal instruction during the lab times that we reserve for open labs. Because of the high productivity gains from course automation we could easily afford to hire a personal tutor for every student that expressed dissatisfaction with the online format.

8. Conclusion

Increasingly educators are being asked to teach students with diverse skills and abilities. For the past two years we have been teaching an introductory computer class online. The online format has helped us manage diverse student needs because:

1. Online asynchronous content allows students to work at their own pace
2. Multimedia types and innovative teaching tools accommodate different learning styles
3. Automating routine teaching and administrative tasks allows staff more time to work directly with students

How to recapture in an online course the motivating influence of regularly scheduled classes remains a research issue.

Planning, Implementing, and Evaluating an Internet Inservice Workshop

Celina Byers

Learning Resources & Technology Services, St. Cloud State University, 231A Centennial Hall,

Abstract: As part of the cooperation between the University of South Dakota School of Education and regional school districts, in the fall of 1998 an inservice training program was conducted to enable elementary and high school teachers to incorporate Internet resources into their courses. Training principles drawn from scholarly literature were utilized, and the training was evaluated to assess the degree of success achieved.

1. Introduction

A faculty member of the Division of Technology for Training and Development (TTD) in the School of Education at the University of South Dakota (USD), this author was asked to join another TTD professor to create a training program. The new superintendent of Centerville school district wanted his schoolteachers to become aware of the Internet's use as a teaching tool, understand how it works, and utilize it to enhance and modernize their curriculum. The training was part of the Fall 1998 inservice program. The Centerville schools Centerville had been conservative in acquiring technology, but the new superintendent worked to install various innovations, including computer laboratories both for elementary and high school. The training request was for the USD professors to prepare a 15-contact-hour workshop that would allow the option for participants to pay tuition and count the inservice as a one-credit class. Although the requested training would not completely fulfill the teachers' needs for training nor enable them to effectively incorporate technology elements into their curriculum, USD was happy to be asked for participation. The TTD division at USD has founded and maintains the Professional Development Center, which works closely with the local schools to improve teacher training. While performing this function, the TTD team has seen local instances of a common problem. Schools sometimes spend most of their budget on hardware and software acquisition, and then do not have enough financial resources to train teachers and staff how to use the technology. The problem seems to be more evident in districts with very limited budgets. They prioritize the purchase of the hardware and software and are immediately reinforced by parent and community satisfaction, but very soon they start wondering why the equipment is not being used [Miller 1996] [Oliver 1997] [Roberts 1985].

2. Workshop Participants and Schedule

The teachers were divided into elementary and high school groups. This paper will address only the 17-member high school group, since that is the group that this author was in charge of. The first workshop session, because it happened before school started, was planned for two consecutive days at USD with a total duration of 9 hours, 6 the first day and 3 the second. The remaining 6 hours were scheduled to be at Centerville during the semester in two-hour sessions after school hours. The school, as a way of showing support and emphasizing the high priority of the technological workshops, provided transportation and lunch arrangements for the entire group.

Before the course started, the superintendent informed the trainers of the disadvantage that the level of computer skills of the entire group was very low. On the other hand, a strong training advantage would be available in the form of the computer laboratory at the school, where the final 6 hours of training would take place and which would be available both for classroom activities and for independent practice. The first two days of training were to be held at the USD facility, a computer-equipped classroom containing 17 Windows-based computers and 3 Macintoshes as well as an overhead projector connected to the teaching station, which allowed an enlarged view of the computer screen. Netscape was the browser installed on all the computers.

3. Planning

The situation freed the trainers from having to deal with the common training burdens of scheduling, participant selection, and budget [Holmes & Duffey 1993] [Bradford, Kannon, & Ryan 1996], but it had the disadvantage of not allowing them to cover important aspects of adult training effectiveness like previous knowledge of the participants, familiarity with participant motivation, and, most importantly, the individual background that each trainee brings to the workshop [Knowles 1987].

Having been informed that the participants were inexperienced with computers and new to the Internet, the trainers to carefully considered basic design elements when laying out the training plan. Research shows that the more computer-naïve the audience is the more detailed the training program has to be in order to be efficient [Humbert & Kefferstan 1995]. Therefore, the topics covered in the training sessions started from point zero. Foreseeing a wide diversity in interest and learning rates on the part of the group members, however, the trainers also included techniques to attend the needs of learners with different levels of knowledge and skills. The training topic was the Internet and its potential use as an educational tool, so a Web page seemed to be the logical vehicle to introduce the program to the participants.

For a training program to make an impact on performance it needs to provide support to optimize the trainees' memory function. This allows them not only to understand the content but also internalize the essential steps that allow them to transfer the acquired skills from the training to their daily activities. When training delivers a large amount of information, sometimes the trainees are unable to incorporate the necessary information into their memory and the training does not produce the desired effect. Providing adequate opportunities for rehearsal, for example, contributes to the success of training by offering the trainees a chance to transfer training course information and skills and carry them into post-training experiences [Clark 1995]. Online Internet tutorials were used to deliver some of the training content, which permitted the participants to explore the topics at their own pace and interacting with the training instead of passively receiving an instructor's lecture. Because the content was available on-line the learners could also visit the page and its associated resources at will from home.

4. Implementing

The teachers were informed about the planned activities for the two-day training and that the Web page containing all of the training material would be available to them from anywhere they had an Internet connection. They were then asked to pair with someone and explore an on-line tutorial that gave them an overview of the Internet. The trainer, observing the principle that adult learners need to feel in control of their learning process, asked the group members to pair with the person they thought most appropriate [Knowles 1987]. The opportunity for hands-on activities seemed to please the group, reinforcing the findings of [Tomei 1996], who points out the importance of hands-on training when promoting teachers' use of technology in the classroom. The trainer answered questions, provided help when asked for it, solved problems that arose, but functioned as a coach and resource rather than a conventional teacher. For pairs who were more knowledgeable about the Internet, the hyperlinks in the tutorial allowed branching to more advanced topics. Bookmarking was chosen for coverage beyond that of the tutorial and was the second activity of the workshop. The trainer walked the group through adding, filing, and editing bookmarks, and the group members immediately saw how they could identify important resources and organize them for easy retrieval in the future.

The third workshop activity, and one that the teachers largely appreciated, was downloading files from the Internet. The trainees practiced downloading clip-art images and , to give some practical point to the exercise, opened a word processor, inserted the downloaded pictures into text documents, and printed the result. They became quite enthusiastic as they realized the Internet held a huge assortment of images available to them from millions of Web sites all over the world. During this activity, the group also practiced downloading and installing programs that they could get free from Web sites. For this, as well as every other activity, the group was always stimulated to think of ways that they could apply the skill just learned in their daily activities.

The fourth workshop topic was using the various Internet search tools. It is a paradox that the Internet, a nearly infinite repository of information, is often the subject of complaints that it has so much information that the user cannot find anything. Although there is some basis for these comments, the fact is that the Internet has an enormous capacity for efficient data retrieval. It is also a fact that some training is required to learn which search devices are best to find given types of data. Yahoo!, for example, one of the first and still perhaps the most popular search resource, is a search directory, which means it searches through Web sites that have been submitted by Web-

site owners and that have been accepted into its system according to criteria determined by Yahoo! If one knows with relative accuracy what one is looking for, a search directory is usually a better choice because the information is already organized and indexed by subject. If one has only a vague idea of what one is looking for, however, a search engine like AltaVista is probably a better choice. A search engine matches the search keywords with sites on the entire Web, returning a correspondingly larger volume of responses, an analysis of which can be used to concretize one's idea, determine appropriate new or added keywords, and refine one's search to retrieve responses that provide the desired support for one's research. In other words, knowing which of the search tools that the Internet makes available best serves one's specific search need allows one to fill that need more quickly and completely. The search topic was delivered to the group through an MS-PowerPoint presentation that was uploaded to the Web. The group also had the opportunity to discuss briefly what would be involved in using search tools in the classroom.

The fifth topic covered in the workshop was e-mail. The group was provided a link to "hot-mail," where they could get e-mail for themselves and go through an on-line tutorial to learn how to operate the e-mail interface. A flood of possibilities to use e-mail in the classroom sprang spontaneously from the participants while they were involved in this activity, and after finishing the tutorial they immediately became so engaged exchanging messages among themselves that it was difficult to move to the next topic of the workshop.

The millions of Web sites on the Internet represents an enormous variety of taste and quality, which suggests that some attention should be paid to Web-site evaluation. As the last activity of the first day the teachers were provided with an electronic form to do such evaluation. They were also provided with a list of three sites containing school-related material. They were asked to pair with someone and visit at least three different sites and then fill out the evaluation form.

Having learned the mechanics of Internet navigation, Internet search, and Internet evaluation on the first day, the teachers were prepared for the second day of training, in which they were expected to put together a lesson plan that used Internet resources in its execution. The second day began with a short lecture about integrating technology into the curriculum. The teachers were then asked to pair with a colleague and, working together, plan a lesson using Internet resources as the principal content.

5. Results

In order to assess the influence of the training on the participants, a survey was applied at the beginning and at the end of the first nine hours of training. The instrument had 27 items, the first 12 of which were to measure the teachers' general feeling toward the Internet. The next 11 items were devised to measure the teachers' skill level on Internet functions. The last four items were planned to measure the teacher's knowledge of how to apply Internet resources to a curriculum.

The pre-test survey results for the first 12 items show that the high school group had a generally positive attitude about the Internet and the use of it into their curricular activities. The 12 items break down as follows:

- Seventy-one percent agreed or strongly agreed that the Internet is necessary in today's society.
- Eighty-two percent disagreed or strongly disagreed that teachers resent being forced to use the Internet.
- Seventy-one percent agreed that teachers are glad to learn how to use the Internet in their teaching.
- The teachers split on whether students take the Internet seriously; 47% disagreed and 41% agreed.
- Eighty-eight percent agreed or strongly agreed that the Internet is a powerful teaching tool.
- Sixty-five percent disagreed that the Internet is harmfully distracting in teaching traditional material.
- Seventy-six percent disagreed or strongly disagreed they lacked time to put the Internet into teaching.
- They did not see the Internet as a confusing environment, as confirmed by 76% of their answers.
- The teachers also confirmed with 76% of their answers that they like using the Internet.
- Ninety-four percent of the teachers indicated that access to the Internet should be carefully controlled.
- Seventy-one percent thought that the Internet was as important as the school library.
- More than half of the group, 65%, thought that books are not a better study resource than the Internet.

Figure 1: Centerville pre-test survey questions 1-12

The post-test survey results for the first 12 items does not show a significant difference from the pre-test results. There was an increase of uncertainty about teachers' resenting being forced to use the Internet in their classes, with "uncertain" answers jumping from 18% on the pre-test to 41% on the post-test. A slight difference occurred in the responses to the statement that the Internet is confusing; 59% disagreed pre-test, 82% post-test.

Figure 2: Centerville post-test survey questions 1-12

The next 11 items in the survey instrument were meant to verify the level of skill of the participants. The group's answers to this set of items confirmed that they were naive in terms of Internet usage. The results were the following:

- Eighty-eight percent (12% uncertain, 41% disagree, 18% strongly disagree) did not understand the logic of Internet site naming.
- Eighteen percent were uncertain, 29% disagreed, and 18% strongly disagreed that they knew how to get where they wanted to go on the Internet, but 35% indicated no Internet navigation problems.
- Twelve percent were uncertain, 41% disagreed, and 12% strongly disagreed that they were comfortable about using the Internet as a resource, but 29% indicated comfort in using the Internet as a resource.
- Twelve percent were uncertain, 59% disagreed, 18% strongly disagreed they could use bookmarks.
- Ninety-four percent of the respondents indicated they did not know how to download Internet files.
- While 24% said they could print Internet pages, 71% were uncertain, disagreed, or strongly disagreed.
- Although 24% agreed they could retrieve data from the Internet, 71% were uncertain or could not.
- The vast majority, 88%, did not know or were uncertain how to save resources from the Internet.
- Seventy-six percent indicated they did not know or were uncertain about how to do an Internet search.
- Seventy-one percent professed ignorance or uncertainty about how to use Internet search tools.
- Nearly all, 94%, were ignorant or uncertain about the difference between Intranet and the Internet.

Figure 3: Centerville pre-test survey questions 13-23

The items represented in Figures 3 and 4 are designed to measure amount of Internet skills, and there was a positive difference between the pre- and post-test answers, especially on the following five items:

- Pre-test, 71% indicated discomfort using the Internet as a resource. Post-test, 71% were comfortable.
- Pre-test, 88% did not know how to use bookmarks. Post-test, 71% had learned that skill.
- Pre-test, 71% said they could not retrieve resources from the Internet. Post-test, 71% could.
- Pre-test, 76% could not effectively conduct an Internet search. Post-test, 76% said they could.
- Pre-test, 71% could not use the Internet search tools. Post-test, 88% reported that they could.

Figure 4: Centerville post-test survey questions 13-23

The following final set of four survey items was meant to measure the trainees' ability to integrate Internet resources into the curriculum.

- Eighty-eight percent indicated they could not set up a lesson using the school intranet.
- Seventy-one percent indicated they could not do class presentations using Internet elements.
- Eighty-two percent indicated they could not guide their students through a hands-on Internet exercise.
- Eight-two percent indicated they could not integrate the Internet into the curriculum.

Figure 5: Centerville pre-test survey questions 24-27

In respect to these four items, the training appears to have been effective. The percentages for these items changed from negative (uncertain, disagree, strongly disagree) on the pre-test to positive (agree, strongly agree) on the post-test. Going through the items in order, the shift was from 88% negative to 53% positive, 71% negative to 65% positive, 82% negative to 53% positive, 82% negative to 65% positive.

Figure 6: Centerville post-test survey questions 24-27

6. Conclusion

When conducting an inservice workshop for schoolteachers to learn about and use the Internet in their professional activities, including adult learning principles described by [Knowles 1987], findings of research into the degree of computer skill within the training group [Humbert & Kefferstan 1995], observations of [Clark 1995] on the methods and importance of assuring continuity of skill acquisition in post-training activities, and data presented by [Tomei 1996] about the use and importance of hands-on activities proved to be elements that promoted success. Although the results of the pre- and post-tests showed no significant change in attitude, the same tests indicated positive results in the areas of skill acquisition and using the Internet in curricular applications.

Abstract: In this paper we describe a new approach for developing adaptive Web based courses. These courses are defined by means of teaching tasks which correspond to basic knowledge units, and rules which describe how teaching tasks are divided into subtasks. Both tasks and rules are used at execution time to guide the students during their learning process by determining the set of achievable tasks to be presented to the student at every step. Adaptivity is implemented by presenting students with different HTML pages depending on their profile, their previous actions, and the active learning strategy. The HTML pages presented to the students are generated dynamically from general information about the type of media elements associated to each task and their layout. The whole approach is exemplified by means of a course on traffic signs.

1. Introduction

Since it was born, the World Wide Web has been used for learning because it allows students to have access to a great variety of information sources [Llamas et al. 1996][Vassileva 1997]. However, an Internet based learning system will be effective not only if it allows students to navigate between different pages but also if it helps students to achieve better their learning goals. It is true that a good design of the navigation space helps, but it is also necessary to provide more sophisticated mechanisms that modify the navigation alternatives by some sort of adaptation procedure.

There are important differences among students. Some of them are related to personal features as age, interests, preferences, etc and to their previous knowledge (if any) about the subject [Nill 1997][Eklund & Brusilovsky 1998]. There are others which have to do with their preferences for a specific learning strategy.

One of the desirable features of any Web based educational system is adaptivity, i.e. the ability to take into account all the above-mentioned features in order to customize the course contents as well as their presentation format [Brusilovsky 1997]. Different approaches have been proposed to incorporate adaptivity into hypermedia courses. One of them is the technique of sensitive links that are used to establish links between hyper-documents whose availability and contents change depending on the state of the teaching [Brusilovsky et al. 1996][Brusilovsky & Anderson 1998]. Other approaches use typed and weighted links to link concepts to documents and to other concepts [da Silva et al. 1998]. The student's knowledge of each concept is used to guide him/her towards the appropriate documents.

This paper describes an alternative approach to the construction of tutoring systems, which is based on the use of teaching tasks and rules in order to guide the learning process towards the desired goals. This approach has been implemented in the TANGOW system, Task-based Adaptive learNer Guidance On the Web [Carro et al. 1999a] [Carro et al. 1999b]. Courses designed by using TANGOW are dynamically adapted to each student by taking into account his/her profile and actions, as well as different teaching strategies.

2. Course design

When creating a new course, the designer must (1) make a conceptual decomposition of the course into tasks, and (2) establish the relation between tasks by means of rules. These steps will be described in the next two sections.

2.1 Teaching tasks

A teaching task is the basic unit in the learning process. A course is defined as a global task to be performed. Tasks can be decomposed into subtasks and students must perform some or all the subtasks to get the main task performed. A task can be defined by giving value to some general attributes such as its name, description, content type, composition type, and ending requirements. Content type distinguishes between theoretical, practical and example tasks. According to the composition type, tasks may be atomic or composed. Finally, ending requirements are implemented by means of functions which decide, at runtime, whether tasks have been completed. This decision is based on parameters directly related to student actions, in the case of atomic tasks, or on subtask finalisation, if the task is composed.

Teaching tasks have other specific attributes which include a list of media elements (text, images, videos, applets, sounds, animations, ...) which will be used for HTML page generation. The way in which these elements will be combined to construct the final pages is described by means of a description language which specifies their relative positions. If any of the media elements corresponds to an exercise, the correct answer is also given. This can be compared to the AHA system [de Bra & Calvi 1998] where filters for content fragments are encoded by means of conditional sentences included as comments in HTML pages. The main difference with our approach is that we create the HTML pages by linking media elements, whereas in the AHA system the pages are already created and it is decided at runtime which portions of them are shown to the student.

A course on traffic signs has been developed for demonstration and can be tested at <http://helena.ii.uam.es/html/courses.html>. The description of two tasks belonging to this course is shown in [Fig. 1]. The 'Circular signs' task is an example of a theoretical atomic task. Its final requirements associated function ('f_teo') will receive several input parameters such as the number of pages visited so far by the student ('pag_visited') and the total number of pages related to the task ('tot_pag'). The media elements used to generate the HTML pages related to this task appear as values for the HTML field. They will appear in a sequence up-down (M1).

A different example is the 'Traffic Agents: Exercises' task which corresponds to a practical task which contains exercises related to traffic agents. It is an atomic task. The input parameters of its final requirements method ('f_prac1') are the number of exercises done by the student ('exer_done'), the number of exercises correctly solved ('exer_ok'), and the total number of exercises that are available ('tot_exer'). The media elements as well as the correct answer for each exercise are specified as values for the HTML field.

NAME = CIRCULAR_SIGNS TYPE = T ATOMIC = Y DESCRIPTION = Description of circular signs END_METH = F_TEO PARAMS = pag_visited tot_pag HTML = CIRCULARES M1 STOP M1 C_PROHI M1 E_PROHI M1 EP_VEHl M1 EPV_SIDE M1	NAME = TRAFFIC_AGENTS_EXERCISES TYPE = P ATOMIC = Y DESCRIPTION = Exercises about signals by traffic agents END_METH = F_PRAC1 PARAMS = exer_ok exer_done tot_exer HTML = eA1 a M1 eA2 b M1 eA3 c M1 eA4 b M1 eA5 a M1
--	---

Figure 1: Two different task descriptions

2.2. Rules

Task decomposition is represented by means of rules. Each rule is given a name and includes information about the task to be divided ('LHS'), the list of subtasks that are part of the task ('RHS') and a keyword corresponding to the sequencing of the subtasks ('SEQUENCING'). XOR indicates that only one of the subtasks must be performed, OR means that at least one of the subtasks must be performed, AND indicates that all the subtasks must be performed in the order they appear in the list, and ANY indicates that all the subtasks must be performed, but that they can be performed in any order. In addition, the course designer can specify a precondition that has to be satisfied for initiating the task ('ACT_CONDITION') and the parameters ('PARAMS') used for evaluating this precondition (which may be taken from other tasks results). The last rule attribute ('CALC_PARAMS') indicates how parameter values for tasks in the RHS of the rule are propagated to the task in the RHS.

The description of two rules in the driving course is shown in [Fig. 2]. Rule R0 indicates that the 'Types' task is decomposed into three subtasks: 'Circumstantial Signs', 'Vertical Signs' and 'Traffic Agents'. The student must perform the three subtasks, but (s)he can do it in any order. There is no precondition for the rule to be activated, and the propagation of parameters from the RHS to the LHS of the rule is done by adding the values of homonym parameters. In rule R1, the precondition 'c_4' indicates that the rule will be active only if the execution of method 'c_4' returns true when it is given the value for the 'exer_ok' parameter from 'Vertical_Signs' as input.

NAME = R0 SEQUENCING = ANY LHS = Types RHS = Circumstantial_Signs Vertical_Signs Traffic_Agents CALC_PARAMS= time_in msum3 time_in Circumstantial_Signs time_in Vertical_Signs time_in Traffic_Agents [...]	NAME = R1 SEQUENCING= AND LHS = Circumstantial_Signs RHS = Circumstantial_Signs_Theory Circumstantial_Signs_Exercises ACT_CONDITION = c-4 PARAM = exer_ok Vertical_Signs CALC_PARAMS = [...]
---	---

Figure 2: Two different rule descriptions

Details about all the tasks and rules of the driving course can be found at the following address <http://www.ii.uam.es/~rcarro/Webnet99/TaskTree.html>, where each cell corresponds to a task. Those rules in which the task appear at the LHS of the rule (or the RHS) are written above (or below) the task name.

3. Why do we call it "adaptive"?

The set of tasks that the student is offered to tackle at a given moment can vary depending on the student profile, the current teaching strategy, actions performed by the student when tackling specific tasks, and the course design.

3.1. Student profile

The student profile includes personal features such as the student age and native language, the relation between the student and the studied subject, etc. The first time that a student enters a course, (s)he is presented with a test where some personal data and preferences fields must be filled. [Fig. 3] shows the test as filled by two different students.

A task may be defined in different ways depending on one or more of these features. As an example, in the traffic signs course, the "Traffic Signs" task is defined by means of two different rules:

- (RR1) Traffic Signs -> Types, Priority
- (RR2) Traffic Signs -> Types, Priority_Theory

The "Priority" task is defined by rule RP.

- (RP) Priority -> Priority_Theory, Priority_Examples

Figure 3: Different student profiles

Both rules RR1 and RR2 have an activation condition which depends on the student's age. This means that the "Signs" task may be achieved in two different ways depending on the student's age. Basically, if the student is younger than 18, (s)he will be presented with examples about the priority of signs. Otherwise, (s)he will study only theoretical aspects on the same subject (see [Fig. 4]).

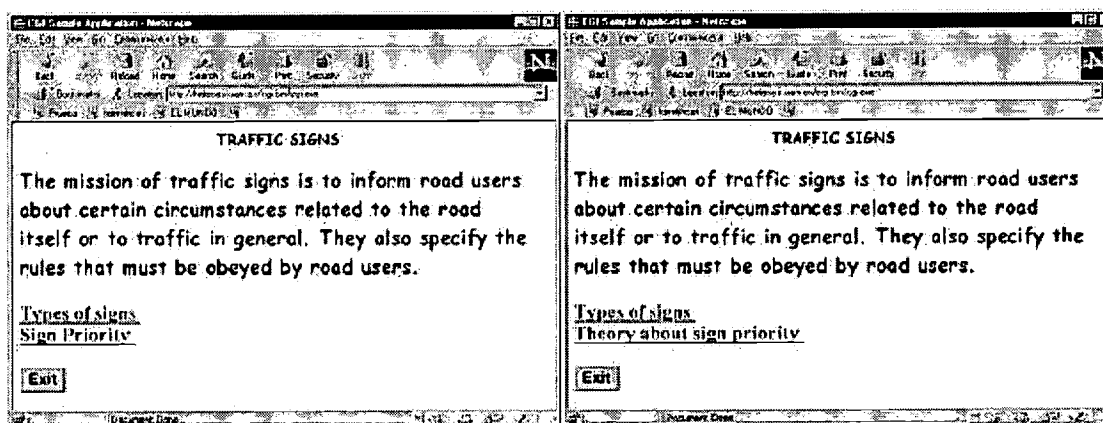

Figure 4: Adaptivity based on student profiles

3.2. Teaching strategy

Teaching strategies have an effect on the order in which subtasks are performed. For example, if the "theoretical before practical" strategy is being used, the student will be presented with theoretical tasks first, and only after they have been performed, (s)he will be able to tackle practical tasks. Similarly, for the "practical before theoretical" teaching strategy (see [Fig. 3] and [Fig. 5]).

3.3. Student actions

A task may be included in the set of achievable tasks at a given moment depending on actions previously performed by the student when tackling a different task. For example, we may decide that a student can only learn about

circumstantial signs if (s)he has successfully solved a number of exercises related to vertical signs (see [Fig. 6]). Note that, in contrast to figure 6a, in figure 6b, the "Description of vertical signs" task is not in the choice set. The reason for this is that the task has already been performed. The "Circumstantial signs" task is accessible because the student has solved correctly the exercises associated to the "Description of vertical signs" task. Other student actions may be related to the time a student has spent learning a task or the number of pages he/she has visited.

Figure 5: Adaptivity based on the learning strategy

Figure 6a and 6b: Adaptivity based on student actions

3.4. Course design

The sequencing specified by the course designer has a great influence in the set of tasks that are offered to the student at a given moment. Initially, when the active task appears in the LHS of a rule with ANY, XOR, or OR sequencing, all the achievable subtasks in the RHS are offered to the student. This is the case for some of the preceding figures. However, if the rule sequencing is AND, only the first subtask in the RHS of the appropriate type (according to the current strategy) and that has not been performed will be made available.

In subsequent steps, three different cases can appear. If the rule sequencing is ANY or OR, the remaining subtasks will be offered to the student by presenting him with a menu page. If the sequencing is ANY and there is only one task left, then the system takes you directly to the information associated with it. In the case of OR sequencing, the student has the chance of exploring new paths before continuing with his (her) learning itinerary. If the rule

sequencing is AND, the student will be offered a single subtask which will be chosen from the RHS of the rule depending on the active teaching strategy. Note that if the rule sequencing is XOR, there is no need to offer additional tasks to the student.

4. Work in progress

The mechanism of teaching tasks presented in this paper adds adaptability to interactive courses, by controlling events about the keystones reached by students at different stages of their learning process.

Work is continuing on the presented system with the immediate goals of (1) extending it so that the teaching strategy may be modified at runtime, and (2) allowing the students to revisit tasks already performed by including frames with task lists in every dynamically generated HTML page.

Third Generation Adaptive Hypermedia Systems

Curtis A. Carver Jr, John M.D. Hill, and Udo W. Pooch
Department of Computer Science, Texas A&M University, USA
Email: carverc/hillj/pooch@cs.tamu.edu

Abstract: This paper examines the development of adaptive hypermedia systems and proposes adaptive characteristics for third generation adaptive hypermedia systems. First generation adaptive hypermedia systems predated the World-Wide Web (WWW) and were primarily single user adaptive hypermedia systems. Second generation systems have exploited the distributed nature and ease of authoring of the WWW to develop more robust and mature adaptive hypermedia systems. While these systems are a dramatic improvement over first generation systems, they have several limitations that limited the effectiveness of adaptation. These limitations include limited adaptation through one-dimensional, stereotypical user models, coarse granularity of adaptive support, closed adaptive hyperspaces with sharp boundaries, limited authoring support, and limited and non-constructive communications between the user and the adaptive model. Third generation adaptive hypermedia systems must address these shortcomings to fully exploit the potential of adaptive hypermedia. Future systems must provide explicit, fine-grained adaptation support that the user can easily tailor and refine to provide highly relevant multidimensional adaptation. Future adaptive hypermedia systems must be open systems with soft boundaries that are expandable and incorporate resources from non-adaptive hypermedia with gradual degradation of support. Finally, adaptive systems must be relatively easy to build and maintain. This paper examines these characteristics of future adaptive hypermedia systems and proposes a framework for development.

1. Background

1.1 First Generation Adaptive Hypermedia Systems

Numerous adaptive hypermedia systems have been implemented over the last fifteen years. These systems can be characterized as first generation or second-generation adaptive hypermedia systems based on when they were developed and what delivery mechanism was used for deployment of the systems. First generation systems span the period from 1985-1993 and are principally adaptive systems that were not distributed in nature. These systems were generally PC or Macintosh-based provided limited adaptability through stereotype-based user models and limited functionality adaptation techniques such as conditional text filters, direct guidance, stretchtext, hiding, and primitive link annotation. EPIAIM [Rosis et al. 1994], Hypadapter [Bocker et al. 1990], ITEM/IP [Brusilovsky 1992], ISIS-Tutor [Brusilovsky and Pesin 1994; Brusilovsky and Pesin 1994], MetaDoc [Boyle and Encarnacion 1994], and MetaDoc V [Boyle and Teh 1993] are examples of first generation adaptive hypermedia systems.

ISIS-Tutor is a good example a first generation adaptive system. It is an adaptive learning environment for the information retrieval system CDS/ISIS/M (ISIS) [Brusilovsky and Pesin 1994; Brusilovsky and Pesin 1994]. ISIS-Tutor provided adaptive support through frame-based presentation, link annotation, and information hiding. It presented an adaptive sequence of tasks and concepts based on the user model and maintained a four state, user knowledge model (not-ready-to-be-learned, ready-to-be-learned, in-work, and learned) on each concept within ISIS. As the user progressed through the system, ISIS-Tutor annotated each concept with color and hiding could be enabled to remove concepts that the user was not ready for. ISIS-Tutor was one of the first adaptive models to incorporate more than a bipolar knowledge model and one of the first adaptive systems to have empirical support for the effectiveness of adaptive interfaces [Brusilovsky and Pesin 1994]. The advent of the World-Wide Web, however, provided new opportunities for the development of adaptive hypermedia systems and led to new systems and more advanced adaptive techniques.

1.2 Second Generation Adaptive Hypermedia Systems

Second generation systems span the period from 1993 to present and predominantly use the WWW as their delivery and presentation means. These systems have worldwide availability and are generally platform independent. Second

generation systems introduced new capabilities such as adaptive multimedia presentation, map adaptation, and link sorting. They also refined existing adaptation techniques to provide greater functionality. User models became more robust and incorporated more user characteristics. AHA [Bra 1996; Bra and Calvi 1998], ARNIE-HyperMan [Mathe and Chen 1994; Rabinowitz et al. 1995; Mathe and Chen 1996], AVANTI [Fink et al. 1997; Rizzo et al. 1997; Nill 1998], Basar [Thomas 1995], CS383 [Carver et al. 1996; Carver et al. 1996], Cameleon [Laroussi and Benahmed 1999], ELM-ART [Brusilovsky et al. 1996], I-Doc [Erdem and Johnson 1998; Erdem et al. 1998], InterBook [Brusilovsky and Eklund 1998], KN-AHS [Kobsa et al. 1994], MediaDoc [Erdem et al. 1998], RATH [Hockemeyer et al. 1998] and WebWatcher [Armstrong et al. 1995] are examples of second generation adaptive hypermedia systems.

ELM-ART (The Episodic Learning Model: The Adaptive Remote Tutor) is good example of a second-generation adaptive hypermedia system. ELM-ART is a distributed intelligent tutoring system on LISP that provides course adaptation through a combination of adaptive annotation and link sorting [Brusilovsky et al. 1996]. Links are color-coded according to user preparation for the information in the node. Red annotations indicate nodes that the user has to meet the prerequisites for, amber nodes represent information the student is ready for but not recommended, and green nodes represent nodes that the user is ready for and are recommended. ELM-ART adaptively sorts links as well so that the links that are most similar to the node that the user is currently on are presented first.

ELM-ART features extensive user feedback and is highly interactive. As the user completes exercises and reads nodes, status bars change to reflect the user's progress through the course. Link annotations change color and the navigational view changes to reflect the user's newly gained knowledge. Users can directly edit the user model and override the navigational choices present to meet their educational goals. An extensive number of exercises engage the user and provide constant feedback both to the user and to the user model on the user's evaluated knowledge.

While second generation adaptive hypermedia systems such as ELM-ART have dramatically improved upon the functionality of first generation systems, there are fundamental flaws associated with these systems. These limitations include limited adaptation through one-dimensional, stereotypical user models, coarse granularity of adaptive support, closed adaptive hyperspaces with sharp boundaries, limited authoring support, and limited and non-constructive communications between the user and the adaptive model. The remainder of this paper will discuss these limitations with second-generation systems and propose framework for solutions.

2. Third Generation Adaptive Hypermedia Systems

2.1 Multidimensional User Models

Third generation adaptive hypermedia systems should support multidimensional user models. Current user models measure limited user characteristics to normally a single dimension such as declared or demonstrated knowledge, or hypermedia nodes visited. For example, AHA [Bra and Calvi 1998] uses the number of nodes visited while CS383 [Carver et al. 1996] consider learning styles as the basis for the user model. Actual users in a learning environment are much more complex and are both multi-dimensional and multi-faceted. Future user models must incorporate multiple dimensions of the user including expertise, user goals, interests, and preferred learning style by subject matter. These dimensions may be declared by the user, measured by the adaptive system, or combination of both approaches.

Not only must the user model incorporate multiple dimensions, the importance of an individual user model dimension may vary over time. As a user progresses through hyperspace, their goals and interests may change as they learn new concepts. The user model must quickly adapt to these changes in the user model so as to present relevant information to the user. Discrepancies between declared and demonstrated user characteristics must be resolved and presentation of material adapted. The users of adaptive hypermedia systems are not one-dimensional but instead are multidimensional. Future user models in adaptive hypermedia systems should be multidimensional and adaptive as well.

Providing adaptive, multidimensional user models raises a number of open research issues. Most current adaptive systems allow their users to explicitly manipulate the user model. This is most commonly done through a long list of checkboxes. Different presentation techniques will be required for users to effectively manipulate multiple user dimensions. The effective manipulation of a multidimensional user model clearly presents significant user interface

issues. Additionally, it remains an open research issue as to what is the proper type and number of dimensions to measure. Adding additional dimensions will not always increase the accuracy of the user model but will always increase the complexity of the user model and the requirements to collect additional user information. There is a balance between the number of dimensions, model complexity, and the accuracy of the model. Finally, techniques for modifying the weights associated with different dimensions dynamically to better represent the user are open research issues.

2.2 Finely Grained, Multimedia Adaptation

Third generation adaptive hypermedia systems should provide a fine degree of adaptation granularity and adapt more than just hypertext. All second-generation adaptive hypermedia systems provide text-based adaptation based on a user model with limited levels of user differentiation. In addition to using multidimensional user models, third generation systems must incorporate multiple levels in each user model dimension so that the adaptation provided is truly tailored to the user. Users are not just novice, intermediate, or expert users but range a scale of many intermediate values. Users are not simply sequential or global learners but instead are some combination of both characteristics. Third generation adaptive hypermedia systems should not only model multiple dimensions of the user, but each dimension should have as much delineation as necessary to truly model the user.

In the last five years, there has been significant growth in the granularity of user models in adaptive systems such as ELM-ART [Brusilovsky et al. 1996], InterBook [Brusilovsky and Eklund 1998], AHA [Bra and Calvi 1998], and RATH [Hockemeyer et al. 1998]. These systems incorporate numerous exercises to capture more accurately user knowledge of hypermedia material covered. Third generation adaptive hypermedia must continue to build upon the successes of these earlier systems.

Third generation adaptive hypermedia systems should adapt more than hypertext. Adaptive hypermedia systems have traditionally focused on text presentation or navigation support. Only one system, CS383 [Carver et al. 1996] implemented adaptation of other media types such as sound, graphics, or video but its implementation was limited to adaptation of media type (not individual media elements) by learning style. Third generation systems must expand adaptation so that appropriate pictures, movies, slideshows, or sound files play to different users.

Introducing fine-grained multimedia adaptation raises a number of open research issues. Like adding additional dimensions to the user model, adding greater granularity to each dimension requires a much greater implementation effort and increases the complexity of the user model. Assessing the proper balance between granularity and adaptive system performance remains an open research issue. Multimedia adaptation adds additional complexity and requires a greater implementation effort. Media elements, other than text, are more difficult to generate and are not as malleable to automatic recombination. It is extremely difficult to automatically adapt video segments on the fly and present the results to users for example. Techniques for adaptation and presentation of media elements other than text are open research issues.

2.3 Open Adaptive Hypermedia Systems

Third generation adaptive hypermedia systems must support open adaptive systems. All known adaptive hypermedia systems, with the exception of Personal WebWatcher [Joachims et al. 1997], are closed navigation systems. Adaptation is provided while the user is in the restricted hyperspace of the adaptive system and there are explicit, well-defined navigational boundaries on the system. The adaptive system is self-contained. Because the system is self-contained, the author of the adaptive system must ensure that all information the user might require is inside the system. If users are not satisfied with the information resources within the system, they can either remain dissatisfied and use the adaptive system, or leave the system.

Third generation adaptive hypermedia systems should allow users to stay within the adaptive system but travel to informational resources outside of the navigational boundaries of the adaptive hyperspace. This tunneling through adaptive navigational boundaries provides the user the ability to gather additional informational resources and return to the adaptive system when ready. These informational resources may be links provided by the adaptive system to

non-adaptive information resources outside the system that are constrained in a separate frame or in a new window, or may be a general-purpose search capability.

This ability to integrate external informational sources within the adaptive system provides a number of advantages that second generation adaptive hypermedia systems cannot. The informational resources of the adaptive system are significantly increased without a large amount of work by the adaptive system author. Users have greater flexibility to more deeply explore information within the conceptual model of the adaptive system and pursue individual goals and interests. But more importantly, based on the number of tunneling attempts outside the adaptive hyperspace by concept, the adaptive system gains a quantitative measure of informational regions within the navigational space that are not meeting user needs. Armed with critical feedback, the adaptive system author can then add new information to the system, remove useless information, provide additional external links to known information resources, or provide a general-purpose search engine. Future adaptive hypermedia systems should be open systems with soft boundaries as opposed to closed systems with hard limitations.

There are significant implications in the construction of open adaptive hypermedia systems. Adaptive hypermedia is no longer self-contained but instead is part of larger body of information. The synergistic integration of search engines and glossaries becomes important. Some second-generation hypermedia systems, such as InterBook [Brusilovsky and Eklund 1998], have already begun to include adaptive glossaries and several systems use extensive assessment to provide more accurate adaptation. As glossaries, digital libraries, search engines, assessment engines, and resources external to the adaptive system are added, third generation adaptive systems will be more of a solution and less of a research prototype.

Opening adaptive hypermedia systems to include informational resources outside of the navigational space of the adaptive system raises a number of interesting research issues. Capturing the tunneling activity and correctly categorizing it becomes an important research area. Are multiple, successive tunneling attempts indicative of a confused, frustrated user, a novice user exploring every link, or a happy, enthusiastic user that wants to leave everything they can about the subject matter at hand? Controlling the effects of context shift is another open research area. Even if the material is appropriate, it may be in a presentation style that causes the student to lose focus or become confused. Ensuring that users do not become lost when leaving the adaptive navigational space is likewise an open research issue. Finally, how to capture and react to user tunneling efforts is an open research issue.

2.4 Constructive Hypermedia

Third generation adaptive hypermedia systems should be constructive in nature. The most accurate user model is the one that users construct themselves. Users should have the capability to easily add material to the adaptive system with a clear delineation of material from the original author and from users. User should be able to view the original material only, all user comments, or their comments only. They should be able to add comments to pages as in the ELM-ART system [Brusilovsky et al. 1996] or annotate links, a technique which has not yet been implemented in an adaptive hypermedia system. Constructive hypermedia provides the most precise and fine-grained form of adaptation. As the complexity or size of adaptive hypermedia systems grows, so too will the need for constructive hypermedia.

There are a number of open research issues associated with constructive, adaptive hypermedia. User construction may be indicative that the underlying adaptive system is not meeting the information needs of the user. Mechanisms for evaluating user constructions and modifying the user model as necessary need to be explored and developed. Providing access to all user comments may not be productive and may confuse the user more than help them. Methods must be developed for assessing the impact and utility of user construction on the user and adapting the system appropriately. Further assessment of this approach is necessary before implementation.

2.5 Other Third Generation Attributes

2.5.1 Adaptation Feedback

Third generation adaptive hypermedia systems should provide better feedback to the user and better incorporation of user feedback into the user model. Users should easily be able to determine where they are, where they have been,

what they have left to do, and what the user model is doing to them. In terms of adaptation, the user should be able to quickly understand the adaptation model and modify it to provide better adaptation. ELM-ART [Brusilovsky et al. 1996] is an example of a second-generation adaptive hypermedia system that provides excellent adaptation feedback. Additional work is necessary particularly in light of the multi-dimensional nature of the user model, to provide the user with clear feedback as to how user activities are influencing the adaptation.

2.5.2 Ease of Authoring

Third generation adaptive hypermedia systems must be easy to build and maintain. Most second-generation adaptive hypermedia systems are handcrafted and not easily expandable or adaptable to other projects. As adaptive hypermedia systems grow in size, dimensions, or the granularity of those dimensions, the ease of construction and maintenance of the systems will increase in importance.

2.5.3 Assessment of Effectiveness

Additional, statistically valid assessments of the effectiveness of adaptive hypermedia are necessary to validate the approaches that are effective and those that are not. Most assessments of second-generation systems were conducted with very small sample populations. Assessments of adaptive techniques, adaptive systems, and user models have begun but remain open research areas.

3. Conclusion

This paper has examined the development of adaptive hypermedia systems and proposed several attributes for third generation adaptive hypermedia systems. Third generation adaptive hypermedia systems must incorporate fine grained, multidimensional user models that support open, constructive, adaptive systems that are easy to build. Numerous research issues require resolution to provide these capabilities. Adaptive hypermedia systems have made great strides in the last fifteen years, but new capabilities and a better understanding of users and adaptive systems opens new avenues of research. Research into these issues raised by the advent of third generation adaptive hypermedia systems will bring us closer to realizing the full potential of adaptive hypermedia.

Abstract

We present a research concerning the best way of structuring educational content on the Web. Our belief is that both the organization of the nodes and the cognitive capabilities of subjects deeply influence the learning process. We built a test with three versions of the same lesson, submitted to three groups of university students: a paper version, a hierarchical version, and a networked version. Having evaluated the cognitive capabilities of the subjects, having looked analytically at their behaviors in the navigation, and finally having measured a "learning" score, we found that the worst performance was obtained by the group that used the networked hypertext. Moreover, the best was not the "paper" group, but the group facing with the hierarchical structure. The claimed educational effectiveness of the WWW seems to be a misconception, to be further analyzed, and probably the Web should be reconsidered only as an extraordinary mechanism for distributing information.

Introduction

In this paper we present the latest results of our long-term research on the problems arising in the learning processes mediated by the hypertext technology, with particular attention to the "lost in hyperspace" phenomenon [Castelli et al., 1991], [Castelli et al. 1997]. Our latest benchmark led us to significant but surprising considerations. We submitted three versions of the same lesson to university students: a paper (sequential) version, a hypertext with a hierarchical organization (tree) and a networked (graph) structure. One interesting indication regards the worst performance obtained by the group that learned from the networked hypertext. Looking at the current studies, these are not completely surprising indications. People like us, who privileged the "web" structure for their educational hypertexts, also on the WWW, are facing with "change of minds". The Web created a tangled network of links in which the "lost in hyperspace" phenomenon is more likely to happen. Many palliatives have been proposed or developed, like backtracking mechanisms, conceptual maps, etc., but in our opinion, the problem is elsewhere.

As with all new fascinating techniques, hypertexts have attracted many people dealing with information, both having to transmit information to others (as teachers) and having to organize information to build information, like researchers, media experts, commercial enterprises etc. However, the same "web" metaphor is not extensible to both the target audiences. For example, the vanguard literature [Landow 1992] immediately felt attraction towards the idea of creating links among text, and teachers found the hypertext a stimulating perspective for creating educational material with the target of creating Open Hypermedia Systems (OHS). The problem is that the student has not the same knowledge of the teacher. This "distance" between them is one of the first recognized reasons of disorientation in hypertext, and it becomes more evident when we navigate through the World Wide Web. Authors build "a priori" conceptual spaces for students they will never meet, without knowing their background, humor, preferences, cognitive capabilities, sex, mental strategies in facing with educational material, etc.

Obviously we are not denying the potential of the WWW as an educational media, but we believe that we all confused the tool with the underlying metaphor, and have applied the metaphor (the web, the network) to everything put on the WWW. Another misconception regards the claimed educational effectiveness of hypertexts (and the Web as a consequence), effectiveness that should be due to the isomorphic relation between the hypertext and the human brain, or between the hypertext and the way we organize thought in our mind [McKendree et al, 1995]. Applying the network organization to the nodes of an educational hypertext seems to lead to unsatisfactory results, in terms of learning, and the experiment presented in this paper confirms this impression.

2. The World Wide Web: is it suited for learning?

"Lost in Hyperspace" is an old issue in the HT research, and surely one of the most difficult to solve by the hypertext / hypermedia community. Since Conklin's cornerstone survey [Conklin 1987] through other specific studies [Edward et al. 89], in every conference or book related with hypertext, disorientation, cognitive overhead, "lost in hyperspace" are crucial problems [Campagnoni et al.,1989]; [Kibby et al.,1989]; [Bernstein,1990]; [Boyle et al.,1990]; [McAleese,1989]; [Jonassen,1990]; [Nielsen, 1990]; [Gay et al. , 1991]; [Tricot, 1993].

There are, however, different ideas to solve it. The first solution is, in reality, a non-solution: "lost in hyperspace" and its negative influence on learning processes do not exist, or they are only marginal problems. According to this, efforts should be channeled to address more interesting and urgent issues - conventional 'human factors', quality of design, response times of the Web etc. [Kellogg & Richards, 1995]. With the advent of the Web, its nature of immense hypertext convinced us that, on the contrary, a further effort must be devoted to the solution of this problem. Many teachers are putting their educational materials on the web, so a new "distributed" way of learning is rising. The implications of the disorientation phenomenon is particularly evident when we try to learn something, but

are not so evident (or crucial) in other activities on the Web. For example, while searching for a new airplane rate, it doesn't really matter if we get lost. With the tools supplied by the browsers (back, previous, history etc.), we can gain the control of the context and start the search again. Nevertheless, if we are learning from web pages, the situation is different. Getting lost is not only a matter of minutes spent to understand where we are in the Web pages, but mostly means to locate ourselves in the learning context, and this is a more delicate issue.

From this perspective, the WWW is a less controllable hypertext with respect to the ones created with hypermedia systems. Many authoring tools, in fact, have a local approach, pages are confined inside the conceptual space that the teacher proposes, and this greatly limits the chances of "getting lost". Moreover, authoring tools use simple programming languages that allow "enterprising" teachers to develop navigational aids to overcome orientation problems. HTML editors have greatly facilitated the creation of web pages, but in our opinion this has lowered the level of carefulness devoted to the navigational structure of the hypertext. Very often, we see educational hypertexts with the navigation mechanisms confined to "next", "previous", "back", "go to index". This is probably enough for a non-disoriented user, but is surely not enough for a possible disoriented, bored, or novice user. In addition, the tracking mechanism is more complex on the Web, and most of all is out of the direct management of the teacher. Tracking users' interactions with the HT is very important, as the teacher can understand the difficulties of the users, where the structure should be simplified, where to add or remove content, etc. In conclusion, if the Web and the HTML language have favored the distribution of educational material, they have reduced on the other hand the possibilities of improving the effectiveness of hypertext technology as a learning medium.

The most frequent reason of learning problems with hypertexts, disorientation, is also amplified by the WWW. Many researchers are studying this problem as a problem generated (and therefore solvable) during the design phase by the author. The rationale is: a coherent and well-structured hypertext should reduce disorientation. Based on this idea we can find many approaches: [Garzotto et al.,1993], [Lange,1994], [Schwabe,1995], [Isakowitz et al. , 1995] are only some examples, while recently many authors are trying to investigate the specific problem on the Web [Brown et al. , 1996] [Svensson et al.,1998]. Following this approach, the most common solutions are:

- predefined paths inserted in the HT, sometimes called trails, guided tours, hypertours etc. [Nicol et al., 1995].
- Providing the hypertext with conceptual and/or graphical maps, both local and global, or other visual aids like fish-eyes views, bird-eyes, zoom viewers etc.
- Providing users' profiling, i.e., creating (before or during the navigation) a set of her/his navigation preferences on the basis of various criteria, to be used for subsequent navigations;
- user is provided on the fly with sorts of "balloon help" regarding what is available and what to do next.

All these tools are valuable and useful, but in our opinion they are too oriented on the author's side. This, in some sense, has a bad effect on the author, i.e., less attention in structuring the HT. In our opinion, we can't improve the way people learn from hypertexts ignoring the problem of disorientation. Not only we have problems related with the structure of a hypertext [Thimbleby 1995], but we also have cognitive problems regarding the performances users provide while reading a hypertext. We believe that the learning process through the hypertext technology deserves a major attention on these two decisive aspects, i.e., the structural aspects of the hypertext and the cognitive capabilities of the users. There is the basis of our experiment presented in this paper.

3. The experiment

The structure of the experiment is quite consolidated: we learned that user's performance on a educational HT is greatly affected by a set of factors, the major of which are in short the following: the influence of some cognitive variables on the subject's performance (like intellectual efficiency, analytical ability, analytical flexibility, synthetic ability, abstract reasoning, cognitive field independence), the presence of a graphical interface, the time of browsing, the differences in performance between males and females, the presence of "loops" on certain nodes and, last but not least, the hypertext structure. We started from most relevant results presented in [Castelli et al, 1997]:

- subjects showed a relevant tendency to use serial mechanisms in "browsing" pages as "a default novice navigation" strategy, thus resembling the traditional approach to text material;
- subjects also showed a tendency to concentrate on information that they associated on the base of a sort of similarity among information, with a partial but preferential use of the hierarchical structure. The preferred structured seemed to be a sort of "cluster" model, consisting of a partially hierarchical framework with branches radiating out to information nuclei aggregated by similarity (by content or by class).

From these considerations, the experiment tried to understand the relation between the level of learning and two other aspects, respectively the cognitive capabilities of subjects and the structure a hypertext. We structured the whole experiments in three steps: (1) making a cognitive profile of the users; (2) submitting the educational material and recording the navigation; (3) evaluating the level of knowledge reached by the users through a questionnaire. Step 1 has been used both to create similar groups and to find relationships between cognitive attitudes and hypertext performances. As regard as the cognitive performances, we submitted the cognitive test called *Raven's Progressive Matrix (PM)* [Raven, 1987], that consists of a series of problematic situations, which, in progression, involve various intellectual processes. Regarding the second step, the structure is the one we firstly experimented in [Castelli et al., 1991], and that has been used in other experiments [Gomes, 1997]: the user reads the hypertext and a hidden program writes on a log files every moves s/he makes with a series of parameters (node id, time on the node, type of node etc.). Based on the target of the research, additional parameters are added to the log files, and the analysis is

conducted matching expected behavior with real behavior of the user on the hypertext. We built two hypertextualized versions of the same paper material, and submitted these two together with the original paper document to three groups of university students. The common task was responding to some questions of a new argument of the course of General Psychology. Students never heard about the topic, a lecture covering a specific argument (Gestalt psychology). The three groups were organized as following:

- one group was given the paper version (we will identify it as the “text” group);
- one group worked on one electronic version with a hierarchical overstructure: the first page of the HT was a tree of the arguments to provide a conceptual and hierarchical map of the topics of the lecture (“tree” group);
- one group with an electronic version structured as a networked set of pages linked together (“graph” group).

The third stage of the experiment was at the end of the time left for learning: a 30-question test was submitted to the students, in order to evaluate the quality of the learning process. The subjects worked on the educational material equally for all the three groups, for about ninety minutes. After an interval of 30 minutes, they faced with the questionnaire, in which the right answer for each question had to be chosen from a list of four.

4. Discussion of the results

[Tab 1] gives the results of the subjects on the cognitive test (PM) and on the learning test (LT), distinct in the three experimental conditions: “Graph”, “Text” and “Tree”. The subjects are identified by the numbers originally assigned to them, with a letter (G for graph, N for normal text, T for tree). [Tab 1] sets out, in order, the raw scores (PM, LT) and centil transformation of LT scores (%LT). The PM scores are yet expressed in centils.

	“Graph” subjects						“Text” subjects					“Tree” subjects					
	g10	g13	g14	g15	g16	g23	n01	N02	n08	n09	n17	t05	t06	t07	t20	t21	t22
PM	68	44	44	75	7	65	49	56	61	57	61	64	61	56	35	63	40
LT	15	8	9	15	14	13	17	18	11	22	19	19	22	8	14	22	15
% LT	50	27	30	50	47	43	57	60	37	73	63	63	73	27	47	73	50

Table 1 – Score on Cognitive and Learning Test

For the subjects who used the hypertext, [Tab 2] presents some indexes for evaluation of the navigation performance. The indexes are derived from processing the navigation raw data, and are mainly concerned with:

- *number of moves*, distinguishing between “navigation moves” and “pages of text” moves;
- *time spent on a node*, again distinguishing between navigation nodes and “pages of text” nodes;
- *repeated visits* to a node
- *difference between* the amount of *time* spent by the subject on a node and “*author time*”, i.e. the time assessed by the author as required to grasp the meaning of the node.

SS	TMV	TT	% RP	% MM	% NM	% HM	% RV	RT-	RT±	RT+
g10	234	5536	85%	34%	66%	21%	55%	15	27	24

t06	231	5405	100%	45%	55%		19%	37	36	9
t07	223	5413	99%	46%	54%		17%	18	47	16
t20	163	6136	97%	46%	54%		6%	14	28	36
t21	198	5361	99%	43%	57%		16%	16	44	21
t22	393	5394	100%	42%	58%		37%	46	21	15

Table 2 – Some indices of hypertext performance

The meaning of the columns in [Tab 2] are the following [Tab 3]:

TMV	Total number of Moves;
TT	Total Time (in seconds) of navigation in the hypertext
%RP	percentage of read text Pages
%MM	percentage of Map Moves
% NM	percentage of Nodes Moves (the sum of: returns to map + multiple pages moves + hotword moves);
%HM	percentage of Hotword Moves; this index is valid only for the graph version of the hypertext, as there were no hotword in the tree version
%RV	percentage of Return to Visited nodes on total moves, excluding the map returns;
AT-	number of pages read with at least 30% of seconds less than the Author Time;

AT±	number of pages read within a ±30% of seconds of Author Time
AT+	number of pages read with at least 30% of seconds more than the Author Time.

Table 3: meaning of columns in [Tab 2]

The first interesting result comes from the learning test ([Tab1] and [Fig 1]), in relation with the type of material used. We see a better global performance of the “tree” subjects with respect to the “graph” group, with the “text” group similar to the “tree” group. Considering the cognitive capabilities obtained ([Tab 1] and [Fig 2]), this result has a particular meaning. In fact, the three groups had similar cognitive capabilities, with a slight predominance of the “text” group. Since the groups were limited, in order to verify the consistency of our results, we carried out two kinds of statistical analysis to verify the following:

1. are the score obtained in the three conditions so different to create three different samples?
2. Are these differences real or are they induced by the different cognitive capabilities of the samples?

For the first issue, we used the *Montecarlo Method* (with a random draw of 10.000 samples): the evidence of the difference in the groups has not been obtained with the mean (only a probability of 12% that the “tree” and “graph” groups were independent), but with the median (the probability of independence of the two groups raises at 97%). This difference seems to be related to the presence of one subject in each group who had a very low score: the median “shades” the effects of these marginal subjects.

For the second issue, we used a linear regression test on the *Learning Test* and the *Cognitive Test*. From this we deduced that, with the same score at the *CT*, the three situations are different, while the “text” and the “tree” have the same influence on the *LT*, the difference between “tree” and “graph” in influencing the *LT* is significant at the level of $p = .10$. From these data, we can infer the following general considerations.

1. “tree” structure facilitates context control, with a sequential approach resembling the reading of a book;
2. “tree” perform better than “graph”, and this could be due to the time spent in organizing the access to the structure. This time absorbed many resources of the “graph” subjects to dominate the HT structure. The hierarchic structure, instead, is already an indication on the organization. This explanation could be supported by the navigational data, that show: a) many “returns” of the “graph” group to nodes already seen ([Tab 2], column %RV) b) in general, an inferior number of moves with respect to the “tree” group (column **TMV**);
3. Sequence and hierarchy of the “tree” HT resemble the traditional text, where a “passive” reading strategy is generally required. Based on our analysis, we can imagine that subjects with less cognitive capabilities were helped by and took advantage from the hierarchical structure during the navigation;
4. A variable related with the final score *LT* is the time subjects stop on the “map” pages. The worst *LT* subjects are exactly the ones who present the highest peaks and average of time of stop on the map. We can hypothesize only the following, as our data are not sufficient: users have different targets. Subjects with high performances use the map shortly to carry out the next move, because they have already a strategy to follow. Subjects with low performances use the permanence on the map right to develop a strategy because, we can imagine, they do not have a strategy yet and they lose time to develop it.

These considerations could be deepened looking at the individual performances in the two groups. [Fig 3] presents the values of the progressive matrix **PM** and the Learning test **LT**, with respect to the top possible performance.

Fig 1 – Learning test average for 3 groups

Fig 2 – Cognitive test average for 3 groups

We can see immediately the different trends in the two groups:

- The “graph” group has a **PM** score higher than the **LT** score, except subject **g16** that has the opposite trend;
- The “tree” group has the **LT** score higher than the **PM** score, except the subject **g16** that has the opposite trend;
- The “text” subjects have minor differences between the scores, except **n08** (higher **PM**) and **n09** (higher **LT**).

The differences in the two trends seem to confirm the above considerations:

- a) Having the same cognitive capabilities (PM score), the tree structure facilitates the browsing and the study of the material, allowing a more “efficient” access to information and a better attention to the content;
- b) Considering the % of the information read, (column %RP of [Tab 2]; the average of %RP is 98.5 for “tree” and 79.3 for “graph”) the significant difference underlines the different result at the Learning Test ([Fig 1])

Fig 3 – Individual comparison between PM and LT scores

In conclusion, we looked move by move to the performance of the “foreign” subjects for the two groups, **g16** e **t07**. G16 has adopted a clear strategy of browsing the nodes, equal to the “tree” subjects, i.e., repeatedly going back to the map without using the hotwords. G16 used the graph HT as it was a hierarchy (column %HM of [Tab 2] with value 0%). The interesting aspect is that with this “Tree” strategy applied on a graph, the subject had one of the best performances of his/her group, in spite of a low cognitive score. This could enforce the previously mentioned idea that subjects with low cognitive capabilities had better perform on a hypertext with a prevalent hierarchical structure. The other “atypical” subject (t07) is most difficult to interpret. We note that: a) the time of reading (RT-, RT±, RT+ of [Tab 2]) was very frequently tightly aligned with the author time; b) on pages that were important for the solution he/she had short time of permanence (2 or 3 seconds). It must be noted that the “author time” is only sufficient for reading the page, probably not enough for learning its content, and sometimes could indicate an erroneous evaluation of the importance of the page. All these reasons can justify, in our opinion, the bad performance on the learning test.

Conclusion and future directions

We presented the results of a research on problems related with learning processes in the Web educational material. We noted that the network metaphor used to organize educational material is not so suited for everyone. First evidences shows that networked information is good for people that already know the corpus, while people facing with new arguments and/or having less brilliant cognitive capabilities perform better in presence of hierarchical material. In our tests, they evidently had a better management of the hypertext, of its structure, they optimized movement on the hypertext’s nodes and took benefit of the time at their disposal because not caught in understanding and mastering the net. These preliminary results lead us to reconsider the role of networked hypertexts in the computer-mediated learning processes. We also obtained other indications concerning the role of the cognitive abilities in the hypertext reading. First, we noted that, having the same capabilities, subjects perform better with a hierarchical hypertext. Second, people with less cognitive capabilities seem to prefer the hierarchical organization of the hypertext as it supplies a more “oriented” navigation.

There was another objective in the experiment, related with the previous one: the influence of possible disorientation problems on the learning performance, with the indication of the variables that facilitate or reduce the onset of this phenomenon. Our data don’t allow us any type of conclusion, because the indexes obtainable from the recorded moves have no unique interpretation. For example, the index that outlines the returns on pages that were already visited could indicate a disorientation state: the user didn’t remember to have already visited it, or the user erroneously interpreted the previous link. However, as the target for the subject was to understand and “learn” the content of the hypertext, it was hard to distinguish these different kind of “returns”: a) the subject wanted to deepen the page b) the subject wanted to read again a concept found in other pages c) the subject wanted to complete a previously incomplete reading of the page. On the other hand, the above elements can be partly indicative of the presence of a situation of disorientation, or at least representative of an objective difficulty in managing the context that could lead to “getting lost in hyperspace”.

In conclusion, the World Wide Web is surely a great step toward the visionary idea of Nelson and his Memex: all information from all the world linked together thanks to an immense hypertext. However, the intrinsic networked structure of the web and the absence of specific aids for navigating are, in our opinion, a problem that challenges the effectiveness of educational hypertexts on the WWW. We therefore believe that further studies are

needed in order to understand how to maximize the learning process from hypertextual materials. We are moving in this direction with another series of fine-tuned experiments:

1. Testing groups of subjects with different cognitive capabilities but using the same hypertext;
2. Learning scores in presence of diversified hypertextual structures: "tree-based" hypertexts with hotwords, "graph-based" hypertext with nucleus of nodes hierarchically organized. This mixed structures better describe the situation of hypertexts currently present on the WWW;
3. testing other cognitive variables that could lead to a better definition of the relationship between cognitive abilities and learning processes, in particular the role of working memory

Abstract: The use of chatrooms as a forum for discussion is increasing in popularity. Consequently there is a need for generic software to be designed which is readily configurable to the requirements of particular domains and which is also extensible. This paper discusses the design requirements of such a system and presents a novel chatroom generation system, ChatterBox, implemented in Java.

1. Introduction

Since the invention of the WWW there has been an explosion of interest in the use of technology, in education. Much of this interest has focussed on the WWW as a vehicle through which to present information to students. Increasingly however, it has been recognised that in order to maximise the value of the infrastructure provided by the WWW in the service of education, *greater interactivity* is needed. On the one hand software is required that facilitates the engagement of the student with the education material and can be readily integrated into the infrastructure provided by the Web. An example of such software would be on-line simulations [Neilson et al 1996]. On the other hand, appropriate communications technology is required to support discussion about the educational material. Educational content requires to be reflected upon and debated if deep learning is to occur [Laurillard, 1993]. The focus of this paper is on communications technology.

The main forms of communications technology readily available on the Internet are email, newsgroups and chatrooms. Both email discussion lists and newsgroup technology such as Hypernews are widely recognised as educationally useful tools [McKendree and Mayes, 1997]. Chatroom technology by contrast has generally been regarded as a somewhat frivolous application. Traditionally, chatroom use has been viewed as a purely recreational activity, something that is done for fun, an opportunity to discuss a hobby with like-minded individuals. Increasingly, however, the potential educational value of chatroom technology is being recognised. Chatrooms may be used to promote learning by providing a forum for critical dialogue on a topic between peers. Chatrooms have the advantage over email of allowing multi-user discussion in real-time. They more realistically support the dynamics of traditional classroom based educational debate in the on-line environment. As societies increasingly promote distance education opportunities and the need to acquire new skills throughout a person's working life, the use of chatrooms as forums for discussion will undoubtedly increase. Large businesses might be expected to provide such facilities as part of the training provision made for a workforce to update their skills or indeed as part of an on-line customer support environment. Chatrooms can thus potentially serve a wide variety of useful commercial and educational as well as recreational purposes.

The disparate nature of the contexts in which chatrooms can be employed, requires that the technology used for chatroom generation be highly configurable to the requirements of a particular context of application. Chatrooms employed in a distance learning context can require a *differentiation of user privileges* between an instructor and a learner that does not apply in the chatroom of a football supporters' WWW site. Often one wishes to *restrict access* to the former but not to the latter type of chatroom. Where chatrooms are open to anyone there must however be a system for *regulating the number of users* who are on-line simultaneously in order to prevent server overload¹. In some chatrooms, it may be desirable for regular users of a chatroom, such as loyal customers or senior students, *to be afforded special privileges* or for certain users, such as an instructors, to be able to *reserve a username* for their use only. In many, though not all, chatroom disruptive users can be a problem. It is thus often desirable for selected individuals to have *policing rights* in particular chatroom contexts

¹ Controlling the load on the server computer is particularly important where Java applets are involved. Security restrictions on applets forbid connection to servers other than that from which the Java classes were served. The chat server thus needs to live on the same machine as the web server.

in addition to the system being capable of *automatically monitoring* and *controlling* anti-social behaviour such as abusive language. In a learning context an individual may wish to hide their ignorance about a topic by communicating only with a trusted friend or with the tutor. There is thus a need of an *option for one to one conversation*, (referred to in this paper by the term *whispering*), that does not perhaps apply so much in a recreational context. There may also be a need for a chatroom to have *filtering capabilities* so that an individual can selectively choose not to receive messages from other users who are found to be irritating- for example fans from a rival football team in a sports' chatroom.

Generic software for chatroom generation also requires to be readily extensible. Most chatroom generation software is based on the client/server model. Increasingly it is implemented in Java with the server residing on the same machine as the WWW server and the client taking the form of an applet embedded in an HTML document². Applets are however also increasingly used to extend the functionality of a WWW site. There is thus a need for chat client applets to be able to communicate with other applets on a WWW site in order to increase the 'interactivity' of the host WWW site. This point is best illustrated by an example. We developed a football commentator system, <http://anfield.merseyworld.com/commentary/>, which allowed details of live football matches of a the Liverpool football team to be broadcast around the world over the WWW along with text transcripts of a game 'as it happened'. This commentator system employed Java applets client side. Our webmaster wanted the transcripts of the match to be fed into the Liverpool football club's supporters' chat room, <http://anfield.merseyworld.com/chat/detach.html>, in order that supporters could see the commentary of a current match as part of the chat. A special interface had to be built to allow the commentary system applet to pipe its output into the chat system applet. A more generic solution than this is desirable.

Finally, many generic chat systems fail to adequately support the use of colour in their interface. Support for coloured text in the chat area would not only brighten the interface but would also be functionally useful. Colour coding can provide a visible means of filtering fast moving discussion and distinguishing between different types of message. Utilisation of icon buttons (instead of AWT text only buttons) would also help to customise the look-n-feel of the chat applet to a particular application context. Finally as Web Sites are frequently quoted in on-line discussions, any URLs within a user's message text should be clickable and operate in a similar fashion to web page hyperlinks.

This paper presents a Java based client/server system for chatroom generation, ChatterBox, which is both configurable and extensible and includes the aforementioned interface features.

2. The architecture of ChatterBox

2.1 The basic client/server system

ChatterBox is a generic system for chatroom generation written in Java. It employs a client/server architecture. However, while in many chat systems server side processing dominates this is not the case with ChatterBox. In ChatterBox, only essential filtering such as that required for security is conducted server side. Conducting filtering client side, as for example through the plug-in system we describe, has the advantage of allowing client systems with vastly different filtering requirements to co-exist on the one server without fear of incompatibility. The robustness of the Java server was tested using a simulated client which waits a random time before starting, then repeatedly connects/disconnects at random intervals, sending a random number of messages each time of a random length at random time intervals. This test client was designed to try to approximate the workload the chat server might have to service and to evaluate the number of simultaneous connections it could reasonably be expected to handle.

2.2 Interface features

The interface is designed to support the use of colour. 24 bit colour values are specified as a decimal integer.. Chat is in black (zero) by default but this can be altered to make a particular user's text stand out. For example the football commentary system which is broadcast into a supporters chatroom uses red as its text colour to make its messages distinctive. A lecturer's contributions to an educational discussion could be similarly flagged. Currently, however, the ChatterBox client does not allow an individual user to change the colour his/her messages will appear in on each client. This facility was originally made available but has been switched off as feedback from users when it was available was negative. Users did not want multi-coloured chat unless the change of colour had functional significance in a particular application context.

² An example of such chat generation software is Parachat, <http://www.parachat.com/>

Colour is also used to cue *whispered* messages. A user selects those names with whom s/he wishes to communicate and then clicks on the SET WHISPER button. This restricts the display of the message to only the named individuals. Whispered messages are prefaced by a line “[Whispered to: ...]” followed by the names of the recipients of the message and is shown in blue. To reply to this sub-group of individuals a receiver has to set their own whisper function to the appropriate names. The system does not do this automatically. The WHISPER function can be toggled on and off. It is a feature that is frequently employed by users.

The icons used by the chat applet can be made appropriate to a particular context by specifying the relevant image files through the ICONFILE param of the chat client applet Any URL quoted in the text of a message is automatically converted to a hyperlink. The normal user interface to the chat system is illustrated in Figure 1. If a user has superuser status the admin interface would be active and accessible through the admin user button. The admin interface allows a superuser to bar, ban or ‘kill’ users and to view chatroom statistics such as the load on the server.

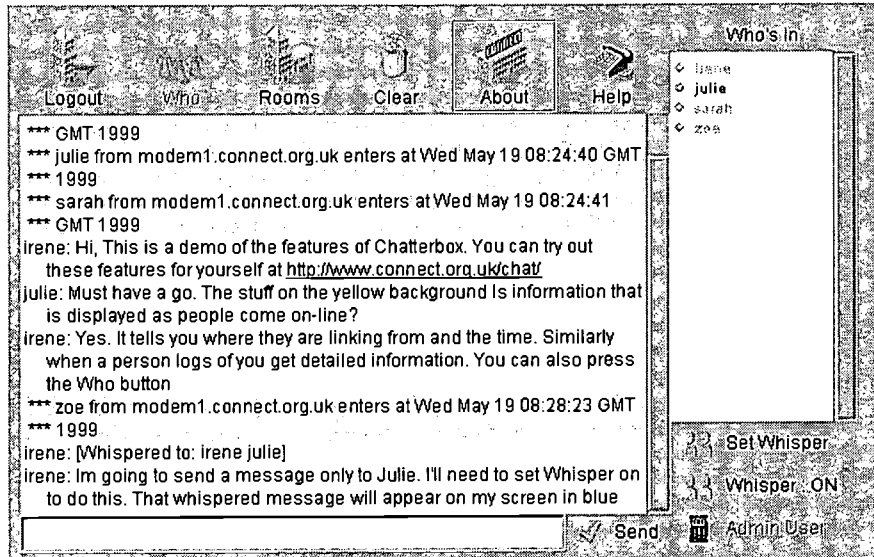

Figure 1: The ChatterBox Client Interface

2.3 Configurability

Messaging format:- To achieve a highly configurable system, a messaging format was required which would enable messages to be constructed from 'tagged' data sections (in much the same fashion as image formats like IFF and TIFF). Program code could then pick and choose which sections to respond to, ignoring those that were not understood. This would also allow multiple types of information to be encapsulated inside one message. For example the 'remove client' message sent to all clients when someone leaves a chat room could be accompanied by an announcement to that effect suitable for displaying on screen. The format chosen is shown below. All messages are sent in plain ASCII text format.

```
<tag> <data>|<tag> <data>| . . . . . |<tag> <data>
```

A pipe character separates each section. For this reason pipe is not allowed within any section - it was picked because it is a symbol that does not appear in English text and as ChatterBox is based around text communication its absence is unlikely to be noticed. A section begins with a tag name followed by a single space, then the data for that section. A real life example of this format taken from a session in a chatroom is shown below. Note that Laura is communicating with two people, one publicly (D.J.) and the other via whispering (Faisal). CHATMSG is the message itself, CHATWHISPER is a list of users to whom the message will appear if the whisper feature is active. CHATADDUSER is transmitted to all clients to introduce a new user. Lines without a USER section are assumed to be system messages. Other examples can be inspected at <http://www.connect.org.uk/chat/>

```
CHATMSG fish from thirl.csc.liv.ac.uk enters at Tue Feb 23 17:22:18 GMT 1999|CHATADDUSER

USER D.J.|CHATCOLOUR 0|CHATMSG I can do it now, but they never asked me to in the test
USER Laura|CHATCOLOUR 0|CHATMSG I have trouble reverse parking as well
USER Laura|CHATCOLOUR 0|CHATMSG have u sent it yet|CHATWHISPER Laura Faisal
```

```
USER Faisal|CHATCOLOUR 0|CHATMSG I'll try to send it|CHATWHISPER Faisal Laura
CHATDELUSER Laura|CHATMSG Laura from usr217-kno.cableinet.co.uk leaves at Tue Feb 23
17:33:27 GMT 1999
```

Use of Profiles:- A capacity to tailor the functionality of a chatroom to the requirements of particular users could be achieved through the use of profiles. Profiles would also allow some users to be granted 'superuser status' giving them the authority, which itself could be varied, to censor disruptive behaviour via an interface built into the client. This would reduce the need to run a special administration programme server side to manually ban people. Policing by users would also complement the automatic censor system³.

ChatterBox features an extensive configuration mechanism based upon a main configuration file. Within this the default user and room profiles are defined. A room profile defines variables such as the maximum number of users per room. The default user profile defines variables such as the period of inactivity tolerated, whether swearing, block capital typing, spamming etc are allowed, whether whispering (the selective sending of messages to particular individuals is allowed). This profile will be assigned to any user who logs onto ChatterBox without a specific profile of their own set up in the configuration file. Individual user profiles are created using the COPY attribute from the default profile (a sort of subclassing of the other profile) and are password protected. The following code illustrates the profile of a user who has 'superuser' status on the Anfield Football Chatroom.

```
<PROFILE=steve_d> COPY=!def_anfield PASSWORD=obscured KILLUSER=y
BARUSER=y BANUSER=n SEEWHSIPER=y SUPER=y </PROFILE>
```

The user has the name 'steve_d' and a password to secure his username/profile from being used by anyone else. He has been given permission to 'kill' user connections and bar users, but not ban them permanently. He can see all whisper messages regardless of whether he is part of the target subset of users. The final attribute 'SUPER' affords him a red S symbol next to his name in the WHO'S IN list on the chat client applet and access to the ADMIN USER interface.

2.4 Extensibility

Use of Plug-in technology:-The key to making the system extensible was identified as creating the ability for plug-ins to interact with the input and output data streams of the applet. Plug-ins could be regular classes loaded from the server or other applets resident on the same web page as the client applet. Plug-ins had to be capable of forming could form input-output chains, intercepting outgoing and incoming messages and altering or extending them if necessary. For example, a plug-in could be devised which scrambled the contents of any CHATMSG section on output and unscrambled them on input - ensuring a degree of privacy for dialog sent from client to client. Plug-ins could also be used to control the input/output to other plug-ins.

Use of plug-ins to extend the capabilities of a chat system has the major advantage of leaving the core code of the chat client/server application intact. When a specific feature is needed for a particular chat context, a plug-in is simply used to provide the feature. Customised filtering can also be provided through use of the plug-in system.

Implementation:-Within the ChatterBox system, the procedure for linking in plug-ins is reasonably straightforward. Upon start-up of the chat client applet, a MessageHandler class instance is created which scans the applet's PARAMs for occurrences of 'PLUG_INx' or 'PLUG_OUTx' (where x is an integer number beginning at zero and incrementing with each successive in/out parameter line). The value of each parameter which is found is then parsed. The data is split on the first colon into two fields. The first field is assumed to be the plug-in name, the second is assumed to be a parameter string.

If the plug-in's name begins with an asterisk the MessageHandler looks for an applet using that name. If it does not then the MessageHandler attempts to load and build a class instance of the named type. If the name is simply an asterisk on its own the chat client applet itself is used. All plug-in applet/classes must implement the *Pluginable interface* designed specifically for the ChatterBox plug-in system.

The plug-in class is initialised by passing it environment details such as whether it is being connected to the input or output chain and whether it is being used on a client or server. (Currently however only the ChatterBox client implements the plug-in system.) The parameter string, which formed the second part of the param value, is also passed. Each plug-in can use this string as they wish - ChatterBox makes no assumptions about its contents

³ Automatic censors are common in chat systems. These monitor all communications and detect system abuses -such as foul language, the sending of messages in ALL CAPS and people vertically writing a message, one character per line. Persistent abusers of the system are generally banned on the basis of their IP addresses or hostnames. In some cases, where IP addresses are dynamically assigned, this might necessitate the banning of a range of addresses using a wildcard option

or purpose. This string is intended to allow individual configuration details for each plug-in to be specified from within the HTML document.

Two chains are formed, one for input and one for output. The plug-ins are linked in numerical order based upon the PLUG_INx / PLUG_OUTx value, from low to high. Once these chains are created they are passed any outgoing message from the client chat applet prior to it being transmitted and any incoming message prior to being processed by the client software itself. Each plug-in in turn is passed the message in a Hashtable format - with each section of the message stored hashed by its tag name.

This is where the sectioned/tagged format of ChatterBox's message system is particularly beneficial. Each plug-in can then append, remove or replace sections of each message before allowing it to be passed down the chain. They can deal specifically with those sections of the message that they understand and ignore all other content - including those added by other plug-ins previously on the chain. Once the end of the chain is reached the message is transmitted (for output) or delivered to the client (for input).

Examples of use: A series of demonstrations of the plug-in system and the capabilities of ChatterBox in general is provided at <http://www.connect.org.uk/chat/>. Two examples are included within this paper for illustration. The first example is of the Debug Plug-in. The Debug Plug-in simply displays to a TextArea AWT widget the entire contents of messages being passed in and out of the client chat applet. It is a useful plug-in in that it allows the actions of other plug-ins to be monitored. The Debug Plug-in is inserted into the input and output chain of the client chat applet simply by including the HTML fragment below.

```
<PARAM NAME="PLUG_IN0" VALUE="*Debug:In> ">
<PARAM NAME="PLUG_OUT0" VALUE="*Debug:Out> ">
```

Figure 2 is a screen dump of the client applet with the Debug plug-in running. The output generated by the Debug plug-in is displayed in the TextArea below the client chat applet display. Thus Debug OUT displays all chat messages transmitted between client and server in the ChatterBox system while Debug IN displays all messages sent by the server to the client, many of which will contain text for display within the chatroom.

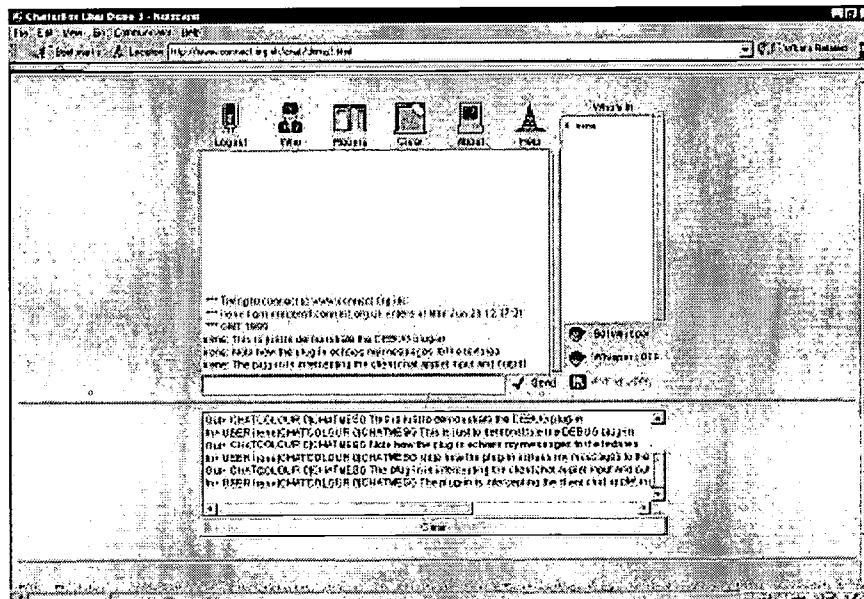

Figure 2: The Debug Plug-in displays messages passing out of and into the chat applet

In our second example, illustrated in Figure 3, a different plug-in, called 'Test' has been inserted in both the input and output chain of the applet by inclusion of the HTML fragment shown below.

```
<PARAM NAME="PLUG_IN0" VALUE="*Test:-">
<PARAM NAME="PLUG_OUT0" VALUE="*Test:-">
```

This plug-in displays the total number of characters etc sent in the CHATMESC section of the message for input and output. It also allows the user to modify the value of the CHATCOLOUR section to change the text colour used to render a transmitted message in all chat client. Different types of messages can thus be colour coded.

Figure 3: Demonstration of the colour modification of chat interface by a plug-in

3. Further developments

The plug-in system allows the client chat applet to be extended without the need to alter the client code itself. While the potential applications of the technology are considerable - effectively it offers outside programs complete control over the ChatterBox's chat client's input and output - there is also scope for improving the system.

Firstly, the fact that plug-ins are tied only to the input and output of the client is a major limitation in that they can only act when the client sends or receives messages. A system where by plug-ins can initiate their own outgoing messages without having to wait for the chat client to send would be more desirable. Originally the plug-in system was seen as serving only the client itself - but with the ability of applets to be used as plug-ins it became clear that this was unduly limiting. Because applets can be entire mini-applications they might need better network support than that provided by the chat client messaging system alone. Secondly, if a plug-in requires a user interface it must utilise a separate applet on the same web page as the client chat applet. It would be advantageous if plug-ins could supply their own UI components within the client's interface, supplementing or perhaps replacing the standard chat area component. Finally, the plug-in configuration is limited to a single string in the PLUG_INx / PLUG_OUTx param line - unless the plug-in reads it's own configuration file from the network. It would be useful if the configuration files associated with plug-ins could be stored as part of the main ChatterBox user/room configuration file.

Other unique features of the system could be further exploited. For example, in many chat system users are effectively anonymous - in that they had no permanent presence on the system. The introduction of user profiles users however effectively gives users an 'account' on the chat system. The personal information by the profiling system could be used in a variety of ways. For example if ChatterBox was deployed in a distance learning context, the ability to look up a lecturer's specialist interests, office and phone details during an on-line conference could prove useful. Highly configurable and extensible systems such as ChatterBox are needed to provide the flexible environments required by the growth of interest in distributed discussion groups.

Abstract: This paper investigates measurement issues related to elements of the Internet and calls for a standardized measuring scheme to resolve the problem of the measurement. In this paper, the dilemmas in measuring the elements of the Internet are identified and previous studies are reviewed. Elements of the Internet are categorized into population, usage, protocol flow, hardware, software, traffic, and visitors. At last, this paper proposes four criteria in measuring the elements of the Internet as the guidelines for Internet research.

1. Introduction

This paper investigates the dilemmas in measuring the elements of the Internet and reviews current attempts in monitoring the growth of the Internet. By examining these important issues, this paper aims to provide guidelines and criteria in measuring the entity of the Internet for further research.

The original ARPANET evolved into the present day Internet which itself has changed much in the last two decades since it came into existence. During the late 1980s, the population of Internet users and network constituents expanded internationally and began to include commercial facilities [Cerf 1998]. Today the Internet is made up of private networking facilities in educational and research institutions, businesses, and government organizations across the globe. It was developed in the era of time-sharing, but has survived into the era of personal computers, client-server architecture, peer-to-peer computing, and network computers [Leiner et al. 1998].

From a human perspective, no single person or single organization has contributed totally or controlled the growth and the development of the Internet. From a technological perspective, from 1969 to 1975, when the Internet (called APRANET) was still in a research and development period, drawing maps and topology diagrams, calculating traffic and performance statistics, and measuring the size and diffusion of the net were feasible. After 1975, when the Internet was turned over to the Department of Defense, tracking the Internet became a headache for the National Science Foundation [Press 1997]. Today, as more and more border-crossing backbones have been further developed and intermesh, tracking the development of the Internet and measuring related growth elements has become harder and harder.

Since it came into existence, the Internet has grown beyond its initial purposes and includes both a broad user community and increased commercial activity. Over the years, the Internet has become a medium with world-wide broadcasting capability; a mechanism for information dissemination; and a medium for collaboration and interaction between individuals and their computers by overcoming obstacles of distance [Leiner et al. 1998]. From a marketing perspective, the Internet represents one of the most successful examples of the benefits of sustained investment and commitment to businesses; and for academic researchers, the diffusion of the Internet represents an interesting phenomenon needing further diagnosis with scientific explorations [Morris & Ogan 1996].

Depending on how the Internet is viewed and what units of analysis are defined, studying elements of the Internet can generate different interpretations and different meanings. There is an urgent need to understand the growth of the Internet. In one sense, the Internet is rapidly growing in its number of users, its volume of protocol traffic, its complexity of topologies, its impacts on human beings' lifestyles, its value in economic activities, and its coverage. In another sense, the global diffusion of the Internet, the fostered knowledge organized by the Internet, the changes in users' behavior, and the impacts to human beings' global perspectives are intriguing issues in academic fields. More explorations of these phenomena would increase our understanding of the implications of this global technology and how it can potentially affect the lives of human beings.

As the Internet continues to evolve, the need to increase our understanding of the elements of the Internet becomes more urgent. Especially, we need a feasible and acceptable standard of Internet measurement which can

allow us to monitor, track, and compare the size of the Internet, the growth rate of the Internet, the usage of the Internet, and the attributes of the Internet. This paper first investigates dilemmas to which researchers encounter when measuring the elements of the Internet. Further, related studies in measuring the elements of the Internet through are reviewed. This paper then provides a few useful criteria in resolving dilemmas of the measurement of the Internet.

2. Dilemmas in Measuring the Internet Elements

Since the Internet is rapidly growing in different dimensions, measuring the Internet from different perspectives becomes more important. However, researchers do not know exactly what to measure and how to measure this multi-dimension issue. Previous studies, such as [Novak & Hoffman 1997, Hoffman & Novak 1996] suggested that lacking the standards for what to measure and how to measure the element of the Internet would limit industries' further participation in the Internet activities. Today, different units of analysis were used when researchers attempted to measure the Internet [December 1996]. Under the circumstance of lacking guidelines and criteria, the problems of inconsistency arose and the results were controversy, and contradicted to each other in many areas.

Depending on how the Internet is viewed and what units of analysis are defined, measuring the elements of the Internet may generate different interpretations. For example, from the new technology viewpoint, the Internet can be measured as its penetration rate, adoptions of innovations, and its evolvement during diffusion process. When taking the viewpoint as mass medium, the measurement of the Internet may then focus on one-to-one, many-to-one, or one-to-many communication schemes, as well as send, recipients and message contents. If the Internet is studied as a CMC (computer mediated communication) multimedia environment, researchers may tend to explore hits, visits, uses and effects of the Internet for its commercial purposes. If the view of information dissemination is taken, it is then possible that researchers would study issues involving information flow across border, content censorship and regulation, or topics related to search engines. If a more behavior-orientated approach is taken, researchers would focus on demographics. From the geographical view, the measurement of Internet then becomes which university, town, city, state or country has the highest penetration rate. From the point of view of economics, researches may look at the relationships between economic development and the uses of the Internet on the linkages between telecommunication and trade flows in the economy.

3. Reviews of Internet Measurement

In order to establish baseline data for standardized procedures of the Internet measurement, the authors reviewed previous empirical studies researched on the Internet measurement issues. When reviewing such a rich data over time, we have limited ourselves on three questions: What were measured? Why were they measured? and How have they been measured? We sought the answers during our review process and later realized that the answers and the questions are intertwined. In reality, how the elements of the Internet were measured and what were measured actually depends upon how the final statistical numbers were used. Different research procedures and methodologies serve different purposes.

In the reviewing process, we made no attempt to review all previous studies. Rather, we tried to extend dimension of the Internet measurement as diverse as possible. Therefore, in this paper we did not list all similar studies in the same dimension. We have created two criteria when constructing this list. First, they must be empirical studies. Second, they must be able to make comparisons with other. To meet the first criterion, a study should provide its detailed description of methodology. To meet the second criterion, a study should present its results by numerical statements. From our preliminary literature review from traditional press format as well as the Internet, we were able to categorize the measurement of the Internet into the following categories:

3.1. Population

The most common measurement of the Internet is about the Internet population. Virtually, there is no way to determine how many users are on the net without making guesses. The approach of counting human heads usually includes two sub-categories: number of users in a social system and attributes of demographics. The former refers to

those studies investigating "how many" research questions, such as "How many Internet (adult or kid) users in United States or in the world" (e.g., <http://www.nua.ie/surveys>, http://www.cyberdialogue.com/free_data/index.html, and <http://www.commerce.net/news/press/fact0699.html>), "How many Web users in California State?" (http://www.commerce.net/news/press/030398_1.html) "What's the most wired big city in the country?" (<http://www.zdnet.com/yil/content/mag/9803/wired.html>) or "Which city in the United States owns the highest penetration rate of the Internet?" (http://www.commerce.net/news/press/030398_1.html) The later refers to those studies investigating "Who are they" questions, such as "What is the age range for those Internet users in June 1998?", "What are their educational background?" and "Are male users still more than female users?" (e.g., (http://www.gvu.gatech.edu/user_surveys/survey-1998-10/) The methodologies used to elicit the population number and attributes were through a telephone survey or through a self-administered Web survey. In the telephone survey, usually random sampling technique and statistical inference were used. In the Web survey, they usually suffered from problems of convenience sample.

3.2. Use

In addition to the study of Internet population, the usage of the Internet is also one of researchers' concerns. This approach attempts to answer the "how often" question. In order to investigate the "frequency" question, researchers usually conduct a telephone survey or a Web based survey. Usually, respondents were asked to identify the time of their last access to the Internet, hours of using the Internet per week, number of years of using the Internet, their Internet connection speed and so on (e.g., http://www.gvu.gatech.edu/user_surveys/survey-1998-10/). Using the methodology of telephone interview or Web based survey to answer "how often" questions usually generated distorted data. For example, because respondents were asked to describe their past experiences with memory, the results may not represent the truth. Respondents tend to increase the number of their Internet uses when asked, and in some cases, respondents are confused with the meaning of "uses."

3.3 Protocol flow

The Internet is comprised of several application layer of TCP/IP, such as HTTP, FTP, SMTP, POP and NNTP. Some of protocols, which have been very active and popular on the Internet, are now fading away (Gopher and Hypernet) while other new protocols (HTTP and POP) provide the majority traffic. One of purposes in measuring the application layer protocols is to observe their variations and to predict the trends of future developments, in addition to the performance of data flow in a timely manner [Monk & Claffy 1997]. In order to predict and observe the trend, research focusing on the protocol measurement should not limit their studies to one shot, and should extend their studies over time. Unlike the measurement of the Internet traffic (discussed later in this section), measuring the Internet protocol focuses on the comparisons among different protocols, their growth and decay over time, and the patterns of traffic flow. They look at the traffic of packets, bytes and flow in a specific time interval and monitor how Internet protocols flow over backbones [Apisdorf et al. 1997]. The traffic flow may include flow type (which protocol is observed), source/destinations of traffic (efficiency of traffic flow) and distributions of packet sizes and duration (effectiveness of networking) [Monk & Claffy 1997]. Today, however, it is practically almost impossible and cost prohibitive to detect the variation of protocols on the whole Internet because there are more than 30 backbone in the United States and more around the world. Detecting the bit flow over backbones in different time slots would be tedious with a considerable expense, if not possible.

3.4. Hardware

Previous attempts in measuring the size and the growth of the hardware focus on the Internet hosts and the Internet domains. See Robert H'obbes' Zakon's Internet Timeline v3.3 (<http://www.isoc.org/guest/zakon/Internet/History/HIT.html>) for the full description of these data and Netsizer for a commercial tool serving this purpose (<http://www.netsizer.com>). Understanding the number of domain or hosts worldwide or in a specific country may potentially increase our knowledge of the diffusion process of the Internet. Since the adoption rate of hardware may relate to culture, social and economic issues, analyzing these data can also contribute to our understandings of the Internet diffusion and societal factors. The basic procedure to collect data of hardware number is to ping the IP addresses through the Internet. By adding the replies after pinging, it is then possible to find out a total number of hosts and domains on the Internet. There are a few potential limitations of using this approach to measure the Internet. First, when some parts of the Internet choose to limit access to themselves to various degrees, the data collected would be distorted. To solve the above problems, researchers in Network Wizards (<http://www.nw.com>) created another new survey methodology in 1998 (<http://www.nw.com/zone/WWW/new-survey.html>). In their survey, instead of ping every 4.3 billion IP address on

the Internet, they tried 879,212 delegations, or just 223,319,848 possible hosts. The potential problem of this newer methodology is that the degree of the precision decreases. Second, in order to collect data over time, researchers need to conduct this procedure frequently. This would increase the unnecessary traffic of the Internet. Third, as the Internet becomes bigger and bigger, it then turns out practically impossible to ping over the Internet in a short time frame. Fourth, the definition of a host has changed in recent years due to virtual hosting. Today, a single machine can act like multiple systems with multiple domain names and IP addresses. Fifth, since an increasing number of domain names are registered in the USA, instead of in their own countries, the measurement of domain names becomes less meaningful.

3.5. Software

The war between Microsoft and Netscape is not about browsers but about the standard. Measuring the Internet software can reveal the fact which software dominates the Internet by studying the ration of their market sharing. Software related to the Internet use includes two parts: server and clients. As Web technology becomes prosperous, studies of Internet software basically focus on Web server applications and Web client applications. The methodology used to collect data of Web server applications and Web client applications are different. To detect which Web server application is running in a Web site, researchers can simply send a request for server's header by using HTTP. Researchers can then parse server's initial response to identify the server type. In June 1999, the Netcraft Web Server Survey (<http://www.netcraft.com/survey>) received 6,177,453 responses from their systematical poll. In their report, Apache takes 56.19% of the Internet Web server market while Microsoft IIS, 22.34%. To find out which Web browsers a Web user is using, researchers can use general telephone survey (<http://www.psrinc.com/browser.htm>) or just analyze the log file automatically stored in a Web server' directory. When a link between a Web browser and a Web server is established, a browser sends its browser type as "User-Agent" to Web server for recognition and communication purpose. Therefore, if a researcher can access log files from some popular Web sites, he should be able to tell the ratio to which each Web browser takes. By studying 2,000,000 Internet session data points over a time period of 21 months, Positive Support Review reported in June 1999 that Microsoft's Internet Explorer's market share has remained consistent in recent months, reaching as high as 66.61% (http://www.psrinc.com/PressRelease/PR_19990623.htm).

3.6. Traffic

Traditionally, issues of traffic are researchers' most concerns in the field of telecommunications because traffic data represent the precision and intensity of activities in a distributed communication environment. By analyzing traffic data, researchers can reveal a clear image of data flow in terms of amounts, directions, and growth. Changes in traffic volume can provide information related to "carrier productivity, tariff levels, market entry and the basis for settlements between interconnecting carriers, both domestic and foreign" [Staple & Mullins, 1989]. Besides, traffic data involves some complicated issues, such as information flow and content regulation. Crossed-border information basically is not a problem when the information per se is neutral and acceptable by people on the other side of border. It starts to cause troubles when the information is considered biased or unhealthy. When a country wants to keep its traditional values, like Singapore, from pollution of the Internet, content regulation becomes a necessary step to shut out border across information. Traffic can be measured by its total amount of bit passing through backbones in a time slot or by the amount of data passing through borders. Measuring the traffic flow on the Internet requires a higher degree of cooperation and involvement by service providers as well as multiple-nation cooperation. In order to make the data sensible, traffic measurement should be conducted over time and make comparisons periodically. In late 1995, Munzner et al. [Munzner et al. 1996] created a visually depicting Internet traffic components, which displayed how information on the Internet was routed over national borders.

3.7. Visitor

Measuring the number of visitors to a Web site or a Web page has its industry value because this summarized number is considered highly correlated to the exposure and interactivity of advertisements on the Web. Several different reporting schemes have been created, such as reach, frequency, duration time, and exposure. Unfortunately, there is no consensus on the definitions of these terms. See [Novak & Hoffman 1997] for detailed discussions of these terms. Those measurement units include hit, request, visits, user, organization, request duration, visit duration, Ad view, Ad click, Ad yield and Geography (see the example in United Expressline Web site: <http://www.unxpres.com/usage/summary.html>). Basically, to measure the effectiveness of a Web site or a set of Web pages includes counting and summarizing the visitor transactions on a Web site. Data from these counting processes

may summarize who visited (visitor identities), when they visited (visitors' accessing time), where they were from (referred Web pages or entry point), what they visited (linkages between Web pages), how long they have stayed (elapse time), what they have done (transactions and interactivities), and where they exit (exit point). These summarized reports may tell managers a possible way to adjust the content and organization of his Web site, also how to charge clients of a Web site's advertisement. Besides, by applying this concept to a Internet Web site, it is then possible to compare the hottest Web sites on the Internet, usually measured by visits & hits.

4. Analysis

The Internet itself, especially with the view of marketing, is characterized by uncertainty. As suggested by [Hoffman & Novak 1997], one way to decrease this feeling of uncertainty is to build up an open methodological standard. However, we tend to argue that today's Internet is like frontier of the big West in the 18th century, where orders and procedures were yet constructed. Further, as the Internet keeps evolving with an accelerated rate, newly contrived procedures and orders may soon be collapsed due to their inability to adapt to the newly evolved world. To decrease the uncertainty and to increase our understanding of the elements of the Internet, a practical and acceptable measuring scheme should be established and a standard of measurement should also be built up.

However, after reviewing those attempts in measuring the elements of the Internet through diverse dimensions, the authors tend to believe that building a standardized, universally acceptable scheme for the measurement of the Internet is not feasible yet. Since the methodology aims to resolve research questions and should be consistent with research purposes, different research purposes would generate different methodologies. A standardized measuring scheme that aims to resolve all research questions related to elements of the Internet could actually be difficult to achieve. Nevertheless, the authors tend to believe building up some general guidelines which may be applied to all diverse research issues is still necessary and possible.

After reviewing those studies related to the measurement of the elements of the Internet, the following guidelines are proposed. These guidelines, which may be applied to different environment, attempt reveal the essential characteristics in measuring the Internet.

First, many studies, which investigated the elements of the Internet, are under the threats of validity and reliability. Due to the uncertainty characteristic built into the Internet, any researchers who want to study the elements of the Internet should first attempt to solve the problems of validity and reliability. Further, validity and reliability check should be the first criterion built into research designs and should be reported in detail

Second, the continuation of the study should be taken care. Since the Internet is evolving, growing up and expanding, the process of data collection should be extended to a longer session. The continuation of the data collection is necessary otherwise the results concluded from today's data may not be effectively in predicting tomorrow's situations. In most cases, multiple data collections over time are required to make meaningful and practical conclusions.

Third, human beings' Internet behaviors are constantly changing. Therefore, the period of data collection should be limited to days, not months. The Internet is like an arena, where different forces keep fighting and wrestling. Consequently, human beings' behaviors are open to change while the external environment constantly moves to different directions. The characteristic of the fast Internet evolution may influence the pattern of data, which later may invalidate analysis. For other academic and scientific research, the researching settings are relatively stable. Even though in some situations the research context may change, these variations are usually observable. It is very different on the Internet.

Fourth, if a methodology can accommodate to serve multiple users' needs and answer multiple questions through different dimensions at the same time, this methodology would be more desirable and useful [Staple and Mullins 1989]. This criterion is important because it can not only limit the resources invested on the Internet but also limit the Internet traffic.

5. Conclusion

In summary, in this paper we have discussed the needs of studying elements of the Internet and dilemmas of measuring the elements of the Internet. We also reviewed previous studies that attempted to measure the elements of the Internet. From the knowledge we learned from the reviewing process, we proposed four criteria, which should be followed in conducting research in measuring the elements of the Internet.

Abstract: Distributed heterogeneous environments are being increasingly used to execute a variety of large size simulation and computational problems. We are developing Arcade, a web-based environment to design, execute, monitor, and control distributed applications. These targeted applications consist of independent heterogeneous modules which can be executed on a distributed heterogeneous environment. In this paper we describe the overall design of the system and discuss the prototype implementation of the core functionalities required to support such a framework.

1 Introduction

Distributed heterogeneous environments are being increasingly used to execute a variety of large size simulation and computational problems. For instance, in multidisciplinary optimization, multiple heterogeneous modules interact with each other to solve an overall design problem. Typically these modules, consisting of various C or Fortran programs, are developed as separate codes, e.g., structural or flow analysis of an aircraft configuration, and are optimized independently. The traditional path for integrating these modules, through the use of scripts makes the process of specifying and optimizing the overall design of such applications, a long and tedious process often taking several weeks. The slowness of this process is mainly due to the absence of a collaborative environment where (i) different modules and their interactions can be specified, and (ii) testing, monitoring, and steering of the overall design can be done by multiple users from different disciplines concurrently. In this paper we describe Arcade, a web-based environment for designing, executing, monitoring, and controlling distributed heterogeneous applications.

A typical scenario for developing and executing a distributed application is as follows: A team of designers collaboratively develops the application consisting of a hierarchical set of modules. That is, individual members are made responsible for specifying the submodules while the project leader is responsible for the overall integration of the application, i.e., connecting the outputs of one module to the inputs of another. The modules can range from simple sequential programs, to data parallel programs capable of execution on a multiprocessor or a network of workstations, to more complex subsystems which are defined hierarchically through the use of submodules. Preexisting modules whose sources are not available may need to be “wrapped” in order to plug them into the overall application.

Once developed, the application is executed in a distributed environment using a heterogeneous network of workstations and multiprocessor machines. During the execution, team members sitting at their individual workstations simultaneously monitor the flow of progress of the application. That is, the team members can see the currently executing modules at any level of the hierarchy. They can also view the intermediate data flowing between different modules including view large data sets using visualization tools.

A team member responsible for a particular subsystem can change data values under the control of the subsystem in order to steer the computation in the right direction. The team member can also dynamically alter the control flow if necessary. For example, in a design cycle, the responsible team member may decide that a particular module is not affecting the optimization and may bypass the module by using old values in each cycle. Similarly, the team could replace a module with a plug compatible module, for example, to use another algorithm. Once the execution is complete, team members again examine the final results using the visualization tools.

The overall goal is to design an environment which is easy to use, easily accessible, portable and pro-

vides support through all phases of the application development and execution. We plan to leverage off of commodity technologies, such as the Web and Java, to implement various parts of the environment. These technologies are capable of seamlessly interconnecting disparate hardware platforms running different operating systems across diverse locations providing an ideal environment for distributed simulation of complex systems.

In this paper we first describe our overall goals and then discuss the current prototype reporting on our experiences and problems in implementing the system. The rest of the paper is organized as follows. In the next section we present some related work. The two following sections describe the overall Arcade architecture and the current prototype, respectively. The last section focuses on future work and conclusions.

2 Related Work

Several software systems have been developed that make distributed computing available to an application programmer. These can be distinguished into different categories. The first category of environments includes systems such as MPI [MPI 1997], PVM [Sunderam 1990], pPVM [Maly et al. 1994] and JAVADC [Chen et al. 1997]. All these environments support distributed computing in varying degrees of generality; however, either they are not web based or they lack collaborative features. Also, they are mostly suitable for running SPMD programs. The second category of environments address large distributed heterogeneous codes but are focused on a single application domain. Examples of such environments include FIDO [Weston et al. 1994] and MIDAS [Midas 1999]. However, both these systems are either hardwired to a specific problem areas or are too restrictive. The other major limitation is that they lack a collaborative environment which would permit different members in a group to interact with the application at various stages of its design and execution.

The third category of environments which includes IceT [Gray & Sunderam 1997], Programmer's Playground [Goldman et al. 1995], PRE [PRE 1999], and WebFlow [Bhatia et al. 1997] supports heterogeneous distributed applications in some form or the other. The front-end for most of these systems, is generally some variation of large-grained data flow graphs with modules being triggered when their inputs are available. In our experience, we have found that to easily express heterogeneous applications requires more control structure than provided by such data-flow based systems. For example, in a multidisciplinary optimization code, the optimization cycle would have to be embedded within a module in a system which only supports data-flow rather than being explicit at the outer level. Also, these systems mainly concentrate on different aspects of the infrastructure required for managing the execution and interaction of the modules making up the application whereas the goal of the project described here, is to build an integrated framework for all phases of the design and execution of distributed heterogeneous applications. Note that systems such as Tango [Beca et al. 1999] and Habanero [Habanero 1999] focus on interactive collaboration between users. Such technologies would be useful in the specification and the monitoring phases of the framework being proposed here. However, such collaborative systems do not provide any support for the management and steering of the execution of distributed applications.

3 Arcade Architecture

The architecture of the proposed framework is divided into three tiers as shown in [Fig. 1].

First Tier: The first tier consists of the Java applets providing the following interfaces to the users:

- *Application design interface* for the hierarchical specification of execution modules and their dependencies. The system will provide support for multi-user specification of hierarchical modules including the specification of module interactions and database access for persistent storage of results.
- *Resource allocation and execution interface* for specifying the hardware resources required for the execution of the application. The resources could be chosen by the users or by the system based on the current and predicted loads of the system and the characteristics of the application. The choice could be made statically or dynamically during the execution of the application. The system will also allow

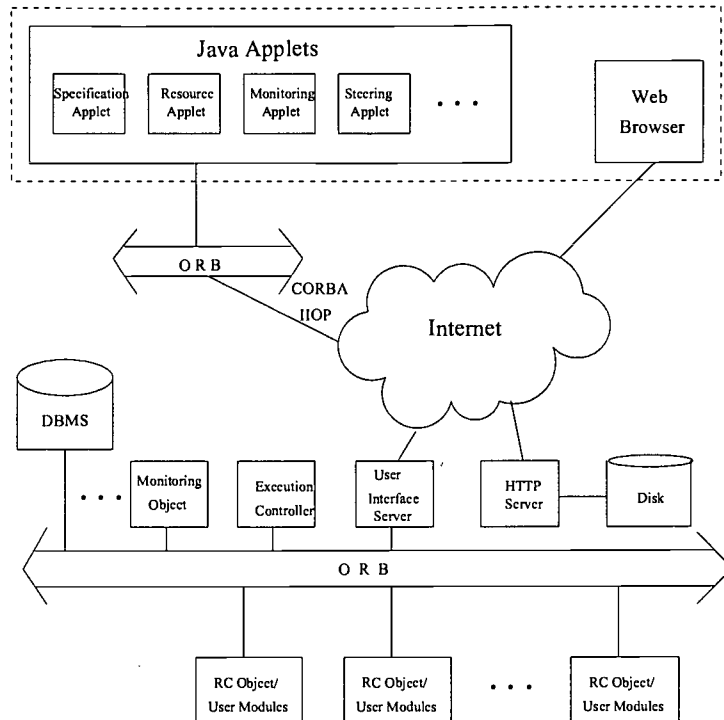

Figure 1: Web Object Infrastructure for the proposed Framework

the users to choose the input/output files and any command line arguments for the modules prior to starting the execution.

- *Monitoring and steering interface* for monitoring and controlling the execution of the application. Multiple users will be allowed to monitor the run both the flow of execution and the intermediate results. However only the subteam responsible for a particular submodule will be allowed to steer its execution by either modifying data values or replacing plug-compatible modules.

Middle Tier: The middle tier consists of logic to process the user input and to interact with application modules running on a heterogeneous set of machines. The overall design is a client-server based architecture in which the *Interface Server* interacts with the front-end client to provide the information and services as needed by the client. When the user requests the execution of an application, the Interface Server launches an *Execution Controller (EC)* which manages the overall execution of the application by firing up user modules on the specified resources as and when required. Other objects in the middle tier handle any monitoring and steering requests from the client.

Third Tier: The third tier consists of *Resource Controllers (RC)* and the *User Application Modules*. Each active resource in the execution environment is managed by a RC which is responsible for launching modules on the resource and also for interacting with the Execution Controller in order to keep track of the executing applications.

The main advantage of a three-tier system is that the client or the front-end becomes very thin, thus making it feasible to run on low-end machines. Also, since most of the logic is embodied in the middle tier, the RCs can be kept lightweight thus keeping the additional loads on the executing machines to a minimum also.

The Web Object approach we are taking will coexist with the regular HTTP server. In contrast to approaches with CGI-to-CORBA gateway or HTTP-to-IIOP gateways, this approach is easier to implement [Orfali & Harkey 1997]. Here, the HTTP server will provide users Web pages with Java applets. These

applets will interact with the CORBA Interface server using CORBA-IIOP protocol. The applets can use static IDL-generated client stubs or a Dynamic Invocation Interface to interact with the CORBA Interface server. The CORBA Interface server will interact in similar manner with other objects on the ORB bus (see [Fig. 1]).

4 Arcade Prototype

We have implemented the three-tier system as described in the last section, in a prototype Arcade system. The current system allows single users to specify applications through either an offline script-based system or through a visual interface. The resources required for the execution have to be statically specified by the user. The current prototype supports only file-based interaction among the modules. The system manages the execution of the modules on a network of workstations in a single domain. The execution status of the application can be monitored by multiple users simultaneously.

4.1 Application Specification

In our framework a distributed application consists of a collection of heterogeneous modules (application codes from different disciplines). We are targeting applications where these modules are very coarse grained. A typical distributed application requires these modules to be executed in some order and possibly on different machines. For certain problems, a set of modules may need to be executed iteratively, for example, until a desired optimization criteria is reached. To be able to support a wide variety of distributed applications, we support the following types of modules: *Normal Module*, the basic module in our framework used to represent the executable parts in the applications; *Control modules*, which support control structure, such as, if and loops; *SPMD Module*, for internal parallelism; and *Hierarchical Module* for module abstraction.

In the current prototype there are two ways to specify a distributed applications: *script based* or *visual*. The syntax of the script used for textual specification in Arcade is simple, allowing users to specify the different modules, as described above along with the properties of these modules including interconnections

The visual specification applet allows a user to graphically specify a heterogeneous application. The objective is to support a visual specification which is: (i) intuitive to build, (ii) can be used for visual monitoring, and (iii) works with the Web. There exist a number of visual language projects – see [Burnett & Baker 1994] for a classification of many of these projects. However, most of the projects which support program specification are either focussed on fine-grained programming or support only data-flow applications. That is, they do not provide any integrated, intuitive approach to specify control constructs in a coarse grained distributed applications.

We have implemented a Java applet that provides a visual specification interface and addresses some of these issues (see [Fig. 2]). The visual specification can be seen as a graph where a node represents a module and the arcs represents data flow. It is easy to see how a data flow based application can be modeled using such a system. It becomes a little trickier to accommodate control structures such as conditionals and iterations, in particular when we want to use the visual specification for monitoring too. We accommodate if-modules and loop-modules by restricting their bodies to be hierarchical modules which are specified through a separate window. Thus, the modules labeled *Then-block* and *Else-block* represent hierarchical modules abstracting the then and else part of if construct respectively. Similarly, the module *Body*, represents the loop body of the while loop. Restricting the bodies of control structures to hierarchical modules eases the task of specification and allows the application to be visually represented. However, it does not provide an integrated view of the whole application in a single window, i.e., the body of a control structure is always shown in a separate window.

4.2 Application Execution

Each application is internally represented by a Java `Project` object. The `Project` object, consisting of a vector of modules objects, is the central object in our framework. All the information related to the application, both static and dynamic, is stored within this object. The `Project` object is a complex object that is shared by all the processes of the middle tier (see [Fig. 1]) and supports methods that are used by these processes. When the user requests the execution of an application, the *User Interface Server* passes

Figure 2: Visual Specification Interface

the corresponding Project object to the *Execution Controller (EC)*. It is the EC's responsibility to manage the execution and the interaction of the modules specified within the application.

For executing the application, the EC needs to call some initialization methods of the Project object followed by its execution method. For example, if the application has been specified using the script-based mechanism, then the dependencies (which had been specified implicitly) have to explicitly computed and stored. The EC then executes the modules using a data-flow approach. That is, it launches the execution of a module as soon as its inputs are available. Note that the interaction in the current system is based on files. Thus, the EC has to ensure that the inputs for a module are in the files as specified in the project specification. That is, if a module produces a file which is physically different from the file specified as an input file by a dependent module, the EC copies the file over before execution is started. Here we are assuming that the application is executing in a single domain with a global file system so that copying files does not raise any security issues.

The system requires the user to specify the resource on which each module is to be executed in the application specification. Thus, to execute a module, the EC contacts the Resource Controller (RC) on the specified resource and requests that the module be executed. The RC starts the execution and monitors it. The RC notifies the EC when the module finishes execution. This allows the EC to determine the modules were dependent on this module and launch their execution if all of their inputs are ready. Once all the modules have finished execution, the user can be notified.

A monitoring applet allows users to monitor the execution status of the application. There are two different interfaces supported: text-based and graphical. The text-based interface indicates the time a module starts executing including the machine being used for the execution. As a module finishes execution, this fact is also dynamically noted. The graphical interface is available only for visually specified applications and uses a pre-determined color-scheme to indicate modules which have finished execution, are currently executing and have finished execution.

5 Conclusion

In this paper, we have described a integrated Web-Java based environment, Arcade, for the design, execution, monitoring and steering of heterogeneous applications in distributed execution environment. We have described the overall goals of the system We have described the current prototype of the system which is capable of executing distributed applications on a network of resources in a single domain. We are currently

expanding the system to incorporate all the facilities envisioned in our architecture in a phased approach, an approach where the driving force is the user of the system. In particular we are focussing on issues such as resource mapping and scheduling, security, and interoperability with other systems. More information on the Arcade system can be found at <http://www.icas.edu/arcade>.

Abstract: The situated nature of social interaction often highlights the interplay between the structure of discourse and the surrounding environment. We introduce the concept of structural duality in order to capture the nature of social dynamics in spatial-semantic virtual environments. The concept of structural duality is developed with reference to the use of a spatial-semantic virtual environment called StarWalker. The spatial-semantic model in StarWalker extends the traditional notion of spatial models and emphasizes a tighter coupling between social interaction in the foreground and the shared content in the background. Such virtual environments not only allow users to access a shared space to communicate with each other, but also provide contextual resources as an integral part of a virtual place for focused social interaction.

1. Introduction

Studies of social dynamics have shown that people draw substantial information from their surrounding environments and incorporate such information into their conversation in a specific social context. Such information often highlights significant aspects of the social context and enables people to communicate with each other effectively.

Bowers et al. analyzed the process of a virtual meeting held within a multiuser virtual environment [Bowers et al. 1997]. They concluded, "the overall design of virtual worlds should be considered in terms of how they afford social interaction and not just in terms, say, of their navigability, capability for presenting masses of information, or their thrilling aesthetics."

StarWalker is a spatial-semantic virtual environment designed to afford and forge social interaction [Chen 1999a; Chen et al. 1999]. It integrates semantic visualization models of a specific subject domain into a multiuser virtual world. The spatial-semantic model in StarWalker extends the traditional notion of spatial models and emphasizes the situated nature of social interaction in a virtual environment and a tighter coupling between social interaction in the foreground and the shared content in the background. The shared visualization model is a key design component of StarWalker. It functions as a referential resource for users to draw information regarding the nature of a specific virtual environment. In such virtual environments, not only can users communicate with each other in real time over distributed computer networks, but they can also use the shared semantic model as a starting point to build a common ground.

Spatial navigation originally refers to navigation guided by geometric or topological properties of a virtual or the real world, for example, sailing in the sea or travelling in a city. Semantic navigation is more abstract. It refers to navigation in which people choose destinations and follow pathways in an abstract world. Such navigation is guided by the semantics associated with a destination and connecting paths. Browsing a conventional hypertext or surfing on the WWW is a classic example of semantic navigation.

In contrast, social navigation refers to a navigation and search strategy commonly used in the real world. People from time to time follow like-minded peers in places such as museums, galleries, and theme parks. The design of StarWalker aims to provide an intuitive medium for people to navigate together in a complex information space and foster social navigation in a virtual environment. Focusing on foraging and affording focused social interaction in StarWalker has led to an integration of spatial, semantic, and social navigation at a deeper level. Our ultimate goal is to build a persistent, evolving, and domain-specific virtual environment as a forum and a resource shared by a community of professionals and users interested in the underlying subject domain.

In this paper, we will introduce the concept of structural duality and illustrate it with examples of the use of StarWalker. In these examples, we are particularly interested in the tension between discourse structures in the foreground and the shared semantic structure in the background. Such virtual environments will allow users to communicate with each other not only *in* a shared virtual space, but also *through* a virtual place with additional contextual cues.

2. Spatial Models

The increasing popularity of spatial models in the design of virtual environments is largely due to their simplicity and intuitiveness. MASSIVE is a good example of using a spatial model of interaction in a virtual environment [Greenhalgh & Benford 1995]. In MASSIVE, each user is represented by a simple avatar. Each avatar is surrounded by a "personal sphere" — an aura. Interaction between users is controlled in terms of spatial interrelationships among these auras. Users can communicate as long as their auras are in touch, or overlapped. MASSIVE also provides two other concepts called focus and nimbus in order to represent the attention and influence of a user in a spatial model.

The analysis of Bowers et al. highlighted some problems with a self-selected turn-taking process in a virtual meeting within MASSIVE [Bowers et al. 1997]. They emphasized that affordances of the virtual world for social interaction and the availability of non-verbal communication channels may all contribute to the identified problems.

Harrison and Dourish challenged the role of spatial models in virtual environments [Harrison & Dourish 1996]. They distinguished the notions of space and place, and argued that it is place, rather than space, that fosters and shapes social interaction. What distinguishes place from space is the critical property that establishes the sense of context and appropriate behavior within this context. In a place, people draw various cues and adapt their social behavior to their surroundings.

3. Social Navigation

Dourish and Chalmers introduced social navigation as one of the three major types of information seeking strategies [Dourish & Chalmers 1994]. The other two are spatial navigation and semantic navigation as explained in previous sections. Social navigation, they claim, is information seeking by following the trail of like-minded individuals in an information space.

Dieberger also used the term social navigation in association with the use of read wear in a Web-based MOO [Dieberger 1997]. The concept of read wear mimics the worn of a book and indicates how often it was read in the past [Hill et al. 1992]. Dieberger incorporated the idea in a MOO by showing how frequently an exit was used by previous users. Similarly, Wexelblat's Footprints system visualizes users' paths of accessing a website [Wexelblat 1997]. A key aspect of social navigation here is the development of search heuristics based on other people's search history or their current behavior.

An appealing approach to fostering social interaction in a virtual environment is to establish a tighter coupling between spatial and semantic aspects of the same virtual environment. By connecting semantic significance and relevance closely to spatial positioning and movements of embodied users we are able to attach significant meanings to the trail of peer users. Such value-added meanings can be used not only to improve the effectiveness of social navigation, but also to afford more focused and direct social interaction.

4. StarWalker

The design of StarWalker closely combines spatial and semantic metaphors in order to establish an intuitive virtual environment for social navigation. An ultimate goal is to transform a virtual environment into a forum as well as a resource of the literature concerning specific scientific communities. The current prototype is available on the Web through blaxxun's Online Community client browser plug-in.

StarWalker's user interface consists of four areas: a virtual world window, a chat window, a content window, and a status window [Fig. 1]. Design details can be found in [Chen 1999a]. In StarWalker, users can perform the following tasks:

- talk in public or private through text- and audio-based chat facilities,
- navigate through the 3D virtual world,
- move to pre-defined viewpoints in the virtual world,
- meet other users through avatar embodiment,
- view the full content of a document on the Web,
- migrate to other virtual worlds,
- generate virtual landscapes in response to ranked search results (restricted to internal users)

Figure 1: The user interface of StarWalker, consisting of four component windows.

Upon entering StarWalker, the user will see a landscape view of the semantic structure. There are a number of ways that users can move around within this VRML-based virtual world. Typically, one can walk or fly, or move directly to a predefined viewpoint. StarWalker currently provides several viewpoints from various perspectives, including an overview, various landscape views in different directions, and a galaxy view. If several people visit the same virtual world, they can see other users' avatars in the same virtual world.

The most special component of StarWalker is the virtual reality model embedded in the virtual world. This model visualizes some latent structures of an underlying data set. A number of visualization schemes have been developed under a generic visualization framework called Generalised Similarity Analysis (GSA) [Chen 1998a; Chen 1998b; Chen 1999b].

The prototype described in this paper is based on a semantic visualization derived from three ACM SIGCHI conference proceedings (1995-1997). Links between spheres represent the strongest semantic relations between corresponding papers. Technical details regarding the visualization can be found in [Chen 1998a; Chen 1998b; Chen 1999b]. In essence, the visualization used a special type of associative networks known as Pathfinder networks. The major advantage of Pathfinder networks is that they represent salient semantic structures with the least number of links. The resultant network is usually a concise representation of structural patterns in the original data. This model was subsequently rendered into a spatial-semantic model in Virtual Reality Modelling Language (VRML).

5. Structural Duality

Research in virtual environments, especially textual virtual environments such as MOOs, has addressed the question of how a virtual environment as a medium shape conversations [Erickson 1997; Toomey et al. 1998].

For example, Erickson analyzed how people communicate in Café Utne, one of the busiest Web conferencing communities on the Internet [Erickson 1997]. Café Utne is built on a metaphor of a place where people come, and find conversations of their interests. Erickson found that the social pressures for participation, often found in face-to-face participation, are missing in the virtual discourse medium. He concluded that mutual awareness would be an important factor that may shape the discourse in such virtual environments.

There are many potentially useful methods for the study of structural duality, for example, Conversation Analysis (CA), Frame Analysis (FA), and Interaction Process Analysis (IPA) [Bales 1951]. In this paper, we will only outline how IPA can be used to detect the structural duality in StarWalker.

IPA is a well-known model of group dynamics in a face-to-face meeting. According to this model, the focus of a meeting shifts back and forth between tasks and social-emotional needs among participants. This model suggests the existence of dual processes between tasks-oriented episodes and social-emotional ones in face-to-face meetings.

According to IPA, the shift of attention is caused by the tension between tasks and social-emotional needs among participants. When attention is given to the task, strains are created in the social and emotional relations of the members of the group, thus the attention turns to these problems. So long as the group devotes its activity simply to social-emotional activity, however, the task is not getting done, and attention would be expected to turn again to the task area [Bales 1951].

This model provides a reference framework for us to explore the concept of structural duality in a spatial-semantic virtual environment. One may seek answers to several significant questions regarding the structural duality. For example, what patterns can we find regarding cross-episode transitions in social interaction within StarWalker? What factors cause cross-episode transitions? Are they related to the spatial-semantic coupling in the virtual world?

6. Structure of Dialogues

The concept of structural duality was studied by analyzing the transcripts of several conversations in StarWalker. In particular, we focus on two aspects of social interaction within the virtual world:

- the intrinsic dynamics of the discourse;
- the relationship between the discourse and the semantics of the virtual world.

This preliminary analysis of discourse dynamics was largely based on IPA's high-level model. We intend to conduct further studies at deeper levels. Our central question is whether the virtual environment affords social interaction.

The following analysis is concerned with casual dialogue in public sessions in StarWalker. The aim was to find out to what extent the course of a conversation was shaped by the spatial metaphor. The analysis particularly focused on the following questions:

Why do people visit the StarWalker virtual world?

What do they talk about in StarWalker?

What do they think of the overall organization of StarWalker?

What is the most interesting feature to them?

What do they think of the semantic network?

Most visitors have been regular users of the blaxxun's Online Communities. They tend to be interested in meeting people and curious to explore a new virtual world. The spatial-semantic metaphor of StarWalker evoked several episodes about the spatial layout and its meaning. Many people thought the semantic model was a molecule. One visitor said "*It is the DNA for me as an avatar and the VR-universe!*" Some users thought it was a star map. Some others thought it was to do with Star Trek or some spaceships.

The transcripts show that StarWalker clearly gave users a strong feeling that it is considerably different from other virtual worlds that they have visited — it represents an abstract world. Unlike many virtual worlds structured based on buildings, cities, and natural landscapes, StarWalker offers a new model of interaction beyond a simple spatial model. For example, a visitor referred to the place as an inner space.

I saw it on the list and never been here. StarWalker sounded interesting, but instead of going to outer space I came into inner space ;-)

In another example, one visitor asked if this place is only for *trekkies* — Star Trek fans. Users were concerned if their social behavior would fit the constraints implied by StarWalker. Of course, a similar question may rise in a more conventional virtual world such as a virtual world called Mars in Active Worlds. What is special to

StarWalker is the combination of an abstract world and the multi-user avatar embodiment [Fig. 2]. The development of StarWalker broadens the range of 3D virtual environments. As one user said:

I have not seen any multiuser environment this abstract before... I always thought the communities looks too much like the "real" world...

Figure 2: Social navigation in StarWalker is viable by following the trails of avatars .

Much of the conversation in the public session was related to the semantic or spatial organization of StarWalker. In parallel, participants engaged in some informative discussions about their interests. Our experience in StarWalker and other 3D virtual worlds such as Active Worlds and blaxxun's Online Community seems to suggest that the overall spatial-semantic metaphor of StarWalker enabled people to maintain interesting and more focused conversations than other general virtual worlds.

7. Conclusions

In this paper, we have introduced the concept of structural duality and illustrated the concept with a spatial-semantic virtual environment called StarWalker. The fundamental design principle of StarWalker is to combine an abstract virtual world with a multi-user avatar embodiment. This combination will allow users to follow the trails of peer users, i.e. to enable social navigation. Ultimately, a tighter coupling between spatial and semantic aspects of a virtual environment will bring more focused and direct social interaction into the virtual environment. The structural duality between discourse structure and the content of the embedded abstract world provides an analytical framework for us to assess the impact of a virtual environment. The concept of structural duality also provides a theoretical basis for the development of spatial-semantic virtual environments. This theoretical basis will be invaluable to consolidate the convergence between interdisciplinary communities such as information visualization, virtual reality, and computer mediated communication.

Embedding an abstract world into a 3D multi-user virtual environment is only the first step to afford social interaction. Much work is needed to develop more adequate models of interaction and behavioral semantics and to accommodate various integral aspects of a virtual environment in harmony, including spatial, semantic, social, ecological, and cultural implications.

StarWalker demonstrates a generic approach to the development of virtual environments, with potential applications in areas such as shared digital libraries, collaborative learning, and virtual conferences for special interest groups and virtual communities. A tight spatial-semantic coupling provides a good starting point for us to explore the structural duality further between social interaction in the foreground and an abstract virtual world embedded in the background.

A great challenge for the future work is how to link the concept of structural duality with observable patterns of social interaction in StarWalker or similar virtual environments. So far StarWalker has attracted many visitors and forged many interesting conversations. On the other hand, the majority of the conversations in general focused more on the spatial aspect of StarWalker than its semantic counterpart. In a recent experiment, three users had a brainstorming session within StarWalker in order to determine the topic of an article they were asked

to write together [Chen et al. 1999]. This experiment started to reveal a tighter coupling between spatial and semantic aspects from the point of views of users. On the other hand, the majority of conversations in StarWalker focused on the spatial aspect of StarWalker rather than its semantics.

We plan to undertake empirical studies, including comparative studies across small group discussion sessions in virtual worlds with different spatial layouts and semantics. We also plan to have larger-scale studies within StarWalker. We intend to study the structural duality across a wider range of settings, such as asynchronous and synchronous discussion groups, textual and virtual-reality-enabled virtual environments. Our aim is to develop virtual environments that can afford social interaction and help people to establish a common ground for both social interaction and task-oriented activities.

Streaming Media for Web Based Training

Chad Childers, Ford Motor Company, USA, www@ford.com
Frank Rizzo, Ford Motor Company, USA, frizzo@ford.com
Linda Bangert, Internet Education Group, USA, lmb@interguide.com

Abstract: Streaming audio became available on the Web in 1995, but with the development of the Synchronized Multimedia Integration Language (SMIL)[1], the technology has reached a new level of maturity. SMIL is based on the XML standard, and allows audio, video, images, and text to be integrated. The implications for Web based pedagogy are tremendous. We now have the opportunity to do training on the desktop in a feature-rich open environment. We will give a basic background in streaming media technology, discuss the standards, the current state of the art, our experience with RealNetworks [2], how to take advantage of it in an intranet environment, and touch on future developments, including the integration of testing engines.

Taking Web Based Training into the 21st Century

In the online world of 1999, what you can do is both empowered and constrained by the technology. A good understanding of the limits of the viewing software, end user hardware, and intervening network allows the instructional designer to make the best possible use of what is available - to push the limits while balancing speed and usability. We are now entering a new world where those limits are being pushed back rapidly, and anything is possible. It is still very important to understand the limits, for now, but it is equally important to break down our preconceived notions of what is possible. For a moment, imagine anything is possible!

The new SMIL (Synchronized Multimedia Integration Language) standard allows multimedia content, including text, pictures, sound, and video to be synchronized for a coherent learning experience. Control of all these media is contained in a simple text file (although the format is quite complex). Tools to simplify creation and editing are rapidly being developed. SMIL can greatly reduce the bandwidth required while delivering an experience similar to watching a fully interactive television channel.

Definitions, History, and Current Status

Streaming media is defined as network based data, which can be presented to the user before the whole data file has finished transferring. If you see a picture begin to appear on your screen before the transfer completes (e.g., a PNG or some JPG files), or hear an audio file start playing as soon as you click it (e.g., a RealAudio file), that is an example of streaming media.

The primary advantage of streaming is that large audio and video files can be played as they arrive on the computer rather than having to wait for the file transfer to complete. For training in particular, this means that the user interface is much more responsive.

Data can be streamed in a variety of ways:

	Pre recorded / on-demand	Real-time / on-demand - pulled	Real-time / live - pushed
Web server	✓		
RealMedia™ server	✓	✓	✓

If served via the web server, when a user clicks on a web link to a RealAudio sound file, the data is delivered over the web's HTTP protocol. One kind of data can be presented. If served via the RealMedia server, the data is delivered back to the web browser via a streaming protocol like RTSP (Real Time Streaming Protocol) or UDP. Pre-recorded content could include online training materials, and real time content could include classes and meetings.

SMIL is important for several reasons. First, it integrates various kinds of media. Second, it is an open standard that can be leveraged across all platforms. Finally, it is derived from the W3C Extensible Markup Language (XML)[3] standard; this is important because anything can be defined in XML, and it can be extended on the fly simply by defining new tags.

A SMIL player can act like any other Web browser plug-in, and display SMIL content over an HTTP connection. However, it can also subscribe to a host group and view an IP multicast, or negotiate the control connection and open a unicast RTSP connection to stream the data.

The TCP/IP protocol upon which the Internet is based is reliable over a wide variety of physical networks because the packets can be retransmitted by TCP, the Transmission Control Protocol. [4] When delivering streaming data over a high bandwidth corporate or university campus network, however, the high reliability of TCP is not required, and retransmissions can slow down performance and take up too much network bandwidth. RTSP is designed to degrade gracefully even if a few packets get lost, and therefore delivers the data faster with lower overhead. Early papers on Real-Time Video concluded that the Web was not suitable for high bandwidth media, because of the inherent delays. [5] The new protocols help deal with these problems.

With IP multicast, a streaming server can send a broadcast message across the network, allowing multiple computers to receive it. The new protocols can allow some packets to expire without retransmission, and new routers can allow the data to go across the network to multiple destinations with only one destination address, the multicast host group address, in the header.

If you want to take advantage of these capabilities, first decide on your needs, then take the time to understand the options. You can then talk with your networking group for help in configuring routers, or to help you decide what technology best suits your needs.

SMIL, the best direction for Web Based Training

Just as web based training (WBT) has some important gains over traditional classroom training, the use of SMIL allows the Instructional Designer (ISD) to take the training experience one step further. SMIL builds on the existing base of XML standards, tools and experience. It allows for very easy indexing and editing because the control files are all plain text with tags, similar to HTML. It can be used inline within an HTML page, and allows simple extensibility for other applications (such as testing engines) within a well-defined framework. Open standards tend to be simple and durable.

Poorly designed WBT can be a waste of time and money as well as an ineffectual tool for training. Many of the streaming videos foisted upon unsuspecting viewers as WBT show a video of a slide presentation with an audio narration, or even worse a subject matter expert as a "talking head" giving a lecture. To take advantage of SMIL, build a presentation including the audio track of the lecture combined with streaming text of the speaker's notes, streaming JPEGs of any presentation slides, and perhaps short video segments of any animated processes required to illustrate the topic. Besides being more informative and imminently more useful to the end-user, the performance gains of the SMIL presentation over the pure video are tremendous. The network bandwidth required for audio playback audio with text and JPEGs can be less than half that of a single video stream. Due to the fact that the JPEGs will take up less bandwidth than the video, the quality of the JPEGs can be much higher and small details on the presentation slides, like text, will actually be readable by the end-user. The audio and text tracks could be localized and presented to the user in the language of their choice without having to re-author the entire presentation in a single monolithic chunk. SMIL gives you the ability to split these data types into separately maintained files and maintain full control over how and when they are displayed to the user. One of SMIL's strongest abilities is controlling when something happens on-screen. The content author can precisely control all events, effects and transitions.

Applications that support open standards tend to be available at low or no cost for academic uses. Many of the instructional design tools available today use proprietary code and custom designed Java plug-ins to display the coursework. Some software companies charge far too much for their WBT solutions and may have simply repackaged their custom computer-based training software engines into a complicated browser plug-in. Using this type of approach to WBT can lead to a variety of problems. Trying to deploy the specialized plug-ins to your client base and dealing with unforeseen incompatibilities caused by these plug-ins can quickly become a maintenance nightmare. Better to rely upon a solution based on open standards where the browser plug-ins are freely available and tested by the Internet at large.

There are still some issues to be resolved with SMIL. Drag-and-drop tools to automatically generate SMIL code are still in their first-generation or in beta testing. Complex SMIL presentations still require hand-coding or at the very least, some hand tweaking to perfect and debug. At the time this paper was authored, writing SMIL presentations complex enough to be called WBT requires knowledge and experience beyond the capabilities of the typical instructional-designer. For now, the use of an experienced web site programmer or a staff member who can be dedicated to learning the technical aspects of SMIL is recommended.

From an authoring standpoint, the emerging collaboration and streaming technologies in Microsoft Office 2000 appear to be simple to use and well integrated into the traditional Office suite of tools. It remains to be seen if the Microsoft products continue to have the server scalability and quality issues which plagued earlier streaming technology releases.

When choosing a streaming technology for WBT many factors must be weighed and evaluated. There are a variety of technical factors such as existing network infrastructure between you and your audience, server platform and availability, and client software maintenance. These will be discussed in "The Real Nitty-Gritty" section below. Other factors, which can sometimes be more important to overcome than the technical issues, include personal experience and comfort level with the technology, institutional politics, and any existing corporate relationships. First and foremost, you need to be comfortable and familiar with the technology you implement. If your instructional designers are all familiar with a specific tool set and very comfortable with the processes and procedures surrounding your existing traditional or CBT training methods, there will probably be a substantial resistance to change. Overcoming any internal training paradigm "inertia" will definitely be an obstacle. Often, training the trainers is the hardest job of all. Convincing the management that a new method of training is needed and it may cost them some money to overcome the technical issues can sometimes be an insurmountable hurdle. Presenting the idea to management requires careful analysis of the actual costs involved. Another potential issue when choosing a streaming technology within an organization can be factoring in any pre-existing corporate relationships. If your organization has, for example, a strong relationship with Apple Computers, then trying to justify a WBT solution utilizing SMIL instead of QuickTime for streaming media may require good analysis and strong justifications.

The Real Nitty-Gritty

Building a WBT module using SMIL follows the same process as building traditional WBT with a few specialized requirements. The first phase of any project is the conceptual brainstorming and storyboarding. This is best done on paper for speed and easy reference. The first step is to define the objective of the WBT module. Decide what information is to be conveyed to the viewer and be specific. Define the project scope, setting definite boundaries encompassing just enough detail to properly cover your objectives. Keep the focus tight and stick to your stated objectives. Next, set requirements for the user experience, thinking about not just what the user will be learning, but how you want them to learn. The idea is to lead them through your learning materials in an organized and straightforward manner. This will help you design the navigational methods used within the WBT module. Try to design the framework first. Don't worry about the graphics yet, work on the layout first. Designing a common look-and-feel that can be reused across modules will help reduce development time on subsequent projects and lend a consistency to your training. Consistent look-and-feel across WBT modules gives the viewer a higher comfort level knowing that even though the subject matter may be new, the process of learning throughout your modules is familiar.

From your storyboard, build a timeline and organize the presentation of your learning materials. Plan the layout of the learning materials and the navigational items. Decide when a particular item needs to be displayed. This will help you determine load orders of your media assets and help identify any constraints imposed on your load order by your target bandwidth. With SMIL different items within your presentation can be specified to load serially or in parallel. It's usually a good idea to make sure that your navigation buttons and other graphics and text load before the user gets to view the video animation on the first page of your presentation.

After the layout and storyboard have been finalized, the next two steps for building your presentation are the design of the interface and the content design of the learning materials. These steps frequently happen in parallel. While one group of graphics artists work on the backgrounds, buttons, graphics and other window dressing, the instructional designers work with the media production staff to plan and create the learning materials.

Interface Design

When designing the interface for SMIL presentations, one must consider how the presentation will be displayed. SMIL can be embedded into a web page or displayed stand-alone in the RealPlayer®. The choice can be simple depending on the level of integration desired, use of any courseware testing engines, and finally personal preference. Either way, standard web design rules definitely apply. To be effective, the interface must be clean and uncluttered. The design should encourage the user to explore while intuitively leading them safely through the learning materials in the appropriate order to effectively teach them what they need to know. The design must support the learning materials. Layout of the presentation should lead the user to focus on the learning materials. With time-based control over all display elements, SMIL provides the ultimate in design flexibility.

As with any web based design project, the module must be designed with the lowest common denominator client system in mind. If your audience is within your organization's intranet and there are hardware and software standards in place to assure that all of your users have at least a certain minimum configuration then it is relatively simple to plan your WBT module to fit within those requirements. Typically, a SMIL presentation should be designed to fit within a 640x480 VGA screen. Remember that the actual usable space within a browser is smaller than the full screen resolution. For a 640x480 VGA display with the web browser window maximized, with default menu settings, the usable screen real estate is approximately 600x300 pixels. When adding a 320x240-pixel video, not much room is left vertically for titles and text.

Learning Materials Content Design

While the graphics artists are busy with the interface, the source materials for the video, audio, and other media clips must be recorded and encoded. Plan and conduct source material recording sessions. Once the project storyboard and layout are finalized, it's time to build the actual "meat" of the presentation. Successfully planning and producing the actual presentation material is simple if you, the designer, have control over the material being presented. More often than not, the audio and video have to be recorded onto cassette or videotape and then digitized and encoded for use on the web.

When dealing with video as a streamed medium, many factors influence the final stream quality and playback rates. The well-known rule of "Garbage in, garbage out." applies to streaming video. The higher the quality of the recording used as source material, the smaller and faster the streaming video file will be. The differences in signal-to-noise ratios and overall resolution between VHS, S-VHS, 8mm, High-8, Mini-DV, BetaCam-SC, and DV-PRO video formats (these are listed in increasing degree of quality) directly influence the playback frame rate and encoded file size of the streaming video file. The better the format you can afford to record in, the cleaner and better your video will stream to your clients.

For important high-bandwidth content, the use of a professional video production staff equipped with proper lighting and recording equipment will always yield a higher quality recording than a consumer-quality video camera. This by no means should be interpreted to mean that low cost, consumer-quality equipment is incapable of producing satisfactory results. However, to provide Internet-based video streams larger than a postage stamp at acceptable quality when network bandwidth is at a minimum, starting with premium quality video recordings is essential. The objective here is to plan the multimedia source materials appropriately taking into consideration the time, resources, and funding required to realistically achieve your design goals.

Building the RealText™, RealPix™, and SMIL files

After the actual content files have been created, the SMIL presentation files need to be created. This is quite similar to creating HTML pages, except SMIL is time sensitive and requires specific timing for each event and transition, and the files need to live on the streaming server, not the web server. For instructions on how to code SMIL files, the SMIL technical documentation can be found at the World Wide Web Consortium Architecture for Synchronized Multimedia [1].

Technological Issues

The topics covered within this section will address issues surrounding manufacture of streaming media for intranet use where high-bandwidth network connections are available. Although SMIL presentations can be adapted to incorporate different sized videos for either high or low bandwidth use, that is outside the scope of this paper.

Once the instructional designer has obtained the source materials for the videos, they need to be digitized. The format into which the video is digitized will affect the final encoded output. Always digitize video uncompressed at 30 frames per second and in Stereo at 16-bit 44-KHz sampling rates. Let the streaming format encoder software have the best quality input so it has all of the data it needs to provide the highest-quality output. The more data the encoder has to work with, the fewer assumptions the compression routines need to make. This will result in smoother, cleaner, and smaller encoded video output.

Digital editing of video and audio sources before encoding is usually required. Certain optimizations such as video cropping and audio normalization can be made to provide optimal output upon playback. Applications for video and audio editing include Adobe Premiere® and Sonic Foundry's SoundForge®.

Encoding content to RealNetworks formats

Audio and video can be encoded into the RealNetworks® RealMedia® format using a variety of third party applications. The easiest encoder to use is the RealProducer® Plus G2 from RealNetworks. It has many different stream options. The RealMedia G2 SureStream™ format option allows multiple streams at different bandwidths to be encoded into the same file. This allows the RealPlayer® and RealServer® to better negotiate how much data to send the player based on network performance. For example, a video may be encoded for 28.8K modem, 56K modem, 64K Single ISDN, 128K Dual ISDN, 220K xDSL and Cable Modem, and 150K Corporate LAN data rates all within a single file. Depending on the available network bandwidth, the player will switch between these different encoded formats dynamically as the user watches the video. This feature provides much better playback than older streaming technologies, which only adapt to changing network conditions by dropping frames or "fuzzing-out" the video into large indistinguishable blocks. Depending on the resolution and frame rate of your video source files it may not make sense to encode at the higher bandwidth settings, such as 220K and 150K, and at the low bandwidth settings, 28.8K, 56K, and single ISDN in the same file. The lower settings may not have enough available bandwidth to stream the file.

Streamed animations can be produced using Macromedia's Flash® technology. Flash is in widespread use for non-streamed web based animations. The same animations can be included into your SMIL presentation after a simple encoding procedure into the RealFlash™ format. Now the use for Flash animations is no longer limited to the realm of the static web page and can be unleashed into the dynamic environment of a SMIL presentation. The RealNetworks site has some good examples of RealFlash™ SMIL presentations.

Bandwidth between you and your target audience is the limiting factor on SMIL design. Designing SMIL presentations includes tradeoffs for each data stream sent to the player. The designer must balance data stream buffering times versus compression and the number of streams being loaded simultaneously. These calculations are also affected by the resolution of the data to be streamed. Resizing a video originally intended to stream at 320x240 pixels down to 160x120 will reduce your bandwidth requirements by a factor of four (assuming constant compression rates). The RealNetworks SMIL kit has exhaustive information on this topic.

Uploading files to stream server

As the streaming media files are created, they need to be stored on a separate server running the RealNetworks RealServer® G2 server software. The content creator will need to place the files in a subdirectory off the mount point for the server, and will need the address and port number of the server, as well as whether the Ramgen file system, for sending temporary small files, is in use. The files can then be linked to from any web page. Links can be of the format `http://server/ramgen/MountPoint/virtual_directory/filename`, and once within SMIL, individual components can be specified in a very similar format, `rtsp://server/MountPoint/virtual_directory/filename`. [6]

Hardware requirements

Hardware requirements vary widely depending on your application. Four sets of hardware requirements are involved: network infrastructure, web server, stream server, and client browser/player. The web server requirements and configuration are outside the scope of this document. Many of the issues discussed here are particularly important to corporate implementers who have controlled environments into which they wish to introduce streaming technologies. The only successful way to implement streaming media in a corporate environment is to work with the

network and computer infrastructure organizations within your company to understand and proactively adapt to the additional requirements imposed by the technology.

Network infrastructure: Both Internet and intranet bandwidth demands should not be underestimated. Careful analysis of current network loads and capacities can help determine how much streaming traffic can be handled before network upgrades are required to provide adequate quality of service to all users. Network upgrades are expensive and time consuming. Always consult with your network operations staff before implementing any streaming technologies on a widespread basis across your network.

Client browser/player: The RealNetworks RealPlayer G2 will currently run on any PC-compatibles running Windows 95, 98, NT4.0, and Power Macintosh. Performance will vary depending on CPU speed and available memory. For fast, responsive control and playback, we recommend a minimum of a 166-Mhz Pentium with 32Mb of RAM. Slower machines will provide sub-optimal playback. PCs also need to be MPC-2 compliant and have appropriate sound-cards, drivers, and headphones or speakers installed. For corporate intranet sites, overcoming the current installed base of non multi-media equipped PCs can be a significant challenge.

Stream server: The RealNetworks RealServer G2 products run on a variety of UNIX platforms as well as Microsoft NT. Hardware requirements vary depending on expected number of users. Consult the RealNetworks website for details.

Future Directions

Most currently available web based testing software requires custom format files, special software, and is not standards-based. New products such as TopClass [7] use plain text and HTML, and are much better suited to integration within a SMIL framework. Testing is the next step.

The evolution of the tools currently available will no doubt give rise to a suite of powerful and easy-to-use tools for creating SMIL presentations. Ongoing development of SMIL with ratification via W3 will assure interoperability. Better integration and tools will allow the potential we see to be realized. Right now, streaming media is at the level of maturity the web was in 1994. The standards are there, and the tools are coming. You can go out and use the technology now. Let us know what you do with it!

Abstract: With the technology of the JAVA, we can do even anything on the web browser. It provides a way for the browser to communicate with the server, which provides useful information, and it can access the most up-to-date information or do some client/server job. Unfortunately, using the Java applet in the browser needs a lot of resource to startup the JAVA Virtual Machine and the applets usually do a little job. For an example, a stock quote Java applet only need to retrieve the current stock every few seconds and it's not economic. On the other hand, client-side JavaScript provides a simple way to manipulate client-side objects. In this paper we provide an extension for JavaScript to manipulate server-side CORBA Object. By the way the browser can communicate with the server and use less resource.

1. Introduction

1.1 World Wide Web

The WWW is originally designed for transparent document distribution over the client-server paradigm. Users can get various kind of information distributed worldwide. Information on the net may change from time to time. Some WWW applications encounter a situation that users need the most up-to-date information. It is not easy to do that on the ordinary design of the HTTP [W3C 99a] protocol. Users need to reload the page to get the newest version of the page, which was updated after his last access. To let users access the current information, some systems add an HTML [Raggett et al. 98] tag to notice the browser to reload the content of specific document:

```
<META http-equiv="refresh" content="3,http://www.w3c.org/">
```

The above HTML tag notifies the browser to reload the content specified by the URL after 3 seconds. In this model, users pull the information that they want. It is only a one-way communication; the server even can not push the updated information.

1.2 Java

To do more comprehensive job, Sun Microsystems introduce JAVA [Arnold 96] technology that provides cross-platform feature by using a Java Virtual Machine with special execution file format. With that we can run a small cross-platform program called JAVA Applet on browser and do almost everything. The applet can create a socket connection or retrieve any other information to a server. It is certain that two-way communication is achievable. The major problem of JAVA Applet is the waste of resources. We need both more memory to startup a JAVA Virtual Machine and more CPU time to process JAVA bytecode. On the other hand, Netscape & Sun Microsystems introduced a client-side script named JavaScript. We can embed JavaScript in the HTML to manipulate client-side object with the DOM [W3C 98]. We can pop up an alert window or verify the data entered by the script easily. The combination of HTML, style sheets [W3C 99b] and scripts allows documents to be animated and is called "Dynamic HTML" [Netscape 97] by some vender. Although "Dynamic HTML" is useful and powerful, it can only deal with client-side objects. We can not retrieve any server-side information other than web pages. The JavaScript itself restricts the capability of the JavaScript.

1.3 CORBA

It is a turning point of distributed computing when the object orientation being introduced into the client-server computing paradigm. Communications between clients and servers are now method invocations between objects. Here comes the distributed object [Orfali 95] computing paradigm. The soul of the distributed object computing

is the Object Request Broker, ORB, which provides a transparent communication channel between objects. Objects only concern interfaces of the communication peer, i.e. what methods they are interested in, not the communication details, e.g. protocols, media, etc. CORBA [OMG 98, Mowbray 97, Orfali 97a, Orfali 97b], stands for the Common Object Request Broker Architecture, is the representative of the distributed object technologies. Objects in CORBA are described by the interface definition language. They can be implemented in any programming languages on any platforms. This is an important feature of CORBA and makes CORBA be capable of integrating systems in heterogeneous environments.

1.4 New Direction

Combining the powerful information distribution capability of the WWW with the powerful system integration capability of the CORBA would be a good idea. Currently, there are several CORBA vendors provide their WWW solution by allowing JAVA Applet to communicate with CORBA objects. Because the CORBA objects can be implemented by any programming languages, the WWW can integrate with other systems easily through this way. However, this scenario still can not escape from the nightmare of wasting resources. In this paper, we propose a new direction of integrating WWW and CORBA in a more efficient and convenient way. We design and implement a system called *CORBAConnect* that allows JavaScript to manipulate remote CORBA objects. In other words, we appreciate the highly interactive communication between WWW clients and servers, like the JAVA Applet does. In addition, we take fewer rescues because we are scripts. In the following of this paper, we will present our design and implementation of the CORBAConnect system. The potential application of the CORBAConnect will also be mentioned. Finally, we make a conclusion and address our future works.

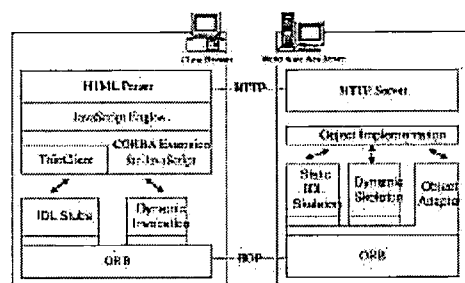

Figure 1. The System Architecture

2. Combining CORBA with JavaScript

2.1 Overview

The basic idea of the project is illustrated by the [Fig. 1]. First, the webmaster designs and implements a CORBA object. Second, the webmaster registers the object to the ORB. The ORB will redirect the client request to the implementation object by a piece of code called *Server Skeletons*. Third, we add some CORBA related classes to the JavaScript Engine. It deals with CORBA objects that are located by the JavaScript through the Dynamic Invocation Interface, DII. The DII allows dynamic use of the CORBA objects without any prior type knowledge of it. Finally, users can view the web pages embedded with the JavaScript. The JavaScript can locate the remote CORBA object and get the object reference. As a result, the script can manipulate the object through the object reference.

2.2 ECMAScript, JavaScript, and Binding

We know that JavaScript is the Netscape-developed object scripting language used in millions of web pages and server applications worldwide. On the other hand, the ECMA Standard [ECMA 98] is based on several originating technologies. The language was invented by Brendan Eich at Netscape and first appeared in that company's Navigator 2.0 browser. It has appeared in all subsequent browsers from Netscape and in all browsers from Microsoft starting with Internet Explorer 3.0. To promote the JavaScript to become an industry standard,

Netscape release a version of JavaScript implementation named *JavaScript Reference Implementation* to licensed company to use it as part of their product. The Netscape browser as well as our project are based on this code and extend some kind of classes.

ECMAScript [ECMA 98] is an object-based script: basic language and host facilities are provided by objects, and ECMAScript program is a cluster of communicating objects. An ECMAScript object is an unordered collection of properties each with 0 or more attributes that may contain another object, primitive type data, or a function. Most of our job is defining a class and the JavaScript engine will call some callback functions when the script want to set or retrieve the value of a property. In this paper we focus on the JavaScript 1.1 which is a part of Netscape Communicator 4 and is a superset of the ECMAScript. There are six data types of the JavaScript. The language data type mapping between CORBA and JavaScript of this project is listed in the [Tab. 1].

JavaScript	CORBA	Description
Undefined	-	"Undefined" is undefined in CORBA and will raise an error if the script pass an undefined value to CORBA object.
Null	Object Reference	Null in JavaScript can only be represented the Nil Object Reference.
Number(double)	Double	JavaScript defined a value of double number called NaN (not a number) which will raise a error when the script pass a NaN to CORBA object.
Number(integer)	Short, long, unsigned short, unsigned long, char	The CORBAConnect will convert the JavaScript integer number to proper CORBA data type according the definition of the CORBA Object.
Boolean	Boolean	
String	String	
Object	Object Reference	Only JavaScript object of CORBA Object class can be converted to an Object Reference.
- [Not Implement]	Structured Types: struct, union, sequence, or array	We don't implement these CORBA data types now. We will map them to some type of JavaScript object in future works.

Table 1: Language Mapping between JavaScript and CORBA

2.3 Two-way Communication

With the previous function we described, the JavaScript can access remote object via CORBA, but it's not really a two-way communication. The client can only pull the information from the server by access the attribute or invoke some operation within a CORBA object. How can a server notify a client when the desired data is updated? The obvious way is to let the server program access the object on client-side, but it's not easy to convert a JavaScript object to a CORBA object via *Dynamic Skeleton Interface*. To solve this problem, we design two type of interface, one of them is named *ThinClient*, and the other is named *JS_Object*.

```

Interface ThinClient {
    void OnServerTrigger1();
    void OnServerTrigger2();
    void OnClientTrigger1();
    void OnClientTrigger2();
};
Interface JS_Object{
    void Register(in ThinClient TC);
    void Trigger1();
    void Trigger2();
};

```

The whole browser will provide a *ThinClient* interface, and the CORBA Objects that want to use the two-way communication feature should inherit the *JS_Object* interface. When a client want to be triggered by the server side program, the client should register its *ThinClient* object by the Register operation in the *JS_Object* interface. And the *JS_Object* maintains a list of *ThinClient* object, the server can trigger them and all clients will invoke the method named *OnServerTrigger1* or *OnServerTrigger2* if it is defined. If one of the clients invokes the operation named *Trigger1* or *Trigger2* on *JS_Object*, it will trigger all of the *ThinClient*'s method *OnClientTrigger1* or *OnClientTrigger2*. In this method, the implementation is easy but useful, we will introduce the use of this method by a simple example in the next chapter.

3. Implementation & Application

3.1 Developing Environment

We integrated the CORBAConnect with the Mozilla Browser, a source code released browser provide by Netscape Communication. The browser is based on the source code of the Netscape Navigator and both of them use the JavaScript Reference Implementation. Thanks to the Netscape Communication for their effort to the OpenSource society.

We also use an ORB named ORBacus [OOC 98] provide by Object Oriented Concepts, Inc. It is free for non-commercial use and the source code is released. Because CORBA is an industry standard and the IIOP protocol, we can use different ORBs between client and server. The ORBacus provides a special operation for ORB, which named *get_inet_object*, we can call the operation to retrieve the object reference in the specific host, port and object name directly. This is a better way then the IOR string to binding.

3.2 Current Status

The current version of the CORBAConnect only supports the attribute and operation within an interface. The "OUT" and "INOUT" types of the arguments are not implemented due to the characteristic of the JavaScript Language. Because the exception is not support in JavaScript 1.1, we do not support it, too. We ignore the exception but provide a global variable named *LastException* which can let the script to know if there raises an exception. We will support exception with the JavaScript 1.4 which built-in the exception feature. In fact, JavaScript with CORBAConnect can access the CORBA Object anywhere, the object implementation is independent with the web server. but security issue is concerned like a JAVA Applet, scripts can only access the CORBA Object on the server where the browser retrieves the web page.

3.3 Application Scenario

Java technology brings everything come true on a browser, but, as we have mentioned previously, it cost much resource. We find three proper situations that the JAVA Applet can used to enhance the web pages:

- **Interactive Graphic User Interface** If you want to open a window for user to input more complex data, to display the news headline in a box like a scroll, or to animate something.
- **Dynamic Information Update** Another situation to use the Java Applet in a web page is that you want some information of this page can be updated dynamically. The most popular application is displaying the stock price. Users can refresh the page by themselves, or refresh it every few seconds automatically. But building a socket communication by a Java applet between browser and the database server is the best way.
- **Collaborative Browsing** An example of the collaborative browsing is chatroom. Many people view the same page and want to exchange their information to each other. Like the situation we discuss previously, you can write a lot of CGI programs or only a JAVA Applet to do this job. Most people will select JAVA Applet to develop such system.

Although JAVA Applet is easy to use, it's is not friendly for user because of it's performance. The JavaScript is another alternative. in situation 1, we can achieve most of these effects easily by JavaScript combined with DOM, Macromedia's Flash [Macromedia 99] or the working standard SVG - Scalable Vector Graphics [W3C 99c].

We have no better solution for situation 2 and 3 now. But the CORBAConnect can solve these problems.

In situation 2, one can implement a CORBA object to retrieve the information from database, and JavaScript can get the information by retrieving the attribute of remote object. When the information is updated, the server can give you a notification by invoking the operation in the ThinClient interface, which will pass to the event handler `OnServerTrigger1` or `OnServerTrigger2`. We have an example in the next section.

In situation 3, one can setup an information repository that stores the information of each client in the server for

all clients to access. When one of the clients update it's information, the client invoke the OnClientTrigger1 or OnClientTrigger2 operation in JS_Object, which will dispatch the event to all of the clients, registered.

3.4 A Simple Stock Quote Example

In this section we will introduce a simple stock quote example to show the power of the CORBAConnect. In this example, we will build a real-time stock quote system. First, we will design the server-side object with following IDL:

```
Interface StockQuote : Interface JS_Object
    // inheriting from the JS_Object to use the capability of two way
    communication.
    {
        double GetQuote(string Symbol);
        string GetName(string Symbol);
    };
```

The implementation of the StockQuote is easy, we only need to lookup the symbol and return the QuoteValue or the company name from the database. And it should trigger the clients by invoke the operation OnServerTrigger1. After the implementation, We can write such a simple JavaScript code to show the real-time stock quote:

```
<HTML>
<HEAD>
<TITLE>Real-Time Stock Quote by CORBAConnect</TITLE>
</HEAD>
<SCRIPT>
/* initialize the ORB and get the StockQuote Object on port 8888 in quoteserver */
orb=new ORB();
StockQuote=orb.get_inet_object("quoteserver","8888","StockQuote");
if(!CORBA_is_nil(StockQuote))
{
    /* if we get the object reference correctly, register the thinclient */
    StockQuote.Register(ThinClient);
}
function update_quote(){
    if(CORBA_is_nill(StockQuote))
    {
        document.forms[0].Company.value="Error on Getting Object Reference";
        document.forms[0].Quote.value="----";
    } else {
        /* update the stock quote */
        document.forms[0].Quote.value=
            StockQuote.GetQuote(document.forms[0].Symbol.Value);
        /* Unknown Symbol ? */
        if(StockQuote.GetQuote(document.forms[0].Symbol.Value)>=0)
            document.forms[0].Company.value=
                StockQuote.GetCompany(document.forms[0].Symbol.Value);
        else
            document.forms[0].Company.value="Unknown Symbol !";
    }
};
/* Setup the triggered function */
OnServerTrigger1=update_quote();
</SCRIPT>

<FORM>
Symbol : <INPUT NAME=Symbol LENGTH=10 OnChange='update_quote()' ><BR>
Company : <INPUT NAME=Company size=40> <BR>
Quote : <INPUT NAME=Quote size=8><BR>
</FORM>
</HTML>
```

the screen shot of the result is the [Fig. 2]. To achieve the same result, you may need to write a Java applet with the waste of resource to run the JAVA Virtual Machine. You can also refresh the page every 3 seconds to get the real-time data and your server will have heavy load when more and more users access it. No matter which method you use, the more resource you need.

Figure 2: a part of the screen snapshot of the result

4. Conclusion & Future Works

Using the CORBAConnect we can easily access remote CORBA Object via JavaScript with minimum resource. Moreover, more and more enterprises use 3-tier model to access database with CORBA. CORBAConnect can let them to access the data directly only via the browser. The biggest problem of the CORBAConnect is standard. We need to use a special version of browser to provide this feature to user. If it can't be a part of a public browser nobody will use it. Therefore, the future works is completing the whole binding between CORBA and JavaScript and submit a proposal.

From Simple Chat to Virtual Reality: Formative Evaluation of Synchronous Communication Systems for Online Learning

C. Candace Chou (chou@hawaii.edu)
Communication and Information Sciences, University of Hawaii

Abstract: Synchronous conferencing systems are under-utilized in most distance learning environments. Appropriate use of the synchronous CMC systems contributes to student satisfaction and active participation in an online environment. This study employed the formative evaluation method to assess students' perceptions toward different CMC systems. The systems are divided into three categories: text-based chat, audio-video conferencing, and virtual reality applications. The results of the study indicates that, among all synchronous CMC systems employed in this study, text-based and virtual reality conferencing systems are more efficient for synchronous online learning.

1. Introduction

Online learning refers to any type of learning activities that takes place over a computer network. Synchronous online learning refers to online learning that takes place in real time. As an increasing number of courses in various disciplines go online, various types of computer-mediated communication (CMC) systems are also utilized to facilitate online learning. CMC systems, as defined by Kerr and Hiltz, "use computers to structure, store, and process communications" (Kerr & Hiltz, 1982, p. 2). Many research studies have shown that the features of CMC systems can not only reduce physical and social constraints but also increase online interaction and knowledge acquisition (Kay, 1992; Verdejo & Cerri, 1994). Many studies have focused on the final impact of technology on student learning. This research proposes to use formative evaluation to study the process of student learning about new technology. The findings will further the understanding of the applications of the CMC systems for online learning as well as student perceptions toward new technology. As Bloom *et al.*, (1971) have noted that evaluation is a systematic way of collecting evidence to determine if learning has taken place in individual students. This research used observation, reflection journals, and social presence ratings to survey student perceptions toward CMC systems.

2. Background

2.1. CMC Systems for Synchronous Online Learning

The CMC systems used in the course for this research are a combination of text-based, audio-video, and virtual reality systems. The main communication system is WebCT, which is a web-based learning courseware. WebCT provides a set of tools for instructors and students to engage in online instruction and learning. These tools include: homepage, presentation area, annotation tools, self-testing, course content, course reference material, email, chat room, bulletin board, calendar, searchable image and file archive, syllabus, course content manager, grading tools, timed online quizzes, file manager, indexed searching, student progress tracking, etc. (Goldberg, 1997). In addition to WebCT, the course in this study also utilizes the following systems for synchronous learning:

2.1.1 Text-based Conferencing Systems

2.1.1.1 *ICQ*: ICQ ("I seek you") is an Internet paging and chat utility. Users can page a partner via the Internet for a live chat. A contact window indicates when another conversation partner has come online. This tool is ideal for small group interaction. Teachers can use it for virtual office hours. (<http://www.icq.com>)

2.1.1.2 *WebCT Chat*: a Java-based chat program and a component in WebCT. Group discussions can take place in four separate chat rooms. Conversations in the chat rooms are recorded. (<http://www.webct.com>)

2.1.2 Audio-video Conferencing Systems

2.1.2.1 *Netscape CoolTalk*: an audio conferencing system that allows people to talk to each other over the Internet. (<http://www.netscape.com>)

2.1.2.2 *CU-Seeme*: a video conferencing system. Users can see and hear each other via a video camera over the Internet. (<http://www.cuseeme.com>)

2.1.3 Virtual Reality Systems

2.1.3.1 ActiveWorlds: a graphically enhanced 3D-conferencing system. Users are represented by avatars which walk, dance, and jump around in a world. A world is a metaphor for the ideal world that a user would like to build in the cyberspace. Programming knowledge is required to build a world in the ActiveWorlds. Conversations are typed into the chat window and logged automatically. (<http://www.activeworlds.com/>)

2.1.3.2 The Palace: another graphically enhanced affective conferencing system that also uses avatars to represent conversationalists. The main difference between this system and the ActiveWorlds is that users can change emotional expressions such as sadness, happiness, and excitement on the avatars. Users can dress the avatars using props in the suitcase or from the Internet (<http://www.thepalace.com>).

The selection of these CMC systems were intended for the students to develop the skills to manage various types of CMC systems. The main criteria of the selections are based on economic considerations. Programs that can be freely downloaded or are easily affordable were first considered. The next section will discuss the online learning activities for synchronous online learning via these CMC systems.

2.2 Synchronous Online Learning Activities

Most of the online learning environments are based on the model of asynchronous learning in which students engage in online activities at a time of their choosing. For courses that emphasize memorization of factual knowledge, asynchronous communication may be sufficient. For a course, such as the one in the present study, that was designed to improve online communication skills, synchronous communication is no less important than asynchronous communication. Students can learn the techniques for online discussions and develop the skills to operate these CMC technologies through synchronous learning. Synchronous communication and asynchronous communication are of equal importance in the curriculum.

There are many options of synchronous activities. For example, one can use guest speakers from remote sites, online debate, and role-play. This course utilizes all these means to enhance student learning interests. To help the students in getting ready for synchronous discussion, two preparations can be done ahead of time: dividing students into small groups and providing guidelines for discussions. Ill-prepared synchronous communication can be characterized as non-linear, chaotic, unfocused, and unproductive. Small group discussions have the advantages of initiating focused, equal, dynamic, interactive, and quality discussions. Sharan and Sharan (1976) postulates that "small groups are an effective organizational medium for encouraging, clarifying, and guiding student participation in planning classroom activities, both academic and social" (p. 10).

Furthermore, all students were given a set of Student-Centered Discussion (SCD) guidelines at the beginning of the semester. The SCD guidelines were adapted from Dr. Linda Shoop's model of SCD (<http://home.kiski.net/~dwright/scd/home.html>). The SCD guidelines were introduced for the purpose of facilitating discussions and increasing the quality of student participation. The guidelines included two main parts as summarized in the following sections.

2.2.1 The role of the participants

Discussants of online forum should follow the etiquette that ensures good discussions.

- 1) Respect for each other—be polite to each other.
- 2) Idea generating—formulate ideas and try to state them in clear terms.
- 3) Listening—read other peoples' messages before jumping into the debate.
- 4) Referencing—always include the names of the past speakers when making references to their messages.
- 5) Display responsible involvement—avoid chitchat in a public forum and try to address the whole group as much as possible.

2.2.2 The role of the moderators

In order to lead a successful discussion, a moderator should make the following preparations to keep the discussion alive:

- 1) Greeting—Moderators should greet every participant when s/he joins the chat room.
- 2) Warm-up activities: Moderators can devise short activities to get everyone ready for the formal discussion. For example, the moderator can solicit a quick poll on current issues.
- 3) Make an opening statement—The statement should provide information for the understanding of the topic of the day before initiating formal debate.
- 4) Step-by-step discussion process—Ask one question at a time and try to keep the discussion focused.
- 5) Asking questions—Have several questions ready before the seminar. When the discussants exhaust one topic, the moderator can either build on what has been discussed or ask a new question to keep the discussion going.

- 6) Scriptwrite the discussion—If necessary, the moderator can write down in advance certain set phrases, e.g., greetings, opening statements, introductions to the guest speaker, etc. It is more efficient to cut and paste these phrases into the chat window rather than keeping everyone waiting until the moderator finishes typing.
- 7) Concluding remarks—At the final round of the discussion, the moderator should try to consolidate the key points that surfaced during the conference and make concluding remarks.

3. Formative Evaluation

3.1 Methods

Bloom *et. al.*, (1971) defines formative evaluation as "the use of systematic evaluation in the process of curriculum construction, teaching, and learning for the purpose of improving any of these three processes" (p. 117). Bloom *et. al.*, states that "the purpose of formative observation is to determine the degree of mastery of a given learning task and to pinpoint the part of the task not mastered" (p. 61). The results of formative evaluation can help instructors improve curriculum design for better learning outcomes. Furthermore, formative evaluation can contribute to the improvement of computer-based educational technology (Flagg, 1990) The results of the formative evaluation in this study can help educators make useful decisions in selecting CMC systems.

The methods used in this study includes reflection journals, observations, and social presence ratings. Students were asked to reflect on the use of each CMC system in their weekly journals. The researcher also took notes while observing student adaptation to a new CMC system. After each use of the CMC system, students were also asked to complete a social presence ratings survey. Social presence is the degree to which senders and receivers can sense each other during their communication (Short *et. al.*, 1976). People interact differently according to the degree of social presence they feel. High social presence can convey multiple, nonverbal communication channels and continuous feedback. The social presence ratings used in this research employed semantical differential techniques that included a number of bipolar questions. For example, students were asked to rate a CMC system on a one-to-seven scale based on the following bipolar pairs: Impersonal - Personal; Distant - Close; Dehumanizing - Humanizing; Expressive - Inexpressive; Emotional - Unemotional; Insensitive - Sensitive. The results will be discussed in section 4.

3.2 Research questions

In order to gain a better understanding of student adaptation to technology, I posed the following questions:

- 1) What are the advantages and disadvantages of the CMC systems for synchronous learning?
- 2) How do students adapt to each CMC system?
- 3) How efficient are these CMC systems for communication?

3.3. Settings and Procedures

The data for this research is based on a writing-intensive online course, "COM459: Theories and Applications for Computer-Mediated Communication Systems", that took place in Fall 1998 in the Department of Communication at the University of Hawaii. The CMC systems employed in this course included the following three categories: text-based systems, audio-video conferencing, and virtual reality systems. The main objective of this course was to better the understanding of CMC systems through efficient use of various CMC systems. The student population consisted of junior, senior, and graduate students in communication, business, journalism, ESL, and philosophy. The majority of students are majoring in Communication.

This course was conducted through both synchronous and asynchronous CMC systems. This research focused only on the synchronous components. The students joined an online seminar once a week via various CMC systems. Each group took turns moderating the discussions. The host group needed to choose a topic related to CMC theories and post questions for discussion in advance. On the day of the seminar, the host group would moderate and facilitate the discussions.

4. Discussion

The following discussion addresses the three research questions. The first research question is answered through the researcher's observations. The second question is based on the analysis of students' reflection journals. The findings to the third question are based on the results of the social presence ratings.

4.1 Pros and Cons of CMC systems

Based on the researcher's observations and student experience in using various CMC systems, the pros and cons of each system are summarized as follows (Table 1):

Table 1

CMC Systems	Pros	Cons
WebCT	<ul style="list-style-type: none"> a. All conversations are recorded b. General and private conferencing rooms for small groups c. A sense of place, i.e., virtual office, student lounge d. Private chat with individuals during a public session 	<ul style="list-style-type: none"> a. Mac users typing interrupted b. Technical glitches—Unexpected server shutdown c. Browser incompatibility (works best in Netscape 4)
ICQ	<ul style="list-style-type: none"> a. Contact list—auto-detect if a friend is online b. Instant messaging—low bandwidth, point-to-point c. Status indication—showing if one is occupied, away, or available for chat d. Student help line—easier to reach the instructor e. IP lookup for modem users on dynamic IP addressing 	<ul style="list-style-type: none"> a. Interruption of work b. One-to-one conversation only
CU-Seeme	<ul style="list-style-type: none"> a. Real interaction—sound and sight b. Conversation of international guest speakers c. Low cost & high quality interaction 	<ul style="list-style-type: none"> a. Time-consuming preparations—required frequent testing of connections b. Time zone differences—difficulty in scheduling with users in different time zones c. Transmission difficulty caused by network congestion d. High bandwidth
CoolTalk	<ul style="list-style-type: none"> a. Efficient voice conversation over the Internet b. Free and easy to setup c. Saves phone bills 	Bandwidth & network congestion
ActiveWorlds	<ul style="list-style-type: none"> a. Personalized avatars b. Constructing your own world c. Exploring 3D virtual campus d. Indicating movements: dancing, waving, jumping, and greeting 	<ul style="list-style-type: none"> a. Initial Disorientation b. Programmer required
The Palace	<ul style="list-style-type: none"> a. Mood indicator—happy, sad, angry, exciting, thinking, etc. b. Wearable avatars—dress the avatars in any customs c. Text-to-speech—for the visually challenged d. Graphic-enriched backgrounds e. Increased interactions and active involvement 	Navigation & room capacity (8 people/server)

4.2 Student Perceptions

Student comments reflect the process of adapting to a new technology and what they like or dislike about these systems. The following sections are synopses from the student reflection journals.

4.2.1 WebCT

"One thing that bothered me is the lack of organization. With everyone talking at one time it is difficult to actually 'hear' anything that is being said."

"I still find chat rooms to be a very artificial means of communication...seemed to have more of a time lag than the other two computers...by the time I posted another question, her reply would pop up."

"When I was in chat and trying to type a message, every time someone else submitted a line my cursor jumped away from where I was typing."

4.2.2 ICQ

"ICQ has a chat function exactly similar to CMC cafe. Real time chatting is easy to follow and you don't have to wait for the other party to respond."

"Using chat for that projects was effective and interesting"

"I started using icq. It's a bit strange at first, but when you get started, it's fun."

"The way you can see the other person typing in everything is so immediate, I thought this was very exciting. You can leave notes if the other person isn't online."

4.2.3 CoolTalk

"The delay was a little frustrating at first, but once we got the hang of it we could work the worksheet well. Nothing is ever fast enough with technology, I guess I expected the communication to have clear, immediate results. I've never communicated through audio or visual so it was a great experience to see and hear the conversation with (guest speaker)."

"CoolTalk activity was fun and also enlightening- I especially like the hands-on experiential qualities of the small group face-to face and through CoolTalk interaction. Due to poor sound (I believe the speaker in the computer I was using is cracked), CoolTalk transmission was not as successful as it could have been, "

4.2.4 CU-Seeme

"At times the audio wasn't all that great on some of the systems but I enjoyed using the system."

"Unless your connection is fast, then the picture quality is very poor. Video allows people to see one another halfway across the world."

"I wasn't very impressed with the synchronous communication systems (CoolTalk and CUSeeMe) we saw last week. The video images were really poor and the quality of the communication was also. I don't think that the current technology is very useful. When improvements in reception are made, then I think people will be inclined to use it."

4.2.5 ActiveWorlds

"The virtual world was an interesting experience. Instead of chatting with another person in text on a screen, you can choose avatars that resemble yourself giving you a feeling of more interactions. The surroundings in the virtual world are also creative and eye catching. The movement is rather slow, but the chats are immediately posted."

"The Virtual University also wasn't impressive. It just seemed like a glorified computer game which just replaced the traditional lecture style classroom with a virtual environment,"

4.2.6 The Palace

"It creates interest in wanting to be there, which is then conducive to learning."

"It has real potential to be used in education. It seemed to me to be the best system out of all the ones we have tried."

"The ability to wear an avatar can give an added sense of personality"

"We were having some difficulties because not everyone showed up and one of the other students had trouble with lag time. But acting out the legend was pretty fun and it was good to have the audio and visual to work with."

4.3 Social Presence Ratings

Students completed the social presence ratings immediately following each use of the system. Some systems were used only once through the entire semester. Some systems were used repeatedly, e.g. WebCT. Pre-test and post-test were conducted for systems used more than once. The results of the ratings are indicated by the mean scores of each system on a one-to-seven scale. The higher the score, the higher social presence ratings each system receives.

WebCT Post-test:	5.3
The Palace post-test:	5.1
The Palace pre-test:	4.2
WebCT pre-test:	4.1
ActiveWorlds:	3.9
CU-Seeme:	3.8
CoolTalk:	3.4

The ratings for the audio-video conferencing systems such as CU-Seeme and CoolTalk are much lower than the text-based and virtual reality conferencing systems. This is partially due to the poor audio and video quality during the seminars. The video and sound quality was constraint by the available bandwidth during the seminars. The time lags during conversations made the communication laborious. Students had to repeat questions several times to get the messages across the wire. Although, in the reflection journals, students seemed to be excited about the possibilities of audio-video conferencing, the results of the social presence ratings indicated that they are not convinced that audio-video conferencing systems were ideal for effective communication at the time that the conference took place.

Interestingly, students complained excessively about WebCT in their journals at the first week of practice. WebCT received the highest social presence ratings at the end of semester survey. This may explain that time is a critical factor in adapting a new system. The more often the students practice on one system, the more comfortable they are with the system. Furthermore, the ease of use of the text-based conferencing (WebCT) made the conversation much smoother and less distracting in online conferencing. The virtual reality system (The Palace) came in second place. This is an indication that the add-on affective components made the conversation more realistic. Students liked to apply emotional expressions to their avatars to facilitate the communication.

5. Conclusions

The appropriate use of CMC systems can contribute to synchronous online learning in the following ways:

- 1) Enhanced cognitive and affective learning outcomes: students come to a new understanding of a course-related subject through in-depth online discussion. They are more motivated to keep up with the learning while interacting with each other in real-time.
- 2) Increased interpersonal connections: students generally appreciate the instant feedback from the instructor and fellow students during synchronous communication. They also get to know each other better through online social interaction.
- 3) Active learning: when students were bestowed with the responsibility to plan and lead a seminar, they became active learners in the process of planning and moderating a seminar.
- 4) Equal participation: shy students tend to speak up more in online seminars than in face-to-face meetings.

To ensure a successful synchronous seminar, in addition to the activity design, the selection of the CMC systems is critical in the planning process. It can be time-consuming in planning an online seminar and technology failure is sometimes unavoidable. Nevertheless, within the controllable variables, I recommend the following criteria for selecting a CMC system: ease-of-use interface, cross-platform, conversation logs, indication of the presence of the attendees, function to create new chat rooms, add-on affective components (e.g., emotional expressions), and strong technical support from the system developer.

In short, the keys to successful synchronous online learning rely on the appropriate activity design (e.g., student-centered discussion) and a good selection of the CMC systems. This study focuses on the evaluation of the CMC systems. Future research should also focus on the effects of the various types of online activities for synchronous learning.

An Evaluation Framework for Web-Based Document Directory Systems

Sotiris P. Christodoulou, Christos M. Papaterpos, Georgios D. Styliaras, Theodore S. Papatheodorou
High Performance Computing Lab, Computer Engineering and Informatics Dept., University of Patras, 26500 Rio, Greece
Emails: {spc, cmp, gds, tsp}@hpclab.ceid.upatras.gr

Abstract: In general, a Web-based Document Directory System (DDS) may be considered as a modular system that enables users to efficiently locate desired documents dispersed or accessed over the network. In this paper, we have focussed on full-text direct querying (search systems) and catalog traversal (catalog systems) and we propose and demonstrate a framework for evaluating such systems, in relation to application requirements. This framework consists of two sets of evaluation criteria classified under specific areas of functionality and an evaluation methodology that demonstrates how the criteria can be used to facilitate the process of selecting the appropriate DDS components. Finally, we provide two case studies for two real life projects in which we have applied it.

1. Introduction

The problem we attempt to address is to introduce an evaluation framework to help DDS developers to choose the appropriate systems/tools that can compose an effective DDS for a distributed document-base according to specific requirements. These requirements are derived from the needs of the main users involved in the life cycle of a DDS, namely end-users and DDS developers (information providers, administrators and programmers). Such requirements include the type of information one intends to organize, the format it is stored in, multilingual support, etc. The following factors accentuate the problem: (a) the large number of such requirements, (b) the large number of available systems with various characteristics and features, (c) the constant and fast evolution of systems' features, (d) the high degree of diversity of content that a DDS should support and (e) the lack of an evaluation framework to easily and accurately select the best system for specific requirements.

We have focussed on the following two, widely accepted strategies for locating documents: Full-text direct querying (search systems) and catalog traversal (catalog systems). These classes of systems/tools complement the functional definition of a DDS in an architectural context, when integrated as components into a DDS. A *catalog system* (alias subject catalog/tree/index/hierarchy) is a tool that provides a structured and organized hierarchy of categories for browsing information by subject. Documents are assigned to (placed in) categories either by their authors or by the subject-tree administrators. Catalog creation and maintenance may be done manually or with the help of tools that accommodate dynamic creation of subject-trees, based on characteristics of the documents that are being organized (namely filename, URL, meta-data etc.). In the case of *search systems*, the transformation on the document base is done through a process of document gathering, parsing (e.g. extraction, summarizing) and indexing. By ranking the extracted information (for instance in the case of text, by its position in the title or text, the number of times it appears in the document, etc.), the database reduces the number of incidental hits, known as false drops, from those relevant to the topic.

Related work on evaluation of search or catalog systems is focused on evaluation of Web Search engines (like Altavista, Lycos, etc.) or Web Directories (like Yahoo) from the end-user's point of view, who searches the entire Web. Thus, such evaluations test the systems on their search capabilities such as Boolean logic, truncation, field searching, etc. and evaluate the performance of the systems with respect to precision and response time. Moreover, most of these are Internet services rather than tools that can be purchased and installed for local use. There exist a large number of such comparing studies, either produced by researchers (like [Barry 96],[Winship 95], [Westera 95]) or by well-known companies specialized in evaluating online products and services like, CNet, PCMagazine, PCComputing, Internet World, etc. (see <http://www.searchenginewatch.com/>). Since the services are constantly changing, these compilations or recommendations are of short validity. Most of them are presenting charts with rated checklists of features and attributes. On the other hand, evaluations focused on the developer's requirements, are very few, like an article of ZDNet that compares six server-based packages (<http://www.zdnet.com/products/content/zdim/0303/278624.html>), but the criteria are very generic and abstract.

Establishment of the framework implies definition and classification of evaluation criteria and introduction of an evaluation methodology, which are presented in [Evaluation Framework]. Evaluation criteria stem from user requirements, some of which are elaborated in [User Requirements]. More detail description of the application of the framework in the two case studies is provided in an extended version of this paper [Christodoulou et al. 98b].

2. User Requirements

The selection of evaluation criteria is based on a broad set of requirements from both end-users and people responsible for deploying a DDS (information providers and administrators, programmers). Most of these requirements have been gathered through real-life projects (ISTOPOLIS [Papaterpos et al. 98] and VHF [VHF]) and web site development efforts we have participated - Hellenic Ministry of Culture (www.culture.gr), Hellenic General Secretariat of Sports (www.sportsnet.gr), Hellenic Ministry for the Environment (www.minenv.gr). Moreover, some of them represent features that are offered by powerful tools or attempt to address emerging functionality of retrieval systems. Some of the most important requirements are discussed in this section.

A basic characteristic of many real life systems is the *wide variety of document formats* that should be all supported by a single DDS. Another important user demand is the support of documents in *multiple languages*. Multilingual support may range from support of multiple collating sequences to full implementation of complex linguistic query processing methods such as phrase recognition, thesaurus and stemming.

Disperse of documents over various sites over the network poses the issue of *distribution of the services and sub-components* of the DDS. Possible scenarios include distributed, centralized or multi-tier configurations and affect the response time, performance and bandwidth utilization of the system. Choice of architecture also affects issues such as data delivery between distributed components and caching. Sometimes, especially in the case of distributed systems, there is the need to exploit an existing DDS component (for instance during a migration period from one system to another) or integrating components from different vendors. The question of supporting *open standards* is vital for achieving interoperability among different systems or platforms. Some of the most popular standards include HTTP, Z39.50, SOIF, RDM, Robot Exclusion Protocol. Another important aspect of an effective DDS concerns its *user interface* (getting user input and presenting results). Requirements on the user interface may include customizability of the interface, format of results returned, etc.

Another requirement significant for both end-users and administrators is the DDS *performance*. A DDS component should provide results of high precision and recall at small response times. *Security* is another broad subject of increased importance in many cases. As far as the DDS is concerned, there are several levels of security requirements, ranging from the ability to access secure documents over secure connections (e.g. in the gathering process) to applying access control lists on the indexes or catalog structures and allowing specific users to search specific parts of the document space. In addition to speed and security in accessing information, *integrity of the information* should be enforced. Data integrity is violated when the DDS returns links to documents that have been removed from the document base. The effectiveness of the search component of a DDS relies heavily upon the ability of the system to support advanced *query techniques*. Such techniques include use of thesauruses and dictionaries, term truncation, stemming and inflection, query approximation.

As far as *indexing* is concerned the efficient and flexible summarizing of documents and incremental indexing constitute important issues. The DDS should utilize *meta-information* contained in the documents (in the form of meta data or document properties) that could assist in more detailed fielded searching and auto cataloging. In special cases, where a large volume of data is organized into a relational database that coexists with documents that reside outside the database, there is a need for a common unified retrieval mechanism that enables the user to retrieve information stored in the database or in the documents with a single query. This scenario is further complicated by the introduction of mixed mode documents that may contain real time data from database tables. This need is commonly addressed at the database level, however, there exist document search systems that offer *interoperability with RDBMS*.

An out-of-the-box tool may not meet all user requirements. Such a tool should therefore be *configurable and customizable*, by providing APIs and toolkits to administrators and developers, in order to extend or customize the capabilities or the interface of the system. Moreover, in order for a DDS to be fine-tuned, it should enable the people that deploy to effectively administrate its components. *Efficient administration* can be in turn translated into a series of features such as easy, secure, remote administration, offering fine-grained control of DDS functions, logging and scheduling of administrative operations.

3. Evaluation Framework

In defining this framework, we have drawn from our experience presented in [Christodoulou et al. 98a], where we introduced an evaluation framework for Hypermedia Application Development and Management Systems. The process of evaluation consists of two steps: (1) *definition and grouping of evaluation criteria* and (2) *definition of an evaluation methodology*.

3.1 Definition and Grouping of Evaluation Criteria

Based on the requirements discussed in the previous section, we propose two sets of evaluation criteria for search and catalog systems respectively. These criteria are grouped into several *basic categories*, which allow the user of the framework to focus on specific areas of functionality of the systems, like searching capabilities, administration topics, etc. Additionally, *cross categories* are introduced, to group criteria of various basic categories, under different contexts. Such categories include multilingual support, security features, etc. The two sets of evaluation criteria, grouped by basic category, are outlined in [Fig 1]. [Fig 2] graphically represents how they are grouped under the basic and cross categories, for both Search and Catalog Systems.

3.2 Definition of an Evaluation Methodology

In this section, we introduce a simple methodology (using a grading algorithm) for a comparative evaluation of DDS components, with respect to specific requirements, based on the above-mentioned criteria. The proposed evaluation methodology consists of four steps that are described in detail below. The same methodology can be used for either search or catalog systems and for each basic or cross category separately.

Step1: Selection and evaluation of candidate systems. For each criterion and for each system under evaluation, a number is defined that indicates the extent to which the criterion is covered by the system. We represent this number as $CD_{\#crit}(system)$, where CD stands for *Coverage Degree*, $\#crit$ = the criterion label (e.g. D2) and *system* is one of the Search or Catalog Systems under evaluation. We assume $CD_{\#crit}(system)$ to be an integer in the range of 0 to $max_{\#crit} - 1$, where $max_{\#crit}$ is the number of all the possible values for the $CD_{\#crit}(system)$. The value of $max_{\#crit}$ depends on the criterion $\#crit$ and could be 2 (the criterion is either supported or not) or greater. The coverage degree of most of the criteria becomes more difficult to estimate as $max_{\#crit}$ increases, while assigning very high values to $max_{\#crit}$ does not seem to have a meaningful effect on results. On the other hand, low values of $max_{\#crit}$ may lead into inadequate representation of differences between two systems on certain criteria. For criteria that accept continuous values, ranges of such values may be defined (according to system features and user requirements). If a user simply requires that the value for the criterion falls into a specific range (and not that the value is smaller or larger than a threshold), then grading is done in the same way as in the previous case. Otherwise, the number of these ranges in a criterion determines the $max_{\#crit}$ for this criterion. If smaller values of the criterion indicate better behavior (e.g. price or size of index), then before calculating $CD_{\#crit}$, the ranges defined are sorted in descending order. Otherwise, (e.g. transactions per second, max number of concurrent users) ranges are sorted in ascending order. In this step, the user of the framework: (a) selects a set of candidate systems, and (b) estimates $CD_{\#crit}(system)$ for all the evaluation criteria.

Step2: Specification of requirements. Based on the requirements of a certain DDS, the user selects the criteria on which he/she wishes to base the evaluation and specify the minimum extent to which each such criterion should be supported. This is represented as $RCD_{\#crit}$, where RCD stands for *Required Coverage Degree*. $RCD_{\#crit}$ is an integer in the range 0 to $max_{\#crit} - 1$. Criteria not selected for evaluation are assigned an $RCD_{\#crit} = 0$.

Step3: Ranking systems. In this step, the candidate systems are graded according to the $RCD_{\#crit}$ values specified by the user during *Step2*. For each of the candidate systems, a number $NRANK(system)$ is calculated, which is the *Negative Rank* of the system. It's a number between -1 and 0, and indicates the ability of the system to efficiently cover the specified requirements. The larger this number is, the more effectively the system succeeds in covering user requirements. For the calculation of this number, the following simple algorithm is used:

```
NRANK = 0; N = 0
for each #crit do
  if RCD#crit > 0 then
    N = N + 1
    if RCD#crit > CD#crit(system) then NRANK = NRANK - ( RCD#crit - CD#crit(system) ) / ( max#crit - 1 )
  end-if
end-for
NRANK(system) = NRANK / N
```

Using the same algorithm on the corresponding criteria of each basic or cross category (*categ*), the number $NRANK_{categ}(system)$ is calculated to indicate the extent to which a system reaches or supercedes the specified requirements in the specific category. Thus, the framework enables evaluation of the candidate systems on specific areas of functionality as these are defined by the various categories, and gives results in various levels of detail.

Step 4: Decision procedure. To reach a final decision the user is presented with a list of the systems sorted by $NRANK(system)$. For each of the systems under evaluation, starting from the one with the largest $NRANK$, the framework provides a list of all the specified requirements that are not sufficiently covered. The user checks

whether these weak points of the selected system are acceptable and proceeds to the acceptance or the rejection of the system. If none of the candidate systems meets the specified user needs to a satisfying degree, the user may return to *Step2* and specify lower *RCDs*, or search for other systems to evaluate through the framework.

4. Case Studies

The framework described in this paper was used in order to select appropriate DDS components in two real-life hypermedia applications, VHF and ISTOPOLIS.

The *Virtual Hypermedia Factory environment (VHF)* [VHF] is a distributed, web-based hypermedia environment providing content and services in the sectors of culture, tourism and publishing. The VHF Project aim to provide a platform, based on Internet technologies, composed of integrated solutions, services and tools. Within this project, the authors of this paper were responsible for the deployment of the VHF DDS. To this end, we introduced the framework under discussion and applied it for the selection of the DDS components twice, at different stages of the project and on different sets of evaluated systems. Based on the user needs collected from users that participated in the project, we focused on the following fundamental requirements: *distribution of resources, multilingual support and flexible / customizable user interface*.

ISTOPOLIS is a network-based hypermedia educational system for history and culture, offering a broad set of services on media rich environment to teachers, students and content providers. The system can operate over the classroom LAN, over a remote connection to a server or as a stand-alone application. Design of *ISTOPOLIS* is based on a concrete set of pedagogical and educational goals and requirements [Papaterpos et al. 98]. In the case of *ISTOPOLIS*, *support for the Greek language, support for IIS under Windows NT, and customizable cataloging* were among the strongest requirements.

4.1 Application of the Framework

In both cases five search systems: Harvest v5.1 (harvest.transarc.com) [Bowman et al. 94] incorporating Glimpse Search Engine (glimpse.cs.arizona.edu), Netscape Compass Server v3.01 (home.netscape.com), Verity Information Server v3.6 (www.verity.com), AltaVista Search Intranet v2.3 (www.altavista.com), Microsoft Index Server (www.microsoft.com) and two catalog systems: Netscape Compass Server v3.01 and University of Patras Interactive Thematic Catalog System [Styliaras et al. 98] were selected for evaluation.

As mentioned in [Definition of an Evaluation Methodology], large values of $max_{\#crit}$ increase the difficulty to accurately estimate $CD_{\#crit}$ and $RCD_{\#crit}$ values. In order to simplify the methodology, without seriously affecting final decisions, we assume that $max_{\#crit}$ equals 4 for all criteria, apart from those accepting binary values (the criterion is either supported/covered or not). For the former, $CD_{\#crit}(system)$ and $RCD_{\#crit}(system)$ are integers in range of 0 to 3, with four discrete values: 0 = not supported, 1 = poor support, 2 = acceptable support and 3 = full support. For criteria accepting binary values, $max_{\#crit}$ equals 2. Naturally, one could make different assumptions concerning the values of $max_{\#crit}$ for each criterion separately. Based on the above assumptions we applied the methodology, in both case studies, in the manner described below:

Step1: We estimated $CD_{\#crit}(system)$ for all the evaluation criteria and for all the candidate systems.

Step2: According to the requirements of each application, we specified the $RCD_{\#crit}$ values.

Step3: For each system under evaluation, *NRANK* was calculated. The values are presented in [Fig 3(a-d)]. Furthermore, *NRANK* was also calculated for the most important criteria categories, namely "search system: architecture" for VHF and "catalog system: cataloging" for *ISTOPOLIS*. See [Fig 3(e-f)].

Step 4: In the case of VHF Search System, we first considered the systems with the highest *NRANK*, namely Compass Server, AltaVista and InfoServer. Since *NRANK* values for these systems are very close (-0.26, -0.27 and -0.28 respectively), we further examined how well they cover the critical requirements of VHF DDS. This process revealed that Compass Server outperforms Altavista and InfoServer, especially as far as architecture criteria are concerned ([Fig 3e]). Since VHF requirements for the architecture were quite strict and could not be modified, we selected Compass Server as the search component. For the selection of the VHF Catalog System, *NRANK* values for the evaluated systems were quite close (Compass: -0.25 and ITC: -0.22). Thus we had to further examine how the systems cover the most important requirements, which were the multilingual support and flexible cataloging. This procedure indicated that ITC is better for implementing the VHF Catalog System.

The framework was applied in more or less the same way for *ISTOPOLIS*. Even though Index Server was ranked third, the requirement for specific platform (Windows NT and IIS web server) and programmatic customizability (through API) led to its selection as the Search System of *ISTOPOLIS* (Index Server is customized through code in the setup process of *ISTOPOLIS* on the classroom LAN). Selecting the Catalog System for *ISTOPOLIS* was rather straightforward, as you see in [Fig 3(d)] and [Fig 3(f)].

Figure 3: Evaluation of Systems for the VHF and ISTOPOLIS case studies

5. Conclusions

In this paper we propose and demonstrate an approach for evaluating Search and Catalog systems as components of a Web based DDS, in relation to application requirements. The most important part of the proposed framework is the identification of the evaluation criteria and their classification / grouping under specific areas of functionality. This helps people responsible for deploying a DDS to formally and systematically formulate their requirements for a specific application. Furthermore, an evaluation methodology is proposed to demonstrate how the criteria can be used for evaluating systems, in order to select the DDS components that are most appropriate for the given requirements. Application of the framework on a variety of cases may suggest important enhancements or modifications for a specific Search or Catalog system. Two such cases involving applications of different functionality and basic requirements have been presented.

Apart from customization capabilities already described (e.g. introduction of ranges for criteria that accept continuous values), the framework may be extended in various ways. For instance, additional criteria may be defined and weighting techniques or other grading algorithms may be applied. Finally, in order to increase its usability, it is in our intention to create a web-based environment that will functionally implement this evaluation framework. In such a case the administrators of the environment will be in charge of estimating and inserting the features of new systems or update them if new versions appear on the market. Thus, the users will not have to be always informed on new products or read all the technical details about their features. By using this environment and specifying their requirements, the framework will assess the products for them, indicating their weak sides.

Abstract: In a WWW-based virtual learning environment where students and teacher are physically separated, the quantity and quality of interaction among students or with instructors have effects on learning. Lack of constructive activity is often identified as one of the major causes for poor learning. We developed support tools (prompts which support students to use self-explanation and self-monitoring strategies) and studied how support tools facilitate convergent knowledge building processes in a WWW-based virtual university engineering course.

For the study, a quasi-experimental study was designed. An engineering class of a virtual university was selected as the research site and the students in the class were randomly assigned to 2 different work environments: 1) without support tools, and 2) with support tools.

This study has an implication for theory that the opportunity to engage in interaction itself is not enough for students to integrate knowledge or develop/improve the coordination of group work in an online learning environment. Students' frequent interaction with their peers is not enough either for students to integrate knowledge or develop/improve coordination of group work in an online learning environment. The type of interaction matters, especially because convergent type of interaction facilitates students' knowledge integration.

1. Introduction

In a WWW-based virtual learning environment where students and teacher are physically separated, the frequency of online interactions among students or with instructors may have an effect on learning. One positive effect is that these interactions may facilitate knowledge building activities in virtual courses. However, negative effects, like lack of interactions, may surface. The lack of such an interaction may be one of the major causes of unsatisfactory learning experiences. However, problems may arise even when interactions between students in distance learning occur. The types and the quality of interactions matter. Many students in a virtual university simply tend to post their ideas or read others' ideas without engaging in deep thinking processes such as analyzing, evaluating, and synthesizing ideas. Furthermore, students often merely browse the WWW superficially and do not engage in thoughtful and active learning (Ritchie & Hoffman, 1997). If students rarely engage in convergent knowledge building in a virtual university environment, the knowledge building process is not complete, and students are not able to construct new understanding or build new concepts.

This lack of knowledge linking and structuring activities in the online learning environment was identified as a problem in the networked learning environment by previous studies (Chung, 1999; Harasim, 1990; Harasim, Calvert, & Groeneboer, 1997; Hewitt, 1997) and can have a negative effect on both the students' efforts to synthesize ideas and group collaborative processes (Hewitt, 1997). This study proposed to develop support tools to

foster learning in such an environment and investigated the characteristics of interactions with the aid of the support tools in a WWW-based virtual learning environment.

The purpose of this research was to study how support tools facilitate knowledge building processes in a WWW-based virtual university engineering course. Specifically, the first objective was to examine whether students engage in different types of knowledge building activities in when they use support tools. The second objective was to assess the effect of support tool use on student performance.

The research result indicates that students did not engage in different types of knowledge building activities when they used support tools. However, the research findings confirmed that the use of support tools enhanced student performance in integrating concepts in group report writing. This study has an implication for theory that the opportunity to engage in interaction itself is not enough for students to integrate knowledge or develop/ improve the coordination of group work in an online learning environment. This study's implication for the design of a virtual learning environment is that support tools be designed to promote student convergent knowledge building and higher knowledge integration.

2. Knowledge building Processes

This research views learning as a knowledge building process through the mediation of social interaction, tool use, and reflection. Knowledge building is similar to knowledge integration (Linn & Elyon, 1996 cited by Davis, 1998) which refers to the process of expanding a repertoire of ideas, discriminating between ideas, and reorganizing the links among them. Exploration and construction represent divergent and convergent aspects, respectively, of knowledge building. On one hand, divergent knowledge building entails exploring and sharing of diverse ideas which can lead to convergent knowledge building. On the other hand, convergent knowledge building involves linking ideas (Harasim, 1990), constructing explanations (Chan, Burtis, & Bereiter, 1997), making connections among different ideas, and bringing ideas together (Hewitt, 1997). In classroom or group discussion situations, students' exposure to many different ideas does not automatically lead them to new levels of understanding, construction of new concepts, or problem solving. Students learn new concepts or reach new understanding only if they engage in both divergent and convergent knowledge building activities. These knowledge building activities are facilitated by using self-explanation and self-monitoring strategies (Palincsar & Brown, 1984).

Learning process is dynamic, recursive, and iterative (Chung, 1996). Students constantly define problems or the purposes of their learning, explore different information and ideas, evaluate their relevance, and accept or reject ideas to be used for one's purpose. During this dynamic process of learning, students' capabilities to plan and monitor their whole learning processes are crucial. A learner's mental activity to plan and control one's learning processes is called reflection, which is a trait of experts (Ertmer & Newby, 1996). Students who received explicit instruction about planning/monitoring and self-explanation strategies (Bielaczyc, Pirolli, & Brown, 1995) develop a higher understanding than those who received implicit instruction do.

Webb, Tropper, and Fall, (1995) found that the number of occasions nor the amount of time students spent on interacting with classmates were not related to learning. What showed to be important was that, after receiving help, students would engage in constructive activity. Students who actually verbalized the work or tried to understand the explanation after receiving the help did learn more than those who did not do those things. Students' engagement in highly constructive activities (i.e., reworks or explains problems) after receiving help was strongly correlated to student achievement. Students who worked at the lower levels of constructive activities such as doing nothing or copying other's work were not very successful in solving new problems. They concluded that in order for students to actively engage in constructive activities, it was important to encourage individual students to seek explanations that they understand and to continuously work on a task until they could work on their own. The authors emphasized the importance of designing instructional interventions such as self-explanation prompts, which support constructive activity and suggest that students study the nature of explanations, which encourage constructive activities.

2.1 Knowledge Building in a Virtual Learning Environment

In virtual learning environment, the same problem emerged in recent studies on student interactions. Researchers pointed out that the lack of convergent interaction as a problem in a virtual learning environment (Chung, 1999; Harasim, 1990; Hewitt, 1997, Scardamila & Bereiter, 1991). Often students merely browse WWW superficially and do not engage in thoughtful and active learning (Richtie & Hoffman, 1997). Students engage

readily in divergent processes of knowledge building but needs help in the convergent processes (Chung, 1999; Harasim, 1990; Scardamla & Bereiter, 1991).

To promote the facilitation of convergent knowledge building processes in a networked learning environment, researchers suggested the following approaches: developing support tools, such as concept maps (Harasim, 1990; Harasim et al., 1997); using linear message systems while rejecting threaded message systems; and developing a networked structured message which can provide easy access to other students' displays of ideas and their relationships (Hewitt, 1997). These approaches would be helpful in developing a system which students would find easy to use in building their knowledge. However, those tool development approaches would not be able to help students to be conscious about their learning processes and to monitor their knowledge building processes. In addition, those approaches would not be able to support students to learn to seek for explanations, which they can understand or to learn to continuously work until they can figure out the problems.

Another approach, which would facilitate seeking explanations and monitoring learning processes is designing the explanation prompts as suggested by Webb et al. (1995). I developed support tools, which would extend the use of prompts not only for explanation but also summarization and planning/monitoring to facilitate active learning in a virtual learning environment.

3. Support Tools

I developed prompts to support three activities, namely, summarizing, explaining, and reflecting. I selected them because these three activities would activate individual background knowledge. For instance, self-directed summarizing helps in knowledge construction by enhancing student comprehension of the lecture and at the same time by having them check their own comprehension (Palincsar & Brown, 1984). Self-explanation and self-regulation activities foster knowledge construction and problem solving performances (Bielaczyc et al., 1995). Finally, reflective activities include monitoring comprehension and learning activities, and clarifying and addressing failures in comprehension.

In asking students to summarize the lecture specifically, I had them identify the main ideas and elaborate their relations to one another. This procedure is related to exploring for new information and identifying the main ideas of the knowledge building process mentioned earlier. Then, in asking students to explain concepts using concrete examples and to connect these concepts to main ideas, I asked them to interpret the lecture, and to analyze and critically evaluate the ideas in the lecture. This process is related to analyzing and evaluating the relevance of knowledge building. Finally, reflective activities asked students to plan and monitor their own comprehension of the lecture and learning activities. This procedure is related to identifying the purpose and planning and monitoring of the knowledge building process.

4. Experimental Study

The purpose of this research was to study how support tools facilitate knowledge building processes in a WWW-based virtual university engineering course. Specifically, the first objective was to examine whether students engage in different types of knowledge building activities in when they use support tools. The second objective was to assess the effect of support tool use on student performance.

For the study, a quasi-experimental study was designed. An undergraduate engineering class of a virtual university was selected as the research site and students were randomly assigned two different environments: 1) without support tools, and 2) with support tools.

Research Questions

1. How do students using the tool to support their learning in an electronic learning environment differ in the knowledge building processes?
 - Hypothesis . 1.a: Students will show different participation frequencies in online group discussion between students with the support tool and those without .
 - Hypothesis . 1.b: Students in the treatment condition with the support tool will engage more in convergent interaction than students in the control group without the support tool during online group discussion.
2. How does the tool supporting learning in an electronic learning environment promote knowledge building?
 - Hypothesis . 2.a: Students using tools to support their learning in an electronic learning environment build more integrated knowledge (number of cited principles, examples, evidences and

other sources).

4.1 Setting

An undergraduate engineering course on "Introduction to the Internet", for Fall 1998 at a big Midwestern Virtual University was selected as the research site. Students learned about broad aspects of the Internet such as the History of the Internet, Internet tools, Design of Web pages, and other technical topics. I created a group activity and the instruction for the two week period of the "Design of Web pages" unit. In the unit, the students' tasks were as a group to discuss and write the strengths and weaknesses of two different university homepages and to write recommendations on how to improve one university homepage. A group leader was assigned as a moderator to coordinate and facilitate the group work. There were online support of TAs and instructor whenever students encountered technical problems. Electronic shared work space was supported by program called "Web-talk". The Web-talk is a group online discussion tool, developed by the virtual university, in order for students to work together by planning and discussing their work online.

4.2 Data Collection and analysis

The participants were college students who were enrolled in the virtual course 'EGRXXX' in Engineering. For the treatment group, We developed cognitive support tools which prompt students to use the learning strategies such as planning/monitoring, summarization, and explanation in the virtual class. For the control group, no cognitive support tools were provided.

Data collection

Four kinds of data were collected in this study: pre-survey responses online, archived communication data online, group project data online, and post-survey responses online. The student responses to both pre-survey and post-survey were submitted through web, and the data were collected online. The online pre-survey was administered in the beginning of the semester and the online post-survey was administered after the lecture unit, "Design Workshop". The online survey data were later coded to SPSS. The communication data among students in the online class and the group project data for the "Design Workshop" were automatically archived in the Web-talk (a group communication tool developed for the virtual university), and the archives on the Web-talk were used as my data. Student interaction data and the group project data were taken from the archives of the Web-talk.

Coding

Interaction patterns examine the pattern of online participation among students. We used the 3 distinct features of knowledge building: reflection, divergent knowledge building, and convergent knowledge building. The pattern of participation, thus, was coded into three kinds: planning and monitoring, divergent knowledge building processes such as self-introduction such as idea sharing, and convergent knowledge building processes such as agreeing or disagreeing between different ideas, synthesizing ideas in writing.

Performance was measured by the quality of the student's two reports (comparison of the two university web pages and a recommendation). The reports submitted as the product of the group project were analyzed and scored to measure how much different ideas and concepts from the lecture were integrated in the recommendation letter.

Data Analysis

To answer the research question 1, descriptive statistics was used to compare the frequency and patterns of discussion participation between the 2 groups. One tail T-tests was conducted between the two groups with alpha level at 0.05. For the research question 2, one tail t-test was conducted with alpha level at 0.05.

5. Results

Research Hypothesis 1.a (about Participation Frequency)

There was no significant difference between the control group and the treatment group in participation frequencies. Students in the treatment group did not participate more frequently than that of the control group. In the categories of idea sharing and individual writing, the control group posted more messages, even though the difference is not big enough to be significant. In the categories of planning and convergent interaction, the treatment students posted almost twice as many messages as the control group.

Research Hypothesis 1.b (about Convergent interaction)

The difference between participation level in convergent interaction between the treatment and control group, was not statistically significant ($p < 0.05$). Students in the treatment condition used a statistically significantly ($\alpha = 0.1$) higher number of shared concepts during their group interactions. The researcher interpreted this result to mean that in the treatment condition certain themes emerged from online group discussion and students were more engaged in their knowledge building than in the control group.

Research Hypothesis 2.a (about integration of knowledge)

There was significant difference between the treatment and control group in the level of integration of concepts represented in the group reports. The treatment group integrated more concepts, examples, and evidences in their project writing than the control group. There was a significant difference between the treatment and control groups in the levels of integration and elaboration of concepts in the group reports ($p < 0.05$). The treatment group used more concepts, examples, and new ideas in their project writing than the control group.

This result supports my hypothesis that students who use the support tools which prompt them to summarize the lecture, explain the concepts, and reflect on what they need to know and what they need to plan to do the group tasks, would build more integrated knowledge than students in the control group, who did not receive any prompts.

6. Conclusion

This study conclude that the support tool use as well as group interaction enhances their engagement in knowledge building, especially knowledge integration such as their report writing in the online virtual university learning environment.

This study finding suggests that the high frequency of group interaction itself is not enough to promote student knowledge building, such as coordinating their group work and bringing different ideas together. While the interaction frequencies of students in both treatment and control groups were almost same, students in the control group, who engaged in group interaction, only reported their divergent knowledge building experience. Moreover, compared to the treatment group, less integration of knowledge occurred in the control group. In other words, students in the treatment group, who had the opportunity to engage in group interaction, as well as using summarization, self-explanation, and planning/monitoring prompts, engaged in more convergent knowledge building experiences and integrated more concepts and examples than student in the control group.

From the study, we can recommend to design support tools to promote student convergent knowledge building and higher knowledge integration in a virtual learning environment. This study finding indicated that the group of students who used the support tools of summarization, self-explanation, and planning/monitoring experienced convergent knowledge building and integrated knowledge more than the group of students who did not use the support tools.

Online School Performance Reports: Grading the Schools, Giving Citizens Data for Reform

John R.B. Clement, Education Statistics Services Institute, Washington, D.C., USA (jclement@dc.air.org)

Abstract: For over two-thirds of the public schools in the United States it is now possible to see a report on school performance over the Internet. Such reports can include student demographics and performance, teacher qualifications and salary levels, funds expended per pupil, and sources of funding. Often, bases are offered for comparing a school with other schools with similar student populations, or financial resources, or from similar locations.

We examine the factors that have made this aggregation of readily-available information possible: a national drive toward education reform; the widespread availability of computers and the Internet in school systems; and advances in methods for collecting, sharing and displaying information. The paper also summarizes policy trends and changes in the ongoing national debate about schools that the availability of these reports will make possible.

Over the past ten years, with little fanfare, a very special sort of information revolution has been coming about in public education in the United States. For over two-thirds of public schools in the country, it is now possible to examine over the Internet a report card stating how students are performing and how qualified are their teachers, often displaying the moneys spent to achieve this performance level. Frequently we can compare one school to another, or to one of various regional, demographic or state averages.

The confluence of several factors has made online school performance reports possible. The most notable of these is the drive toward education reform, which has renewed interest by parents, administrators, policy makers, and concerned citizens in how schools are doing. Given the motivation, technology has provided the means: widespread Internet access; and the development of World Wide Web technologies for displaying and sharing information in a platform-independent manner.

The availability of this information, and the debates that should result on school issues, imply significant changes for U.S. education. It will certainly change how we talk about schools and what we expect of them – it is already doing so. It may not be excessively optimistic to expect this kind of open disclosure to extend itself to other areas of government and public service: the questions that we can and do now ask, but didn't before, are novel and fundamental.

A preliminary estimate (based on school year 1996-1997 data¹) is that building-level report cards are available online for just over 70 per cent of the nation's public schools in 28 states. More state education systems are producing these reports, and it is only a matter of time until they too are placed online. It is only a question of time before an online report card is available for every school in the nation.

Perhaps most interesting is the participation of private enterprise in this disclosure effort. For example, the New Jersey school report card site was developed and is maintained by the Philadelphia Inquirer, although the data are collected by the New Jersey Department of Education (see <http://www.phillynews.com/packages/njschools/>).

Describing a “typical” school performance report

Although they vary widely, there is a common kernel. Consider the 1998 school report for Kalkaska Middle School in Kalkaska, Michigan, in the Traverse Bay area. The report includes three years of student performance data, mean teacher salaries (but no information on teacher credentials), school accreditation information, and financial data – a snapshot (actually, a three-piece short film) of the school. It shows trends over time (in this case, general increases in 7th grade math and reading percent satisfactory, and increases in 8th grade science percent satisfactory but

decreases in 8th grade writing percent satisfactory). For demographic context, the report provides the percentage of individuals who receive either free or reduced-price lunches through the school.

Other sites provide more information on teacher education levels and certification – for example, in New Jersey the percentage of teachers with a Master’s degree or more. Other states also provide a variety of comparison possibilities, either to statewide averages or to schools with similar demographic characteristics. In a couple of states (California and Massachusetts), data are provided on the availability of technology in the schools. Performance reports are provided for school districts, and also for entire states.

Student data in school report cards shows a national shift, from nearly exclusive dependence on norm-referenced measures toward criterion-referenced measures adapted to, or derived from, state content or performance standards. This is part of a broader reform and accountability trend, and we discuss the trend and its implications later in this paper. For now we will simply mention that performance-based measures have a face validity that norm-referenced tests lack, but in return criterion-based measures lack direct comparability across state boundaries². Also given are the basic demographic facts of the school’s student population, including one or more estimates of poverty levels in the school (or its district’s) coverage area. A final piece of information provided at upper secondary levels concerns dropout and completion/graduation rates.

Teacher data are most often given in terms of teacher educational background, experience and certification levels; less frequently information is presented on school accreditation.

Finally, we add school finances. The basic cost unit is the cost per student full-time equivalent (FTE), which is accounted for in a variety of ways. Revenues are often given in terms of the local tax base, or presented with state contributions as a fraction of the total.

Some systems integrate these numbers into school performance values. Composite scores are generated by state performance systems in Kentucky and North Carolina. These numbers have disadvantages from the viewpoint of citizen understanding and information, but they have one overwhelming advantage: they allow decisions to be made. While multiple numbers, some of which go up over time and some of which go down, are susceptible to argument, single numbers can be incontrovertible – they either are larger or smaller. The disadvantage to the average citizen is loss of face validity, leading to difficulties of interpretation. A composite score can be difficult or impossible to interpret if it is based on weighted numbers from completely different areas, such as student performance and finances. Systems such as those in North Carolina and Texas compensate by basing their performance evaluations primarily on student performance. They set as targets a given proportion of students at or above grade level, say 50 or 70%.

Measuring student performance and holding schools accountable

It is a simple step to move from developing target performance levels and measuring student performance against these targets, to creating accountability systems in which good performance or improvements over time are rewarded, and sanctions are created for remaining at less-than-satisfactory levels. By the author’s informal count, there are accountability systems in place or being implemented in eight states: Alaska, Florida, Indiana, Kentucky, Mississippi, North Carolina, Ohio, and Texas.

The Texas Academic Excellence Indicator System (AEIS) serves here as a model for discussion. It is based on a criterion-referenced testing system, the Texas Assessment of Academic Skills, developed, reviewed and revised by many constituencies across the state over a period of years. As issues have been raised, they have been dealt with; for instance, concerned about differential levels of test-taking in different regions and the possible impact on performance evaluation, the state has made special efforts to create versions of the TAAS for students of limited English proficiency and for students in special education. Schools are given overall ratings. Schools and systems unable to improve risk various penalties, up to takeover by the state.

The reward system is much more visible than the sanction system. Schools showing marked improvement or achieving high performance levels are given “merit badges,” such as inclusion on lists of “schools of excellence” or “schools of distinction.” (North Carolina)

Some systems (Kentucky) establish complex rules for generating composite scores. These systems may provide more complete and comprehensive ratings of school and system performance, but they pay for this in being hard for the average citizen to comprehend. Such rating systems serve administrative purposes within the educational system, rather than public governance functions.

Changing what we know about schools, and how we talk about it

In any case, the dialogue about school issues has already been altered. The issues raised by performance-based systems are highly central to strongly-declared purposes of education: rates of completion of standards-based performance by high school graduates, for instance. In Texas, 70% of all students must complete the high school exit exam, which is first given in the tenth grade and taken until it is passed. Every high school's performance is measurable by this (admittedly, minimal) standard, and so is the performance of the school system of which it is part. Suddenly, dialogue about "how schools are doing" deals with an issue that all citizens recognize as of vital personal importance (after all, it is easy for those not college-educated to dismiss statements about excellence based on SAT scores or college admission rates). And the Texas system proposes to raise the passing percentage in the coming years.

To borrow a further point of discussion from the Texas setting, the dialogue about who takes the test has shifted the focus of conversation and action onto higher-risk populations: those with limited English proficiency and even students in special education. This brings everyone under the education tent for what may well be the very first time: all students now share the responsibility for the school's performance, and a school that wants to lift itself must deal with all of its students equally. If this principle can "stay the course," the consequences for education will be truly revolutionary.

With a dose of optimism, we can anticipate a more participatory community surrounding our public schools – quite the opposite of the viewpoints expressed with such pessimism just a few years ago. Ironically, opening the schools and school systems up, through technology, to public scrutiny, might increase rates of participation and involvement, or at least increase the rationality of argument.

Open discussion of priorities such as high school graduation with adequate preparation might well open the way to discussion of what "adequate preparation" might actually be. We might actually see alternatives presented for citizen consideration, and not simply isolated from public discussion by alienated constituencies.

Note: the opinions expressed in the paper are those of the author and do not represent the views of any Federal or state government agency.

¹ This number is a first-order estimate. Building-level performance reports are available online for 28 states, which in 1996-1997 had a total of 60,464 schools. This represents just over 70% of the 86,058 schools reported for that

academic year. See [Clement et al. 1998] for an analysis of performance reports by state; see [NCES, 1998a], table 1 for a count of schools by state for the 1996-1997 school year.

² Actually, comparability between states might be achieved where state standards are established by reference to national standards; however, alignment efforts of this kind largely remain to be undertaken.

Legal & Ethical Issues Related to Student Use of the Internet

Abstract: Access to the Internet by students in elementary and secondary schools raises issues of censorship, the responsibility of schools *in loco parentis*, and the treatment of students as learners and future citizens. The Internet's ease of access and the volume of information available, as well as the difficulties of controlling access to information deemed undesirable for minors, has caused authorities to devise new methods of asserting control—or at least supervision. Some of these means may impose restrictions on the civil rights of students.

1. Internet usage in schools.

Student Internet usage is being limited by various entities—legislatures, school districts, software companies, and Internet service providers, to name a few. The forms of Internet usage (and consequent risks) vary by the educational contexts in which student access occurs. The level of legal protection varies, as well, according to the context in which the Internet is used.

The risk in any limitation is that students may be missing out on information that they have legal rights to access. This paper seeks to describe the legislative and filtering issues as they relate to students. The paper supports the contention that educating student users, not blocking speech, is the best policy to implement in schools. The paper also reviews case law on the rights of students to receive and disseminate information and attempts to exemplify corollaries between those rights and the case of Internet use. Finally, this paper seeks to preserve the rights at risk for students by suggesting alternative solutions for parents, educators and legislators to consider when creating policies that mandate students' educational futures.

2. Legislative Cyber- Solutions—Global legislative efforts, the CDA and COPA.

The issues arise in the context of protecting students from the "inappropriate" material that can be accessed on the Internet by an unsupervised minor. In the United States, as well as in the European Parliament, the Japanese Parliament and the German Legislature¹, there has been discussion and debate as to the proper means by which to keep children safe and regulate the flow of information. U.S. Legislatures, both on federal and state levels, passed laws to address this protection of minors only to find, in some situations, that their laws could not hold under the strict scrutiny of the courts hearing them as First Amendment cases. The Communications Decency Act of 1996 ("CDA"),² which, most notably, subjected to criminal penalties of imprisonment and a fine, or both, anyone who created and initiated a transmission of material which was indecent or obscene, knowing that the recipient of such material was under 18 years of age, regardless of whether the creator of the materials placed the call or initiated the

² Communications Decency Act of 1996 ("CDA"), Pub. L. No. 104-104, 47 U.S.C.A.223 (West Supp. 1997).

communication, was held to be vague and over-broad; therefore, it was found unconstitutional by the Supreme Court in June of 1997.

Last October, Congress passed the Child Online Protection Act (“COPA” which more narrowly tailored the concept written into the CDA. COPA imposes criminal and civil penalties on persons who “knowingly and with knowledge of the character of the materials, in interstate or foreign commerce by means of the World Wide Web, make any communication for commercial purposes that is available to any minor and that includes any material that is harmful to minors.”³

These laws do not pass muster not only because they unduly restrict speech, but also because courts feel that laws passed in the United States, for example, will not be effective in other countries and that without a unified, global rule, there can be no effective protection. Without an effective method coming from legislatures to protect children and with growing concerns by parents and schools to limit access to resources deemed suitable for children, software designers found a demand in the marketplace and promoted their newly created blocking and filtering software. The software, distributed by a variety of private corporations, is designed to keep out certain information while allowing other information to be accessed. Filtering software, however, has lack of support as an effective method for protecting children:

The software, as well as the legislative activity of keeping inappropriate material from minors, has brought into question the rights of one particular sub-group of minors whose use of the Internet is especially crucial to their fundamental purpose—students. The rights of students to gain full access to the information available through the Internet, as well their rights to create and disseminate information over the Internet while they are in school, is at the very core of this debate, as restrictions would significantly affect this group's fundamental activities.

3. First Amendment Test Cases and Students, School Libraries, or Textbooks

The “First Amendment . . . does not tolerate laws that cast a pall of orthodoxy over the classroom.”⁴ While some states have passed laws or have bills pending to require filtering software on Internet terminals in public schools, there is still a question as to the validity of this sort of regulation, from a Constitutional perspective. It is critical to look at court precedent that has analyzed and interpreted the First Amendment of the U.S. Constitution as it applies to a student’s right to disseminate and, more crucially, to receive information.

It is crucial that students’ rights are kept in the forefront of decision making. However, the authors do not suggest that minors should be subjected to “inappropriate material” available on the Internet but rather that, given the present circumstances, filtering, monitoring and blocking devices are over-broad in their function and may deny students access to much needed information. Alternative forms of governance, such as proper guidance of ethical conduct, the imposition of classic rule, self-regulation and the fundamental tenets of contractual law, must be the solutions for protecting our children.

“[A] child merely on account of his minority, is not beyond the protection of the Constitution.”⁵ The First Amendment provides, in pertinent part, that “Congress shall make no law . . . abridging the freedom of speech, or of the press.”⁶ It is important to note that the right to free speech guaranteed to all Americans, via the First Amendment, is viewed as not only the right to send information but also the right to receive it. The rights of students come into question when students are denied access to certain content-based categories on the Internet via a school’s policy. In the case of using filters to restrict access to the Internet, the policy would not hold as constitutional because there are many less restrictive means available. Designing an Acceptable Use Policy (AUP), using privacy

³ 47 U.S.C. § 231 (a) (1). (The Child Online Privacy Protection Act also requires that Web site operators and online services operating Web sites directed to children obtain parental consent before collecting information from children under the age of thirteen.) *Id.* at § 231.

⁴ *See id.* at 870 (quoting *Keyishian v. Board of Regents*, at 603).

⁵ *Bellotti v. Baird*, 443 U.S. 622, 633, 61 L.Ed. 2d 797, 99 S. Ct. 3035 (1979) (plurality opinion).

⁶ U.S. Constitutional amend. I.

screens, educating students on Internet use, placing time limits on use, monitoring use solely for counseling purposes, and enforcing disciplinary actions when Acceptable Use Policies are violated, are examples of these means.

First Amendment cases, decided in the context of other media also shed light on the validity of limiting Internet access and clarify student rights to Internet use. Court precedent reconfirmed and clarified student rights to receive information in a case called *Minarcini v. Strongsville City School Committee*. The court drew a distinction between information students obtained from textbooks and that from libraries. In Strongsville, the school would not allow certain books to be used in its school as texts or as library books. The court opined that, with respect to the issue of textbooks, there was no constitutional violation on the part of the school board. With respect to the library usage of the books, however, the court stated that the school board had less discretion to limit access:

Neither the State of Ohio nor the Strongsville School Board was under any federal constitutional compulsion to provide a library for the Strongsville High School or to choose any particular books. Once having created such a privilege for the benefit of its students, however, neither body could place conditions on the use of the library that were related solely to the social or political tastes of the school board members.⁷

This court precedent can be paralleled to the rights a student has with respect to the use of the Internet. If the Internet use in question was in a library, or if the particular student use can be analogized to his or her use of the Internet as a huge digital library, then one could conclude that access to the sites and resources on the Internet, once provided, cannot be limited where the limitation may have been done solely for a school board's social or political tastes. If the Internet usage is to benefit from its infinite resources as a library in cyberspace, then the *Strongsville* argument can certainly be made

A similar factual scenario exists in the Supreme Court case of *Board of Education, Island Trees Union Free Sch. Dist. No. 26, et al. v. Pico(Pico)*. It stated that "Our Constitution does not permit the official suppression of ideas"⁸ and that a school does have a duty to inculcate community values, but that it does not extend to non-compulsory domains including a school library. The Court ruled that the school did violate the First Amendment in removing books from its libraries. The majority decision in the case established from the outset, however, that the case was limited in scope because it dealt only with library books and not textbooks. The distinction was made because library books "by their nature are optional rather than required reading."⁹

This case would allow us to interpret the discretion a school can have over controlling access to the Internet by studying the characteristics of the Internet and the way it is used. If the Internet is seen as a digital library and is used in a non-classroom, non-compulsory setting, then it would seem that the *Pico* situation would apply and would prevent schools from, in essence, "removing" material available on the Internet, by installing filtering software or by some other means of denying access. Where a school is using the Internet for classroom purposes, *Pico* suggests that a school may restrict its use. In a school library or as part of an extracurricular activity, it seems that a school's action to install filtering software would not hold constitutional muster.

Through the growth of case law that will evolve as more "censorship" laws are put in place and as blocking software is integrated into school systems, a new "wing" in First Amendment law will be created. The new body of law will, hopefully, reflect a greater understanding of specifically how the Internet works and how it is, at times, different from the textbook, the newspaper, and even the library.

4. Software Solutions—Why filtering is not the means to an end

When the Supreme Court found the Communications Decency Act unconstitutional last summer, they clearly indicated that it was the responsibility of schools and parents to protect young people from objectionable material.

⁷ *Minarcini v. Strongsville City School Committee*, 541 F. 2d 577 (1976).

⁸ *Pico*, 457 U.S. 853 (1982).

⁹ *Id.* at 862.

The job of "protection" the court suggested, could be done by the newly developed software programs that were designed to block out "objectionable" content from reaching minor students.

Who determines what is "objectionable," however, is an important question. Should it be the parents? The local school board or administration? Perhaps, the teacher who is most familiar with a student's particular information needs? Or, should it be a corporate third party, unrelated to the students and the community in whose environment the school exists? Americans have traditionally fought long and hard to protect their local control of schools. The infrequent, but still occasionally occurring, local book banning attests to this fact. Why then, is a nation of "rugged individualists" turning over control of what information enters the classroom to unknown distant corporate entities? What motivates filter manufacturers and distributors? Is it merely the profit motive and seizing the moment, or are there philosophical underpinnings to the filters? These and similar questions beg to be answered, especially so in view of questions about computer filters and their efficacy.

In January 1998, *Electronic School* devoted its cover to "Censorware, the Hard Task of Internet Safety." The author, Lars Kongsheim, describes three ways in which filters operate: by keyword blocking, individual page blocking, and by rating systems. Keyword blocking searches text and images against lists of objectionable content. It frequently leads to mistaken identity or sometimes simply deletes offending lexical items from Web pages and delivers misleading text.

Blocking individual Web pages is another type of filtering. Providers create databases of objectionable pages, use them for their software, and license them to others. The problem lies in the fact that the Web is growing at far too fast a rate to allow software providers to keep up. This is exacerbated by filters' incapacity to efficiently separate the "undesirable" without also taking away that which may be "enlightening."

A third method of controlling access is the rating system. Rating systems are dependent on the entity that decides the ratings. Mr. Kongsheim points out, "any system that depends on strangers to apply subjective ratings to . . . Web pages runs the risk of being out of touch with the local community norms." This, after 200 years of community control of schools, is disturbing indeed. Furthermore, the underlying philosophical bent of third-party ratings providers is another variable. What drives their selections? Is the philosophy compatible with that of the community, and is it reinforced by local mores and instructional practices or at odds with them? It is essential for communities to look at any filtering solution that they are considering before installing anything that lends outside influence to what their students can and cannot access. But is this the best solution?

Unnecessary censorship can be highly detrimental to students and their learning processes. One of the co-authors had first-hand experience observing the effects of censorship on her students in a society that has, for years, extended it to all media. Upon examination, it became obvious that this country had invested large sums in developing and implementing a sophisticated censorship system before the Internet became operational. Why then were two ordinary male students in a classroom able to enter a risqué lingerie site? The boys were looking for something and so they found it, even in the face of the massive effort that the local government had made to avoid exposure of its population to what it deemed morally offensive. Censorship had made the inappropriate material even more attractive to the boys. This is an obvious argument for training students in ethical decision-making skills. It is the province of the educational process (and the educators involved) to teach students how to discriminate among available materials and to make informed, ethical decisions about which material to choose.

The idea of "teaching" ethics is a tricky one, but it can and must be done. The scenario analysis method has always been a popular one in ethics training in both academic and corporate institutions. Lockheed-Martin, for example, has combined the scenario analysis method with both a cartoon character, Dilbert, and game playing. These are ideas that are attractive to students and might be adapted to teach computer ethics.

Jim Lichtman, an ethics specialist, has another method for training students. His book is called The Lone Ranger's Code of the West. Lichtman says that the Lone Ranger doesn't drink or smoke.¹⁰ Could one extrapolate that he wouldn't access unacceptable material on the Net? There are any number of heroes who could be put in the Lone

¹⁰ [writer], Who is That Masked Ethicist?, The Washington Post, "" May 11, 1998; at D4.

Ranger's place to familiarize students with how ethics work. ROTC students use a book by Anthony L. Edler that includes Gene Autry's "Ten Cowboy Commandments."¹¹ These address topics like honesty, fairness, and Good Samaritan activity. This last topic was also addressed in the final Seinfeld episode. When a popular show like this gives its superficial, yet beloved, characters their comeuppance in the final episode, one might conclude that Americans want ethical, fair behavior and solutions to problems.

One way of dealing with ethical training and student empowerment that is gaining popularity with principals is the Acceptable Use Policy ("AUP"). An AUP is a written set of rules or guidelines for Internet use that includes sanctions to be enforced for breaking the terms of the AUP. Frequently, the AUP is a community effort and is composed by a team of administrators, teachers, students, and parents or other concerned community members. The AUP can be used as a teaching tool to develop ethical judgment skills in students, especially if they are involved in its development.

Limiting student access to the treasure trove of information that the Web can deliver might ultimately be as destructive as exposing students to objectionable material. Not enough of the right material could be just as damaging as the wrong material; however, placing the responsibility for self-policing must be preceded by ethical training.

5. Conclusion

Practices that have long been successful in dealing with children—clarity and consistency—are still appropriate with regard to the new technology. A community-developed AUP can be the vehicle for setting boundaries that protect minor children from whatever the community deems objectionable, while developing ethical decision-making skills in the next generation. AUPs can focus the responsibility for teaching moral judgment on the parents, who can choose to delegate it to teachers *in loco parentis*. Blocking and filtering simply substitute some corporation's judgment for that of the parents. These (inevitably) imperfect blocking or filtering mechanisms deny students the educational experiences that help them develop good judgment. If judgement is automated, where will students practice evaluating material and making informed judgments, as they will have to later in the larger world?

Abstract: Distance education has been receiving a great deal of attention recently. Many courses and programs are now being offered at a distance. Under the distance education umbrella, Asynchronous Distance Learning Networks (ADLNs) are quickly growing in popularity and attractiveness to learners, teachers, and administrators. However, prior to implementing this type of learning environment, several important issues need to be reviewed and discussed. This paper reviews those issues and solutions that have proven successful in an ADLN that has been in existence for several years.

1. Introduction

As technology continues to advance in society and particularly in education, new opportunities become available to both learners and teachers. Many of these opportunities change the format of the traditional learning environment [Sherron 1998]. One of the most recent opportunities receiving a great deal of attention is distance education [Beekman 1997]. Distance education can mean different things to different people, but generally speaking it is thought of as the learning process where the learner(s) and teacher are separated by physical distance. This could mean the learner was physically located in another part of the building, city, state, or world than the teacher. Media such as two-way audio and video are used to allow the learner and teacher to communicate in "real time."

The type of distance education described above is synchronous in nature. However, this is not the only type of distance education available. A second and rapidly expanding type of distance education is asynchronous in

nature. For purposes of this panel, this second type of distance education will be referred to as an “Asynchronous Distance Learning Network” (ADLN). An ADLN not only allows the learner and teacher to be separated by physical location, but also by time. In other words, the learner and teacher do not have to be present in any one location at the same time. The primary media used to establish this type of learning network is the World Wide Web.

Coupled with the flexibility afforded by synchronous distance education, ADLNs allow even more flexibility in the learning process. This additional flexibility provides many opportunities for students around the world to participate in the learning process when under the “traditional” learning environment they might not have been able to do so. These opportunities are particularly noticeable with non-traditional students such as single parents and others who juggle many responsibilities including full-time employment, families, and school.

2. Analyzing a Successful ADLN

As ADLNs become more attractive to educators and trainers, several important issues need to be discussed and considered before implementing this type of learning network. This paper will be devoted to reviewing those issues and solutions that have proven effective in a successful ADLN. This successful ADLN has been delivering instruction completely asynchronously primarily using the World Wide Web for over five years. The ADLN has approximately 250 students located throughout the world. Some of the most important issues that will be discussed by the panelists include:

- The design and presentation of course materials
- The type of media used in a Web-based environment
- Student/teacher interaction
- Student access
- Student assessment
- Handling large numbers of students
- Marketing
- Advising students
- Administrative support
- Technological support for both students and teachers

3. The Design and Presentation of Course Materials

A teacher in a Web-based ADLN will need to have special skills in order to prepare the course materials for presentation. Some of these skills include the creation of Web pages, video editing, and the use of asynchronous conferencing software. Additionally, course materials can be presented in many different ways in an ADLN environment. Some of these include lectures, assignments, activities, and case studies.

It is important for a teacher to be familiar with the skills required for preparation and the options available for presentation of those materials. In some cases, there will be support personnel that can assist a teacher in designing and developing the course materials. This support can be a lifesaver for those teachers with limited experience with technology and/or instructional design. However, even with technological support, teachers need to quickly develop proficiency using asynchronous conferencing software to be able to carry on interactive discussions with their students.

4. The Type of Media Used in a Web-based Environment

Traditional course materials can consist of many different types of media and can be presented on many different communications channels (i.e., voice, computer, video, etc.). This is also true with Web-based ADLNs. However, due to constraints associated with current technologies certain types of media and channels work better than others. Some of the more successful media include streaming audio and video, asynchronous conferencing

software, text and graphics.

Streaming audio, video, and animation are an Internet-based information delivery system that provides "on demand" media materials. In general, digitized audio and video files are quite large. They can take a long time to transfer from a source on the Internet to the user, and then they take up a large amount of storage space on the user's computer until they are played and deleted. Streaming media addresses both of those problems through the use of special software at both the delivery and recipient ends.

When the user's computer "requests" a certain media file from a serving computer, the two machines remain connected while a compressed version of the digitized file is sent from the server to the user's machine. Software at the user's end immediately plays the media file without having to save it to storage. Because such files are compressed (think of a motion picture film that has every second or third frame removed), the end product is not going to have the same high quality as the original. But it is a way to provide video and audio materials on demand, from one Internet user to another--anywhere in the world.

5. Student/teacher Interaction

As in a traditional classroom, student/teacher interaction is important in a Web-based ADLN environment. However, it can be challenging to develop and foster this type of interaction due to the separation of both physical location and time. This is where asynchronous conferencing software becomes invaluable to the process. There are many different "brands" of this type of software, but essentially they have similar functions. They allow individuals (learners and teachers) to post messages and reply to messages on the Web. Each of the "strands" of messages is visible to the class members to read and comment upon. Each strand becomes an interactive conversation between members of the class. A teacher can monitor the strand making comments when deemed necessary. Many teachers feel this gives them the opportunity to move from the "sage on the stage" role to the "guide on the side" role.

There are several keys to the success of this type of student/teacher interaction. Possibly the most important involves the structuring of the initial question or case study. If the initial question is open-ended and provocative it can generate a lively debate. Teachers should avoid initial questions that involve a one or two sentence standard response, which will be the same for every student. For example, a poor first question would be "What are the main pieces of hardware in a computer?" This type of question would elicit the same basic answer from each student. There would be little or no interaction among students and the teacher. Better initial questions might be "If you could build a better computer, what pieces of hardware would you use? How would you use them and why?". These questions are more open-ended and allow students to share their ideas with other students and the teacher. They can also comment on other student's ideas and begin an online interactive discussion.

6. Student Access

The ability of students to easily and effectively access Web-based instructional materials is becoming increasingly important. If students have difficulty accessing the instructional materials the overall effectiveness of the learning experience will be diminished. Issues associated with this topic include hardware requirements, software requirements, internet service provider requirements, and technology support personnel.

Establishing such standards often means balancing the needs of the course provider (especially, the ability to use new technology) against restraints imposed upon members of a diverse student body (the cost of hardware and software, differing availability of Internet connectivity, individual levels of computer literacy, etc.). In general, this is accomplished by determining two sets of standards: one that will give the student optimal results, and one that will give the student adequate--if marginal--results. Students are encouraged to meet the highest level of standards early on, with the expectation that only minimal upgrades will be required for that student's access to stay within at least the "adequate" range throughout the two-year cycle of the degree program.

7. Student Assessment

Many people perceive one flaw in ADLNs. That is student assessment. The question is often asked, "How

can you test a student who you never see?" This is a legitimate concern for newcomers to ADLNs; however, there are options available that meet most requirements. These options include using an electronic portfolio of assignments for assessment purposes. These assignments can be prepared using software like Adobe Acrobat and sent to the teacher as an e-mail attachment. Once received, teachers can attach written comments to the electronic documents and even highlight sections of the document if desired. In practice, there can be very little difference between the type and method of written feedback provided in a traditional classroom and that provided in an ADLN using software like Adobe Acrobat.

If teachers choose not to use software like Adobe Acrobat, assignments can also be posted on the Web. The assignments can be graded and then comments can be sent back to the student in an e-mail message. If this type of assessment does not meet the needs of the situation there are other options including Web-based online testing and the use of an off-site proctor. Both of these options have been used successfully in different situations. The type of assessment used depends on the situation. However, the necessary tools are available to successfully collect student's assessment.

8. Handling Large Numbers of Students

The attractiveness of a good course offered in an ADLN environment can result in a large number of students from around the world enrolled in the course. This can be troublesome for teachers when they have classes much larger than they are accustomed to accommodating. This can be handled in many ways including breaking up the class into sections and providing section leaders. The teaching requirements can then be divided among the course instructor and section leaders. For example, the course instructor could carry the responsibility for course material preparation and presentation as well as grading. While the section leaders could maintain the online interactive conversations. This type of organization can result in slightly higher costs, but the quality of the educational experience can be greatly enhanced.

9. Marketing

In an ADLN, matriculated students are no longer limited to those who can physically be present in the classroom. This opens the door to many new opportunities for educational institutions to provide instruction to an international body. For this to happen, a well conceived marketing plan must be established. The plan should be made up of several phases including identifying demographics, identifying key information providing resources, evaluating the available options, preparing and running advertisements, and collecting feedback for evaluation and revision. Once a high-quality course or program has been successfully delivered at a distance, there is no reason why student enrollments cannot be dramatically increased through well-conceived marketing plans.

10. Advising Students

When working in an ADLN environment, student advising can sometimes be challenging. One way of handling this is to create a "frequently asked advising questions" (FAQ) list and posting it on asynchronous conferencing software or as Web page(s). The initial investment of time needed to create this type of list can be well worth the effort in the long run because students will become accustomed to looking at the FAQ list before asking someone a question. FAQ lists should be periodically reviewed for their accuracy and timeliness. A way of handling advising is to utilize e-mail and attachments as discussed previously. Finally, phone support for advising is a great supplement to asynchronous means of communication. A synchronous phone call to a confused student can go a long way toward putting them on the right track. No matter how it is handled, advising is just as important in an ADLN as it is in a traditional learning environment.

11. Administrative Support

In an ADLN environment, administrative support is crucial to the success of a Web-based academic program. This includes support for both students and teachers. Because students (and sometimes teachers) are

located throughout the world, the traditional face-to-face administrative support is not available. Administrative support at a distance takes on new meaning and importance. The use of "Frequently Asked Questions" Web pages and continual monitoring of e-mail accounts becomes significant and time consuming. Some other important issues associated with this topic include responding to general program informational inquiries, admissions, registration, transfer of credits, budget and phone support.

In general, administrative support personnel can act as a liaison between the distance education student and the various student service offices on campus: admissions, registrar, student accounts, the financial aid office and even the University bookstore. As the number of distance education courses increase at the university these student service offices will become accustomed to working with distance education students directly and the need for the "liaison" will slowly diminish. Many of these offices are beginning to post policies, contact information and administrative forms on the Web. Some of the offices have also agreed to accept credit card payments for tuition and textbooks over the telephone. Web-based registration for classes is already a reality. In the near future, students will also be able to access various aspects of their student records, and even submit "change of address" information directly on-line.

Some information that is currently posted directly to the web includes course registration and withdrawal procedures, requests for an "incomplete", test taking procedures, and graduation information. Other non-student administrative information that is posted on the web includes faculty hire forms, tax forms, and employee eligibility forms.

Because distance education students need timely responses to questions, on-campus work/study students are sometimes employed to assist with administrative support functions. In many cases they are the first point of contact with the program for a student's e-mail inquiry or a phone call. An enormous number of calls come into the program office and it is critical that these calls and inquiries be sent to the right person for a response or handled without a referral. The questions are usually very simple to answer, yet the job can be very time consuming. Most of the questions occur during registration times concerning classes, billing, registration problems, etc. The administrative support work done behind the scenes may not have the most direct impact on student learning or get much publicity, but it does promote student success.

12. Technological Support for both Students and Teachers

The quality and timeliness of technological support for both students and teachers cannot be understated. It will make or break a Web-based ADLN. A poorly designed or implemented technological support plan will directly effect the learning environment. This not only includes the understanding of various technologies, but how they can be effectively used in an ADLN. Some of the important issues associated with this topic include maintaining an e-mail and phone help desk, maintenance of servers and accounts, streaming of audio, video, and animation, and exploration of new technologies.

Key to effectively supporting students and teachers is first determining that new students and faculty have the fundamental computer literacy skills necessary to participate in a distance education program, then training them to use the specific tools implemented by that program. This must be accomplished before the semester has begun.

Since asynchronous distance learning programs are especially attractive to working adults, care must be taken to provide technical support during the times that students are most in need of support services. This includes evening, weekend, and holiday hours. From the student's standpoint, little is more frustrating than to plan a weekend devoted to coursework, only to have those plans cancelled because a technology "glitch" could not be resolved until the beginning of the following work week. Because such frustrations can easily build to the point that a student may feel that they are incapable of learning at a distance, the support structure must be available during non-traditional work hours.

13. Conclusion

ADLNs are growing in popularity and attractiveness to learners, teachers, and administrators. Before

implementing this type of learning environment, several important issues need to be reviewed and discussed. They include the design and presentation of course materials, the type of media used in a Web-based environment, student/teacher interaction, student access, student assessment, handling large numbers of students, marketing, advising students, administrative support and technological support for both students and teachers.

When the Learner is in Charge: Student Technological Literacy Patterns

Dr. Dorothy Valcarcel Craig
Department of Educational Leadership
Middle Tennessee State University
PO Box X-147
Murfreesboro, TN 37132 USA
dvccraig@mtsu.edu

Abstract

The study examined technological literacy patterns and the process of inquiry in a student-centered summer program designed around student research and Internet use. Five case studies consisted of various configurations of fifth grade students from a variety of educational backgrounds. A qualitative approach to research was implemented using grounded theory and the constant comparative method of data analysis. Data in the form of observational field notes, transcripts of video and audiotapes resulting from each of the daily sessions revealed interesting findings regarding emergent technological literacy, "computer talk," work patterns, and the process students followed as they conducted technology-assisted inquiry. Pronounced differences between male and female participants showed variation and specific preferences to project design, inquiry, Internet usage, and group configurations. Results of the study are offered to classroom teachers as implications for instructional practices in computer-enhanced classrooms.

Current Practices in Classroom Technology

The tools human beings have for obtaining information and solving problems have drastically changed across the century. Innovations in the areas of occupations, transportation, and communication—due to technology—have had an enormous effect on education. The urbanization and industrialization that so attend the American way of life that began in the early part of the century continues today. In the forward to his futuristic book, Gates (1995) suggests that we are beginning another great journey. We aren't sure where this journey will lead, but it is certain to touch many more lives. The major change coming will be in the ways people carry out their jobs and communicate with each other. However, even though computers and various pieces of hardware are present in most, if not all schools, the cultural change accompanying earlier innovations has not yet taken place for technology in most classrooms today.

While visiting local schools and classrooms, it was observed that the small amount of equipment currently in classrooms is too often turned off, disconnected, or layered with dust. The teachers who are utilizing their machines usually structure computer time with programmed software, such as games or drill and practice packages. Computers—though visible—are not sufficiently in use and they are certainly not doing the job they could be doing. Technology for the most part remains on the periphery in many classrooms. Recent research has revealed that computers are still commonly, and sometimes only used for word processing (Grunberg and Summers, 1992; Downes and Fatouros, 1995). A large number of teachers remain apprehensive regarding computers and computer-enhanced instruction while their students continue to embrace new technologies in out-of-class settings making schooling appear even more useless and irrelevant to the lives of young learners. Still, computers are being purchased in large numbers by school systems. The availability of classroom computers has increased from approximately one computer for every 125 students a decade ago to approximately one computer per fifteen students today (Dryli and

Kinnaman, 1994). Networked computers are becoming as common as maps, globes, dictionaries, and encyclopedias in many classrooms. In addition, computers with Internet access are available for students to provide information and to assist them throughout the learning process.

In terms of student research and problem solving, the Internet-connected computer has the capability to take students far beyond the classroom. The amount of information each student can access is essentially infinite. Selecting, managing, and organizing this expansive amount of information is becoming crucial to the student learning process. With the level of comfort students display regarding technology, the enthusiasm they exhibit at the prospect of computer-time, and the availability of computers with Internet access, several questions surface regarding the process of examining what teachers need to know and how students can learn from being exposed to a school situation where: a) computers, b) the Internet, c) library resources, and d) a lab-type setting were available to assist with individualized student-generated inquiry.

Examining Technology Driven Student-Generated Inquiry Practices

As cited by Negroponte (1995), approximately half of what students learn is provided by teachers, however the other half comes from exploration, reinventing the wheel, and finding out for oneself. Until computers were introduced in schools, technology was limited to films, television, and other audiovisual devices which magnify the activity of teachers and the passivity of students (Dixon-Krauss, 1996; Negroponte, 1995; Papert, 1980; Solomon, 1987).

A synthesis of the works of Piaget (1932), Vygotsky (1987), and Cole and Wertsch (1995), conclude that in order for true learning to take place, a combination of active child and active environment must be present. This combination creates a "co-constructionism" which maximizes student learning and emulates a "learning-in-the-wild" environment. Students who are allowed to "construct" their own explanations in order to make sense of the world around them using what is for them new information and knowledge, learn how to learn and will be better fitted for life in the next century. The source of new knowledge should be available within an enriched classroom environment (Cole and Wertsch, 1995; Piaget, 1932; Vygotsky, 1987).

Furthermore, Papert (1996) suggests that our entire structure of school is primitive. Knowledge is cut up into little unrelated pieces and offered by a teacher who is commonly found in front of a classroom of passive students. Because of the new digital technologies of today—present but not being implemented fully in classrooms—a demand for a future workforce equipped with skills such as abstraction, systems thinking, experimentation, and collaboration, student-generated inquiry and Internet utilization is necessary. These are critical skills which are not understood by most educators and are not being taught or fostered in our classrooms (Goldberg and Richards, 1995; Reich, 1992).

Based on these assumptions, the purpose of the study was to examine, document, analyze, and provide a rich, thick, and dense description of how students access information and what organizational processes they employed while utilizing the Internet as they engaged in their own individual inquiry pursuits. Using a qualitative approach outlined by Bogdan and Biklen (1994), Strauss and Corbin (1990), and Guba and Lincoln (1985), the researcher became a participant observer in conducting five case studies consisting of upcoming fifth grade students selected from a purposive sample in a lab-type setting where they engaged in individual self-generated inquiry with the assistance of networked computers, peers, teachers, and all other resources available in the school and community. Data sets were collected through observational field notes, transcripts of video and audiotapes of each session, student journals, and photo essays. The project was constructed as a *Summer Technology Institute* and was offered at a local elementary school where parents frequently seek summer educational opportunities for their children. Observations and data collection spanned a four-week period. Library access and a collection of electronic research materials such as electronic encyclopedias, electronic atlas programs, and various other CD ROM programs designed for student research provided students with additional research material as needed.

Throughout the study the researcher delved into the essence of student action and interaction and attempted to convert "raw" experiences into insights and useful patterns. The following questions framed the study and provided the researcher with a set of overarching themes:

1. How do students use the computer and the Internet to assist in their own research and inquiry pursuits?
2. What patterns of technological literacy emerge as students engage in inquiry?

3 . What do teachers need to know and do to support these processes?

Findings and Conclusions

In reflecting on methods of research and the process an inquirer follows, Boyd (1961) writes that Charles Kettering once suggested that research is nothing but a state of mind, a friendly welcoming attitude toward change, and an effort to do things better. One of the initial questions that framed the study converged on what teachers needed to know in order to support student-generated inquiry and promote technological literacy. This question implied a focus on change. The change—aimed at common instructional practices—would provide students with an opportunity to engage in self-generated inquiry. In an attempt to offer classroom teachers insights into the process of student-generated technology-enhanced inquiry, general findings are presented in the chronological order in which they occurred. As data collection took place, the researcher recorded daily reflections as a means of gaining understanding as well as to compile a list of implications for classroom teachers. In addition to daily entries in an observational field journal, videotapes and audiotapes of each session provided additional information to aid in understanding the nature of student interactions with peers and computers.

The first major findings that emerged as early as the first pre-institute interview session was that students displayed an apprehension and shyness regarding sharing opinions and interests. The entire group sought teacher approval and were reluctant to grasp the freedom bestowed upon them as participants in the project. For example, during the first pre-institute session when asked, "What do you think would be important enough to find out more about?" a student participant answered, "I'm just a kid. I don't know what's important!"

Another major finding was that after the second pre-institute sessions where students became familiar with the Internet, Netscape, and simple navigation, one could not differentiate between students who had prior placement in a technology-enhanced classroom—as defined by the state—and those who had no prior placement. In fact, those who were never in a technology-enhanced classroom in grades K – 4, were more apt to attack simple computer problems, conduct searches, and offer their "expertise" to others. There was some difference, however, between students who spent a large amount of time on home computers—up to two hours per day—and those who did not. With the exception of the one student with no computer in the home, students who spent larger amounts of time using their home computers emerged as "experts" in assisting other students, offering suggestions, and conducting in-depth searches. The emergent technological literacy these student brought from home had more of an impact on student processes and progress than the level of emergent technological literacy other students brought from experience within a classroom setting where computers were present.

Perhaps the most glaring finding was the distinct differences between male and female participants. Beginning with the first summer session, videotapes and field notes show that female students sought help from the researcher and teacher participant at a ratio of 14:1. Videotapes of the first session show that female students raised their hands for help fourteen times for every one time a male participant asked for help or assistance. Females did not leave their computers, but stayed in their seats while male students got up and walked to the researcher or teacher participant with questions. This of course enabled the male help-seeker to obtain assistance quicker. Male participants often sought help from other students whereas female participants would wait for the researcher or teacher participant.

Moving Forward With Technology

The project offered students opportunities to engage in self-generated inquiry, and utilize the Internet within a non-threatening, student-centered environment that promoted technological literacy and student research. Findings from the study show that students need a specific environment in order to thrive and develop the skills needed to operate in a technology-driven world. Time for thinking, conversing, and movement are essential in this environment. The ability to choose and select topics of interest, develop work patterns, and operate within a self-selected group configuration allowed students to move through the inquiry process naturally. Sharing, assisting, and offering expertise are essential components which must be present in a technology-enhanced classroom in order to provide students with optimal opportunities to engaged in Internet-assisted inquiry.

In order to better prepare today's students for the technology-driven world they will be part of in the future, educators must examine current instructional practices, past instructional practices, software purchases, and technology integration and implementation. The study showed that it made no difference how many years a student was placed in a technology-enhanced classroom. That experience had no impact on the inquiry process nor did it have an impact on any technological literacy patterns, work habits, or utilization of the Internet. However, the instructional practices, non-threatening environment, encouragement provided by the teacher participant, and the allowances made for each student's preferences seemed to have the most influence on the process. With the abundance of funds allocated for classroom technology, software, and computers, it seems that these things are essential in developing the type of classroom environment needed by students who will make up the future workforce.

ubiquity is driving organizations to move strategic business functions to the web as quickly as possible. Second, many people think web site development is cheap and easy, not realizing the great difference between a glitzy web page and a carefully designed WBA that supports a specific business function. The net effect of both forces is a very real pressure to compress schedules and keep development costs down. Under this pressure, a formal software development process may be the first thing sacrificed. However, the activities of such a process (planning, estimating, scheduling, monitoring, and reviewing) remain important for successful WBA development. *A WBA development process needs to include well-defined management activities, yet be unobtrusive; documentation and process overhead should be kept to the minimum necessary to preserve accountability.*

Another challenge is that, contrary to popular opinion, user interface development for the web is difficult. The users of web applications are potentially more diverse (in experience, age, language, and training, among other qualities) than is the case with most software applications. Furthermore, they are running applications on a variety of platforms and using functionally diverse web browsers. This increases the challenge of determining appropriate interface content and appearance, and makes early and frequent user review essential. *A WBA development process should produce a complete and functioning user interface as early and often as possible.*

A final challenge is that the stakeholders of a WBA are often geographically scattered, making frequent meetings impractical. As a minimum, these stakeholders include the developers, the clients who are commissioning the development, and the end-users of the system. *A WBA development process must promote success despite the lack of face-to-face interaction between the project's stakeholders.*

3 Process Description

We propose a lightweight development process that addresses each of the challenges described above. This process is based on our recent and successful experience with implementing a grant application system for the Federal Highway Administration (FHWA), National Scenic Byways (NSB) Program, as well as other previous WBA development projects. We provide an overview of the process below and describe our experience in Section 4. Related work is discussed in Section 5.

Our process model is similar to the evolutionary prototyping model which consists of cascading phases of interdependent waterfall processes. However, it differs from the evolutionary prototyping process model in several ways. Specifically, it involves just two phases instead of an undefined number. The first follows a modified incremental development model with an emphasis on rapid prototyping. The second follows a lean waterfall model with an emphasis on quality. See Figure 1. Our process also deals with poorly understood requirements early in the development life cycle; whereas, the evolutionary prototyping process is more likely to start off with well understood requirements [Davis et al. 1988].

Abstract: From a software engineering perspective, moving a business software application to the web presents interesting challenges. These include frequent changes to requirements, changes to the underlying business function as a consequence of moving to the web, tight time and cost constraints, and producing quality user interfaces within the restrictions of the web environment. This paper describes a lightweight, two-phase process that integrates advantages from incremental development, throwaway prototyping, and waterfall process models to address these challenges. A successful development experience using this process is summarized.

1 Introduction

Businesses of all kinds are clamoring to migrate key functions to the web. As contract software developers, we have seen much of this development effort occurring in a haphazard and rushed manner, with little room for a formal process. This lack of management makes it difficult to plan a project, estimate costs, schedule resources, monitor and report progress, and review quality. A process must be established which can meet the unique challenges of developing quality software for the web in a timely manner. In this paper, we define a lightweight development process that does so and we describe our experience using it. We also generalize this experience for similar development projects.

2 Challenges of Developing Web-based Applications

Below are five challenges of developing Web-based Applications (WBAs). These challenges are not comprehensive and individually they are not unique to web development. However, in our experience, they do occur frequently and together in web-based applications. A WBA development process must be designed to deal with these challenges directly.

The first serious challenge concerns the difficulty of pinning down the requirements early. This is caused by several factors. At the start, the users may be unprepared or unwilling to abandon old methods in favor of new web-based processes. They may lack a vision of just how much the web-based application (WBA) can do for them. Consequently, as the user discovers what can be done, he or she adds requirements piecemeal throughout the entire software life cycle. This can lead to dramatic and frequent changes which ripple through every work product. *A process for WBA development must adapt to changing requirements.*

A related challenge is that the business function itself evolves as a consequence of migrating it to the web. As the user sees what can be done, he or she also begins to rethink the underlying business model. This also changes the developing WBA's functional requirements throughout the entire life cycle. One industry example is when revenue once generated from product sales is replaced by revenue from advertisements on a web page offering the products for free. *A process for WBA development must allow the underlying business function to evolve.*

Another challenge is that the severe time and cost constraints of typical WBA development often compel project teams to discard formal development processes. Severe time and cost constraints are nothing new in software development, but with WBA development, two forces make them even worse. First, the web's popularity and its

Phase 1 is based on an incremental process model and therefore involves the iteration of core development activities. However, it focuses on just five: requirements definition, systems analysis, design, coding and testing. Here, the requirements definition uses one-on-one conversations with the users to produce an outline of desired features. The systems analysis focuses on understanding the key entities and their relationships, interactions and behavior. It refines a model describing the existing business functions and their reincarnation on the web. Although any reasonable conceptual model language can be used, we prefer Object-oriented Systems Analysis [Embley et al. 1992] and Unified Modeling Language [Booch et al. 1999] for their expressiveness and solid foundations. The design activity includes high-level organization, user interface, and database design. It produces module specifications, screen sketches, and database schema. The coding involves programming, graphic artwork, and writing, and it produces incremental versions of the system with all the necessary icons, backgrounds, decorations, and on-line documentation. In some cases, particularly during early iterations, the coding is for prototypes that are intended to be thrown away and redone in later iterations. The testing focuses on both the validation and verification of the software system and is done at unit, integration, and system levels. During early iterations the programmers test their own work. In later iterations, team members test each other's work, and in the final iterations, the selected users participate. In all cases, the testing activities produce feedback for the next iteration.

The activities and work products of the first phase include only those which are essential to capture the core ideas, communicate with the customer, manage the project, and produce a usable product. Several common activities, such as system specification and detail design, are explicitly not mentioned in the process model. Although these activities can still be performed when appropriate, they are de-emphasized and folded into other activities. For example, some specification for defining high-level modules occurs during design and some detailed design occurs as part of coding.

The first phase is similar to a traditional incremental model in the way features are completed through successive iteration of the development cycle. It differs from the traditional incremental model in several ways. First, it is as lightweight and informal as possible and yet still produces a usable product with a well-defined, repeatable process. Second, the requirements during the first phase are more fluid than would otherwise be desired or allowed. Third, it integrates the notion of throwaway prototypes for high-risk features which are either poorly understood, have a large impact on the rest of the system, or are of particular importance to the client.

Phase 2 is based on a waterfall model and therefore consists of well-defined steps that correspond closely to development activities. Work products from one step become inputs for the next. Unlike the first phase, progress is measured in terms of completion of development activities, instead of the completion of features.

The first step of Phase 2 is system analysis and specification. This step will use the entire set of work products and experiences from the first phase as a basis for re-analyzing the system and coming up with a concise and accurate specification. The second step is design which produces module definitions, screen sketches, and database schema. The coding step implements the entire system. The testing step includes unit, integration, and alpha testing. The last step is beta testing which involves testing with a selected set of users. Like other waterfall processes, Phase 2 allows for feedback loops to correct problems and respond to issues raised during testing.

Like Phase 1, Phase 2 is kept as lightweight as possible. Some steps are intentionally excluded or folded into other steps. For example, requirements definition doesn't exist since the entire first phase serves that purpose. Also, system analysis and specification are combined and produce a single work product.

It is important to note that both phases are critical to the overall success of the development process. The first, more fluid phase is necessary because the process must be adaptable while all involved parties react to change. The second, more measured phase is necessary because it gives developers an opportunity to integrate the requirements found during the first phase into a more maintainable, extensible, and long-term architecture. Such qualities are not likely to be found in the first-phase product. Also, the second phase gives all parties time to complete the all-important mental and procedural shift to a web-based system.

4 Our Experience with the Process

The FHWA-NSB required a cost- and time-effective means of gathering and reviewing submitted discretionary grant applications. At that time, the submissions were paper-based and entered by hand into a single data table which was then used to generate the necessary reports. This old method took many man-months. We used our two-phase process above to develop a WBA to automate the entire discretionary grant application and award process.

Initially, our client, the FHWA, was reluctant to abandon the old method and switch to the new one. Many of our experienced end-users (associated with the state byway programs) also resisted the change. In addition, the FHWA was revising the older method even as we worked.

Our client was in Washington, D.C., we were in Utah, and our ultimate users were scattered throughout the U.S. Funding allowed for just one face-to-face meeting, so phone calls, faxes, and the Internet were the primary means of communication.

Time constraints were severe, especially for the 1998 grant program. The FHWA and the state byway agencies required delivery of a working product just seven weeks after assigning us the project so they could meet deadlines imposed by the legislature.

Our objectives for Phase 1 were:

1. produce a working product in time for that year's discretionary grant deadline
2. enable byway agencies to submit correct and complete applications
3. enable state and federal agencies to review them
4. start the transition from a paper-based system to a web-based system

Phase 1 began June 3, 1998. During the subsequent seven weeks, we iterated through the Phase 1 development cycle several dozen times. The early iterations took 2-3 weeks and focused on systems analysis, database design, and user interface design. The coding and testing activities during these early iterations resulted in prototypes that addressed specific analysis and design issues. Subsequent iterations focused on coding and testing, although some analysis and design activities continued as requirements changed. On July 6th, we held the first major review of the complete system with our client. This was followed by several more iterations of the development cycle, each concluding with an outside review. We froze the requirements for the final iterations so as to converge on a public release. These final iterations focused on polishing look-and-feel, terminology, and online help. The public release of the Phase-1 product was made on July 24th, one week before the legislative deadline. For unrelated reasons, the grant application deadline was moved to Aug. 7th. The final release contained sufficient features to enable the end-users to submit and review grant applications. Between July 24th and Aug. 7th, 38 different users submitted 83 grant applications online.

We tested the WBA with the team and FHWA. After the release, our end-users discovered several minor errors, one major error (a data field overflow with subsequent loss of data,) and one serious conflict between required functionality and software capability (printing multi-page, formatted documents within the limitations of browser software.) Most errors, including the major one, were fixed within 24 hours if not while the customer was online and talking to us. The resolution of the printing conflict and the correction of some cosmetic problems and navigational inconveniences were intentionally postponed to the second phase.

During the first phase, frequent review sessions with the client were essential. These review sessions had several benefits. They provided valuable feedback on the emerging software system. They kept us focused and on track. Finally, they helped the client envision how the web-based system could not only augment but supplant the paper-based system. This set the stage for the second phase.

Our objectives for Phase 2 included those for Phase 1, plus

1. solidify and refine user requirements
2. develop an extensible and maintainable system that can meet the FHWA's grant program needs for the next five years

3. complete the transition from a paper-based system to a web-based system

Phase 2 began Nov. 18 and 19, 1998 with a face-to-face meeting with the FHWA. This meeting was both a post-mortem on Phase 1 and a heads-down design session for Phase 2. After this meeting, database redesign took two additional days and user interface redesign one additional day. The design was completed by Nov. 31. A beta release was completed Dec. 18, which met and exceeded expectations. Beta testing was Dec. 28-31, and the product was ready to release Jan. 4, 1999. It lacked only help and examples to be supplied by the FHWA. The final product could not be officially released to the public until the FHWA announced the year's discretionary grants fund, which finally occurred Feb. 23. Between this release date and the June 30 deadline, 280 applications were completed, reviewed, and submitted.

During beta testing, testers found 16 errors and submitted 52 suggestions. Most of the errors were minor, such as spelling mistakes, formatting, and other cosmetic problems. Six of the suggestions were major, requiring additional functionality, or changes to the database scheme and user-interface behavior. Since the release, users and support personnel have reported 3 major and 7 minor errors.

Although the second phase was as time-constrained as the first (seven weeks, counting holidays), it went more smoothly. Schedules were kept, milestones met, and the reaction from the FHWA and end-users was, in general, positive.¹

The amount of time spent in Phase 2 on requirements, analysis, specification and design was drastically reduced. In effect, Phase 1 embodied the requirements definition and systems analysis. The experience we gained during the hectic weeks of Phase 1 paid off in Phase 2. We gained a better understanding of the discretionary grant business function and developed a more comprehensive WBA in equivalent time. The FHWA switched from resisting a completely web-based application to enthusiastically supporting it. Even our end-users, having been exposed to the Phase 1 product, were better prepared for the Phase 2 product.

5 Discussion and Related Work

A strength of our two-phase process is that it directly addresses all the challenges stated in Section 2 without introducing unnecessary overhead or process complexity. Many existing process models successfully address some of the challenges, but not all five. For example, some formal processes have trouble reacting to the time and cost constraints of WBA development because of undue emphasis on lock-step activities and ancillary documentation.

Most of the concepts found in the two-phase WBA development process are found in other development process models. For example, rapid prototyping, like that of Phase 1, is a common means of analyzing requirements and reducing errors [Gomma 1990]. It can be found in several landmark models, like the Spiral Model [Boehm 1988], the Throwaway Prototyping model and the Rapid Application Development (RAD) model [Martin 1991].

Another common concept is incremental development. Phase 1 supports incremental development by encouraging multiple iterations of the development cycle, each focusing on the addition of a few features or components. Experience has shown that incremental development can help solidify the requirements of an emerging system, particularly when the scope or functionality of that system is changing due to shifting user paradigms and evolving business processes [Davis 1988]. However, the consequence of using incremental development as the sole process model is that, eventually, the software system outgrows its original infrastructure and needs to be completely re-engineered [Webster 1995]. Phase 2 of our model provides an opportunity for developers to rethink the system's infrastructure and develop a long-term, maintainable architecture, at just the point when users have had a chance to digest the possibilities and benefits of a WBA and before they have locked into a long-term solution.

¹Readers interested in this site can find it at <http://www.byways.org/grants2>. We recommend that readers who wish to test the site do so on our development site, <http://ubn.cs.usu.edu:8080/grants2>. The sites are functionally identical, but are on different machines and use different databases. The scenic byways community will appreciate the courtesy.

6 Summary

The two-phase process described in this paper successfully addresses the challenges of web-based application development. The first phase plays a key role in helping the development team understand the requirements and adapt to frequent changes. It also helps all stakeholders grasp the potential of this new medium and assist with unleashing its full potential. The second phase builds on the knowledge gained from the first phase and produces a product that has a better user interface, and is more extensible and maintainable. Both phases are as lightweight as possible without compromising a manager's ability to plan a project and evaluate its progress.

A key aspect of this process is that it works well even when the involved parties are geographically separate. Such far-flung teams have become commonplace with web-based application development.

The experience presented in this paper provides evidence that this two-phase process can work. We plan to apply the same process to additional projects in the coming year. We expect that these projects will share the same challenges as the NSB grant application project.

Distance Education: Early Lessons Learned

Caroline M. Crawford
Assistant Professor
University of Houston-Clear Lake
Houston, Texas, USA
crawford@cl.uh.edu

Abstract: Distance education has become an integral aspect of higher education in recent years. This expansion of institutions of higher education into the foray of a digital learning environment has offered opportunities to the institutions to not only increase the size of their student body, but also offered opportunities concerning the digital learning environment and the impact distance has upon such environments.

The impetus that has led higher education institutions towards the development and introduction of digital distance education into their array of course offerings have not gone unnoticed in recent years. The availability of higher education course offerings through digital distance education would not only offer the ability of a wider range of persons to obtain further educational situations that would not have otherwise been available, offer numerous higher education institutions the ability to branch out into different parts of not only the country but of the world, and to develop courses that would be free of restrictions pertaining to the obtainment of physical space in which to meet, which has become a serious consideration in recent years for all institutions of higher education.

These issues are positive manifestations of real-world concerns that lead to lofty theoretical and philosophical goals within higher education institutions and have the possibility to considerably alter the world of higher education, as we know it today. Yet lessons learned through out the distinct areas of design, development, evaluation and implementation processes have led to careful consideration, reflection, discussion and understanding of distance education and the early lessons learned within such a process.

The lessons learned through such a new, innovative arena have left numerous other designers and developers feeling alone, misunderstood, and without hope of realizing the dream of distance education; however, through the trials and tribulations of the author, along with fellow faculty within the Instructional Technology specialization area at the University of Houston – Clear Lake, numerous early lessons learned are apparent and will aid future designers and developers in their quest for a strong distance education course or program. Early lessons learned within the arena of distance education are worthy of discussion and will lead to a greater understanding of the conceptual, theoretical, subject matter, design, and development issues that are apparent to the distance education coursework designers and developers.

Conceptual Issues

The conceptual issues pertaining to the overall view of exactly what is distance education as defined by the designers and developers of the digital distance education coursework is a serious consideration. Each of the persons who are in place to develop the distance education course must delineate their conceptual understandings of the situation and, after numerous discussions and reflections upon issues of concern, come together to provide an overall concept of exactly what they are trying to accomplish. Only through this initial phase will all the persons involved in the distance education course be able to conceptualize the overall plan, formation and aesthetic values that are impacting the final product. The concept is of utmost importance and, secondly, theoretical issues surrounding the design, development and implementation of the distance education course is a primary concern.

Theoretical Issues

Theoretical issues perhaps more commonly referred to as epistemological underpinnings, drive a course. Three aspects of theory must meld in order to develop a successful course: the instructor's theoretical belief structure; each individual developer's theoretical belief structure; and, the group's theoretical belief structure. Although each individual developing a course will have significant differences in their personal theoretical beliefs, the important aspects are the differences through which problems may arise. The persons developing a course must become aware of differing theoretical viewpoints, become comfortable with other's theoretical viewpoints, calmly and logically discuss theoretical issues that may arise through out the design and development of the distance education course, and agree to respect each other's differing theoretical views. Without such an undertaking at the beginning of course development, issues and misunderstandings may arise because theoretical viewpoints were not clearly delineated, discussed and decided upon at the beginning of the design and development period. Although this task may take a significant amount of time and reflection on the part of the design and development team, perhaps up to a few months of what may be considered as "lost" time, it will aid in the clarity of purpose and understanding that will occur at a later time in the group process.

A question that may arise is whether an individual, who has decided to take upon himself or herself the process of designing and developing a course, must work through their own personal theoretical issues before beginning the design and development of the course. The answer, most simply, is: yes. It is most useful for anyone who engages in this process to clearly articulate their own theoretical beliefs and understandings so that an understanding of "why" something is chosen or "what" should be included can be rationalized. Without such an understanding, diligent effort through out the design and developmental periods may be more of an emotional reaction rather than a clearly defined and articulated plan. Once the theoretical issues are worked through, the subject matter issues begin to arise.

Subject Matter Issues

Subject matter is always an issue when developing a course. How much to include, when to include it, within what framework should the subject matter be introduced to the student, what type of learner assignments and evaluative methods should be introduced to obtain the highest level of understanding? An even more difficult question that the subject matter expert must address is whether the course should be offered as an online course, rather than a face-to-face course. Theoretical coursework may be offered as online coursework in a successful manner but what about hands-on, production type of courses? Should these be offered online, as well? What would be the considerations surrounding an online course for an introductory technology course in which basic technological understandings are introduced to the learner? Would this be a course that would be successful in an online environment? Such thoughts race through the subject matter expert's mind while considering the course content. Numerous issues must be addressed through out the subject matter planning stage that

Design Issues

The design issues surrounding online distance education courses are numerous. After all, the design of a face-to-face course and the design of a digitally transferred distance education course are completely different. The instructor's ability to react to students' nonverbal cues in a face-to-face situation may be useless in an online environment; the instructor's wit and charm in a face-to-face environment may be perceived as tacky and rude in an online situation. Questions and concerns such as these surround the design of the coursework. How will the instructor manage such different environments, especially since online distance education courses are environments in which the instructor may not be familiar and/or comfortable? These are difficult issues. Further, such issues as motivation, the development of an online community, and there is not yet a mention of the obvious question surrounding knowledge attainment, are clearly apparent through out the design process. If such issues are not addressed, there may be a significant opportunity for the course to not successfully meet expectations. Perhaps the design issues for each course are the most thoughtful and time-consuming phase of the whole course initiative.

Development Issues

Once the theoretical, subject matter and design issues have been worked out to a satisfactory end, the development of the distance education course becomes a central theme. If funding is available to have more than one person developing a distance education course, persons available to address each of the following roles would be useful:

- Videographer
- Graphic Artist
- Programmer
- HTML Developer
- Subject Matter Expert
- Instructional Designer
- Instructional Developer (not necessarily the same person as the HTML Developer)
- Audio Developer

Although this is an exemplary situation in which very few persons find themselves, it may be more efficient to have at least one person focusing upon their own specific duties.

Unless the subject matter expert is significantly skilled within the areas of instructional design and instructional development, it may be best to leave such considerations to an expert in the respective areas. Perhaps the most difficult aspect of the team process is allowing the group members the opportunity to realize that they may not be the best choice to address more than one specific role. For example, the subject matter expert may be of the opinion that, since they know the knowledge, they are also the most appropriate person to act as instructional designer and instructional developer; although this may be true for some persons, it may not be true for all and herein lies the difficulty. Clearly articulated roles within a group environment must be defined at the outset so that problems do not arise during the design and development phases. Emotions and ownership will become issues during the design and development of the distance education course and the role assignments of each team member will be an additional impediment that could seriously sidetrack the course development and cause hard feelings within working relationships.

Evaluation Issues

Formative and summative evaluations of the developing online distance education course are of utmost importance to the development timeline. Numerous areas will be important to address through out the developmental process and the most efficient way of gauging the development of these significant areas is through evaluations.

Formative evaluations are, most simply, evaluations that take place through out the developmental process; these formative evaluations aid in the possible redesign and/or redevelopment of the course. Areas that may be necessary to address during formative evaluations are:

- Navigation Issues
- Interactivities
- Flow of Information
- Knowledge Attainment
- Assignments
- Interface Issues
- Course Structure
- Video Integration
- Graphic Understanding/Compatibility
- Meeting ADA Standards

Although this list is merely a few of the numerous areas that will be addressed during formative evaluations, such evaluations will aid in the development of a superior course.

Summative evaluations, most simply, are evaluations that occur at the end of the developmental period in order to evaluate the final product. Such evaluations, when implemented after numerous formative evaluations, are positive in nature.

Implementation Issues

Once the developmental period is complete and summative evaluations have been obtained, it is time to implement the online distance education course. Initial implementation of the distance education course may be best as a pilot project, in which several students work through the course to offer feedback on areas of success and areas that may require further thought. The pilot of the course can easily be implemented during a normal semester time period in which the students not only may take the online course as course credit, but may also act as reviewers and offer feedback on different aspects of the course. After the formative and summative evaluation periods, the implementation of the course should be successful with only a few points of further development being of significance.

Conclusions

The design and development of a digital distance education course offers several topic areas through which to navigate. The careful consideration, reflection, discussion and understanding that is not only apparent but also clearly a mandatory undertaking to the design and development of a successful distance education course are of utmost importance. Each aspect of the design and development is of primary concern and will offer numerous benefits once the sober realization that this type of development can not possibly transpire through one person's determination occurs. The professional working relationship of a group of persons will result in a successful, superior product that will offer learners a positive environment through which to obtain knowledge, successfully integrate this knowledge into a prior knowledge base, develop quality assignments and the comfortable evolution of an online community.

Computer-Supported Distance Art Therapy: Beyond Computerization

Davor Cubranic*, Kate Collie+, Kellogg S. Booth*

*Department of Computer Science, +Department of Counselling Psychology
University of British Columbia, Vancouver, BC, Canada
cubranic@cs.ubc.ca, kcollie@interchange.ubc.ca, ksbooth@cs.ubc.ca

Abstract: In the recent years, distance mental health services using the Internet have become increasingly common. However, this expansion has occurred in the absence of research about the effectiveness, safety, and legality of such services. This paper presents a study in which we have actively involved mental health practitioners in the development and evaluation of the system for computer-supported distance art therapy that we have created, and discusses some of the broader issues that emerged that might be of relevance to the development of groupware systems.

1. Introduction

Recent developments in the computer industry and telecommunication infrastructure have given rise to *telehealth*, health care delivered from a distance. In the United States, the federal Medicare agency is promoting telehealth — with funding through the Federal Communications Commission — and several states have passed legislation mandating third-party payment for both physical and mental health services provided by means of videoconferencing or Internet [Sleek 1997].

With the emergence of telehealth there has been a rapid expansion of distance mental health services. There are already hundreds of text-based counselling and therapy sites on the Internet [see Marson 1997; Sampson, Kolodinsky & Greeno 1997], and telepsychology and telepsychiatry networks employing videoconferencing technology are being established throughout North America. This expansion has occurred in the absence of research about the effectiveness, safety, and legality of distance mental health care [see King, Engi & Poulos 1998; Preston, Brown & Hartley 1992; and Robson & Robson 1998].

Mental health professionals are being called upon to be involved in the development as well as the assessment of telehealth systems, by collaborating with computer scientists in human-computer interaction (HCI) and computer-mediated communication (CMC) on the development of telecommunications systems specifically for telehealth [Lee 1998; Sanders & Rosenfield 1998] — rather than relying on computer communication systems designed for corporate communication or leaving the design of telehealth systems in the hands of the telecommunications companies that are pushing the telehealth movement forward.

The study we discuss in this paper directly addressed the need for research about distance mental health care and the need for active involvement in the development of telehealth systems on the part of mental health clinicians. We used participatory design to develop and evaluate an innovative computer system for distance therapy. One of the authors (KC) is a graduate student in Counselling Psychology who is also a professional artist. The other two are a graduate student (DC) and a faculty member (KB) in Computer Science who are working in human-computer interaction (HCI) and computer graphics. The computer system is designed to address the needs of people with mobility limitations, such as people with disabilities or long-term illnesses, but has application for online art therapy or creativity training with a variety of populations.

In the remainder of this paper, we give the background information on art therapy and the state of telehealth today, briefly describe the development and evaluation of the system for computer-supported distance art therapy that we have created, and discuss some of the broader issues that emerged that might be of relevance to the development of groupware systems.

2. Art Therapy and Telehealth

Telehealth has the potential to make health care more available to people who in the past have been underserved, such as the elderly, people in remote or rural areas, people outside the cultural mainstream, people in lower socio-economic groups, and people with illnesses or disabilities [Brauer 1992; Sampson, Kolodinsky & Greeno 1997]. Telehealth shows particular promise for people who have disabilities that affect communication, as

computers with assistive devices can facilitate basic communication as well as making it possible to span geographical distances.

While email is currently the most common way to conduct therapy on the Internet, it has a significant drawback that everything said has to be reduced to text as clients and counsellor type on keyboards, and the directness of face-to-face therapeutic encounters is lost. Email is also asynchronous, an even bigger problem. The system for distance art therapy that we have designed allows a much closer approximation of face-to-face session than does email, and does so without the additional expense and network bandwidth required for video conferencing. Our system allows speech communication and the transmission of hand-drawn images. Communication is direct and synchronous: the therapist sees the images created by the client as they are being made, and the client and therapist can speak to each other as if they were using speaker phones. The presence of the art images provides some compensation for the lack of a visual dimension to the therapeutic relationship.

One of the foundations of art therapy is the idea that the creative process is intrinsically therapeutic [Tibbetts 1995]; in art therapy, the client's art becomes a metaphor for the change process, and can be a symbolic arena for creating preferred scenarios --- for bringing what is desired into the realm of possibility [Fryrear & Corbit 1989]. Making art is thought to promote a sense of mastery and control, to improve self-esteem, and to strengthen identity [Brooke 1995; Hagood 1991]. The fact that these therapeutic aspects are somewhat independent of interaction with the art therapist is an additional reason art therapy is suitable for online counselling. Art therapy clients have therapeutic relationship with their art images as well as with their therapists [McNiff 1992], and in distance art therapy, clients are still co-present with their art even though the therapist is somewhere else.

Our primary target population when we began to conceptualize the project was clients isolated by illness or disability, people we thought could benefit from group support as well as therapeutic help from a counsellor. We decided the computer system should support group art therapy for this reason. This decision was made in light of the recognized benefits of group support during recovery from long-term illnesses [Fawzy et al. 1994], and the growing popularity of Internet support groups for people with medical difficulties [Weinberg et al. 1996].

3. System Development and Evaluation

Our system supports a form of group art therapy where participants use networked computers to communicate with each other using speech (in the computer equivalent of a telephone conference) and hand-drawn images that everyone in the group can see and collaborate in drawing.

We used participatory design for the development and evaluation of the computer system. Two themes govern the practical implementation of participatory design principles: *mutual reciprocal learning* and *design by doing* [Floyd et al. 1989]. Thus, structuring the project as a participatory design study well suited its interdisciplinary and exploratory nature.

There were three stages to the participatory design process. The first was an initial collaboration between DC and KC, during which we learned the possibilities and constraints of the other's discipline and began designing the system. When we had a working prototype, we worked with groups of graduate student volunteers to refine the system and to determine what kinds of communication it could support. In the final stage, the evaluation phase, ten people with expertise or experience relevant to online counselling used the system and participated in a series of group and individual interviews. We emphasized that members of the team would be co-researchers with us, and that their observations were the focus, not our observations of them. Detailed descriptions of the design of the system and the collaborative process have been published elsewhere [Collie, Cubranic & Booth 1998; Cubranic, Collie & Booth 1998]. Work on the system continues, with ongoing projects to port it to Microsoft Windows NetMeeting platform and to provide a Web-based contact point for the therapist and clients.

The purpose of the evaluation was to bring to light issues relevant to the design and implementation of telehealth systems beyond the issues that had already been identified or postulated. The data we collected during the evaluation phase consisted of: transcriptions of group discussions; our own observations; notes taken by various members of the team during the sessions, including notes made by participants while observing art therapy sessions from the point of view of the art therapist; notes made by participants between sessions; and notes made by KC after the group sessions, and during and after the individual interviews. We conducted a content analysis of these data to create a clear picture of the counselling issues that emerged. The main result of the evaluation was a list of considerations regarding the development and implementation of distance mental health services [Collie, Cubranic & Long].

4. The Emergence of Protocols

Many problems or potential problems were discussed during the evaluation, but the co-researchers generally were able to suggest solutions to the problems they identified. These solutions were usually in the form of communication protocols for using the system, that would ensure such things as confidentiality, privacy, autonomy, and a non-judgmental atmosphere --- as well as ease of communication. The content analysis of the evaluation data revealed a fairly comprehensive set of communication protocols that were generated during the study. Some were suggested by the co-researchers as they used the system; others were suggested in retrospect during the round-table discussions. What follows is a list of these protocols that is in two parts: a set of general guidelines for online group communication in a therapy setting, and guidelines that are specific to online group art therapy when people are looking at each other's art works.

General protocols:

- identify yourself by saying your name before you speak
- speak more frequently than you might expect to in order to maintain a sense of connection with the group
- expect pauses and silences during group interactions
- provide information about your surroundings as you talk with the group
- let the group know if anyone is present with you
- provide information about how you are feeling and what is going on for you

Guidelines for looking at other people's art works:

- only look with permission to look
- say that you are looking
- use *active looking* (i.e., have your pointer present and activated in the image you are looking at, use it to track your gaze, and point to the parts of an image you are talking about)

When working with computers, it is easy for the equipment to become a focus of attention, and for the distinction between the computer system and the information it carries to get lost [Kling 1995]. The fact that protocols for online communication were an important theme in the research team's discussions suggests that, when developing online counselling services, the focus needs to be on the communication as much as on the system that is the vehicle for the communication. In describing how *communication work* is crucial to the success of computer-networked design teams, Robertson [1997] makes the point that this work, and the skills of communication, relationship building, and coordination, are often overlooked. She suggests the reason that this aspect of computer-supported collaborative work is often de-emphasized is that these skills have traditionally been women's skill. Robertson is an advocate for "making communication work more visible within the discourses of technology design", and for designing systems that are flexible enough to "accommodate the highly specific ways that language is used to accomplish ... communication work".

The results of our study corroborate Robertson's perspective. The discussions sometimes centred on the pros and cons of the computer system and on specific human-computer interaction issues, but they tended to gravitate back to issues of human communication. It has already been noted that people adapt to the communication channel available [Vera et al. 1998] --- we feel that with the human dimension of the system being the dimension with the most flexibility, it is no wonder that is what the co-researchers talked about the most. This flexibility is all too often disregarded in favour of a technological cure-for-all; if systems and procedures were developed together, then there would be more potential to take advantage of this untapped resource.

5. Conclusion

When developing a new kind of system like this, it is not just the computer system that is being developed, but also the procedures for using it. The two go hand-in-hand and are developed in an iterative process with feedback going both ways: Just as the capabilities of the system influence the development of methods of communication, so do the new requirements of those methods influence further system development. If these two aspects of a new system are developed in parallel with attention being given to both, then the quantum leap long-

promised by CSCW might come significantly closer to realization. Attention also needs to be paid to how the procedures are going to be taught to the users of the system. Technical manual exists for learning the *mechanics* of using new software, but training and practice are required to learn new communication modalities afforded by it. It is easy to get caught up in the development of a groupware system itself (and what it can and cannot support) and fail to pay adequate attention to the difficult process of creating the new methods of communication to use with the system. Perhaps this is yet another, more subtle reason, why groupware applications may fail [Grudin 1989].

Why to use a dynamic adaptive hypermedia for teaching, and how to design it?

Nicolas Delestre, Jean-Pierre Pécuchet, Catherine Barry-Gréboval

Abstract : For many years, hypermedia has been a new research area in the field of computer aided teaching systems. Three kinds of systems have successively appeared: first classical hypermedia, then adaptive hypermedia and finally dynamic adaptive hypermedia. Dynamic adaptive hypermedia systems are more efficient, but they are rarely multimedia and hardly ever use the Internet to send courses. This paper begins with a historical reminder then introduces the architecture of METADYNE, a dynamic adaptive hypermedia system. This system allows to create and to distribute multimedia-based courses adapted to the learner, and to transmit courses via the Internet. An open architecture and the respect of standards allow the user to connect to the system with a simple browser, and enable the system to connect a large range of pedagogical multimedia databases.

1. Introduction.

Further ITS (Intelligent Tutoring System) [Baron 95] and ILE (Intelligent or Interactive Learning Environment) [Dillenbourg 93] researches on Computer Aided Teaching have taken an interest in hypertext system. However the main advantage of those hypertext systems, i.e. the liberty of navigation, has quickly become a major inconvenient for many systems (for instance information systems, help systems, research systems, etc.) and especially teaching systems. Therefore, researches have tried to lead the student according to his knowledge, by changing the content of pages and links between pages: adaptive hypermedia was born. But afterwards, other studies have shown that those systems were not perfect. So there is now a third kind of hypermedia system: dynamic adaptive hypermedia system, i.e. systems which build, in a dynamic way, the pages and the links of the hypermedia according to the student's characteristic. The aim of the METADYNE project is to design a dynamic adaptive hypermedia system, which is really multimedia and uses Internet to send the courses.

First we are going to study the advantages and disadvantages of the different kinds of hypermedia systems. Then, we are going to introduce the architecture of our system. To conclude, we will introduce the perspective of our work.

2. The hypermedia systems for teaching.

In this section, we are going to introduce the three kinds of hypermedia systems, defining their characteristics and analyzing their advantages and their disadvantages in an educational use.

2.1. What is a hypermedia system?

The word *hypermedia* is the concatenation of two words : *hypertext* and *multimedia*. A hypertext system is a system that allows somebody to introduce different information in a non-linear way. Hypertext is constituted of nodes and links. The nodes, or the pages, of the hypertext are made up of textual information, and the links allow the user to activate other pages. Hypermedia stands out from hypertext by the contents of the nodes. Nodes are not only made up of textual data, but they are also made up of multimedia data, like pictures, sounds, videos or interactive applications. Therefore, some authors use *hypermedia* or *hypertext* words indifferently to show that the main interest of those systems is not the content but the architecture.

2.1.1. Why to use a hypermedia system for teaching?

In fact, there are two points that encourage authors to use hypermedia for teaching. These two points are the consequences of the architecture of the hypermedia system, i.e. multimedia and hypertext aspects.

First, different researchers tried to estimate the interest of multimedia system for teaching. Then [Hoogeveen 95] emphasised some criterions, like “Level of Multimediality”, “Level of Man-machine Interactivity” and “Level of Congruence” that allow us to estimate the teaching quality of this kind of system. While reading this paper, we conclude that multimedia increases the educational quality of teaching system because visual and play aspects are more attractive for students.

Second, hypertext component can perform educational quality of teaching hypermedia, because the architecture of those systems allows the student to structure his knowledge, to understand better the ins and outs of each concept of knowledge. By the non-linearity of his progression, he has to build his knowledge by creating links between each concept. Indeed, like J.F. Nadeau wrote in [Nadeau]:

Learning like thought can not be structured with isolated ideas but with significant or associative links between ideas [...] The hypermedia system becomes a tool to structure the thought.

2.1.2. Why not to use a hypermedia system for teaching?

Those two advantages can become disadvantages, since they are able to disorientate the student, as they introduce too much media to the student we call it: *cognitive surfeit* [Rhéaume 93].

First, the disorientation is the consequence of the opportunity for the student to move in the structures of the system. This freedom risks finishing to cloud him, and the student may wonder some question like “Where am I?”, “Why am I here?” or “Why must I do?”. Rhéaume explains that this is the result of our short-term memory, since as Miller proved it in [Miller 56], human-being are only able to memorize in one moment little information, about seven topics.

Second, cognitive surfeit is the result of the avalanche of information that the system risks sending to the user. Indeed, the redundancy, to be good, must be built in an intelligent way. For instance, the same information must not be introduced to the student with different media which need different levels of knowledge.

2.2. What is an adaptive hypermedia system?

Researchers have tried to minimize negative points of hypermedia for teaching by making adaptive hypermedia. The main goal of this kind of system is to adapt the way to introduce knowledge to the student and to lead the student in the hyperspace¹. Therefore, in this kind of hypermedia, the system can modify the content of pages and the links between them [Brusilovsky 96]. In order to lead the student, different techniques have been created [Brusilovsky 98]. We can find for instance techniques of direct guidance, adaptive ordering, adaptive hiding or adaptive annotation.

The architecture of adaptive hypermedia systems as in many teaching systems, is mainly based on two models: the domain model and the student model. The domain model represents the knowledge in a rough way, the student model represents student’s knowledge.

There were three generations of adaptive hypermedia system. The first one used the *index page method*, where each concept is connected to a page. Through this page, the user can reach all other pages dealing with this concept. The next generation of systems used an index page again, but those index pages allowed to reach significant fragments of pages. It was called *fragment indexing method*. This technique is similar to the first one, but leads to a more accurate index. The latest generation of adaptive hypermedia systems has based the hyperspace on the domain model structure [Vassileva 97]. Each concept is linked to one or few pages and the relations are represented by hypertext links.

2.2.1. Why use an adaptive hypermedia system for teaching?

Adaptive hypermedia system is better than a classical one because techniques that are used allow the student to be guided without deleting his free navigation, and allow the teachers to structure better their knowledge (mainly in the last generation of hypermedia). Indeed the fact to distinguish the knowledge from the media that will be used to introduce them allows the teachers to structure better their jobs. For that they first organize the knowledge and they think how to introduce it.

1. The hyperspace is the graph that forms by the page and the links of the hypermedia system.

2.2.2. Why not to use an adaptive hypermedia system for teaching?

However, there are some issues left. First researchers were interested mainly in how to lead the student in the hyperspace, but not in how to perform the content of pages that are introduced to the student. We can explain this established fact because researchers experienced their new technologies on existing hypermedia systems. And it is easier to hide or to annotate links than to replace the element of pages by others. Second, as the courses are not adaptable, in some cases the structure of these courses may change, and therefore disorientate the learner.

2.3. Dynamic adaptive hypermedia for teaching.

As a consequence of the two disadvantages of adaptive hypermedia, dynamic adaptive hypermedia appeared. The main characteristic of this kind of system is to propose to the user a virtual hypermedia [Vassileva 95]. Such systems are not implemented with physical pages: these ones are dynamically built. The architecture of these systems is based on four components: the domain model, the student model, a teaching materials database and a courses generator [Vassileva 92]. The domain model, like the latest generation of adaptive hypermedia, allows to determinate the hypermedia structure. There are therefore two bijections:

- between knowledge concept of domain model and hypermedia pages,
- between relations between those concepts and links between hypermedia pages.

2.4. Conclusion.

During the fifteen last years, researches about hypermedia teaching system have continuously performed different techniques. First, researchers used classical hypermedia system, then they created adaptive hypermedia system and now the focus is on dynamic adaptive hypermedia system.

However, dynamic adaptive hypermedia systems are often dynamic adaptive hypertext systems, but rarely multimedia. Moreover those systems are often private, they are not distributed, they do not use the Internet network.

The goal of our system, called METADYNE, is to be a real dynamic adaptive hypermedia, by taking into account all the characteristics of the user. The adaptation must be effective as many links as content of pages, by using multimedia data to build courses and by using Internet network to distribute them.

3. METADYNE.

Figure 1 - Architecture of Metadyne

METADYNE is a system of design and distribution of courses via Internet network. In addition to intrinsic characteristics of dynamic adaptive hypermedia systems, it must:

- propose uniform and really multimedia courses,
- take into account the knowledge level of the student as well as his tastes or his goals,
- offer tools allowing to represent the knowledge of a group of teachers, allowing them to put their knowledge in common and allowing the system to perform its adaptation.

As we can see in the figure 1, the architecture of our system is based on four classical components: the domain model, the student model, multimedia database and the courses generator.

In this section, we study these four components, by putting original things forward that will allow us to reach fixed goals. To perform this presentation, we use some examples, from a course about RLC electric circuits. We have made this choice, because we can use a lot of multimedia to introduce RLC electric circuits, for instance textual data for definition or demonstration, picture for electric assembly diagram or vector representation, video to explain how to make electric circuits and simulation software to manipulate virtual electric circuits. Moreover, this course requires many prerequisite, mainly in mathematics and physics, and allows the student to choose different tools to resolve some issues.

3.1. The domain model.

It defines the structure of the hypermedia system. We use a semantic network to represent it. There is an appropriateness between the couple concept-relations of the semantic network and the couple page-links of the hypermedia system. The concepts of this network are linked together with four kinds of relation:

- *is sequentially composed by*, enables to brake up the teaching of a concept into the teaching of a succession of concepts. For instance, a course about derivate can begin with a course about simple formulae, then a course about calculation of derivate functions, and finally a course about slopes of tangent.
- *is derivated in*, enables to show a concept through different points of view. For instance, a course about the light can be a course about corpuscular theory or about ondulatory theory.
- *needs the knowledge of*, enables to select what has to be known to understand the concept. For instance, courses about derivate and limits are prerequisites of a course on asymptotes.
- *is able to be helped by the knowledge*, allows to urge the student to go and see one concept as well as to initialize user model on the current concept. For instance, having the knowledge of the Pascal language can be considered as an advantage while learning the C language.

The two last relations are weighted. These weights allow the system to lead better the student in the hypermedia system. For instance the system considers that a student needs to revise a prerequisite if his mark is lower than the weight coefficient of the link.

Finally, we consider that it is important to provide to the teachers a way to put their knowledge in common, allowing each one to preserve his own vision of the model. Therefore, with this model, we want each teacher to be able to access to the different points of view about the model (i.e. the point of view for a given teacher, the point of view of a group of teachers and of all the teachers). So each concept, each relation and each weight coefficient are labeled. This kind of annotation has two main advantages. First, each teacher can estimate his vision of a domain model according to his colleagues' vision. The second advantage concerns the student: the system can choose different pedagogical strategies. For instance, if the student wants to consult a course for an exam, the system will mainly use the point of view of the teacher that will give him a mark. On the other hand, if the student freely uses the system, then the system will let him have a larger vision on the subject.

3.2. The student model.

Besides the domain model, a good representation of student model is essential. As researches about user model is a full filed of artificial intelligence, our aim is not to perform existing model. So we decided to use a model introduced in [Nicaud 94] and [Balacheff 92]. This model is made up of two sub-models: an epistemic model, and a behavioural model.

3.2.1. The epistemic model.

This model allows the system to know what the learner is supposed to know or not to know. As this knowledge is closed from the knowledge represented by the domain model, the epistemic model can be regarded as a derivative of it. Then each concept of the domain model is linked with the epistemic model of the learner by a weighted relation. Until now, teaching systems use three kinds of weights [Brusilovsky 96b]. There are binary weights (the learner knows or does not know the concept), discrete weights, by defining different categories (for instance, novice, middle, expert), and continuous weight (values are chosen between two extremes values). It is this last technique we decided to use because we think it is the most efficient one. Moreover, it is the only one that allows the system to take time into account an easy way, and time is a parameter that we decided to use (the idea came from mnesic network of [Jorion 89]). Indeed, to

perform our epistemic model, time is considered as a variable of forgetting, because everybody who does not revise regularly a knowledge, may forget them partially or totally. Finally, the system does not confuse its ignorance and learner's ignorance.

To resume, our epistemic model exists by relations that are built between itself and the domain model. These relations are weighted with a value. They underscore what the system knows about the learner's knowledge about one concept. This value is either "I ignore the state of the learner's knowledge" or "I know the state of the learner's knowledge" and in this case a real value is associated, proportional to the level of the learner's knowledge, and updated according to the date of the last rereading of the concept.

3.2.2. The behavioural model.

Whereas the epistemic model is always used in teaching system, the used of behavioural model is often limited or lacking. Our adaptive system wants to be as near as possible the student, i.e. the system must take into account his preferences, his aims and his intellectual abilities.

- The student's preferences will have an impact on the organization of course pages. Indeed, while the student profile is initialized, student will set all the characteristics of what we call the 'canvas'. This canvas will be used as a model to define the structure of all the courses that will be introduced to the student.
- The student's goals will have an impact on the system behaviour. Indeed, as the student wants to revise for an exam or not, the system will have to be more or less flexible.
- The student's ability will be taken into account, not in a global way, but in changing the model according to the teaching subject. Then, depending on the subject, the system will suppose or require a specific level knowledge for the student, and in the same way the temporal weights of the epistemic model will change according to the subject.

To finish, let us notice that those two sub-models are intimately linked. For instance in the epistemic model, the temporal variation of weights is according to the behavioural model.

3.3. The multimedia database.

The third component of our system is the multimedia database allowing the system to introduce every concept. This database is made up of "elementary brick". Each brick is associated with one concept of the domain model. They are characterised by three attributes : the cognitive type, the cognitive level and the physical type.

- The cognitive type allows the system to sort media according to their teaching nature (for instance an introduction, a definition, an exercise, an abstract, etc...). That allows to get hypermedia pages that follow the structure of the canvas.
- The cognitive level allows the system to associate a media with a knowledge level that is required for a good understanding of the information introduced.
- The physical type allows the system to specify the multimedia quality of each media (text, picture, video, interactive application, etc...). This attribute allows once again the system, when it built a hypermedia page, to follow instructions defined in the behavioural model.

Moreover, [Recker 95] proposes to associate in an intelligent way physical and cognitive types. For instance, it is preferable to use textual media to introduce examples, annotations or definitions. But it is preferable to use sound media to introduce abstract or to warn the user.

To finish, this database will be able to be local, away or distributed. That allows the teachers to use his elementary bricks or to use elementary bricks that will be placed in another server, for instance SEMUSDI [Delestre, Rumpler 98].

3.4. The courses generator.

This last component builds the pages that will be introduced to the student. Its job is to:

- As soon as the student has chosen the course that he wants to follow (in our case the course about Force damped oscillator), the system selects the good concept in the domain model.
- Then, the system takes the canvas of the student (from the behavioural model) and gets his knowledge about the chosen concept (from the epistemic model).
- Then, the system chooses the various media to introduce the concept according to the structure of the canvas, and the student's preferences (from the behavioural model). This selection is the result of the use of three fil-

ters. The first one sorts the elementary bricks according to their cognitive type, the second one according to their cognitive level and the last one according to their physical type. If the selection does not allow the system to choose an elementary brick, the system can deactivate the filters and begins by the last one.

- Then, the system determines the relations according to the domain model, the student's knowledge (epistemic model) and the student's goals (behavioural model). For instance, in our case, for the demonstration about the calculation of phase difference between the intensity and the voltage, the system will be able to activate two different prerequisite relations (either on mathematical concept of Fresnel construction or on mathematical concept about complex number).
- To finish, the system builds the hypermedia page (HTML page) and sends it to the student.

The student actions (for instance when he clicks on link or when he resolves exercise) allow the system to update the current student model and to propose another page.

4. Conclusions and perspectives.

Dynamic adaptive hypermedia systems are a real new way of researches compared with the other computer aided teaching system. Although the architecture of our system looks like the architecture of some another system, it stands out by:

- the use of filters to choose the media that allows to introduce the knowledge with the better way,
- the standardization of course structure thanks to the use of canvas,
- our will that the adaptive system takes into account not only the student knowledge, but the student preferences and goals too (the system is not only an adaptive system, it is an adaptable system too),
- our will to offer to the teacher a tool which allows them to put their knowledge in common.

Until now, we have mainly worked on the SEMUSDI Server, on the global design and on the object design of METADYNE. Now, we work to resolve technical issues, and mainly on communication between the client and the server (between JAVA applet and the server). We have the opportunity to test our system with the student of the INSA of Rouen.

Introducing Web Based Training (WBT) to a Web Illiterate Company

Tammy Dewar, Ph.D.
President, Calliope Learning, Canada, tdewar@telusplanet.net

Gregg McMurchy
President, Opstrain Ltd., Canada, mcmu@telusplanet.net

Abstract: WBT was introduced to a web illiterate company over a two-year period. Three regulatory training courses and 17 entry-level technical modules are now delivered over the corporate Intranet. The implementation design, successes and lessons learned are documented.

1. Introduction

The American Society for Training and Development (ASTD) suggests that the number of companies using Intranet or Internet-based training is growing each year. The advantages of WBT are well documented (see Gayeski (1998), Pieterse (1998) or Wilson (1999) for example), and concrete examples of implementation projects are becoming more visible (Cohen (1997), Driscoll (1998), Eline (1997), Wynn (1997)). We utilized an action research framework of repeating cycles of planning, acting, observing and reflecting (Stringer, 1996) over a two-year period with a mid-sized company to introduce web based training. Three regulatory training courses and 17 entry-level technical modules are now delivered over the corporate Intranet. Our implementation design, successes and lessons learned are documented.

2. Company Description

Technophobe (a pseudonym) is a mid-sized company of 800 employees in the oil and gas industry in Alberta. Employees are located throughout the province, in seven main centers and numerous smaller offices. While most jobs in this company were originally hands-on, they now involve a fair bit of computer work on a daily basis.

A computer skills assessment completed in 1998 determined that employees considered themselves novice computer users. These figures stand in direct contrast to the sentiments expressed by many team leaders and managers that "their employees are computer illiterate and would never use any form of computer based training."

Despite the general computer skill level of most employees and the presence of a corporate Intranet, most employees were, in fact, quite web illiterate, as we discovered in the computer skills assessment. Employees rated their web browser use (Netscape) as very little. Additionally, the corporate Intranet was not being used for any sophisticated database or communications applications. It was mainly a static location for information, much of which was outdated and not accessed consistently by most employees.

Training in this company was split between in house developed and delivered training and training delivered by equipment vendors. Most training was centralized out of a southern Alberta office and run by a Learning/Training team there. Training courses ranged from a few hours to five days in duration. The most utilized training technique was lecture, followed by hands-on sessions in equipment labs. Training was "grocery store" in that employees would pick from a list of courses offered by the Learning/Training team. While this team acknowledged the need to move from a training focus to a performance or learning orientation, that shift was taking place slowly, if at all.

3. Rationale for introducing WBT

The decision to convert training to modules delivered over the corporate intranet was a result of formal feedback received on course evaluations; informal feedback from field employees who had discussed issues with the team's learning consultants; and informal feedback from team leaders during meetings. Many writers have noted the benefits of web-based training and the organizational issues it addresses. Gayeski (1998) suggests that "Many of the problems of conventional training and job aid approaches, such as difficulty of updating, cost of distribution and duplication, challenges in scheduling training and finding necessary content, and barriers to providing just-in-time information are now much easier to overcome." Wilson (1999) suggests that the benefits include cost savings, increased productivity, no fear, fun, and continuous tracked learning.

The issues identified by the employees/leaders in this company were similar to those cited in the literature:

- Time away from work to attend training. This company, like many others, had undergone several rounds of downsizing. Taking employees away from their jobs to travel to a two or three day training program was a major concern.
- Travel costs of attending training. Many employees would travel a day in each direction to attend courses.
- The utilization of training results. Employees often did not use the knowledge or skills from a course for months and, therefore, would forget what they had taken.
- Requests for training to be held in rural areas. Due to the above factors, many of the rural areas requested that training courses be held in their location.

WBT also addressed the following issues from the Learning/Training team's perspective:

- Difficulty maintaining current training materials. Because of the traditional labour intensive instructional design approach used by this company, finding the time and resources to keep materials updated on an ongoing basis was a challenge.
- Difficulty in finding instructors to deliver the course. Most trainers were content experts seconded from their regular positions in the company to assist the Learning/Training team with the development and delivery of courses. With downsizing, these individuals became less and less available to train. Many courses were cancelled due to an instructor not being able to keep his commitment to deliver a training course.
- Cost of instructors and meals.
- Course cancellations due to low enrollment.
- Labour intensive aspect of organizing training events.

Additional benefits of WBT that we thought would also impact our project:

- Development Costs - The development time for an online module is about the same, but implementation and delivery are cheaper. The cost of updating materials is substantially less.
- Ease and expediency of updating content.
- Convenience - Anyone can access the modules at any time, so there is no need to schedule events.
- Strategic use of instructors.
- WBT is more interactive than a lecture delivered by an instructor in a classroom.
- Flexibility - Employees can schedule their training in chunks and build it into their work schedules.
- Employees can return to modules as often as they like to review content.
- Large-scale distribution of materials is not necessary; they can be accessed from any location.
- Prepares employees for continuous and self-directed learning. Training opportunities now exist on the WWW on almost any topic.
- Integrates with other online job tools/processes/company handbooks.

4. Implementation Process

Our implementation started with a "train the trainer" process. Tammy assumed that educating the current Learning/Training team members and local training coordinators about online education and WBT would facilitate

them being able to build in appropriate web solutions as part of their ongoing work. An 8 week course delivered entirely online through a web based conferencing system was held, but participation was uneven and most people did not finish the course. The reasons given were that they did not have time to devote to the course. Upon reflection now, the other reason this approach did not work is that participants were quite web illiterate and needed some kind of concrete example of WBT taken from one of the existing courses already held in the company. Without this, they could not see how WBT could become a training solution for them.

What did happen, however, is that Gregg was in this course and was one of the few to finish the course. He put together a number of sample WBT modules from his own work context. At the same time, a major cross-functional training project was underway by the Learning/Training team, which was being stalled because of implementation issues, many of which are documented above in the "Rationale" section.

We brought together a focus group of employees who had taken this training and showed them the WBT demos. The suggestion was that we would reduce the 5-day training course to 10 modules delivered over the corporate Intranet, followed by a 2-day lab. Response was favorable and so we converted ten modules. The focus group also noted that this would be a great way to complete some of their government mandated safety training - Workplace Hazardous Management Information System (WHMIS) and Transportation of Dangerous Goods (TDG).

Our initial scope was to convert an existing course manual for use as a self directed online course. It became apparent early in the project that the material we were to convert had the following characteristics:

- The manual was designed as support material for lecture based delivery rather than to provide a self-study tool. It was a compilation of information from several sources that had been formatted but not edited for continuity or flow. There was little or no transition between sections of the manual. Continuity and flow, apparently, were left to the skill of the instructor delivering the course.
- The objectives had been added to the course material as an after thought rather than being used as a design tool. Consequently there was often little or no correlation between the stated objectives of the modules and the content provided.
- It became apparent that there was a great deal of information that was either secondary or totally unrelated to the objectives when we finally determined what they were.

Based on basic instructional design theory and the available information on applying it to web based teaching instruments (see for example, Jakob Nielsen's web usability guidelines, <http://www.useit.com/>; the Yale Style Guide <http://info.med.yale.edu/caim/manual/index.html> ; King's suggestions <http://www.gactr.uga.edu/internet/development.html>) we decided to re-design the content and delivery to provide the following:

1. Clearly stated and accurate objectives for each of the modules.
2. Frequent learning checks and reviews that would allow learners to gauge their grasp of the content. These took the form of multiple choice questions that were evaluated by JavaScript routines so that immediate feedback could be delivered automatically. We also included buttons that displayed remediation if the learner wanted it. Review questions were interspersed throughout the content and we also compiled them into a module review quiz that was evaluated using JavaScripting and which automatically notified training coordinators of successful completion. In some cases, the form that was generated on successful completion of the test also updated an online database so learners and coordinators could track a learner's progress through the modules.
3. Content that was reduced to main ideas that could be displayed and explained on a single screen. This was done to reduce the need for the learner to scroll through large pieces of textual material. This proved to be quite effective but it did require good planning and content layout to ensure that the flow from screen to screen was logical and effectively transitioned. In some cases, a single idea or concept could not be covered in a single screen. In these cases, we presented the concept with a bold heading on the initial page and on subsequent pages, the same header appeared in a smaller font in the upper left corner of the page. The idea here was to keep the learner well oriented.
4. An interface that allowed learners to stay well oriented as they went through the course. We used a three-frame screen layout to accomplish this.
 - A side menu frame provided links to each of the units within the module as well as the module home page, feedback form, and module test pages.
 - A header frame contained the unit title and the navigation buttons for the specific unit being viewed

- A content frame displayed the actual course content. In some cases the content frame was further divided to allow learners to use links from an image map on one side of the frame to bring up explanations on the other side of the frame. This was especially effective when offering explanations of equipment or single line process flows. The intent from a design perspective was to keep the learner oriented by providing the information without requiring the learner to leave the current page. In the event that we needed to display a larger text intensive document, we generally presented it in a new window with a header frame to allow easy return to the main course material.

We coded the main title page to present the content in a bare window (without menu, navigation, or location bars) to allow more screen space for content and also to create a greater sense of being "inside" the course. Navigation was provided and controlled by the JavaScripting in the header html files. We also provided a module map in most cases that offered a graphical representation of the module and links to the individual units by clicking on them in the image.

After the conversions had taken place, we set up a pilot where one group of employees took the 5-day training and a second group took the online modules and a 2-day lab. Feedback from the pilot participants and instructors included the following benefits:

- Employees can work online modules into their "down" time.
- Employees can integrate modules into job shadowing.
- Employees were better prepared for the lab portion of the training.
- Employees could review the modules as often as they liked.
- There was a better retention of information because employees worked through the information in "interactive chunks".
- Employees liked the modules. Several of them commented on the effectiveness of the animated gifs we used for equipment explanations. Instructors, who felt that this interactive component was more effective than they had been in presenting some concepts, also noted this.
- There was a more strategic use of instructors for the hands-on, lab portions of the classes.
- Employees outside of the immediate target group for the training were able to access and utilize training. Some interested head office staff started to access this training and take it.
- Modules were integrated with company manuals/policies on the Intranet.
- Training was tracked online.
- There was a substantial dollar savings. \$14,160 was saved delivering the course with online modules and a 2-day lab as opposed to a 5-day program.

We did not put together any sort of communication plan to inform the entire company of these modules, but word of them spread and we were approached by several other groups to help them use WBT for training they needed implemented. This eventually included the WHMIS and TDG mentioned above and a Quality Systems training program which was required as part of the implementation of government initiated changes to one of the company's core processes.

While we did have plans to officially roll out this training after our series of pilots, the company went through a corporate merger and all work in the WBT area was halted. We sent out an email message to team leaders across the company in December 1998 informing them of the online modules. To date, people are still "finding" the modules and completing them, as evidenced by the online database we created to track participation.

5. Issues Encountered

Gayeski (1998) notes that the adoption of new media fail because of an interplay of factors such as technophobia, inhibition of human contact, disruption of legal/economic status, lack of appropriate designs and advice, technology that doesn't work reliably, no standardization, and lack of local production ability. Many of these factors were at play in our own project and included:

- Computer anxiety encountered by some employees. Some of the employees had never used a web browser and so we would spend an hour on the phone guiding them step by step to the location of the online modules.

- Effective communication vehicles for letting employees know of the training available. To date, we have not utilized a company wide roll out of training. It continues to be “found” by people.
- Perception problems - Leadership must realize that being at a computer is a “legitimate” training activity. Many employees reported frustration that their team leaders thought they were wasting time while they were going through the online modules.
- There were challenges with some employees who were not self-directed when it came to their own learning. They were used to being told when to attend a training session by their team leader and being told what was important by a trainer in a classroom. Taking the initiative to access these modules as part of their own ongoing learning and development was a significant paradigm shift.
- Format limitations for content in current browsers. This company’s LAN infrastructure was NT based with the standard desktop being a 486 DX 66 PC with no soundcard. The standard browser was Netscape Navigator Version 3.02. This prevented the effective use of full multimedia or proprietary plug-ins in the design of training software. With limited support from the IT department in the early phases of the pilot, it was determined that what interactivity we could build into the software would be developed using client side Java Scripting. This allowed for a high degree of control by the learner over the flow of the training and for the inclusion of review questions and exercises that could be evaluated and remedied immediately.
- Bandwidth/browser limitations prevent use of full audio/video. In the absence of video and audio capability, we elected to use animated gifs extensively for those units and modules requiring detailed explanations of the functioning of various types of equipment. This format had the advantages of simplicity of development and ease of downloading. The size of the animated gifs used ranged from 30kb to 92 Kb with the majority falling into the range of 40 Kb to 60 Kb. This allowed relatively short download times when compared to comparable avi or mpeg format animations and required no special software or plug-in to view.
- Some employees do not have reliable access to the Intranet. A number of northern employees dial in on lines that are not stable.
- Employee assessment is limited and based on the “honour” system. The primary advantages of the WBT produced were the universal access on a 24-hour basis and the elimination of the need for structured classes and examinations. Inherent in this design is the potential for collaborative answering of exams, or simply having an “expert” enter the answers on your behalf. Our discussions on this aspect of WBT have led us to the conclusion that employees choosing to cheat will find a way around any of the safeguards the developer can install in a program. The solution for total security of examinations, for now at least, may reside in the use of scheduled examinations at central locations. In our experience, the problem has not been considered significant enough to justify the added expense and resources required to resolve it.
- It is necessary to ensure that content in an online course is concise and complete. Strict adherence to the principles of sound instructional design is critical to success. Much of the material in modules that we converted from existing courses to WBT was poorly organized and contained a lot of extraneous information. After beginning the development based on the stated objectives we were told “Don’t go by those objectives; we just stuck them in afterwards because someone said we needed them.” There were a few issues that had to be worked before the subject matter experts agreed on some realistic objectives and fully grasped the concept that sometimes “less is more”.
- One of the primary advantages of WBT is the ease of access over a wide geographic area. That can also pose some problems in the area of tracking and recording completions. A necessary part of each of the modules and courses we developed was the development of the infrastructure to manage it. We relied on automatically generated e-mail and CGI based administration databases. Training administrators had to be taught how to deal with these systems.

6. Lessons Learned

- Employees are more eager than management. We initially looked to management for a go ahead on this training, but their perspective was that employees would not want to and did not have the skills to complete training this way. In fact, once employees were given an orientation, they were quite happy to complete it via the Intranet, as it reduced their travel time and allowed them to spend more time at home with their families.
- The online modules must be rolled out with a face to face (f2f) orientation. Initially, we tried to use email to inform people of the training and get them to try out the modules. This had limited success. We should have done a “road show” to every main area in the province and done a f2f demonstration. Whenever we actually

showed employees the modules, they were quite keen and followed up. Whenever we would send out an email, it was largely ignored.

- Start with a quick win first. We stumbled across the mandatory training halfway into our project. In hindsight, choosing a course that can be developed relatively quickly and must be done every year may be the sort of quick win to kick-start WBT. Choosing a project that is comparable to the CBT training that many companies use for common regulatory training has the added advantage of providing a realistic assessment of relative development costs. A WBT course on WMHIS, for example, might cost \$8,000.00 to develop online as opposed to \$40,000.00 for traditional custom developed CBT produced using proprietary development software.
- Involve as many employees/trainers as possible in the pilot sessions. We found that once people viewed the online modules they were quite excited by the potential and they then became initiators of future projects. These projects (e.g. WHMIS, TDG) have been well received and easier to implement than the ones that we initiated.
- Look to the change management and organizational development literature for guidance when introducing WBT to a company. We didn't realize at the time (although it seems quite obvious now!) that what we were trying to do was a significant change initiative in a company, not just a slightly different way of delivering training. The actual conversion of materials to WBT was the easiest part of the project!

7. Future Considerations

Our project was halted before we could implement some solid evaluation in terms of learning outcomes. Although we have anecdotal reports that WBT is as effective or even more so than some of the 2f training sessions held in this company, we do not have any solid data to substantiate this.

Applying Social Navigation Principles to the Design of Shared Virtual Spaces

Andreas Dieberger

Abstract: A shortcoming of the World-Wide Web is that users get the perception they might be alone in information space. We see a strong trend to more populated information spaces that increase one's awareness of other people's activities. This awareness is beneficial to judge the utility of certain information, its recency and its rate of change. We modified a collaborative Web server to enhance the user's feeling of being part of an active virtual community. These modifications extend the server into a social navigation system, which allows us to study how people react to improved awareness of other people within an information space. Our experiences suggest that the awareness information gives a good feeling for the rate of change and for the level of activity in a site and helps people find information of current interest. We further describe how social navigation principles can be applied in the design of an online store to buy food. Food stores are very social places and the design of virtual food stores needs to incorporate social aspects much more than online stores typically do.

The Web is a lonely place

Although many people may access a Web site at the same time, the Web mostly maintains the illusion of a dedicated resource. The only indication we might get that a large number of people access a site at the same is a slower than usual response time. Although humans are very social animals, most of our social skills are ignored and unused on the Web. Virtual communities and chat systems are only small pockets of social activity in a sea of anti-social information spaces.

Navigation is a social and frequently a collaborative process [Hutchins 1995]. Research in social navigation tries to make better use of our social abilities to navigate information spaces. Social navigation can be direct, when people give recommendations or guide each other, or it can be indirect. In this second form of social navigation the system creates a feeling of awareness for other people's activities and indicates where people went and what they found interesting. This kind of information, when incorporated into the information space itself can be valuable navigation tool see [Dieberger 1997] or [Munro et al. 1999].

Social navigation processes are very common in everyday life. Simple examples are the number of cars parked in front of a restaurant as an indication for its popularity and the length of a waiting line outside a theatre. We often base the choice of a movie or restaurant on friends' recommendations or on articles written by well-known critics. Most people would prefer choosing a dentist on a friends' recommendation, rather than picking a dentist from the phone book. The same is true for buying cars, selecting books and sometimes even meeting people.

Empathy is basic to human thinking. Usually we assume that other human beings, animals, and sometimes even inanimate objects, are intentional creatures with emotions and interesting relationships to others and us. A large part of typical conversations concerns discussing why people have performed certain actions, or what their intentions could be. Some researchers, e.g. [Dunbar 1998] actually claim that social "grooming" and its evolutionary

advantages caused the development of the large human brain and complex language. Also the success of chat rooms and Web bulletin boards shows that people feel a need to interact and to share thoughts and information.

What is interesting for other people is probably of some use to us, especially if these other people are in a community that shares certain interests with us. This reasoning forms the basis for recommender systems, which are a branch of social navigation systems [Resnick & Varian 1997], [Shardanand & Maes 1995]. Furthermore we know that recency of access to information is an excellent predictor for future access [Pitkow 1997], [Pitkow & Pirolli 1997]. It is reasonable to assume that a system that actually shows what information is accessed can improve a group's focus on documents or general interest.

A collaborative Web server

As first example we describe modifications to a collaborative Web server, called Swiki, standing for Squeak-Wiki. Mark Guzdial of the Georgia Institute of Technology has implemented it in Squeak (a free dialect of Smalltalk) based on earlier work by Jim Cunningham (Wiki Wiki server) and influenced by Tim Jones's WebTalk system. What attracted us to the Swiki is that fact that every user can easily modify and extend pages. It thus forms a middle ground between a Web server, a bulletin board and a collaborative writing tool.

To modify a page on the Swiki (or Co-Web, for cooperative Web) a user clicks a link called "Edit this page", which brings up a simple Web form with the content of that page. Pages consist of plain text, but people can use HTML if they like to. The ease with which people can contribute on a Swiki server makes it an ideal tool to support collaborative writing, open discussions etc.

We decided not to password protect the Swiki. One might fear that a completely unprotected server would get easily be abused by hackers. In practice rarely happens on any Swiki, probably because hackers don't perceive a challenge in breaking a Swiki.

The first author modified the Swiki to be a social navigation system. Among the modifications is a different layout of the pages. We also eliminated several Swiki features to further simplify the system. Instead we added functionality to enhance the awareness of the community's activities.

From dead spaces to socially enhanced places

All Swiki servers maintain a list of recently modified pages, but as there are many more consumers than producers this list doesn't give a good indication of the activity of the community [Figure 1]. Our most significant change to the Swiki is a feature that marks every link leading to modified pages. Hand-coded "new" markers appear on many Web sites, but they seldom give a good indication for the newness of the information. Also they are hard to maintain. On the Swiki we show 3 levels of newness. Pages that have been modified within the past 24 hours are pointed out with a different marker than pages that have been modified within the past 3 days or pages changed within the past week. In addition, we point out links that indirectly lead to new or modified pages (2nd level what's new marker) and thus point out paths to new information [Figure 2].

Social navigation information always has to be seen in context. As the system maintains the markers automatically it is guaranteed that the markers are up to date and show correct information, wherever a link is placed. Therefore these markers are visible also in the list of 'recent changes' [Figure 1]. The markers thus provide social navigation information both in a global as well as a local context.

Originally we used more levels of newness for pages that were modified up to 2 weeks ago. We soon discovered that more than three levels don't really add to the system, but are even distracting. We also found that recency information beyond one week was relatively useless in our community. However, each virtual community is different and its level of activity changes over time. Our simple implementation does not take this into account. We plan to implement activity markers that adapt both to the level of activity and the rate of change within a community.

Recent Changes

Figure 1: List of recently modified pages

So far we discussed only functions that show what information is new but those don't give an overview of the general activity in the community. This information is visible in two ways on the Swiki. As a global activity indicator we maintain a list of "recently accessed pages" [Figure 3]. Secondly we use symbols of footprints to point out links leading to pages that have been used within the last 24 hours. These footprints are not a property of the link itself, but of the page the link leads to. This approach is significantly different from the "read wear" markers used in the Juggler system [Dieberger 1997], where you could follow a trail of heavily used links to information. A Swiki footprint instead shows aggregated usage information for pages over all possible paths to that information.

Figure 2: Typical Swiki page

We use 3 levels of footprints. For pages that had no access for over a week we show a little dinosaur. At first the dinosaurs were implemented as a joke, but we soon noticed, that they are an excellent tool to show whether a community has more or less died out or whether certain subjects are of no interest any more. An example of such a situation is shown in [Figure 4].

We found that the footprints and dinosaurs give a pretty accurate feeling for the activity of a virtual community. The reason for pointing out accesses within the past 24 hours is [Pitkow & Pirolli 1997], who found that Web pages that have been accessed within the past 24 hours are likely to be accessed again.

Figure 3: List of Recently accessed pages

The Swiki also has a couple of other features that support social navigation. For very active communities we provide a function that shows the activity within the past 5 minutes. We recently added a Java-based navigation popup, which provides fast access to all links on a page and visualizes both newness and the footprint levels for every link. This tool also uses sound to convey footprint information. As was to be expected, some users find the sonifications very useful, whereas others found it confusing or even annoying.

Figure 4: Inactive Swiki

Like many social navigation tools, our modifications of the Swiki seem to be most useful within a small closely knit group of users, for example a small work group, where people are aware of each other's interests etc. We do not think that the model of the Swiki can or should be used on very large Web sites or even the entire Web. Instead we see the Swiki modifications as a useful enhancement in collaborative Web sites for virtual communities. Examples are Web supported courses or project teams, where there are shared interests and common goals for the use of the information space and where people know each other.

On-line shopping for food

In our second example we look at a larger community, where people are likely to be unknown to each other and where the social aspect is less obvious. One such domain is on-line food shopping. Existing on-line food stores are 'dead' spaces where users simply specify how many milk packages, etc. they want sent to their doorstep. There is no indication of other users and no feeling of a social place like in a physical food store. [Richmond 1996] found that users in virtual store crave the social aspects of a physical store, that they want to socialize with other people and desire a multi-user experience. Shoppers in a Stockholm on-line store frequently travel to the corresponding physical store in order to get a better picture of the items. They also want to get an impression of the store's personnel – probably since this makes the on-line store come alive with imaginary people, so that it is no longer a dead space.

We could approach the design of an online food store using a 'traditional' view of human-computer interaction and ask how to make it easy for users to find the items they need, put them in their shopping basket, and make sure they

get delivered at the right time. We could also approach this design from the aesthetic side or whether the design allows users to be 'effective' etc. While all of these design considerations are highly relevant and should not be taken lightly, they are all based on a one-computer-one-user view of interaction. Food shopping is a very social process. Using social navigation features we try to socially enhance the virtual store.

First of all, we assume that other people are 'around' in the store so we get a lively space where (in some way) the user can see other shoppers moving about, can consult or instruct specialist agents and 'talk to' the personnel of the grocery store. Perhaps more interesting is the question how to accumulate trails of people in the store to visualize community preferences or recommendations. In the context of the food store, recipes can function as accumulated pieces of knowledge. Through our choice of recipes – which in turn influences our shopping list -- we convey a lot about our personality, which culture we belong to, our habits, etc. Making recommendations on which food to buy based on recommending recipes is an interesting functionality in itself. Imagine adding accumulation of user behavior so that we understand which groups are most likely to choose which recipes.

In the online food store currently being designed at SICS a user will get a recommendation for a recipe, based on popular downloaded recipes in the community for category of people the user is in (for example vegetarian). The user can add the recipe to her shopping basket, which in turn adds the ingredients from the recipes to the list of items that will be delivered to their doorstep. The user can ask for the next-best recipes that fits with her category of users – much in the same line as Amazon.com recommendations ("other people who bought this book also bought these books"). The recommended recipe will be chosen on the basis of three different characteristics that the user can manipulate: the group of users that the current user belongs to, the category of food (Italian, Thai, etc.), and any particular ingredient that should be included (shrimps, beef, etc).

The problem with recommendations in general, is that they provide the user with very little insight into who else is in her group why she was placed there. Therefore we decided to put an editor back into the loop. The editor will look at the clusters of users (based on which recipes they have chosen) and label those with fuzzy names that conveys somewhat of their content. Examples of such labels might be vegetarians, light food eaters, spice lovers, etc. The user can then in turn choose to have a look at the recommendations done for another group of users that she does not belong to. This way, she can try out being a vegetarian for a week and get some insight into the inner workings of the recommender system [Höök 1999].

The shopping system will also provide comments (and discussion of recipes), an optional image of the person who contributed the recipe, an image of the dish etc. to provide richer social trails on top of the recipe. Our solution will provide the users with more insight into both the social trails of their own actions as well as other users' actions that have lead to the recommendations they finally get.

Related work

Our work touches only a small facet of the field of social navigation. Despite the name, social navigation is concerned with all forms of decision making based on the behavior and activities of other people, not only on navigation activities. One is tempted to put social navigation into one basket with recommender systems, but this would be an oversimplification. However, recommendation based systems, like Amazon.com's book recommendations and earlier work on recommender systems, for example [Shardanand & Maes 1995] are important aspects of social navigation. Other directly related work is the study of how people perceive spaces and places [Dourish & Chalmers 1994], [Erickson 1993], and Dourish's and Dieberger's chapters in [Munro et al. 1999] or work on visualizing histories, for example [Wexelblat 1998] and the original work on history-enriched information spaces in [Hill & Hollan 1992].

An interesting aspect of indirect social navigation is the aggregation of information. It helps avoiding some of the issues recommender systems struggle with, in particular issues of trust and privacy see Dourish's chapter in [Munro et al. 1999]. Another aspect of social navigation concerns the design of the environments and the difference between virtual space and place. The design of a virtual community can shape opportunities for action and understanding for permissible or frowned upon activities which has obvious impacts on systems like the Swiki and an online shopping mall and again gives context to the activities of the user population -- see Dieberger in [Munro et al. 1999].

Summary

We see a wide range of application of social navigation. They give not only useful information for making decision, but create a sense of community, and belonging which can inspire people to return. Besides social navigation's utility in shopping systems and small, closely knit cooperative communities, showing usage within a community can also be useful in education systems, or any system where certain members of a community might act as trailblazers through information. Instructional systems can show the paths of experts through an information space to guide novices without restricting deviating from an established "path".

We mentioned the importance for context for information. Information on who is accessing information and who isn't can be as important an aspect in navigation as the validity of the information itself. Harper describes an example in [Munro et al. 1999] where an information source was not considered useful, because the 'people who count' didn't use that particular resource.

For the close future we see a host of more socially enabled systems appearing on the Web. We have reached a point where people want to interact in social settings on the Web, where online resources become places instead of being sterile information repositories. Today's systems have reached a level of sophistication where they can be communication tools and interfaces to socially interact with people near and far. Social navigation is an important ingredient for making systems true social places.

Abstract: One of the main difficulties in the area of web based training systems are expensiveness and great efforts that have to be invested in production of good courseware modules. While the problem of creating new pages cannot be solved easily, costs can be reduced by providing efficient methods for reusing already existing material. In this paper we will introduce a concept to collaboratively and adaptively administrate modules that may reside either internally or externally. This idea can also be extended to fully automate the creation of whole courses or information units consisting of a certain structure and dealing with a specific topic.

1. Introduction

A system called GENTLE (GEneral Networked Training and Learning Environment) [Dietinger et al. 1998a] is currently being developed at the Institute for Information Processing and Computer supported new Media which deals with many aspects of web based training. Its main purpose is to provide an integrated platform for students and teachers that offers all functionality that is required for web based training, like communication and collaboration tools, course and user administration, etc. Most of this functionality has already been implemented or is nearing completion. However, we decided not to develop a new authoring application for course modules because there already exist numerous good ones on the market. Our intention is to improve integration of those tools and even more important to provide methods for easy administration and reuse of already existing materials: The creation of high quality courseware is still quite cumbersome and expensive and superfluous work like recreating an already available module should be avoided.

The demand on such a module repository is flexible categorization and thus ease of location of required information and modules, in combination with simple usage. Especially efforts that can only be accomplished by IT and domain experts have to be reduced to an absolutely required minimum and substituted by automatic methods like computerized generation of content description, or incidental tasks that do not bother users. It also has to be considered that not all data may reside within the system, but can also be found externally at a different place or just somewhere on the Internet. This means that the system does not have control of outside modules and thus might not modify or add e.g. meta data. Additionally, external information may be dynamic and change

without notice. Nevertheless, it might be valuable to include this kind of information because of topicality and quality.

Another important feature is personalization: by this we mean that a group of users (or a single user) may have their own view about the meaning of some modules, because the same data can be used differently in various situations: E.g. a chapter about multi media concepts might be introductory or advanced material, depending on the course topic. This can only be accomplished if situation dependent meaning and object oriented properties like title, creation time, author etc. are separated, because the first one can change with the point of view. Adaptive views can also be used to automatically suggest certain modules to authors if they specify a course profile that describes the meaning and aim of the course by e.g. a table of contents etc. The system can achieve this by trying to match the profile. This information about the course can also be used for suggesting suitable courses to students, if students also own a profile about their preferences.

The whole system could not only be used to find appropriate course components but also for retrieving relevant information in more general terms, like a background library for students or within a knowledge management or intranet system to be used by employees. In the following chapters we will examine already existing strategies and present a concept for an adaptive, associative, joint, dynamic and location independent module and information repository.

2. Meta Data Alone are Not Sufficient

The most obvious storage of categorized data is to save it in a data-warehouse with a static hierarchical structure similar to the file system organization of a PC. For example the History of Hypertext and data about HTML are saved in the Hypertext subcategory, which belongs to Hypermedia that is categorized under Computer science. Such inflexible data organization brings many disadvantages. The static keyword categories must be very precisely specified and regularly updated and reorganized, so that categorizing and storing of data can be efficiently supported. Otherwise stored data cannot be found again because they have not been categorized properly. Such a complex structure results in poor performance.

A possible solution to avoid the inflexibility of mentioned hierarchically structured data-warehouse is the usage of metadata. Nowadays, there are many standardization initiatives e.g. Dublin Core, Warwick framework, LTSC, IMS and others, trying to define the metadata structure [Weibel et al. 1998][Daniel et al. 1998][Hodgins & Wason & Duval 1998]. The standardization efforts are coming from different backgrounds e.g. technology suppliers, aviation industry, learning technology users, etc.. Because all of the different initiatives are aware of the great importance of the metadata for categorization, structuring of knowledge and finding relevant information, they try to be compliant within reasonable boundaries of other initiatives.

One of the definitions still being discussed within IEEE Learning Technology Standardization Committee (LTSC) is that Metadata are data about data, meaning that metadata are providing us with information about certain objects e.g. documents. This additional information about the objects can be information about the author of the object, language used, date of creation, topic, key words, possible use of the object, conditions for use, etc. We can add supplementary attributes that explain e.g. different possibilities to use the object, pedagogical values or other categories like learning style, learning level and prerequisites, which are relevant for re-use of the objects within the learning environment. Thus, metadata can be seen as a feature that facilitates finding of specific requested information (text documents, pictures, video clips, course units, etc.).

Metadata compared to the first solution mentioned in this chapter introduces tremendous improvements for the categorization and knowledge management process but there are still some problems left regarding the gathering of relevant, reliable and up-to-date information. In the categorization process different key words are assigned to the object. Exactly which key words provide the most appropriate description of the *content* or *meaning* of the object is the decision of the person, creating the metadata. This leaves the difficulty of finding the required object to the user, because it may be described in a different way than expected. The fact that equal key words have different meaning within different contexts is also causing some problems for users, who want to find a specific object. A possible way for useful and sufficient metadata can be probably achieved by combining human knowledge and technology. The disadvantage of metadata being rigidly coupled with the object can be avoided.

Grouping of metadata offers a solution to that problem. Grouping of metadata means that metadata which describe physical appearance of the object stay coupled with it. Other metadata which describe some more general concepts e.g. topic, category, key words can be transformed into separate objects. Those meta-objects exist independently and can be linked to many different objects. Meta-objects can be shared within many objects and relations can be defined between meta-objects themselves. One possible implementation of this concept is described in the next chapter.

3. The Concept of Knowledge Clusters

A cluster usually describes a collection of objects that are relatively close to each other according to a chosen criterion. Cluster analysis is used for grouping similar, related objects. One possible application of clustering algorithms is document retrieval. In a dynamic environment content changes are made also in the content indicators attached to the documents. In such cases clustered file organization is preferable because similar sets of content identifiers are automatically grouped into common classes or clusters. The search is performed looking only at those clusters that exhibit close similarity with the corresponding query identifiers. A clustered file produces fast search output.

In real life, concepts are never isolated nor very simple, so clusters may overlap allowing that data, documents or part of documents (e.g. sections) belong to more than one cluster. To get better results we can use conceptual clustering. The difference between conventional and conceptual clustering is that in conceptual clustering the entities are grouped based on a conceptual cohesiveness (e.g. set of neighboring examples) [Michalski & Bratko & Kubat 1998]. Unlike statistical clustering methods, these algorithms rely on a search for objects within same or similar concepts. As an example of conceptual clustering we can use the term *virus*. If we search for *virus* we can get as a result different documents which describe the topic in computer science or documents which deal with viruses in medicine. Using the conceptual clustering, those documents are put into different clusters because they belong to different concepts.

What we need to accomplish is a network of meta data, where each meta data object correlates on one hand with the information it describes (meta data and data may also physically be the same object) and on the other hand with other instances of meta data. We suggest to use pure meta data (without a document content), so called base terms, which are related to other base terms to describe main concepts and thus work as a seed for new clusters. To improve effectiveness and versatility relations themselves should also contain some meta data: A *type* that specifies what kind of relation exists between two nodes (e.g. sub- and super-concept, cause or result, opposite or synonym, prerequisite, introductory, etc.), a *weight value* that specifies to what degree this type applies to that relation (e.g. fuzzy values like perfect, good, average, bad etc. expressed by a certain percentage) and a *quality value* that specifies the reliability of the connection (also percentage). In this way users can give feedback about the correctness of the relation during browsing and searching of the cluster and thus influence weight and reliability of the relation. This has the advantage that a new relation need not be completely correct right from the beginning, but can converge to a commonly accepted status by collaborative voting. Thus it is not important any more whether the creator of the relation is completely trustworthy or not, it just influences the starting reliability value. That means that not all connections have to be created by domain experts but can also be created by other e.g. novice users or algorithms. If we combine these relation attributes with access rights like private, group and public access and ownership even different points of view of concepts are manageable because relations can be seen differently by different users.

Similar approaches of sharing ideas and opinions within the society and building the contacts between people who have related interests, opinions, is described in Automated Collaborative Filtering (ACF) and Semantic Transports of information [Chislenko 1997a][Chislenko 1997b]. The semantic transport of information can be seen as a social tool, overcoming the side effects of the present-day individual isolation. Implementations of some fragments of these ideas can be also found in Recommender Systems [Resnik & Varian 1997] such as Alexa (<http://www.alex.com>) and Phoaks (<http://www.phoaks.com/>) or in new generations of search engines like Google (<http://www.google.com>).

Figure 1: Examples for relation meta data

To avoid a possible confusion we would like to define what we understand by using the term *knowledge cluster*: The combination of a knowledge broker point (KBP), expert knowledge and collaborative community system as well as the automatic processing modules can be seen as a *knowledge cluster*. The task of knowledge broker points is managing static and dynamic knowledge sources within the learning environment. An automatic process module e.g. a knowledge cluster can help to categorize information entities, to position them as new pieces of knowledge in the system, and to store and to find them when necessary.

3.1 Creation of Knowledge Clusters and Addition of Documents

Typically, the creation of new knowledge clusters will be started by defining a skeleton of related base terms describing a certain knowledge area by domain experts. As all relations created by trusted experts get assigned a maximum reliability value, the quality of the network is more important than its extent and number of nodes. Additionally depending relations like "A is an introduction to B" and "B is an introduction to C" can dynamically be calculated by multiplying its weight and quality values and need not be created manually [see Figure 2].

Figure 2: Determining the total weight

However, if in special cases dynamic relations do not result in meaningful values from some point of view, they can be shortened by static relations which have higher priority than the calculated ones but e.g. might not be seen by everybody, because access rights for these relations are restricted [see Figure 3].

Figure 3: Modified shortest path rule

In this context we speak about a modified shortest path rule because here the shortest path is the one with fewest relations and not with the smallest edge length. It should be noted that in some instances the calculation of two paths of the same length (equals the number of relations between nodes) and same starting and ending node can lead to different results. However, this is absolutely correct because different paths also mean different contexts or conclusions [see Figure 4]!

Figure 4 : Context dependant paths

New base terms, meta data (including information content such as documents and course modules, or pointers to data like references) and also relations between new base terms and meta data cannot only be created by experts but also by ordinary users or even algorithms like user profiling, content analyzer, etc. The quality of these relations then depends on the status of the user. E.g. an anonymous user or a not too trustworthy algorithm only leads to quality values that are starting quite low, whereas identified users who have gained a certain expertise within the specific knowledge area may create more promising relations.

Whenever users browse or access a knowledge cluster they should have a possibility to provide feedback whether the visited relation proved helpful and they thus found what they were looking for or whether the relations had been misleading. Such a feedback could be given just by clicking on a plus or minus sign, indicating approval or rejection, or by a more complex form where the user has the possibility to suggest a different type, weight and quality values. The feedback can also be provided by a profiling algorithm that just analyzes behaviors of users. For examples, users starting all over again with a search after following a lot of relations express with this behavior that they did not find what they had been looking for and thus that these relations in their context had not been very helpful for them. In each case, the influence of the feedback on the attributes of the relation again depends on the trustworthiness of the user or algorithm which provides the feedback. Identified users can gain higher trustworthiness in a certain knowledge area if relations and objects they created for this area get higher ranking through feedback. The effect of this concept is that the whole cluster as well as quality values of contributing users and algorithms converge into a commonly accepted status. This means that newly created relations need not be perfect right from the beginning but are 'polished' on usage. In this way, also the effectiveness of an algorithm which automatically creates new structures only has an influence on the duration as long as the resulting relations evolve to a high quality network influenced by users.

3.2 Searching and Browsing Within Knowledge Clusters

Access to a knowledge cluster starts by defining an entry point to the data structure. This can either be a common root term or more likely a traditional keyword query on the meta data stored within the base terms and relations. The list of search results can be linearly sorted by priority or even better displayed as several clusters or clouds of documents and relations that indicate which terms belong together and what are their neighboring nodes. From now on users may browse through the clusters by putting the focus on a selected term or altering the *filter* values. The filter specifies how many and which adjacent nodes and documents will be displayed and thus form a new cluster. We have the following possible filter values: type of relations (e.g. introductory), threshold values for weight and quality, number of relations displayed, visibility expressed by maximum length of path that is dynamically calculated and of course also document meta data like mimetype, creation time, author, e.g. Dublin Core attributes etc. The filter can also be used for the very first display of search results. As mentioned before users can give feedback to the displayed relations or add new ones during the browsing process.

Another interesting feature is the so-called *rucksack* which is used to store documents for later reuse or may be used to execute more complex filtering by combining items collected in the rucksack as additional filter criterions such as 'all items displayed in the neighborhood have to be a sub concept of rucksack item X and an introduction to rucksack item Y' etc. An intelligent rucksack could also log or analyze the behavior of users and define a certain task and user specific profile which can be used to foresee the next action and suggest suitable filter settings and items. Certain rucksacks or more generally speaking agents can also be reconfigured for a specific task like chapter creation (e.g. a chapter consists of an introduction, a main part and a summary) or even the creation of new clusters.

4. The Prototype

The prototype, like the rest of the WBT system is based on the Hyperwave Information Server (<http://www.hyperwave.com>). In fact the concept and features of Hyperwave proved to be very helpful for this special demand, since it supports an object-oriented approach for storing documents and hyperlinks (so-called anchors). All objects within the database, including anchors, may store arbitrary attributes like keywords, owner, access rights etc.. This provides the possibility to use anchors for creating our specialized relations, because the required meta data such as type, weight and quality can be stored within the object. Further anchor-object relations are bi-directional, which means an application can find out which links are pointing to an object and which are pointing from this object to a different one which is also an important requirement. Hyperwave objects without content (like a Remote Object) have been used to implement base terms or external meta data that just have pointers to their accompanying documents. Personalization has been easily added by using access rights which are also applicable to anchors and which are used to specify which user(s) may see a relation.

Currently our prototype supports the creation of base term skeletons, adding of documents and personalized relations and simple querying and filtering during cluster browsing. Collaborative voting and the rucksack feature will be added soon. Thus the prototype can be used for jointly administrating a module repository or a reference and background library. Another simple application for the prototype would be shared bookmark archives, which might be helpful when doing task oriented teamwork like student exercises etc..

5. Conclusion and Future Work

As we have seen the concept of applying attributes to relations that interlink meta data provides a possibility to add additional meaning to course material which is a basic prerequisite for further automatic processing. Combined with situation and user dependent views and collaborative rating techniques it can be used as a fundamental model not only for managing courseware repositories and background libraries but also for administrating all kinds of related data. One of the next steps will be to examine the usefulness of this concept for adaptive tutoring which could be realized by courses that are generated on the fly and depending on users preferences. Future work will also include the integration of our ideas about dynamic background libraries and intelligent knowledge gathering [Dietinger et al. 1998b][Dietinger et al. 1999] to expand the model to a generalized and distributed concept.

CoFIND- an Experiment in N-dimensional Collaborative Filtering

Jon Dron, Richard Mitchell, Phil Siviter, Chris Boyne
Faculty of IT, University of Brighton, UK
E-mail: jon.dron@brighton.ac.uk

Abstract: This paper reports on the development of CoFIND, a web-based n-dimensional collaborative filtering system that seeks to guide learners to relevant resources based upon not only the content of the resources but the qualities exhibited by those resources that make them useful learning material. Qualities provide the n-dimensions of this collaborative filter. Qualities and resources are generated collaboratively by the users of the system. CoFIND is designed to allow evolution to occur, which is discussed in the context of Darwinian theory and includes reference to current theories relating to the development of complex systems. The paper goes on to describe the implementation of the system and the results of an early pilot experiment involving a group of 42 students. It is concluded that, despite encouraging early results, some further work is needed to develop an effective interface and to embody the kind of complex interactions needed to generate spontaneous evolution.

Introduction

As any web-aware teacher will know, there are many excellent, freely available resources for teachers and students on the World Wide Web, such as individual web pages, whole web sites, mailing lists and newsgroups. The biggest difficulty we face in using them lies in finding good resources and, having found them, identifying whether or not they are useful in a given context for a given learner. A teacher's eye view will be different from that of a student, but each student will differ from the next in content requirements and preferred learning style. Although there may be some common measures of excellence, there are few ways to measure the relevance of a given resource to given learner. Of the available options, the methods we use can be broadly split into two main categories:

1. Appeals to authority
2. Collaborative filters

Appeals to Authority

Appeals to authority are an effective way of finding resources for learners. Recommended texts provided by teachers and references in papers can help to filter the useful from the unhelpful, as can the recommendations of friends and colleagues. The Internet extends this concept through the use of such technologies as newsgroups, email, mailing lists and IRC to provide direct recommendations. More structured variations on the theme include hierarchical directories such as Yahoo (Yahoo, 1999), which provide vetted links provided by human beings. Combined with a search engine to narrow down the returned results, this is a powerful way of getting hold of good quality and potentially relevant resources. Similarly, the opportunities to review books provided by sites such as Amazon (Amazon, 1999) allow us to share our experiences with others. Another worthwhile technology is the PICS (Platform for Internet Content Selection) system (Resnick, 1997) which allows documents to be labelled and described in a standard manner. If we trust the labellers this can work very well, although it relies on a high uptake of the system- unlabelled documents are filtered out.

The disadvantage of all such systems for prospective learners lies in our diverse learning styles. There is no such thing as a perfect learning resource for all learners. Even if we can find reliable resources in the right subject area, there is no guarantee that they will help us to learn effectively. We learn in different ways.

Collaborative Filters

An Automated Collaborative Filter (ACF) allows us to overcome the problems of differences in viewpoint and needs by automatically identifying commonalities between users of a system and providing suggestions for resources that are closely matched to needs. Based on the assumption that if you and I like the same 100 resources then we are probably going to feel similarly about the 101st, the seminal Firefly and many other collaborative filtering systems (e.g. Amazon, PHOAKS, GroupLens) are immensely effective ways of identifying resources that we will probably like or enjoy.

N-dimensional Filtering

An ACF is superb for such areas as book and movie recommendations, but starts to founder when we seek novel resources. By its nature, learning is to do with bringing about changes in the learner. It follows that matching our previous likes and wishes may not always provide us with the most suitable resources for our current learning needs. As my past list of preferences for learning resources includes many works relating to English Literary Culture, it is relatively unlikely that my current need for resources relating to Network Management will be adequately met. Given divergent needs, different learners' paths may branch too dramatically for existing ACF systems to provide much more than an approximate match to their requirements.

N-dimensional collaborative filtering seeks to build on the power of ACFs by introducing further explicit dimensions of value beyond like/dislike or good/bad into our assessment of resources. These dimensions are exhibited as the qualities of resources that make them useful to us. For instance, the qualities of learning resources for English Literary Culture might include 'comprehensive', 'good for beginners', 'amusing', 'formal' or any number of other descriptive terms that would be equally suitable as ways of describing resources relating to Network Management. In essence, a quality is something that a learner values about a resource.

CoFIND (Collaborative Filtering In N Dimensions)

CoFIND is a web-based n-dimensional filtering system that we are developing for collaboratively creating databases of URLs pointing to learning resources. It is intended to be maintained and created by the learners who use it. Although a teacher is not necessarily excluded, the system is designed to require no teacher-intervention. Resources that have been found to be valuable in the learning process are entered onto the system by the learners themselves. Qualities are also created by the learners, as selection of qualities is too important to be left up to the 'experts'.

When entering resources, we encourage users to also enter qualities that they find useful in those resources. We then encourage all users of the system to vote for how well those qualities match not only these but also the other resources in the resource-base. Resources may thus be rated according to how well they match the collaborative sum of learners' opinions of different qualities.

Evolving a Solution

If references to resources and qualities were allowed grow unconstrained, the system would soon become clogged with less-than-useful detritus. Therefore, CoFIND has been designed to let appropriate qualities 'evolve', allowing more-used qualities to thrive at the expense of the less-used, a process which in turn affects the 'success' of the resources themselves. This mechanism for evolution is provided by a combination of ordering (more popular qualities are presented first, so are selected more often and thus thrive more easily) and planned retirement. After a configurable number of days unused, qualities are humanely 'retired'. It is still possible for retired qualities to be voted for and thus to reappear on the list, but it is made significantly more difficult for this to happen than for those that are commonly selected.

A similar fate awaits resources that receive few votes for any quality- resources naturally drop to the bottom of the list as a result of vote-starvation. However, even popular resources do not stay consistently at the head of the list, as not all qualities will apply to every resource. By providing many qualities for learners to seek we are creating multiple dimensions, allowing us to cater for many different learning needs and styles. A variegated evolutionary landscape develops where speciation can occur and there are many evolutionary niches to be filled.

Evolution

CoFIND has been designed to be self-sustaining, driven by the activities of its users. It should provide an evolutionary landscape where adaptation of qualities can occur and where there is little or no need for sky-hooks (Dennett 96) or an external agency of change. We wish it to be learner, not teacher-driven.

William H. Calvin sums up the requirements for evolution to occur as “a pattern that copies with occasional variation, where populations of the variants compete for a limited workspace, biased by a multifaceted environment, and with the next round of variations preferentially done from the more successful of the current generation” (Calvin, 1997).

Within CoFIND, qualities thrive according to the numbers of votes cast. Successful qualities get votes and survive, less successful qualities fade away. Variation occurs by users identifying qualities imperfect for their needs then choosing semantically similar or (in an analogue to gross mutation) dissimilar words or phrases which, if successful, will oust their predecessors as descriptions of what is valuable in a resource. This can meaningfully be called reproduction on the grounds that ideas will spark other related/similar ideas and words will suggest other words, a way of thinking not unrelated to memetics. Even if this is hard to accept, the fact that semantically similar qualities exist at all should result in variation and competition. There is a potential for many ecological niches or fitness peaks, which may be more or less successful, but within a range of semantically similar qualities it is likely that few will survive. For instance, if the qualities 'good for beginners' and 'simple' are semantically close then the quality that is more widely used will render the other extinct. If they are sufficiently distinct and both of some use then both can survive as they will occupy different evolutionary niches. We achieve a multifaceted environment through the many shifting requirements of the learners using the system.

Each CoFIND instance is isolated from others. Different instances of the system are installed for different subject areas and purposes. As Calvin notes, “Parcellation (as when rising sea level converts the hilltops of one large island into an archipelago of small islands) typically speeds evolution” (Calvin, 1997). However, we have found it useful to be able to transfer an existing population of resources and qualities to a new context (again, reflecting what happens when islands are separated from mainlands).

Care has been taken to ensure that change is neither too slow nor too fast. Kauffman has observed that evolution happens best at the edge of chaos (Kauffman 1995). If the evolutionary landscape is too ordered (a ‘Stalinist regime’) then a stagnant stability is reached and interesting change does not occur. If it is too chaotic, no high peaks of fitness are ever reached and the system slips into a state of flux. Kauffman calls this the ‘Red Queen regime’, where we are always having to run to stay in the same place. Several methods implemented in CoFIND help to prevent this fall into chaos. For instance, we make it easy to vote for qualities that have been selected but hard to vote for those that have not; it is deliberately difficult to add new qualities or resuscitate retired ones; even the way that resources are displayed (slowly, five at a time) is designed to limit rapid change. Together, these mechanisms create a kind of stickiness- success breeds more success and it is fairly difficult for new species of qualities to usurp the existing dominant values. However, the system remains dynamic through the constant input of new resources and qualities, so that there is little danger of too much stability or order setting in. Getting this tuned to the right level of dynamism remains the subject of ongoing research.

A Brief Description of the System

CoFIND is written using Microsoft’s Active Server Pages running under IIS on Windows NT, and uses a Microsoft Access database as its back end. To cope with a potentially large number of resources it is searchable. It uses a basic pattern matching search engine that looks through the descriptions and comments that users have posted about resources.

Upon logging in to the CoFIND system, a user is presented with a screen providing a selection of qualities (by which the returned resources will be ranked) and a simple search field. The qualities are listed in order of frequency of use- those that have been voted for most appear at the top. There is no requirement to enter any quality nor any search term, but unless one or both are entered the result is an unordered list of all resources in the resource-base.

Upon clicking a button to perform the query a user is presented with a list of resources, five at a time, ranked according to the sum of votes for preferred qualities and matching whatever search terms were entered. Only preferred qualities are shown, with a small bar-graph against each quality indicating the number of votes already cast. A hyperlink will take the user to a given resource, displayed in a separate browser window so that CoFIND remains available. Hyperlinks also provide a mechanism to vote for resource/quality combinations.

Users can quite easily add resources on a form that also provides a means to reinstate retired qualities. It is

possible to add comments to existing resources, providing a mechanism for effective use of appeals to authority as well as ACF.

For a given link, a detailed page may be selected listing comments and giving a detailed breakdown of who has voted for a particular resource as well as its overall profile of votes for all qualities. The page also gives further information indicating the pattern of votes for the resource and specific information on each individual vote cast.

An Example Use of the System

CoFIND has been deployed in a number of environments so far. Users of the system range from an international group of teachers and trainers of Object Oriented languages to final year students of network management and a group of lecturers with a shared interest in learning technologies. Further uses of the system are planned for the near future, including application to the needs of language students.

The results presented here come mainly from a short self-contained assignment for to a group of forty two postgraduate students who were required to design network, a task that would require significant research to complete. The students had participated in a pilot trial of the system for one week prior to the start of the assignment. CoFIND was provided as a database of resources relating to the assignment, and students were offered up to five percent of their marks for their contributions to it, whether adding resources or commenting on existing resources. They were also asked to use the database to submit the URLs of their finished reports.

We had primed the system with three relevant resources and seven qualities ('interesting', 'useful', 'reliable', 'informative', 'a good gateway to further resources', 'of broad coverage', 'accessible') that had arisen in the earlier trial session. Throughout the experiment, conscious of the need to avoid behaving as a skyhook we did not make further contributions, despite strong temptation. We see the starting state of the database as simply part of the shape of the evolutionary landscape. We are interested in the dynamics of the system, what happens next rather than how it came to be.

Some Results

The system was very popular- comments along the lines of 'we should have had something like this for the entire course' were common. The main appeal to students was that it was a searchable collaborative resource database- a shared space for storing useful URLs and associated comments. From a user perspective, CoFIND is only a little different from a traditional search engine and indeed some students added qualities that made it behave that way- for instance 'about firewalls'.

Thirty-six out of the forty-two students discovered over seventy relevant resources over the two week assignment with a range and quality far surpassing the authors' attempts spanning several years to build a similar list of links. All the remaining students made comments on existing resources, indicating that they had spent some time looking at them.

Although the system is designed explicitly for resources that can be specified with a URL, it proved flexible enough for one of the students to use it to recommend a book- the ensuing votes and comments showed that this was a very successful choice.

Growth of qualities was generally restrained. Only a few new qualities were added to the original seeding values until the final hand-in day, at which point a Cambic explosion of qualities occurred, mainly along the lines of "Brilliant!", "Top !" and "Spot on", all applied to the students' own work. Until that point we had suspected that the students had not grasped the mechanics of adding qualities and that we had made the process too obscure, but this showed otherwise. With sufficient motivation, qualities were rapidly added.

Early questioning suggests that students may not have added new qualities because the existing ones mostly suited their needs and they were avoiding unnecessary effort. Similarly, voting was not as common as we had expected- the process was apparently too tedious and went virtually unrewarded.

Although we adjusted the interface following feedback from the pilot trial, difficulties understanding how to vote may still have influenced the results. A similar issue was that the students were at first unsure of the difference between quality-selection and inputting search terms. One student made the comment that a resource was 'good for beginners' without voting for the quality 'good for beginners'. There are clearly some user interface issues to be resolved.

Some qualities were a lot more successful than others, with the most popular qualities gaining nearly three times as many votes as the least popular, when measured over an equal period. We believe that such qualities provide a clue as to what students really want out of their learning resources, but this is as yet not fully proven. Qualities that started successfully remained successful.

To simplify the voting process we have only provided a mechanism to allow users to agree that a resource exhibits a certain quality, not to disagree. Some students questioned this and in one of the other instances of CoFIND this has even led to the appearance of negative qualities- e.g. 'not available'.

Evidence for Evolution

Useful Qualities

Qualities rose up the list relative to other qualities. For example, the quality 'brilliant!' was initially created as a quality of one group of students' report, one day from the end of the assignment. It was immediately taken up by all the other groups as they handed their work in on the final day (clearly a successful quality when applied to students' work), and within a day of entry was being applied to other resources and appeared half way up the list.

Competing Qualities

We have as yet gleaned no evidence of a discernible effect of votes for one quality affecting votes for any other. However, the relatively short duration of this experiment and relatively small number of qualities only allows us to represent the coarsest of trends. It is hoped that we might be able to determine longer-term interactions in other experiments taking place over the next few months.

Self-sustainability

We have to ensure that participation takes place, as without it we cannot see the growth and variation required to make the system self-sustaining. Although participation was strongly encouraged in this experiment by the allocation of marks, aspects of the system which were not marked (e.g. voting) were not as widely used as we would have hoped for, partly as a result of user interface issues already mentioned. We are still seeking ways to make voting a natural consequence of using the system, either transparently or by providing an incentive to participate. For example, An ACF such as Firefly cannot recommend films unless it can identify patterns of likes and dislikes. Thus user-input is essential to use the system in the first place, but we do not have that advantage. If nothing else, voting should be simple and fast. We had hoped to leave part of the system in a small frame whenever an URL was selected, allowing the user to vote for the resource in front of them without seriously interrupting their work. However, the security model of scripting languages in browsers made this an untenable solution.

We are investigating a further enhancement to the design to allow a more volatile shift in qualities. At the moment, a quality's list-position is based solely on how many votes it has been given. An option that may be implemented in the next iteration of the tool is to make selection of qualities from the search screen feed back into the position of the qualities in the list. An advantage of this would be that no active participation in the voting process would be required, merely selection of qualities.

Other Problems

We have not given users the ability to change details after a resource has been posted, mainly because it would be too easy to cheat- for instance, a user could amass votes for a known popular site and then redirect it to their own home page. However, this makes it very difficult to deal with resources whose URLs change. No simple solution to this has yet occurred to us, with the existing mechanism requiring an email message to the administrator.

The current system for ordering resources is based on a simple count of votes for selected qualities, accompanied by a bar-graph display of those votes. This could become unwieldy as more votes are generated. We have looked into the possibilities of scaling votes, either by percentages or amalgamation, but we have yet to reach a sufficient number of votes for the issues to come to a head.

Conclusions

This is the first working iteration of our tools. We have designed an environment to allow evolution to occur but as yet we are only seeing fairly coarse changes and little evidence of complex relationships developing. In addition, further work is clearly needed on the HCI aspects of the system, particularly as it relates to managing and motivating interactions and ensuring that a sufficient range of qualities is generated. Possible avenues include providing 'rewards' (such as a mention for successful resource providers on the front page), a reduction in the number of steps and pages needed to add to the system and vote, and the explicit positioning of CoFIND as a useful bookmark repository for individuals and groups. This latter mechanism may allow selfish motives to drive the growth of the system.

However, in many ways (particularly from the point of view of our students) our early experiments are a success. Not only do the learners collaboratively generate a useful database of resources, but more valuably we are coming to know what it is that those learners desire in a resource, through the evolving sets of qualities that they seek. As providers of resources, this in turn means that we can start tuning our resources more effectively to the needs of our students, and concentrating on more relevant areas. We have laid the foundations of a self-sustaining feedback system that could result in ongoing improvements to the online resources we provide as well as putting the selection of learning resources firmly into the hands of the learners.

Virtual High School

"I want everyone to know that this year has been the best professional development year for me in 27 years of teaching. I not only feel part of a new wave of education but I feel that I have re-fallen in love with my subject - biology." -- Richard Clevenstine, VHS teacher, Ridley High School, Folsom, PA

"Virtual High School is of special interest to us because it gives our Deaf students the opportunity to participate in classes with hearing students and teachers on a fairly equal basis without the need for interpreters. Students agreed that using the computer communication in VHS allowed them to feel comfortable interacting with the hearing students in their class." Joyce Barrett, VHS site coordinator, Model Secondary School for the Deaf, Washington DC

Abstract:

I. The Virtual High School Cooperative

The Virtual High School is an extraordinary project that is having a positive impact on thousands of high school students and hundreds of educators in schools across America. Like other Technology Innovation Challenge Grants, VHS is using the best of educational technologies to give students and teachers access to resources, curriculum, and training of the highest quality, and to prepare educators and learners to be skilled and confident participants in an increasingly technological world. Like other Technology Innovation Challenge Grants, VHS is bringing these benefits to more than just a select group of participants: VHS students and teachers represent a spectrum of different ages, ethnicities, backgrounds, learning abilities, and educational experiences. Similar to other Technology Innovation Challenge Grants, the effect VHS is having on education reaches far beyond the thousands of participants involved in the project. Teachers who have had access to the VHS professional development course find that they are bringing new technology skills, new teaching strategies, and a revitalized enthusiasm for teaching back into their local classrooms, thus passing the benefits of their experience on to countless additional students and colleagues. Students who have taken a VHS course find that the experience has helped them become independent learners and capable technology users, and they pass these skills on via daily interactions with peers, family members, and even teachers. High schools, communities, and entire states have found that the success of VHS has generated strong partnerships between corporate and educational entities, as well as support for additional technology and educational initiatives within their regions. VHS has become a model for similar programs across the country and around the world. In this testimonial, you will read about the simple yet powerful VHS model, and hear from VHS participants who talk about the far-reaching ways in which VHS has touched their lives.

What is VHS?

The Virtual High School (<http://vhs.concord.org>) is a cooperative of over 125 high schools across the U.S. that offers netcourses taught by teachers for students in the cooperative. Each school contributes teachers who, with the help of teacher mentors, instructional technology experts, university faculty, and businesses, design and offer innovative courses over the Internet. Each school in the cooperative can enroll 20 students in these netcourses for each section of a teacher's time it contributes to the pool. [This allows schools to offer a range of courses usually found only in large high schools.] Quality is maintained by requiring each virtual teacher to successfully complete a graduate-level professional development netcourse on the design and development of network-based courses. At the halfway point in its five-year grant, the VHS project is now turning from concept development to large-scale implementation.

This academic year, there are over 100 schools in the project offering 105 courses to approximately 2,000 students. In addition, over 90 new teachers from as many schools who are completing a yearlong professional development program will offer their first courses in the 2000-2001 academic year. Thus, next year, we expect over 200 courses to be offered serving 4,000 students from at least 200 schools nationwide.

VHS Course Design

VHS courses are either one-semester or full year courses, based on an asynchronous, scheduled model structured around online discussion groups. Due to its asynchronous nature, students can access the network anytime at school or at home to read assignments, participate in discussions, and submit completed work. At the same time, courses are carefully scheduled with all the students in a course participating in the same activities and thinking about the same issues. Teachers are trained in structuring and moderating these online discussions. Without this emphasis, online courses can become conversations between individual students and the teacher thereby generating an overwhelming volume of posts. This maximizes the value of the online discussions and helps ensure that students can learn from each other and construct their own understandings. This is not only good pedagogy, but it is essential to making a manageable load for the teacher.

Most VHS courses follow a weekly rhythm that includes a major topic, assigned activities, online discussions, and student contributions. Activities have, for instance, included readings, lab experiments, music composition, critiquing a video, locating Web resources, and taking a poll. A master schedule for each course dictates these events and expectations in detail, to help ensure that all participating students are able to make meaningful contributions to the class.

Student evaluation is entirely up to the teacher who delivers each course. As part of their professional development, the VHS project helps teachers develop "alternative" evaluation strategies that foster online contributions, collaboration, and student creativity. The project insists that the evaluation methods and criteria be clearly stated as part of each course description.

VHS Courses

With over 200 courses in the current catalog, it is difficult to grasp the range of VHS courses offered. VHS courses are open to students in grades nine through twelve and address specialized content not typically available in most high schools. One powerful motivation for teachers to participate in the project is the opportunity to offer a specialized or advanced course for which there would never be sufficient enrollment in the high school. As a result, the project attracts and encourages some unusual courses. The following sampling of course titles gives a flavor of the resulting range of courses offered. This list

represents only 12 of the courses in the 1999-2000 catalog. All the course descriptions can be found online at <http://vhs.concord.org>.

101 Ways to Write a Short Story
A Shakespeare Who-Dun-It
American Music Heritage - Song and Society
AP Statistics
Biology II -- A Second Year Course
Business in the 21st Century
Calculus for Business
Career Awareness for the New Millennium
Chemistry II
Computer Graphics on the Internet
Eastern and Western Thought - A Comparison
Employability Skills

VHS Costs and Sustainability

Participation in VHS does not alter the basic teaching cost structure of a school. One or more teachers are assigned to a virtual course instead of a "real" one. Because the students enrolled in the virtual courses are outside the school district, this re-assignment reduces the number of students in the district who are taught by district staff. Assuming an average class size of 20, this loss is exactly compensated by the 20 students for each section contributed who are allowed to register in VHS courses. The net result is no change in the number of sections offered and students taught. This "zero sum" feature of the VHS has three important consequences:

Easy expansion. Each school can tailor its level of involvement to its own needs. A school that wants more students enrolled in VHS simply has to offer more sections to the cooperative. Because this decision has no cost impact on other schools, the project as a whole can easily expand to fill whatever need is generated.

Decentralization. Most virtual course projects are highly centralized, offering new courses from a distant center. This model is difficult to finance, reduces the autonomy of the recipient, and threatens school faculty. The VHS model because it is highly decentralized, avoids all these problems. One of the strengths of this national program is that it leaves control in the hands of states, schools, and local teachers and administrators.

Union acceptance. The VHS, on the other hand, has strong union support because it does not alter employment levels and does offer teachers professional development and new employment options.

Participating in the VHS, however, does entail costs. Of course, computers and network access are required. Surprisingly, this is not a major problem for most high schools, since student access to just a few computers can be spread out over time. The major costs to schools are the time required for online professional development and the local site coordinator functions. In addition, the project generates central costs for project coordination, student registration, technical support, server support, and evaluation. One of the major issues being addressed by the project is what these costs are, how they can be minimized, and whether they can be sustained.

It is reasonable to assume that VHS site management will become routine, that the technology will improve, and teacher professional development will require less time. When this happens, the VHS model will be easily and economically duplicated. Rather than simply growing the original VHS, we anticipate that there will be numerous virtual high school cooperatives. Any large district could establish one. Some might be organized around content or language. It is conceivable that highly specialized virtual high schools would be created. If all the virtual high schools adhere to the same quality standards, there can be cross-enrollments between them, increasing the range of courses and student diversity. Small high schools could become more attractive since they are no longer restricted in the courses they offer. It is even possible that the good pedagogy demanded by world-class virtual courses will spread throughout high schools.

“How are we doing?” - VHS Evaluation Efforts

More than two and a half years, three and a half semesters, and dozens of courses into the VHS project, VHS participants have gained unparalleled insight into the many factors that make up a *quality* high school netcourse. In this last year, the project has focussed on the quality of course design and delivery, with the appointment of a national standards board that has established quality standards for netcourses. This board, the NetCourse Evaluation Board, or NCEB, has synthesized the enormous expertise of university-level distance learning experts, state department of education (DoE) curriculum experts, as well as VHS teachers, trainers, administrators, and students, to create a set of netcourse standards by which all VHS courses will be reviewed. In addition, the project will appoint independent “department chairs” (content experts) who will periodically check on the progress of 5-10 netcourses for which they are responsible. The VHS netcourse standards will be adopted not only by VHS, but also by other groups who wish to develop and evaluate high-quality netcourses based on a proven national model.

II. Virtual High School Participants

The best way to begin to understand the enormous impact that VHS is having on American education is to let the VHS participants – students, teachers, site coordinators, and high school administrators – speak for themselves. VHS and all the Challenge Grant projects are designed to serve these students and educators, and they are the people who make these projects truly powerful. In the testimonies that follow, VHS participants explain the impact that the project has had on their lives. They are from different backgrounds and all walks of life. They range from 9th graders to teachers with 30 years’ experience. They come from at least eighteen different states and 120 high schools across the country. They live in large urban cities and rural farming communities. What these participants’ testimonies have in common is that they point to positive outcomes far greater than the designers of the project ever could have imagined. VHS students talk about the confidence they have gained not only in course subject matter, but also in taking responsibility for their own learning, and using technology and the Internet for real-world applications. Students and teachers talk about the empowerment that comes from gaining access to technology resources, hundreds of courses, and a national community of peers they’d otherwise never have access to.

Teachers talk about the shift to more encompassing teaching strategies that comes from having students of varying ages, backgrounds, and learning abilities together in one class, and about the way perspectives broaden for students who have the opportunity to learn with kids from different parts of the country. All of these lessons and skills will be invaluable to teachers and students as they move into the increasingly more technological and connected world of the 21st century. The following testimonies are grouped into several broad categories that describe the benefits of VHS and the Technology Innovation Challenge Grant program as a whole.

VHS expands horizons and builds communities of learners

"What I find most remarkable about my student's experiences is that they don't feel that they are involved in a distance learning course. They feel that they are members of a virtual high school. The difference is most important. They became part of a national community of learners and explorers. They are excited about their education. The skills and lessons they gain from the VHS program spill over into their regular high school classes. They share their virtual education with fellow students and are able to add unique perspective to regular classroom discussions. They are truly becoming self-disciplined, nationally orientated students. They have moved far beyond the boundaries of our local high school. Ironically, a number of our students have found their virtual courses to be more "real world" than their regular classes. Often the VHS courses are more self-directed, production oriented, less memory based educational experiences. They will take these lessons to college and to life. Any program that adds over one hundred courses to a high school's curriculum, enhances the students' technological skills and links them to students and teachers throughout the United States would have to be considered a great achievement. The fact that Virtual High School has been able to do this while giving the program a very personal community based feel is remarkable. It is an honor to be part of the Virtual High School experience." -- Mark McGrath, VHS site coordinator, Collingswood HS, Collingswood NJ

"..about asynchronous discussion- there are a lot of people who don't really *like* that idea. I emphatically disagree...I love it! I think it works better than face to face discussion, actually. And not necessarily for the reasons that everyone usually says "it gives people time to think about their answers" and "it helps shy students express themselves more easily", etc (although those are advantages....just not the ones that directly apply to ME :P) I like it because everything that everyone wants to say...can get said. It's not like a 'real' conversation where one person says something, and someone else responds, and then someone picks up on a tangent to THAT and you can't really go back the first thread of the conversation....or you could, but you'd have to abandon that new tangent. Either way, you lose out on something. And then there's the fact that we have a complete record of the conversation on hand...which can be useful. I really do think that this 'discussion factor' is one of the BEST things about VHS, and one
WebQuest: A Literary Odyssey'

I think that VHS is a wonderful experience, I learned not only about the subject - Russia and Soviet Union, but I also learned about myself a lot. I learned how to develop more discipline in my ability to study, I learned more about other teenagers from other vhs classes through vhs students' discussion etc. Surprisingly, I even like my vhs teacher very much! She taught me a lot. Ms Terry Haugen is really a wonderful teacher. It is not easy to do all homework on time but it is great working with her." -- VHS student, *Russian, Soviet, and Post-Soviet Studies*

VHS is a place where kids from all over the country, from all sorts of backgrounds come together and share in learning. Imagine in the future, all high schools being interconnected, and kids from everywhere having the opportunity to experience on a daily basis their peers from communities across the nation. In a nation so vast, that changes so rapidly, whose population is so diverse, we must provide the opportunity to understand each other no matter where we come from, no matter what our cultural heritage. I see Virtual High School as the vehicle for such an opportunity and an incredibly positive use of internet technology." -- John Dye, VHS teacher, *History and the Silver Screen*, Dublin Scioto High School, Dublin OH

"I am very pleased with my course and the experience I have received from it. It has helped me to become more independent and more self-disciplined when it comes to my school work. I enjoyed getting to know my classmates as well as my instructor. I am registered for another class during the spring semester and I can not wait to get started."
-- VHS student, *A Model United Nations Simulation Using the Internet*

"The English AP course I took was one of the most valuable courses I have ever encountered. I believe the success of this course and many other courses depends mainly on the teacher. I enjoyed the course

very much. It was a great learning experience. The people I met and the work I did was different from the regular coursework I had been used to. Mrs. West was a dedicated teacher, that's probably why I learned so much." -- VHS student, *AP English: A Web-Based College Level Course in Literature & Composition*

VHS is enabling teachers and students to become confident technology users

"One of our LHS students enrolled in a VHS course would not have graduated this spring without VHS. She had family problems, moved out of the house, worked full time, and had a difficult schedule. VHS was the only class she could fit into this chaos, due to the flexibility of LS. Otherwise, she would have had to attend summer school (at a personal financial cost), and would not have graduated with her class." -- Curt Stedron, VHS teacher, *Screenwriting Fundamentals*, Littleton High School, Littleton CO

"As an English teacher for VHS, I immediately noticed how open students are in their writing. I think they feel more comfortable sharing their thoughts on-line rather than in the traditional classroom. In light of all the focus lately on different high school cliques and some feeling like outsiders, VHS offers students a chance to be a part of something new. Students are not put into a category; I know them through their work. The result is a chance to really share what they think without the fear of being judged." -- Peter Stefanisko, VHS teacher, *Exploring America through its Writers*, Windsor High School, Windsor CA

VHS offers unparalleled professional development opportunities for teachers

"From a teacher's standpoint, it has given me a new adventure and definitely a new challenge. After 26 years of teaching, it has really given me the boost I needed in my teaching career. Sometimes we as teachers become complacent and do the same thing year after year. This type of course makes teaching more exciting and more meaningful. It has really given me more ideas to use in my present classes."-- Joann Collins, VHS teacher, *Exploring the Wonderful World of Multimedia*, Lincoln County High School, Lincolnton GA

VHS greatly increases access to courses and educational resources

"As the Director of Technology at a small rural school district I have found VHS invaluable to our program. With the selection of courses available to us, we can now compete with other local schools both public and private. With only 305 students in both the Jr. and Sr. High, North Brookfield notices every time a student leaves. When asked why they were leaving the response usually includes lack of course selection. With VHS this argument does not have merit. VHS has helped keep our doors open by offering high caliber classes and a teaching staff that is dedicated to educating our young people. We ask that you support VHS as much as possible so that more students have the opportunities that we have had." -- Trevor Bruso, VHS site coordinator, North Brookfield Jr/Sr High School, North Brookfield, MA

"Kalida High School is a small school of only 360 students in grades 7-12 located in the small farming community of Kalida, Ohio. Becoming a part of VHS is one of the greatest things that has happened to the students in recent years. Next year we will have students taking a wide range of courses in a variety of disciplines that was never available before. We will have a teacher teaching a course (Marketing With Probability) that we could not offer here because of a lack of enrollment. -- Dale J. Nienberg, Principal, VHS site coordinator, Kalida High School, Kalida, OH

Rich Environments for Active Learning on the Web: Guidelines and Examples

Joanna C. Dunlap
University of Colorado at Denver
U.S.A.
Joni_Dunlap@ceo.cudenver.edu

Abstract: Rich environments for active learning (REALs) are student-centered learning environments that rely on authentic contexts, collaboration, intentional learning, generative learning, and reflection. They are highly interactive, and depend on a great deal of intellectual probing by the instructor/facilitator and collaboration among students to be successful. Can REALs – typically established in a face-to-face classroom setting – be replicated using distance learning technologies, specifically the World Wide Web? This presentation provides guidelines for creating REALs on the Web, and demonstrates how those guidelines have been applied in a variety of Web-based learning environment (WBLE) contexts.

Rich environments for active learning (REALs) are comprehensive instructional systems that engage students in dynamic, authentic learning activities that increase their control and responsibility over the learning process while they learn problem-solving and collaborative skills and content (Dunlap, 1992; Dunlap & Grabinger, 1992, 1993, 1996; Grabinger & Dunlap, 1995; Grabinger, Dunlap, & Duffield, 1997). REALs are based on a constructivist view of learning, which holds that knowledge is acquired through “a process of subjective construction on the part of the experiencing organism rather than a discovering of ontological reality” (von Glasersfeld, 1979, p. 109). This is then, by definition, a student-centered process. It is also a social process of negotiation, conversation, testing, and challenging (Bauersfeld, 1995; Cobb, 1994). In order to be student-centered, REALs have the following attributes:

1. Promote intentional learning by encouraging the growth of student responsibility, initiative, decision making, and intentional learning;
2. Apply dynamic, generative learning activities that promote high level thinking processes (i.e., analysis, synthesis, problem solving, experimentation, creativity, and examination of topics from multiple perspectives) to help students integrate new and old knowledge and thereby create rich and complex knowledge structures;
3. Utilize authentic learning contexts to promote study and investigation;
4. Encourage collaboration to cultivate an atmosphere supportive of knowledge building communities; and
5. Reinforce reflection by embedding opportunities to reflect on the learning process as well as on the content acquired to promote both learning and metacognitive skill development.

The following are guidelines for creating REALs, and examples of how these guidelines can be realized in a Web-based learning environment (WBLE).

1. Promoting Intentional Learning

REALs support intentional learning. Students engaged in intentional learning are purposeful, effortful, self-regulated, and active learners (Palincsar & Klenk, 1992; Scardamalia & Bereiter, 1985; Scardamalia, Bereiter, McLean, Swallow, & Woodruff, 1989; Scardamalia & Bereiter, 1991; Scardamalia & Bereiter, 1997). REALs attempt to give students more executive control over their learning to enable them to take more ownership, find more relevance, and learn lifelong learning skills. Creating autonomous, lifelong learners, REALs teach students to manage their own learning: identify their learning needs, set learning objectives, select and employ learning strategies, identify and use appropriate resources, and assess their overall process. To be intentional learners, students must identify learning deficiencies and strengths, make and implement plans, develop metacognitive awareness, and revise those plans and actions based on that awareness. To teach for intentional learning means to cultivate those general abilities that make it possible to become independent, lifelong learners (Palincsar, 1990).

Therefore, support for intentional learning begins with fundamental operational behaviors and moves on to learning and metacognitive strategies.

1.1 Support for Transition to an Online Learning Environment

“Students need support and direction to enable them to make the transition from traditional classroom environment to self-directed learning – particularly tools to help them monitor their progress and obtain timely feedback on their activities” (Sherry, 1995, p.352). Hardy and Boaz (1997, p. 1) define student development as the process of preparing “the student for a distance education experience, beyond the technical orientation.” This orientation needs to include learning to operate within the online/Web learning environment and refining metacognitive skills. To be successful, students will “need guidance in putting information together, reaching their tutors, and completing and submitting assignments” (Sherry, 1995, p.352).

Regis University does an excellent job of setting the stage for students entering a Web-based learning environment. For each course, students are provided with detailed information regarding getting started in the course; what to expect in the course; how to access course and technical support; what it means to be an online learner and how to be a successful online learner; and how to engage in the course structure, with the course content, and with other students, resources, and the instructor. See: <http://www.cudenver.edu/~jdunlap/webnet99/regisoverview.html>

1.2 Setting Goals

An important part of operating intentionally is the ability to set realistic and appropriate goals. Since an online/Web learning environment relies heavily on independent initiative and study, these goals need to be meaningful to the student. Part of setting goals is the ability of students to identify what they know and what they do not know. Learning contracts (Knowles, 1975) and action plans are useful tools for providing students structure for goal setting while encouraging independence. For an example of a simple Web-based action plan structure, see: <http://www.cudenver.edu/~jdunlap/webnet99/actionplan.html>

Problem-based learning (PBL) is an instructional methodology that engages students in formalized, explicit goal setting activities. Some great examples of PBL in a Web environment exist. See: <http://www.uchsc.edu/chancellor/offedu/pbl/pbl.html> for a Web-based PBL activity on ethical decision-making, and <http://education.indiana.edu/~ist/courses/r590/la/critical.html> for a Web-based PBL activity on Internet rights and responsibilities in a K-12 environment.

1.3 Metacognitive Awareness

Metacognition is an individual’s “knowledge about their own cognitive processes and their ability to control these processes by organizing, monitoring, and modifying them as a function of learning outcomes” (Weinstein & Mayer, 1986). Being aware of one’s own cognitive processes involves the utilization of metacognitive skills – “the steps that people take to regulate and modify the progress of their cognitive activity: to learn such skills is to acquire procedures that regulate cognitive processes.” (Von Wright, 1992, p. 64) Glaser (1984) describes metacognitive skills as: knowing what one knows and does not know, predicting outcomes, planning ahead, efficiently apportioning time and cognitive resources, and monitoring one’s efforts to solve a problem or learn. Metacognitive skills include taking conscious control of learning, planning and selecting strategies, monitoring the progress of learning, correcting errors, analyzing the effectiveness of learning strategies, and changing learning behaviors and strategies when necessary (Ridley, Schutz, Glanz, & Weinstein, 1992).

Reflective journals can be an easy way to help students focus on their metacognitive skills. See the following URLs for simple implementations of reflective journals (more on reflection in section 5 below):

<http://transition.alaska.edu/www/SOE/ed626/journals.html>

<http://www.cudenver.edu/~jdunlap/5990/conferencejournal.htm> (student response to reflective journal questions -- <http://clem.msced.edu/~woodleyx/wbi/online.htm>)

1.4 Time Management

Distance learning (DL) students must be more focused, manage their time more efficiently, and they must be able to work independently as well as in a group (Hardy & Boaz, 1997). Attrition rates in DL programs are extremely high, variously reported from 50% to 80%. Failure to manage time appropriately is a major cause of this attrition. Students are accustomed to attending classes at regular times, which provides a major time management structure. Online learning environments often leave time for participation up to the student. While faculty need to create an environment that allows students to manage their time and be flexible, they must also not allow so much flexibility that students become frustrated or procrastinate. One way of helping students manage their time in an online learning environment is by providing them with clearly defined activity requirements mapped to a calendar or an assignment matrix. See the following URLs for examples:

<http://www.cudenver.edu/~jdunlap/webnet99/calendar.html>

<http://www.cudenver.edu/~jdunlap/5990/5990syllabus.html#Calendar>

2. Applying Dynamic, Generative Learning Activities

REALs involve students in dynamic, generative learning activities. Generative learning activities require students – individually and collaboratively – to be responsible for creating, elaborating, and representing domain knowledge in an organized manner (Cognition and Technology Group at Vanderbilt, 1992; Hannafin, 1992; Scardamalia, Bereiter, McLean, Swallow, and Woodruff, 1989; Scardamalia and Bereiter, 1991). In other words, students are engaged in meaningful and important activities as participants rather than observers. Some generative learning activities provide students with a context or situation requiring them to take action (e.g., a problem that needs to be solved or a case that needs to be analyzed). Other types of generative learning activities require students to determine what it is about a particular content area they wish to know, and then take responsibility for answering their own questions through research and synthesis and representing the acquired knowledge in an organized and accessible way. It is through this process of “generating” knowledge, instead of passively receiving information, that help learners develop structure, strategies, and habit for lifelong learning. Dynamic, generative learning activities, therefore, involve students deeply and constantly in the process of creating solutions to authentic problems through the development and completion of projects. These kinds of learning activities require a shift in the traditional roles of students and instructors. Teachers become facilitators and guides, rather than presenters of knowledge. Students become active investigators, seekers, and problem solvers working purposefully on a challenge.

2.1 Create, Create, and Create

“Dynamic” means active and powerful. Dynamic, generative activities require that students create something meaningful and visible. The Web provides many ways of creating materials and sharing them, either with the class or the worldwide community of practice. Web pages, presentations, papers, or programs are within the means of students to create. The learning activities need to have students create important products that recognize their peripheral participation in a community of practice (Lave & Wenger, 1991).

An example of a Web-based dynamic, generative learning environment is the Web-based Performance Support System (WPSS) (Dunlap & Waterman, 1997; Dunlap, 1998a; Dunlap, 1998b; Dunlap, in press). Similar to electronic performance support systems (EPSS), a WPSS uses the Web to provide on-demand access to integrated information, guidance, advice, assistance, training, and tools to enable high-level job performance. In fact, using the Web to create performance support systems is a perfect fit because the Web is actively used by professionals as a forum for the distribution of current and up-to-date references, instruction, and guidance. By creating a structure that supports individualized and collaborative knowledge building by the people who will actually be using the knowledge, the higher-order thinking, problem-solving, and decision-making regarding the selection and utilization of appropriate learning materials and performance support is done by those who can get the most out of the process. Enabling students to utilize an easy-to-use tool to develop their own WPSS accomplishes two goals:

- a. they learn about the domain while they are locating, evaluating (which requires utilization of resources), and organizing resources to support their learning activities; and
- b. once the WPSS is completed it can be used to support further learning activities.

In this way, the WPSS not only enables learners to build a learning resource that will provide them with immediate support and guidance, but also helps them develop structure, strategies, and skills for subsequent lifelong learning activities. For examples of WPSSs in action, see <http://www.cudenver.edu/~jdunlap/wpss.html>

2.2 Provide Access to Resources

REALs are resource intensive. Learning activities usually include the need to find new information to support positions, accomplish tasks, and create products. In a WBLE, therefore, students should be engaged in activities that require them to use the Web and Internet to conduct research – including, as part of the process, the evaluation of the Web and Internet resources employed during the research process. Web-based Performance Support Systems (WPSS) require students to conduct research on the Web and evaluate the usefulness of the Web resources utilized. See the WPSS discussion and examples above.

3. Utilizing Authentic Learning Contexts

In REALs, learning requires the use of authentic cognitive, psychomotor, and affective skills. An authentic task, activity, or goal provides learning experiences as realistically as possible, taking into consideration the age and maturation level of the students and environmental constraints such as safety and resource availability. Authenticity is an important part of a REAL for three reasons. First, realistic problems hold more relevance to students' needs and experiences because they can relate what they are learning to problems and goals that they see every day (Blumenfeld, Soloway, Marx, Krajcik, Guzdial, & Palincsar, 1991; Pintrich, Marx, & Boyle, 1993). Second, authentic situations that reflect the true nature of problems enable students to develop deeper and richer knowledge structures (Albanese & Mitchell, 1993) leading to a higher likelihood of transfer to novel situations. Finally, authenticity encourages collaboration and negotiation (Johnson & Johnson, 1979; Lowry & Johnson, 1981). Ill-structured, complex problems require a team approach that provides natural opportunities for learners to test and refine their ideas and to help each other understand the content.

3.1 Contextualize Learning

REALs make sure that learning arises from an authentic context. This can be a simulation, case, problem, or task. Contextualized learning is more easily transferred to other situations than decontextualized learning. Regis University uses authentic case studies to drive learning of content and to give focus to student online interaction and collaboration (<http://www.cudenver.edu/~jdunlap/webnet99/regiscase.html>).

3.2 Make Learning Complex

Authentic learning is complex learning. Over simplified learning is neither authentic nor valuable in a contextualized sense. Simplified situations often provide incorrect understandings that get in the way of future learning and refinements (Spiro & Jehng, 1990). Students exposed to a situation in its natural complexity create richer knowledge structures more useful for future application and learning. Additionally, complex learning contexts encourage more meaningful collaboration. Students do not mind collaborating when it is necessary to achieve a goal that one person could not attain on his or her own. The Curry School of Education at the University of Virginia has developed a number of interactive projects that involve students in authentically complex learning activities such as frog dissection, a multimedia teaching case, and instructional design practitioner cases:

The Interactive Frog Dissection: <http://curry.edschool.virginia.edu/go/frog/home.html>

Multimedia Teaching Case: <http://www.people.Virginia.EDU/~tedcases/>

Instructional Design Practitioner Cases: <http://curry.edschool.Virginia.EDU/go/ITcases/Terry/>

3.3 Increase Meaningfulness and Realism of Activities

Meaningful activities are crucial to REALs for three reasons. First, meaningful activities provide motivation for working in an online learning environment -- the reason for logging on and checking the Web discussion forum, for example. Second, meaningful activities help learners develop knowledge structures that will enable them to transfer

their learning to new situations. Meaningfulness provides context that prevents the formation of inert knowledge (Whitehead, 1929). Finally, meaningful activities are seen by students as more realistic -- they are meaningful because they relate somehow to the students' "real world" situation.

The WWW – through the use and integration of multimedia, video, audio, databases, hypermedia, networks, and e-mail – allow us to create micro- and virtual worlds that can engage students in meaningful activities that reflect the real world (Collins & Brown, 1986). Examples provided by the Curry School of Education demonstrate how the use of multimedia can enhance the realism of the learning activities being presented (see URLs above). A good Web site for finding virtual tours that can be used for classroom applications is Virtual Tours at <http://www.dreamscape.com/frankvad/tours.html>. This site lists dozens of museums, exhibits, real time tours, and virtual cameras from around the world. The American Museum of Natural History <http://www.amnh.org/> is a rich source of exhibits covering topics from the sciences, social studies, and more. They sponsor online expeditions and Webcasts with scientists and researchers. Other examples of virtual learning activities include:

The Virtual Electron Microscope: <http://www.uq.edu.au/nanoworld/online.html>
Virtual Tourist: <http://www.vtourist.com/>

3.4 Encourage Research

REALs require some kind of research activity. One of the major strengths of online learning environments is their access to people, resources, and databases of information. Research, and especially the search process, should be important components of online learning activities. In an online environment, students can more easily come into proximity with communities of practice because the Internet serves as a gateway to a world community of learners and practitioners. Browsers and search engines are vehicles for exploration providing students with critical skills of goal setting, self-directed learning, and testing hypotheses. There are a number of Web-based examples of engaging students in projects that encourage research. See the URLs below for contextualized examples of projects that have research as an important component of meeting the requirements of the larger challenge.

Hosting a Virtual Conference Activity:

<http://www.cudenver.edu/~jdunlap/5990/conference.html> (See, also, examples of the virtual conferences designed at <http://carbon.cudenver.edu/~jdunlap/seminar/> and <http://web-education.net/fall98conf/>)

Web Site/Unit Evaluation Activity for K-12 Teachers:

<http://www.cudenver.edu/~jdunlap/webnet99/siteeval.html>

4. Encouraging Collaboration

REALs demand collaboration among students to achieve complex goals. Collaboration acknowledges the social nature of knowledge construction (Bauersfeld, 1995; Cobb, Yackel, & Wood, 1992; Roth, 1990). Through collaborative work, students experience and develop an appreciation for multiple perspectives; they refine their knowledge through argumentation, structured controversy, and the sharing and testing of ideas and perspectives; they gain an appreciation for the value of cooperation and the individual strengths that members of the team bring to the group; and, they are more willing to take on the risk required to tackle complex, ill-structured, authentic problems when they have the support of others in the cooperative group. Therefore, with the support of others in the group, students are more likely to achieve goals they may not have been able to meet on their own. Collaboration also facilitates generative learning.

Web forums and threaded discussions are easy ways to establish an environment for group discussion and collaboration. However, in order to make sure that students are motivated to participate in online discussion and collaboration, it is advisable to have a problem, challenge, case, or project drive and provide a focus for student participation in an online environment. For an example, see: <http://www.cudenver.edu/~jdunlap/mess.cgi>

More elaborate examples of collaborative learning environments on the Web also exist. A great example is the Learning Through Collaborative Visualization Project (CoVis). CoVis is an online community of thousands of students, over one hundred teachers, and dozens of researchers all working together to find new ways to think about and practice science in the classroom. See: <http://www.covis.nwu.edu/>

5. Reinforcing Reflection

Self-reflection activities need to be embedded into REALs in order to support the development of metacognitive skills. "Self-reflection implies observing and putting an interpretation on one's own actions, for instance, considering one's own intentions and motives as objects of thought" (Von Wright, 1992, p. 61). Von Wright describes the process of self-reflection as the ability to think about one's self as an intentional subject of personal actions and to consider the consequences and efficacy of those actions. This involves the ability to look at one's self in an objective way and to consider ways of changing to improve performance. Dewey (1933) described the value of reflection as a component of educated thinking. Even though reflective activity is important, it is possible for students to be so caught up in completing a task that they fail to reflect, hindering what they learn. "We can keep students so busy that they rarely have time to think about what they are doing, and they may fail to become aware of their methods and options" (Wheatley, 1992, p. 536). Schön (1983) refers to this as being "in the action" rather than reflecting on the action. If students do not have opportunities to examine their methods and options, they will not develop the metacognitive skills needed for lifelong learning. Therefore, learning activities need to support students in reflecting on their own learning and problem-solving processes, as well as on what they have learned (Schön, 1987).

Engaging students in reflection on the content learned and the learning process itself can be done simply by having a set of questions that students answer throughout a learning activity and once the learning activity is completed Possible reflective questions that address the content and skills learned include:

- How did your prior knowledge affect your approach to the project? Be specific in describing your prior knowledge and how it affected your approach.
- What are three of the most important things that you learned about your topic while working on this project? Why do you consider them important? Be specific.
- Do you believe that your learning from this project represents the breadth of the topic? Why?
- Do you believe that what you were able to learn something about this topic in depth? If so, what is that?
- What did you learn that you could apply to other problems or projects? How?
- What topics did you encounter that you would like to study more? How will you do that learning?

Possible reflective questions that address the learning process include:

- What did you learn about your ability to learn? What new learning/metacognitive skills did you acquire? What did you learn that will make you a more efficient and effective learner on future assignments?
- What kinds of learning problems did you encounter while working on the topic? How did you overcome them? Did anyone else offer useful assistance (who and how)?
- How can you improve as a learner? What are your weaknesses? How will you strengthen them? What will you do differently the next time?
- How has the communication environment affected your learning?
- What could make communicating with the instructor or other students more meaningful?
- What resources did you identify that you will use again? Why?
- When you had trouble finding the information that you needed, what did you do?

Reflective journals can be implemented online very easily using email or Web forms – see:

<http://transition.alaska.edu/www/SOE/ed626/journals.html>

<http://www.cudenver.edu/~jdunlap/5990/conferencejournal.htm>

Conclusion

REALs are one way of conceptualizing and applying the attributes of a rich, active learning environment. It helps to break those attributes down into guidelines when determining how to create these types of learning environments for face-to-face or Web-based settings. This paper only presents a few examples of the many excellent implementations of REAL guidelines to Web-based and other online learning environments. Because of the power of the Web -- to provide information in a just-in-time manner, establish immediate access to people and resources, utilize multimedia and hypermedia technologies, provide a forum for communication and collaboration, etc. – it is fairly easy to realize the promise of REALs in an online learning environment.

Note: For references and more examples of REALs on the Web: <http://www.cudenver.edu/~jdunlap/webnet99/references.html>

Design and Implementation of Interactive, Web Based Courses

Abstract: Setting up virtual, Web based courses has become very popular among teachers recently. Still, most of them are not familiar with the proper implementation of training material for the Web. This was, at least in parts, also true for the authors of this paper. In this paper a comprehensive course construction concept using novel Web technologies is proposed, featuring simplicity and practicability especially for non technically experienced authors. All vital features like a learning environment, treatment of written basics and interactivity are briefly discussed and introduced with a pilot course.

1. Introduction

Today most universities and an increasing number of big companies all over the world feel the necessity to offer virtual Web based courses to educate their students or employees. Therefore, many teachers and authors of Web based lectures are in search of a complete concept to create virtual and interactive courses from text based scripts and books used for traditional lectures. Beside an excellent mastership of the subject area, there are a lot of additional requirements like programming experience, knowledge of Web technology and so on.

The Institute for Fundamentals and Theory in Electrical Engineering at the Technical University of Graz mainly deals with the numerical calculation of electromagnetic fields and the optimization of electromagnetic devices. Up to now, the use of Web technology was more or less reduced to the application of a browser. But the change of teaching and learning paradigms, the need for spatial and temporal independence for local students as well as “far distance” availability for non local and worldwide spread students, make it necessary to offer virtual courses. There have been some initial experiments with online electromagnetic field calculation examples using the CGI and TCL scripts to remotely control a Finite Element Software package and its Pre- and Postprocessors [Preis 1997]. Nevertheless, there has been neither a real concept how a virtual course should be designed, nor the technical know how to implement it, which, however, seems to be a common problem. This paper proposes a way to overcome these difficulties at the example of a highly interactive Web based course of the lecture “Optimization in Electrical Engineering”. Although the implemented course comes from the field of engineering, many of the suggested solutions, which had to be totally programmed by the authors, can be adapted for other fields. This is even more applicable as upcoming tools will virtually simplify the process of treating dynamic contents. Also users, who are no experts in Web technology, will be able to use these tools.

Basically, the task should be divided into two major parts: The Web based learning environment, which builds up the backbone of any good course and the handling of the contents. The content itself is again divided in two elements:

- Theory and Basics
- Examples and Interaction

Nearly of same importance is the evaluation of the students advancement and their self assessment which accompanies and completes a course.

2. The Learning System

The quality and comprehensibility of the course content is definitely one of the most important parts when teaching a certain topic with the support of the Web. Unfortunately the course pages can not exist alone, at least some sort of navigation like leafing forwards and backwards, a table of contents etc. has to be provided. Also it would be nice if the learning and teaching process is supported by communication and collaboration facilities between distant students and teachers and among students themselves to utilize the possibilities of the Internet. Of course it is desirable that authors do not have to invest much time and work to accomplish this, in contrast routine tasks like interlinking pages should be performed automatically and it should really be easy to configure an environment that optimally embeds courses, so that authors can fully concentrate on the actual content creation process. To provide all this is exactly the purpose of a learning and training/teaching system! After evaluating a few available systems [WBT Systems 1999] [WebCT 1999] we decided to use GENTLE (GEneral Networked Training and Learning System [Dietinger 1998] [Dietinger 1997]) which is a research project currently under development at IICM (Institute for Information Processing and Computer supported new Media at the Technical University of Graz).

GENTLE is based on a Hyperwave Information Server [Maurer 1996] and only requires a JavaScript capable browser like Netscape 4.x or Internet Explorer 4.x (or greater) on the client side because the whole user interface is implemented using HTML, DHTML and JavaScript. The working prototype is also called Hyperwave Training Space. The WBT system currently distinguishes four different types of users and provides different features and functionality for them. These types are participating students, teaching staff like trainer and tutors, courseware authors and system administrators. Users can also belong to several types at the same time (e.g. an administrator could be a student at one course and a teacher and author at a different one). Within the environment various so called *rooms* separate different scenarios and tools provide additional functionality to the users.

Typically users enter the environment through the *registration desk* where they can register for a personal account, read the introduction and an overview to the system or look at the list of available courses. After the users have registered they will get a unique login name and a private space on the courseware server, which is called *study room* and can be entered upon successful identification. The study room is the main working place and also provides access to all other rooms. Here students will get a list of suggested courses (depending on the users' profiles), may enter enrolled or review already finished courses. Teachers and authors may also create new courses by using a tool called *course wizard* which upon activation asks a few questions concerning the lecture (like aim of the course, prerequisites required to master it, time and place of live lectures if appropriate, tutors etc.) and automatically creates a course skeleton and some introductory HTML pages. The course content itself can easily be added either by using the Web browser or via drag and drop by using the *Hyperwave Neighborhood*, a Windows 9x/NT Explorer extension. Access to the *administration office* is only granted to teachers, authors and administrators and is used to maintain user accounts, teams, courses and modify system settings. Of course not all functions are available to all three user types in the same manner, e.g. teachers can suggest or assign their own courses to different students but may not remove other courses or delete user accounts. Although students do not have access to the administration office they can directly change their own profile by altering the settings of the electronic business card. Most parts of the business card like photo of the student, the name and other personal data may be made public and can be viewed by other members of the system whenever they click on a visible user name. This has the positive and important effect that a personalized virtual community can be created because users can imagine how other users look like or what their hobbies are, which simplifies teamworking and collaborating. The study room also contains a personal Web space where the students can develop their own projects or work together in shared areas.

If students select one of the listed courses in their private study rooms they will be moved to the *class room* of the specific course. The class room provides access to the course content, which is dynamically interlinked (including e. g. the creation of a table of contents) and adaptively presented, which means that it can vary depending on the students preferences. Furthermore the classroom offers different tools for communication like a messaging system which can be synchronized with Internet mail, a discussion forum with sophisticated functionality that surpasses e.g. Usenet News, and personalized and typed annotations. Annotations can be

directly attached to a certain area within the HTML content page (or to the whole page if it is non HTML) just by selecting the text area and adding the note. Afterwards an icon indicating the annotation and heading the selected area will be visible only for the author of the note, or for a team or the public depending on the assigned access rights. Annotations can also contain attachments and a certain type like remark, question, answer and supporting argument. If a student poses a question note, the tutors of the course will be notified automatically by the messaging system so that they can answer the question as soon as possible. After doing that, the student that asked the question will also get a notification that it has now been answered. To minimize question answer dialogs and thus supervising effort the system supports various sophisticated searching techniques like fulltext query within every part of the system and a course specific section for storing background material called the *background library*. This should improve the chance that students can find an answer to their questions on their own.

This just describes the current state of the system at the time of writing, however as we know huge enhancements like more tools that automate routine tasks, more support for collaboration and personalization and also a hybrid version that combines the advantages of online and offline learning and teaching are planned.

3. The Theoretical Part of the Lecture

The theoretical part of a technically oriented lecture in general consists of written text, figures, equations, tables and references. Standard Multimedia contents like mpeg videos or spoken audio files can easily be added without special plug-ins – which was a major requirement for our course. Nevertheless, the preparation of high quality multimedia content often exceeds many authors capabilities.

But even generating a single, multipage document caused great problems at the time this project started. So far, no proper HTML editor is known to cope with automated page numbering, figure numbering, equation and table numbering as well as chapter and section numbering and header and footer insertion which are standard features of nearly any text editing systems like WinWord or Latex. HTML editors like MS FrontPage98 or Netscape Composer were and still are supporting single pages only and deal with multiple pages in a unsatisfying way. To overcome this problem a couple of small utilities were developed using Perl programming language following the model of the Latex text editing system [Wall 1996] [Lampport 1994]. Each figure, table and equation is assigned a reference name in the plain HTML text which is processed and the respective numbering is inserted in the correct way. Headers and footers and any desired HTML parts can be inserted at marked positions in a similar way.

To ensure reusability of individual course chapters within other courses, a modular concept was adopted. Each single chapter is treated as an independent module with few hyperlinks to other chapters and no links to the Internet. Modules can be detached from one course and easily reused within another one by deactivating or reorganizing the hyperlinks. Instead of a flood of links within course pages, advanced searching and browsing facilities and additional reference links are provided via the background library.

But even inside a single chapter one can easily get lost somewhere in the hyperspace, between the current page and some auxiliary pages which are referred to and displayed [Dietinger 1997]. The authors have overcome this problem by keeping the current page always visible. Figures, tables, equations and even references which are not part of the actual viewed hypertext page are overlaid in extra windows on demand and closed automatically when the user browses to the next main page. This supports the generation of short and efficient pages.

Another feature, well known from offline education software but not easily available for Web based systems until Dynamic HTML, is a series of figures with a corresponding explanation successively displayed at the same location of the main page. Series of pictures with correlated text and little animations were implemented in Java Script using Cascading Style Sheet (CSS) features. Applying DHTML, figures and text can be separated and text remains text in contrast to “slideshow” figure/explanation series. Animations can be easily inserted. It has turned out that this is a good way that even complex subjects can be understood more easily.

Another special element is used to visualize program flowcharts or more complex (sequential or parallel) processes. An image map is controlling accordant images and illustrations with DHTML which may again be combined with animations. Applying such elements has the positive effect, that normally inactive text is enhanced with some interactivity. The students are called to click the image maps and serials, watch the

animations and changing figures according to their learning style and speed, which is much more challenging than plain text. Java Script program modules can easily be reused in other pages or courses with only few adaptations required.

4. The Interactive Part of the Lecture

There are two philosophies to allow interactivity for online courses:

- the Client Solution
- the Server Solution.

Examples executed at the client computer, mostly implemented as Java Applets, do not need an additional server and could be also used in offline mode (e.g. on a CD-ROM edition). Many authors strenuously realize sophisticated examples as Applet programs, but really complex examples like Finite Element calculations are absolutely impracticable with a client solution. Server side run programs are much more powerful, but the interface is hard to implement, and an additional online, administrated server is needed to provide full performance for both the learning environment and the examples. Therefore, we use a combination and benefit from both methods.

Simple numerical and theoretical examples are realized as client applications. For example, the student is asked to derive analytical formulas and the result appears directly within the page without a Hyperlink to click. This is the same method often used in text books, where the solution of examples could be looked up in the back of the book, but much more comfortable and faster. Simple numerical examples may either use the click and show system which is also applicable for ordinary text questions or the students are asked to enter their solutions which are validated by the system. The students receive either a confirmation that their results are correct or an invitation to redo the calculation with a text depending on the number of trials already performed. The design and implementation of these objects is fast, efficient and technically not too difficult, in particular because there already exists a growing number of commercial applications supporting such DHTML objects.

To deal with more complex examples, we have been using a server side solution. Like in modern class room lectures where computer applications are often used to support and improve the traditional lessons, Web courses can make use of these applications if they can be remotely controlled. Application programs in our implementation are MATLAB [Mathworks 1999], Fortran optimization routines and a Finite Element Package solving electromagnetic field problems. Using these software the design of very complex, real life simulations and examples is mainly reduced to conceive the example itself while its implementation is strongly supported by the program packages. The functional elements for user input are standard HTML forms and input data are transmitted using the "Post" method. Input data for training examples are mostly parameters – in the optimization case strategy parameters and problem parameters, formulas, sometimes instructions – and the output data are pictures, text, numerical data and animations packed into HTML pages. Online calculated animations are provided as image frames and displayed using an appropriate Java Applet.

The amount of data transfer over the Internet can be kept fairly low this way, all calculation and generation of HTML output is done on the server. The performance bottleneck of the whole chain is the application server. If there are too many students to be served at a time a splitting to multiple application servers can be done [Kovács 1998]. We have experience with about 150 students doing extensive Finite Element calculations within a month which was done with one server in a satisfying way. Since the calculation period of our examples lasts from some seconds up to some minutes a pure CGI compliant interface using Perl scripting language is sufficient. A simple, but relatively easy to implement form of remote controlling is possible if the application supports a scripting language and the transfer data is passed via files. Therefore our data transfer between applications and CGI is mostly handled by files and DDE (Dynamic Data Exchange), but it could also be worked out by another direct link between server programs and Web server (NSAPI, ISAPI) or with FastCGI, depending on the remotely controlled application [Göschka 1998]. A semaphore concept using file locking guarantees error-free concurrent multi-user service of the application server. The whole system structure can be seen in [Fig. 1].

Figure 1: The Learning System

5. Evaluation of the Student's Progress

Beside the most obvious form for evaluation in Web based courses, the multiple choice quiz, written statements, reports or exams with open questions are other possible options. Either an automatic grading (easy to gain with multiple choice quizzes) or manual assessment may be used by the teacher. At the time of writing of this paper no evaluation concepts were implemented in the GENTLE learning environment. Despite a rather high level of personal engagement, we decided to implement question forms with open questions and questions to be answered by a statement which are both graded manually. Although designed for self assessment, the objects described in the interaction section are very well suited for test and evaluation purposes. A number of questions can be based on a server based example module which has to be used by the student to answer the question. For example, the students are asked to run an optimization problem with different optimization strategies and interpret the results. Answers to the questions are automatically formatted and prepared for database access by CGI scripts. To ensure objectivity, examinations are held at fixed times in computer rooms with a person in charge.

6. Conclusions and Further Development

All necessary parts to successfully create a Web based course have been briefly discussed in this paper. The GENTLE system fulfills all requirements for an excellent courseware and the further development of the software benefits from persistent feedback of the course authors. Nevertheless also other courseware systems like WebCT or Topclass are suitable choices [WBT Systems 1999] [WebCT 1999].

The "first time" development of the quoted Java Scripts, HTML modules, Perl programs, CGI programs etc. is expendable and time consuming. Once available the modules can be adopted for other courses very quickly with few adaptations. Up to now the time consuming implementation of proposals has been reserved to technically experienced people with programming skills, but forthcoming application software like Dreamweaver2 will ease the task significantly [Macromedia 1999]. The most difficult job remaining will be the adaptation of server based software especially because no practicable solutions for that can be expected in the near future.

Currently, there is much work in progress to apply solutions for interactive tutorials for Finite Element Software applications also in offline mode. In the future we plan to transfer many more lectures from the traditional way of teaching to the virtual one with a high grade of interactivity. Concurrently, further progress takes place in the development of the GENTLE virtual learning system and new features like standardized evaluation methods will be added.

Creating Websites on CD-ROM for Educational Use

John English
School of Computing and Mathematical Sciences
University of Brighton, Brighton BN2 4GJ, UK
Email: je@brighton.ac.uk

Abstract: The BURKS project produces non-profit CD-ROMs for students of Computer Science. Now in its fourth edition, BURKS is a set of two CD-ROMs which incorporates a pre-installed copy of Netscape Navigator and which functions as a single self-contained website. This paper describes the techniques used to implement the CD-ROM, which include methods for avoiding having to install any software on the target system, avoiding interfering with any existing browser installation, and managing disk changing to make the two disks act as a single website.

1. Introduction.

Although there are many useful resources for Computer Science students available on the Internet, it is wasteful to expect students to find and download individual copies for their own use. More importantly, students need access to these same resources to be able to work at home, and although it is now the norm for our students to own PCs with CD-ROM drives, off-campus Internet access is at present much less widespread. This is largely due to the high cost of telephone services in the UK where local calls are charged by the minute in addition to line rental charges. BURKS, the Brighton University Resource Kit for Students [English 1998], was initiated in 1996 as a non-profit, zero-budget project to provide Computer Science students with a selection of useful resources from the Internet on CD-ROM. Four editions have now been produced in August each year since 1996, with the fourth edition appearing in August 1999. Targeted at IBM PCs running Microsoft Windows 3.1 or later, it is now a 'recommended text' on several courses worldwide (e.g. [van Scoy 1998]).

BURKS is essentially a local mirror on CD-ROM of a large selection of resources available elsewhere on the Internet, including tutorials, reference manuals, specifications, published papers, textbooks, compilers and other software, and a dictionary of computing. This is organised as a website, using HTML as a common language for indexing the collection as well as the documents it contains. Although it is completely self-contained, the use of HTML as a common format also allows the CD to provide links to external resources to cater for users who do have access to the web. This also makes it possible to provide the entire collection online at the BURKS website, <http://burks.brighton.ac.uk/>.

Students entering our courses are usually complete novices, and the intention of the project is to cater for the needs of such students. This means that ideally it should not be necessary to install any software before the CD can be used, and that installing software packages from the CD (compilers etc.) should not require any special skills or knowledge on the part of the student. In addition, it should not be necessary for a user to have a web browser already installed on their system. The solution adopted by BURKS is to use an integrated web browser which runs directly from the CD with no separate installation step. For systems which already have a web browser installed (a fairly rare situation in 1996 but now a commonplace), the CD is carefully designed so that the preinstalled browser will not affect the configuration of the user's existing browser, and thus it is usable on any system with or without an existing browser.

Supplying a pre-installed web browser on the CD has some additional advantages:

- It removes problems due to browser incompatibilities, such as support for frames and tables, rendering differences, and JavaScript support
- The browser can be preconfigured with settings such as a specific home page and a set of helper applications for an assortment of file types provided on the CD.

This paper describes the techniques which have been used to implement the BURKS series of CDs.

2. The First Edition (1996).

The first edition of BURKS was essentially a pilot project to assess the viability of building a self-contained website on a CD. Due to the timescales involved, the only web browser that the author could obtain permission to use was Cello, a free browser from the Legal Information Institute at Cornell University. The main disadvantage of Cello is its lack of support for all but the most basic HTML constructs. However, it could be run directly from the CD, with only two files (`CELLO.INI`, the initialisation file, and `CELLO.STY`, the style file) needing to be copied to the user's Windows directory. This would cause problems if the user already had a copy of Cello as these two files would override any existing settings, but the risk of this was considered to be extremely small.

The initialisation file `CELLO.INI` needed to be located on the user's hard disk rather than on the CD so that options such as the default window size and position could be altered by the user, either in the user's Windows directory or in a directory specified by an environment variable. `CELLO.INI` specifies a number of settings, including the following:

- The URL of the home page to be displayed at startup, or when the 'Home' command is selected;
- The location of the style file;
- The window geometry (size and position);
- The applications associated with particular file extensions.

The Cello executable and other required tools were held in a subdirectory on the CD, together with default versions of the `CELLO.INI` and `CELLO.STY` files. A startup program called `BURKS.EXE` was stored in the root directory on the CD which was responsible for the following actions:

- Copying the default versions of `CELLO.INI` and `CELLO.STY` to the user's Windows directory if they did not already exist;
- Setting the URL for the home page in `CELLO.INI` to refer to the main index file on the CD;
- Setting the desired applications to be invoked for particular file extensions in `CELLO.INI`;
- Launching the Cello executable.

Unlike Unix systems, an MS-DOS or Windows executable is able to determine its full pathname. This allows a program on a CD to discover the drive letter for the corresponding CD drive, which can then be used to build full pathnames for other executables on the same CD as well as URLs for the HTML documents it contains.

BURKS uses the autorun feature for CDs introduced in Windows 95, so that inserting the disk on a Windows 95 system will launch the startup application automatically and thus launch a web browser to display the main index page on the CD. No separate installation step is necessary.

The file associations in the `CELLO.INI` file specified that files with the extensions `.ZIP` and `.EXE` were to be associated with a helper application provided on the CD, and files with the extensions `.I`, `.S` or `.GZ` were to be associated with another helper application. `ZIP` and `EXE` files are the two formats used for software packages on the CD; `ZIP` files are compressed archives and `EXE` files are self-extracting executable archives. `I`, `S` and `GZ` are the file extensions used for the installation disks for the copy of Linux (the Slackware distribution) that was included on this version of the CD.

When a URL with one of these extensions is selected, Cello launches the specified application and passes it the full URL as a command-line parameter. The first helper application (that used with `ZIP` and `EXE` files) copies the file to a user-nominated local directory on the user's hard disk and then allows the user to unzip the file or execute it, depending on whether the file has a `ZIP` or `EXE` extension. The copying step caters for the fact that the file is not necessarily one supplied on the CD; it might be one found at a remote site which will require downloading before it can be processed. The other helper application will treat the file as a raw disk image; it will copy the file directly to a floppy disk, thus simplifying the process of creating Linux boot disks for novices.

3. The Second Edition (1997).

The first edition was released in limited quantities as a proof-of-concept prototype. The smallest possible production run was 250 copies, which was more than could realistically be sold to students at Brighton. The size

of the print run meant that the CD was priced at £7.00 per copy to cover manufacturing and distribution costs. Copies were distributed to other institutions and review copies were sent to a number of publications to gauge interest elsewhere. Copies were also distributed to industrial delegates at a one day conference in London in November 1996 which was sponsored by Ada UK, and to the author's initial surprise it proved extremely popular. This is apparently because Internet access in industry is often more restricted than it is in academia, and few people have the luxury of being able to spend hours scouring the net for potentially useful material. A further 250 copies were therefore printed in January 1997 to accommodate this demand.

As a consequence of the popularity of the first edition, GEC-Marconi and Pavilion Internet agreed to fund the production of a second edition in the summer of 1997. The second edition was distributed primarily by the University of Brighton, but also by the George Washington University in Washington DC to cater for orders from the USA and Canada. An initial print run of 3,500 copies was produced, which allowed the price to be reduced from £7.00 to £3.00 each (\$5.00 in North America). About 2,000 free copies were distributed to educational institutions throughout the UK, and over 11,000 copies were distributed altogether. The BURKS website (<http://burks.brighton.ac.uk>) also registered an average of about 20,000 hits per week from over 100 different countries.

The major difference between the first and second editions was that the second edition used Netscape Navigator 3.01, by permission of the Netscape Communications Corporation. This is a considerably more complex piece of software than Cello, with support for frames, tables, JavaScript, and many other features that Cello lacked. It was also more likely that users would already have a copy of some Netscape browser installed on their system than it would be for Cello. Using Netscape Navigator made it necessary to devise a method to pre-install the browser so that it would have as little impact on the target system as Cello did in the first edition.

Experiments showed that installing Netscape Navigator from the standard distribution copied several megabytes of shared libraries into the Windows directory of the host system. However, as the first place Windows looks for shared libraries in the same directory as the executable file which is trying to access them, the need to copy shared libraries could be eliminated by identifying the files in question and putting copies in the same CD subdirectory as the main Netscape executable. They would therefore be found on the CD regardless of whether they were already installed in the Windows directory tree.

The next problem was identifying the Netscape initialisation file (`NETSCAPE.INI`). This was slightly more problematical than in the case of Cello, as the chances of a user having a copy of Netscape Navigator are much higher than for Cello. For 16-bit versions of Windows, if the initialisation file is not in the Windows directory, Netscape Navigator uses an entry in the central Windows initialisation file (`WIN.INI`) to locate it. 32-bit versions of Windows use the central Windows registry for all initialisation details and have no separate `NETSCAPE.INI` file. Any existing copy of Netscape Navigator would be seriously affected if the initialisation file were changed by the copy on the CD. However, Netscape Navigator inherited several command-line options from its predecessor, NCSA Mosaic. One of these options was a `-i` switch to identify the location of the initialisation file, which is still supported by 16-bit versions of Netscape prior to version 4. (This switch was undocumented prior to version 4, but although it is now documented for version 4 it no longer works as advertised!)

In summary, this scheme requires all the shared libraries to be placed in the same directory on the CD as `NETSCAPE.EXE`, and the startup application must copy a default version of `NETSCAPE.INI` to a directory on the target system and modify it as described above for Cello before finally launching Netscape Navigator using a command line like this:

```
X:\TOOLS\NETSCAPE.EXE -i C:\WINDOWS\BURKS\NETSCAPE.INI
```

where `X:\TOOLS` is the directory on the CD which contains `NETSCAPE.EXE`, and `C:\WINDOWS\BURKS` is the directory to which `NETSCAPE.INI` was copied. Netscape Navigator then starts up using the specified initialisation file (which has been placed in a dedicated subdirectory of the user's Windows directory tree for the sake of convenience).

The scheme described above has the advantage that no executables or shared libraries need to be copied to the user's hard disk, and that any initialisation information is kept in a special initialisation file on the target system which is unconnected with any other installed browsers. This means that the impact on the user's hard disk is minimal, and existing browser installations are not affected.

4. The Third Edition (1998).

The third edition was released in August 1998 with sponsorship from GEC-Marconi and ROCC Computers. Since the second edition comprised a full 650M of material, there was no space left for expansion, and so for the third edition it was necessary to move to a dual CD edition. This entailed a number of significant changes to the design of the system so as to preserve the appearance of a single connected website, while still allowing the two CDs to be installed for public use as a single entity on the BURKS website. The easiest way to deal with this was to put the software archives (the ZIP and EXE files) on the second disk, leaving all the HTML documentation and the Linux distribution on the first disk. This meant that the 650M of the second edition was split into two roughly equal halves of about 300M each. Both disks were provided with identical copies of the browser and index files, so that either disk could be inserted initially. The main problem was the need to prompt the user to change disks if a resource on the other disk was accessed. As an extra complication, Netscape Navigator reports an error if a local URL refers to a file which does not exist or is empty (zero bytes in size), so there must be a complete set of corresponding non-empty files on both disks.

The solution adopted was to use the URL syntax for document subsections [Berners-Lee et al. 1994] (e.g. `http://site.org/document.html#subsection`). Experiments show that when a helper application is invoked, Netscape copies the target URL into a local file, and then passes the name of the local file (usually something apparently meaningless like `x5qp3stv.zip`) to the helper application. At the same time, a temporary entry is made in the initialisation file under the heading 'Temporary File URL Resolution' which maps the local filename to the original URL. All that is needed is a reference to a file (called `INSTALL.SW` in the case of BURKS 3) that will be guaranteed to exist in every software-related directory on both disks, and together with a subsection reference this will result in the initialisation file containing a line mapping the filename to a complete URL, e.g. a line like this:

```
c:\temp\x5qp3stv.sw = file:///x:/burks/software/langs/install.sw#2:gnat307d.zip
```

The helper application will then be passed the name 'c:\temp\x5qp3stv.sw' as a command line parameter, and from the entry in the initialisation file it can extract the directory name (`x:/burks/software/langs`), disk number (2) and the name of the file (`gnat307d.zip`) that needs to be installed. The inclusion of the disk number allows this scheme to be extended to work with any number of disks. The file `INSTALL.SW` will have been copied to `c:\temp\x5qp3stv.sw` from the directory `x:\burks\software\langs`, and the only thing required by Netscape Navigator to make the trick work is that `INSTALL.SW` should exist and be non-empty.

As one of the project requirements is that the CD be available online, the `INSTALL.SW` files need to contain genuine HTML content (and the BURKS webserver needs to be configured to serve up *.sw files as HTML files) so that external visitors will see something worth looking at when they reference the online equivalent of the URL above:

```
http://burks.brighton.ac.uk/burks/software/langs/install.sw#2:gnat307d.zip
```

Since web browsers ignore white space in HTML text, a little judicious formatting allows the installation instructions to be expressed using valid HTML syntax, and this formatting is easily accomplished by a Perl script which generates the index files from the master file list during the CD production process. Here is an example:

```
<DT><A NAME="2:gnat307d.zip" HREF="gnat307d.zip"
>gnat307d.zip</A><DD>
<B>Directions:</B>
Unzip into an empty directory, then
run SETUP.EXE
<BR><B>Notes:</B>
Be careful: if you have GCC installed
anywhere else on your system, make
sure that your path is set up so that
you pick up the correct version. Using
the wrong version by mistake will usually
crash your system.
```

Despite the eccentric layout, this is valid HTML [Raggett 1997]. When viewed online at the BURKS website, a standard browser will display it like this:

gnat307d.zip

Directions: Unzip into an empty directory, then run SETUP.EXE

Notes: Be careful: if you have GCC installed anywhere else on your system, make sure that your path is set up so that you pick up the correct version. Using the wrong version by mistake will usually crash your system.

When the same URL is referenced from the CD, the associated helper application interprets the HTML text shown above as an installation script where the first character of each line determines its role. The file name is given on a line which begins with '>'. Lines beginning with '<' are ignored; lines beginning with 'U' indicate that the file must be unzipped, lines beginning with 'r' specify the name of a setup utility (SETUP.EXE) to be executed, and so on. Lines beginning with a space (the last six lines in the example above) are displayed as installation notes by the helper application to provide additional guidance for the user.

The helper application asks the user to remove disk 1 and insert disk 2. Users can specify an alternative drive letter for disk 2 if they have multiple drives; the helper application records the drive letter for each disk in the Netscape initialisation file. It then parses the installation instructions in the INSTALL.SW file that has been copied to the hard disk and installs the software as instructed, and finally asks the user to re-insert the original disk if the same drive is being used for both disks. The helper application checks for the presence of a file called README.1 or README.2 in the root directory of the CD to identify which disk is currently loaded.

To maintain the illusion of a single shared website, despite it being split across multiple CDs, it is possible to insert either of the two disks to start with. Both disks contain identical copies of Netscape Navigator and associated software, as well as copies of all the top-level indexes. However, on the second disk the opening page of each document from the first disk is replaced by a stub page containing some simple JavaScript which displays a blank page together with a JavaScript-generated dialog prompting the user to remove disk 2 and insert disk 1. If the OK button is pressed, the current page will be reloaded; if disk 1 has been inserted, this will now be the opening page of the requested document. If the Cancel button is pressed, the browser will go back to the previously displayed page, which will be the index page which referenced the missing document.

5. Summary and Conclusions.

The use of a web browser which is pre-installed on a CD has a number of benefits:

- It is unnecessary to rely on the user having a web browser already installed
- The material on the CD can be targeted at the specific browser supplied, thus avoiding problems with HTML and JavaScript incompatibilities between browsers
- The browser can be tailored to use a specific home page and a specific set of plug-ins, helper applications and so on.

Since CD-ROMs can hold up to 650M of material each, it is important to provide comprehensive indexes to allow specific items to be located in the mass of material available. HTML is a convenient means of indexing which can be processed by standard web browsers, eliminating the need for any special-purpose index processing software. It also allows links to external sites to be provided. (An important requirement not covered in this paper is the need for tools to automate the generation of the HTML index files on the CD.)

There are some limitations: since the browser is not being used in conjunction with an active server, the scope for automation is limited to JavaScript, helper applications and plugins. Another problem is that 16-bit versions of Netscape have been used, both to support users of 16-bit versions of Windows and to use the *-i* switch to specify the location of the initialisation file. These versions do not support long file names or Java applets. 16-bit versions of Netscape version 4 browsers support Java, but have complications which prevent their use as described above (the *-i* switch, although documented, does not work correctly, and there are also some issues related to the use of the registry).

As this paper shows, it is a fairly simple matter to produce a CD-ROM which behaves as a self-contained website and which has a minimal impact on the user's system, although there were a number of interesting problems to be solved along the way. The BURKS project has been successfully producing such CDs for the past four years, and the current version is a 2 CD set which still behaves as a coherent integrated website. It is hoped that this paper will stimulate others to produce similar products, and indeed the author has received a number of

queries from others who wish to produce similar products for subjects other than computer science. Developments such as DVD [ECMA 1997], XML [Bray et al. 1998] and increased Internet accessibility will undoubtedly require the product to continue to evolve, or might even eliminate the need for it altogether, but as long as the demand persists the BURKS project will continue to investigate better ways of providing large amounts of material for students at the lowest possible price using whatever technology is appropriate.

Educator as Trainer: Technology in Action

Beverly Enns, Ed.D.
The Study Circles Series, Ltd
Philadelphia, PA, 19040 USA
enns@iamareader.com

Abstract: Educators can make the transition from the classroom to a virtual environment to prepare graduate-level, web-based coursework in specific areas of technological expertise. These experts who have become knowledgeable in an area of technology can receive recognition for their efforts as they share this expertise with other educators. The steps educators take to become trainers and independent vendors of course work is both exhilarating and frustrating as new virtual spaces are created by teachers who have only known the four walls of their classroom. This paper examines the steps educators can take to become web-based independent vendors offering graduate-level, web-based courses to other teachers in their field of expertise.

Introduction:

In a recent study, Technology Counts '98, test scores demonstrated that "Computers can raise student achievement and even improve a school's climate" (Archer, 1998). The test scores of this report, 1996 National Assessment of Educational Progress, were analyzed for *Education Week* by Wenglinsky, a research scientist for Princeton University. These findings are significant to the position of this paper:

Eighth graders whose teachers reported using computers primarily for drill-and-practice scored lower on NAEP--by more than half a grade level--than students whose teachers reported other primary uses of computers. Students whose teachers concentrated on simulations and applications, meanwhile, scored higher by two-fifths of a grade level.

The same factors that were tied to better achievement also appeared to be linked to an improved school climate. Where teachers had professional development with computers and used them for teaching higher-order skills, schools tended to enjoy higher staff morale and lower absenteeism rates.

Teachers who had received any amount of professional development with computers within the past five years were more likely to use computers in ways that Wenglinsky found to be more effective than teachers who had not received such training. (Archer, 1998)

If the evidence is conclusive that trained educators who use computers in effective ways to raise test scores and improve morale, then educators need to be the trainers for other educators. Many classroom educators have demonstrated tireless efforts to integrate technology in their teaching and learning process. Although these educators recognize their experience as invaluable, they lack the skills or know-how to present this expertise to a large audience. Who becomes technology trainers in educational settings is often a mystery and the infrastructure for the delivery of technology training is ambiguous. This is a memo I received from an educator enrolled in a graduate class:

Hi Dr. Enns...I was reading the text and could not stop thinking about the possibilities of what I could do next year in my school district...there are chances for me to work as a technology specialist in the district...my questions are what can I do to *shine*, get noticed by others...I just wish to come across as a person who knows his stuff and demonstrates his confidence...I do not want to be overlooked.
(Anonymous Graduate Student, 1998)

This is only one of many comments educators have made in my graduate level courses that have led me to develop a program called Technology in Action (Enns, July, 1998). By participating in this program, educators can learn to become web-based trainers as independent vendors.

Background

In 1989, a corporation, The Study Circles Series, Ltd., was formed to provide educational programs for teachers, parents and students. At first all courses were presented in on-site format, but with ever-advancing technological advancements, it is now possible to present courses in a web-based format. However, for the successful delivery of web-based courses, an infrastructure needs to be in place. First, educators need a web site to prepare and deliver web-based courses. Second, educators need a host or college or university that will validate course work and provide incentive or college credit for course work. The infrastructure for this program, Technology in Action, is presented as a web-based course at a privately owned web site, <http://www.studyircles.net>. In an agreement with the instructor, The University of St. Thomas in Minneapolis, MN, the course is approved for credit through their Continuing Education Program. Program information and course offerings are available at <http://www.soe.stthomas.edu/websoew>.

The idea for the program, Technology in Action, originated from my experiences in the early 1980s. Since the earliest applications of technology have been available to educators, some teachers have taken the initiative against all odds to integrate technology into their teaching and learning practice. Because these educators are active innovative practitioners who are stimulated by on-going technological advancements, they need opportunities to share their insights with other educators. Support for educators to become technology trainers is often not available or accessible for educators. Technology in Action prepares educators to teach other educators the technology they have found so successful in the classroom. Educators participate in a web-based course that follows a traditional format of three continuing education graduate-level semester credits. Throughout the course, educators actively experience the motivation and engagement of web-based instruction.

Reflective Active Participation:

The process of transition from educator to trainer and as independent vendor includes an understanding of reflective active participation. (Enns, March, 1998) In this collaborative learning process, educators focus on the organization of a digitized portfolio that includes a professional assessment of technology skills needed for training and web-base presentation. Educators are encouraged to engage in a web-based dialogue on the process of assessment leading to the mastery of technology skills needed for professionals who provide leadership and training. The following questions prompt educators to reflect on areas of expertise:

1. Briefly explain how you came to understand and use this technology in your teaching?
2. What experiences have you had with technology that will be of value to other teachers?
3. What specific technology skills are included in the integration of technology in your curriculum area?
4. What have you observed about student learning when you use these technology skills in the classroom?
5. Have you done any reading and research that supports the use of these technology skills in the classroom?

As educators gather their reflections on these questions, they are also gathering the beginnings of course descriptions, course objectives and references that will be used later in the course. What is important in this reflective stage is for educators to realize their own growth process and active engagement with technology. With this realization, educators can begin to consider how to disseminate their specific areas of expertise. Developing spaces for reflective activity strengthens the realization that constructive learning opportunities as events can successfully occur in web-based instruction. (Harasim, Hiltz, Teles & Turoff) The process for reflective active participation continues to provide an avenue to understand, manage and trust their own ability to provide innovative learning opportunities.

Introspective Assessment

Educators wonder if they will be able to train. They wonder if they can hold the attention of other adults. They wonder if the skills of trainers are the same as the skills for educators. As educators move through this process of introspection, it is helpful to offer them opportunities to engage in actual assessments that provide appropriate feedback and benchmarks for them to use as they consider their role as a trainer.

The *Learning With Technology Profile Tool* found at <http://www.ncrel.org/capacity/profile/profile.htm> offers educators a way to think about engaged learning with technology. It also assists educators in the selection of *current practice* and *best practice* indicators. This profile stimulates discussion and energizes educators to continue the assessment process in the transition from educator to trainer.

The MAPP, *Motivational Appraisal of Personal Potential* (IAN, 1995), is a diagnostic tool measures individual's potential and motivation for given vocational areas. This individual assessment can be taken by educators in a web-based format at <http://www.assessment.com>. The Personal Appraisal or print-out of this assessment provides a narrative and graphic representation of such areas as interest, temperament and aptitude. With this assessment, educators can analyze their motivational strengths as educators and as trainers. A study on the comparative data on educators and trainers is now in progress. When this study is complete, it will offer additional support for educators as they follow this assessment process.

Technology in Action

This is it! This is the educator's expertise. The experience the educators have had with technology in the classroom to promote successful learning is technology in action. It is this action that educators are encouraged to replicate and disseminate in a web-based course. As educators consider an instructional design that will be appropriate for the delivery of their area of expertise.

Reeves & Reeves provide ten dimensions of interactive learning that serves as a model as educators align course content with pedagogical and andragogical philosophies. This model offers educators choices and suggestions that permit flexibility and encouragement to be innovative in the instructional design of technology-based course content. (Khan, 1996 pp. 59-66) A representation of this model is also available at <http://itech1.coe.uga.edu/higherEd/index.html>.

Within the development of an instructional design, educators realize the learning experiences in a web-based environment as a series of events. Considering the learning experiences as events is helpful because a web-based course is not in a familiar classroom. Each learning experience must be pre-designed and thoughtfully prepared. Categorizing learning experiences by these seven events (Williams, 1980) is very helpful as educators move from classroom thinking to training in a web-based environment:

1. Motivational attention-getting events
2. Presentation Events
3. Observation Events
4. Experimental Events
5. Checking for Understanding Events
6. Energizing Events
7. Transfer Events

Through collaborative discussions, educators design, organize and construct teaching and learning activities that will form the series of events of their first graduate-level, web-based course. The process for reflective active participation introduced at the beginning of the course continues to provide an avenue to understand, manage and trust their own ability to provide innovative learning opportunities. Reflecting on such issues of pedagogy and andragogy in new learning environments challenges the deep-seated belief and value systems of teachers and trainers. Developing spaces for reflective activity strengthens the realization that constructive learning opportunities as events can successfully occur in web-based instruction.

Educators as Entrepreneurial Vendors

When educators prepare a web-based course and package it for delivery, it is their responsibility to find a college or university that will include the course in their existing programs. Educators may find that courses they design are picked up by their local educational institutions and marketed in-house. Many educators are satisfied with this delivery format while others seek a larger audience. It is a stretch for educators to gain an understanding of the role and responsibility of an independent vendor while realizing the potential to become entrepreneurial. Porter presents this challenge.

Who should (or eventually will) participate in distance learning programs? Ideally, the answer is *everyone*. Although, that may not be practical, the possibility for reaching more people through distance learning is greater than ever before, as is the need to educate, train, or retrain greater numbers of people. (p. 5)

Educators who have been trained as classroom teachers appreciate a very basic orientation to the management process leading to the dissemination of course materials in a web-based environment. Such topics as software for course development, internet providers for course dissemination, and server access that accommodates database collections and strategies for marketing and advertising all present may questions that provide rich web-based discussions.

1. What is your greatest strength as a trainer?
2. How can you bring this strength into a web-based course?
3. Will your role as a vendor strengthen or challenge your best practice?
4. What weakness in your teaching/training may also surface in a web-based course?
5. Do you know a trainer who is an independent vendor?
6. Will you be comfortable being the only trainer you know who is also an independent vendor?
7. Will you be comfortable continuing as a classroom educator, but beginning your vendor endeavors?
8. Will the practice of an independent vendor change you in some way as a classroom educator?
9. Do you have moral or ethical concerns about becoming an independent vendor?
10. Will you be comfortable making money (maybe a lot of money) as an independent vendor?
11. Will you be comfortable if your course is financially a loss for several semesters until the concept catches on?
12. Can you manage money meaning that you will have to collect course fees and pay UST or other educational institutions for the credit. Can you separate profit from financial obligation?
13. What have been your entrepreneurial adventures to date?
14. Will you be prepared to make some financial investments to get your course going that may not be returned immediately?
15. Will you enjoy being the taking all the calls with concerns and questions about your course?
16. Will you be able to take and make calls from your home phone?
17. Will you be comfortable preparing mailings and marketing materials at home?
18. Do you have the resources at home to prepare course materials? Where will you go if you don't.
19. A distance course means that you may have students out of your calling area. Will you mind making long distance calls?
20. Will you enjoy the management of your course as well as teaching the course?
21. Will you be comfortable telling your friends that you are a trainer and an independent or private vendor?
22. Will it bother you to be teaching one course while preparing or marketing another one?
23. Will your role as an independent vendor change your family role at home?
24. Are you prepared to discuss these changes in advance or as they occur?
25. What will your family notice first about your change in roles?
26. Will you be comfortable working out of your home?
27. What frustrates you about risk-taking adventures?
28. Who will you call if you are frustrated?
29. Would you like to stay connected to others who are learning how to become independent vendors?
30. List five more questions that we can add to our collection.

Collegial Collaboration

Within a network of support provided by all educators who participate in Technology in Action, educators, now trainers, realize a safe haven for nurturing, mentoring and collegial collaboration as they share bumps and bruises of first-time web-based instructional experiences. Collegial collaborationS is not only an activity for participants in a web-based course, it is also a great support for trainers who are discovering new skills and innovative practices that transform the educational practice with every new experience. To give and receive support in the same web-based environment as the instruction, trainers gain confidence in new-found abilities to teach and learn.

The steps educators take to become trainers is a reflective process that leads to a greater understanding of models of learning and instructional systems design that leads to innovative and transforming web-based teaching and learning experiences. Those who have participated in this reflective discussion have offered these comments. (Anonymous Graduate Students, 1999)

Why are you interested in preparing a web-based course?

When I think of the time I waste driving to work, trying to reach people on the phone, waiting for late arrivals to class, I start dreaming of the day I can work like....

Wasn't the theory of gravity discovered while enjoying nature under the apple tree? Some days I think anyplace would be more conducive than a classroom without windows!!

My reflex response is that I need to be an independent teacher practitioner in order to continue earning and retire with my husband. But lately I have found there are many people who need a great deal of flexibility within the field of education in order to pursue their career goals. For the French teacher struggling with cancer, the family oriented with young children at home, The coach who is needed on site darn near 300 days of the year...online curriculum seems to have answers for them...

I agree. Flexibility is a major component that can determine the success of the prospective student. I have often contemplated the importance of deadlines and schedules, and realize they are impossible to escape from, but why must we be confined not only to a deadline, but a 9 to 5 workday as well. I have found that I am much more productive at times well outside of the typical workday, but this doesn't fit with our current paradigm of a day.

I see new dimensions appearing for the way we learn, and the way we teach. Any thing that I can touch someone. I am also interested in teaching adult learners for continuing education classes. It is surprising how little most teachers now about the computer in our school. The standard use is word-processing and grading programs, a few surf the net for fun. I would like to be able to help change that, along with bring in extra income if I decide to take time off to stay home to have a couple children. What better way to accomplish both than on line instruction?

Virtual Learning Spaces in the Web: an Agent-Based Architecture of Personalized Collaborative Learning Environment

Gustavo Núñez Esquer

Computer Science Research Center, National Technical University, Mexico
gustavo@cic.ipn.mx

Leonid Sheremetov

Computer Science Research Center, National Technical University, Mexico
sher@cic.ipn.mx

Abstract: This article reports on the results and future research work within the paradigm of Configurable Collaborative Distance Learning, which we have named EVA. The article focuses on the description of the main concepts, multiagent architecture, implementation of particular agents, software and LAN/ATM hardware platform developed for the EVA environment. Prototypes of agents have been developed using VC++, JAVA, LALO, and JATLite for Unix and Windows platforms.

1. Introduction

Since their conception, knowledge-based learning environments have offered significant potential for fundamentally changing the educational process [Mark & Greer 95, Chan 96, Youngblut 94]. Nevertheless, despite of many expectations, few learning environments have made the difficult transition from the laboratory to the classroom, so the development of pedagogically sound tools has been the time challenge. Recent trends in Web-based learning environments involve collaborative work as embodied in Computer Supported Cooperative Work for human-computer interaction and Distributed Artificial Intelligence for learning. These resulted from the proliferation of networks ranging from local sites to the Internet. Computer Supported Cooperative Learning (CSCL) systems have been built on the lessons learned from the past approaches such as Computer-Based Training, Intelligent Tutoring Systems and Interactive Learning Environments. Perhaps their most important significance is the ability to offer a collaborative environment that utilizes the experiences of other students, different teaching strategies, the recorded group expertise and the capabilities of software tools to arrive at a particular convergent solution in a group fashion.

The investigation project *EVA (Espacios Virtuales de Aprendizaje* in Spanish - *Virtual Learning Spaces*) applies the CSCL methodology to obtain a new paradigm of the Configurable Personalized Collaborative Learning [Núñez et al. 98]. This project is dedicated to the research and development of pedagogic models and information technologies that provide spaces of knowledge, collaboration, consulting, and experimentation for supporting the learning activities of teams separated geographically.

Agent technology is the promising way to approach these problems. The notion of agents is the central part of contemporary learning environments, where they act as virtual tutors, virtual students or learning companions, virtual personal assistants that help students to learn, mine information, manage and schedule their learning activities [Müller et al. 97, Barros & Perkusich 96, Gordon & Hall 98]. The main purpose of our project is to develop models, architectures and multi-agent environment for collaborative learning and experimentation. The focus of this paper is the multiagent system (MAS) architecture of the EVA environment.

2. EVA concepts

The main concepts of EVA are the following:

1. The Virtual Spaces of knowledge, collaboration, consultation and experimentation as the collection of agents and conventional software components working over the knowledge domains.
2. A "Multi-book" concept, a personalized electronic book, generated by concatenating of selected units of learning material (ULM) and associated personal and group learning activities along the learning trajectory for each knowledge domain.
3. The intensive use of agent-based tools

- as virtual tutors, virtual students or learning companions, virtual personal assistants that help students,
- for mining information, managing, planning and scheduling learning activities, information retrieval and filtering, student assistance and tracking for evaluation of their intentions and performance, and
- to organize the workgroups and groups activities, and re-configure their work and knowledge spaces.

The conceptual architecture of EVA is structured into four essential knowledge elements, which are information deposits and sets of programs called Virtual Learning Spaces. These spaces are: *knowledge* - all the necessary information to learn, *collaboration* - real and virtual companions that get together to learn, *consulting* - the teachers or tutors (also real and virtual), who give the right direction for learning and consult doubts, and *experimentation* - the practical work of the students in virtual environment to obtain practical knowledge and abilities. To represent knowledge we have proposed a model based on the hierarchy of domains and concept graph representation of knowledge and learning activities. This model is used for learning trajectory planning, virtual space configuration and student tracking.

3. Agents in EVA

The core of the EVA environment consist of a number of components, composed of a set of deliberative and auxiliary agents, considered below. Agents form the intermediate layer between the users and virtual spaces (fig. 1).

3.1 Multiagent environment of personal education

The environment of collaborative education and smart personal assistance for tutors and students, consists of several agent types:

Internet search and filtering agent (A_{SF}): automatically searches for additional teaching material in the Internet, not yet located in the Knowledge Space, according to student's learning trajectory and through natural language searching tools (such as Clasitex [Guzmán 98]). Synthesizes information compiled of several sources about the same topic and filter redundant and repetitive information.

Collaboration agent (A_C): compares student's academic development and profile to form collaboration groups, requests help or information from other assistants and make collaborative decisions on how to select, integrate, and order information to be shared between the tutor and students or inside the students group.

Personal advisor (A_{PA}): suggests a personalized study plan to student according to its academic formation, interests, abilities and advances, and modify study plan, if it is necessary. Selects, integrates, and orders the information to study; advises for the learning problem solving, tells where to find learning material and tests, help the student to choose sources, suggests topics of thesis or projects, indicates to the student virtual labs, where it can make practices. This agent communicates with the search agent to find information according to the topic, it communicates with collaboration agent to collaborate with the rest of the group members. Also reminds a student about events, conferences, videoconferences, courses, tasks, tests, etc.

Evaluator agent (A_E): verifies periodically the learning advances, tries to find causes of misunderstanding, communicates with the advisor agent to re-organize the information to study.

Our prototype of learning community incorporates also a *Group Monitor agent (A_{GM})* and a *Learning companion agent (A_{LC})*. The most of agents have been implemented in JATLite package with rule-based inferencing capabilities, programmed in Jess [JATLite 98, Friedman-Hill 98]. All agents collaborate through the message passing mechanism in agent communication language (currently, KQML) [Finin et al. 97].

3.2 Multiagent planning

A learner navigates the virtual learning spaces by routes (*study plans*) suggested in an automatic manner by EVA. So, the purpose of the planning system is to design a particular learning trajectory for each student in the knowledge space, formed by ULM, which is organized in knowledge domains. At the next stage, personalized books, called Multibooks, are armed by concatenating of selected ULM along the learning trajectory for each knowledge domain. In the same way, groups of students with similar interests are arranged. Finally, student learning activities must be scheduled to satisfy temporal constraints.

Initial study plan and learning activities scheduling is generated on the bases (i) of student's initial knowledge in each area of Computer Science at the graduate level according to the model, proposed by the ACM [ACM 91], and detected, for example, at the admission exam stage, and (ii) his interests in terms of sub-specialty or separated courses from the area, which defines student's final state in the knowledge space. Initial student's knowledge is considered as initial conditions for the common domain.

To perform planning and scheduling within the MAS paradigm, we have proposed to associate a planning agent (A_p) with each domain model. When viewed from the perspective of the system goal, the global study plan appears as an AND-OR tree progressing from the system goal (at the root), down through goals and plans, to local plan fragments distributed among the agents. Constraints are associated with each node of the tree. Since local goals and decisions are interconnected, developed multistage negotiation algorithm provides means by which an agent can acquire enough knowledge to reason about the impact of his local decisions and modify its behavior accordingly to construct a globally consistent decision [Sheremetov & Núñez 99].

Learning Activities Planning System with Multistage Negotiation is implemented using JATLite. It is composed of n planning agents and a *coordinator agent*, which inherit their methods from the RouterClient class. Agents are implemented as JAVA applets, so they also inherit methods from the Applet and Frame (to support graphic interface) classes of JDK 1.2 package.

3.3 Agents for virtual laboratories

Even though the virtual learning environments has been studied from a pedagogical perspective in the last years, few researchers has formulated clear methodologies how to create Virtual Laboratories for to cooperation in the WWW [Rodríguez et al. 98, Forbus & Kenneth 96], even less based on Virtual Reality Modeling Language (VRML) scenarios [Lemays et al. 96].

The EVA project contemplate in an integrated way, the following key elements:

- Tele-presence, including the monitoring and smart remote control of systems.
- Computer aided experimentation (real and virtual).
- Assistance in performing the experiments that enables configuration, performing and explanation of results.
- Distributed and collaborative work environment, based on VR interfaces.

We've developed a CASE tool, called EasyVRML to assign more complex behaviors to the VRML scenarios in a more simple form then conventional tools [Quintero et al. 98] (fig. 2). VRML allows to change the object and agents features of a scene (shape, color, position, size, orientation, etc) in function of determined events through the script languages [Mitra et al. 95]. We have developed several applications for the experimentation space of "Distributed Intelligent Systems" and "Virtual Reality Design" courses, which allow the students to develop their agents, execute them and visualize their behavior in the virtual worlds. These agents include the following types: *Behavior Agent* (A_B), which visualization must be generated in virtual environment, *Interface Agent* (A_I) to generate a user's interface (a Web page) and to allow the user to control the *Behavior Agents*, and *Experimentation companion* (A_{EC}), which pertains to the learning companion type, discussed above.

Actually, the implementation scheme is based on the integration of four programming languages: (1) LALO like agent programming language, (2) VRML for the generation of the virtual environment and the graphical representation of these agents allowing to generate 3D representations of dynamical scenes through a browser, (3) VC++, resulting code of the compilation of LALO source programs, (4) Java programmed interface between VRML and VC++.

4. A Unifying Framework for Agents in EVA

Since there exist a great number of education technologies, pedagogical models and styles, as well as software technologies to be reflected in the architecture of potential learning environment, we need to be concerned about whether any software architecture has a possibility of outliving its designers and of providing a suitable foundation for unanticipated additions of significant new features. Current consensus on these issues is probably that the most robust unit of reusability is a "framework" making use of "objects" or "components" and agents [Bradshaw et al. 97, Grimes & Potel 95, Smirnov & Sheremetov 99]. In EVA, we have prototyped various components of a framework, with agents providing dynamic coupling and interoperability between components using standard interfaces and data formats.

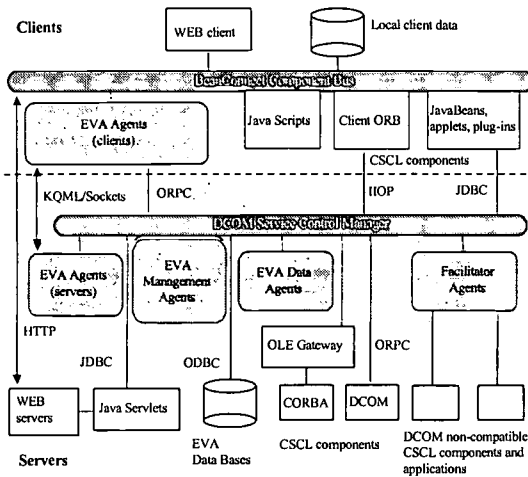

Figure 3. EVA Unifying Framework

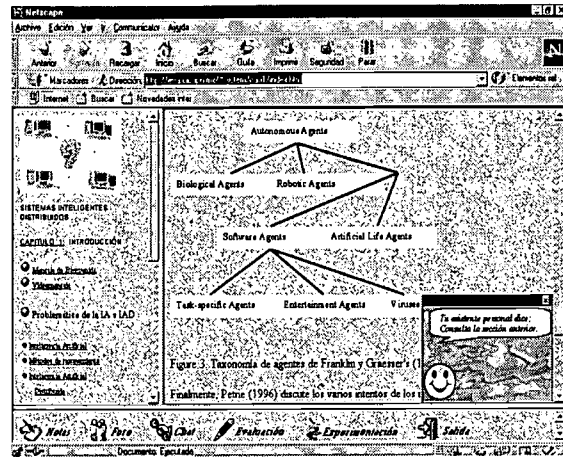

Figure 4. EVA user interface in the knowledge space

5. EVA platform

Developments like those proposed in this paper would not be possible without nowadays achievements of computer networking and telecommunications. So, we explore the advantages of the key communication technologies like Asynchronous Transfer Mode (ATM) and SONET (Synchronous Optical Network) as a transmission standard [Martinez & Su 99]. Then, to be able to test the EVA environment, the LAN/ATM based Experimental Distance Learning Laboratory was installed. The core of the system is an ATM switch with 8 gates at 155 Mbps, with the possibility to extend the capacity up to 622 Mbps, connected to the IPN ATM backbone and to an ATM LAN switch with 24 Ethernet inputs (10 Megabits each).

This Laboratory is the key element for the development of the ATM Experimental Center of Information Exchange, where the following on-going projects are being developed:

- Development, implementation and testing of teaching/learning activities in EVA environment
- Testing of performance of multimedia applications via assignment of virtual channels and bandwidth of the LAN/ATM network
- Transmission of signals and images over ATM using different compression techniques.

We also consider as the future work the integration of the Center into the Internet2 Mexican initiative, which is now at the planning stage and will be operative in 2001.

6. Conclusions

The EVA environment makes intensive use of agent technology, developing models, architectures and multi-agent environment for collaborative learning and experimentation, such as (i) multiagent generic open environment, based on federation architecture, models of knowledge sharing, and generic agent template with multi-level communication architecture, making use of KQML and ActiveX controls, (ii) personal learning assistants with information filtering capabilities (iii) agents for individual and collaborative learning with artificial learning companions, (iv) agents for planning of learning trajectories, and (v) multiagent experimentation space.

EVA is effectively used by the students of the CIC-IPN in the domain of the Master and Doctorate education in Computer Science. At the current stage of the experiment we are also developing the course on "The Potential of Virtual Reality in the Teaching of Engineering" to be delivered at the University level for about 200 teachers of engineering. We are working in a strict evaluation of the improvements brought by the mentioned techniques.

Acknowledgments

The EVA project is the effort of many people. We would particularly like to thank our colleagues from CIC-IPN for their determination and contribution to the system development, especially Jesús Martínez. We also thank the students of Doctorate and Master Programs for contributing ideas and talent to EVA programming, especially R. Peredo, L. Balladares, R. Quintero and A. Armenta.

Telementoring Middle School Girls: Eyes to the Future

Joni Falk, TERC, USA, joni_falk@terc.edu
Brain Drayton, TERC, USA, brian_drayton@terc.edu

Abstract: This paper describes the design and initial finding of an innovative mentoring program which connects middle-school (MS) girls of all abilities to female mentors working in math and science related fields. The purpose of the project was to provide urban middle-school youth with role models who have pursued math and science in high school and beyond. Unlike many school-to-work initiatives which inspire young adolescents to think about alternative long-term futures, this project also concentrated on the path that lies more immediately ahead of MS students -- high school. The paper provides evidence of the power of a long-term mentorship program to engage students of all levels of academic achievement with the content of math and science, and with issues particular to female students in MST. This project was funded by Arthur D. Little, Inc. and is housed at TERC, Inc. of Cambridge, MA.

There is still a wide gap in girls' achievement and rates of enrollment in science courses in comparison with boys. The gender gap in attitude and achievement progressively widens from age 9 through twelfth grade (Kahle & Meece, 1994).

Studies suggest that girls benefit from engagement with adult mentors through increased knowledge about possible future paths and improved self-confidence with regard to Science, Math and Technology. Adult mentors can supply emotional and academic support critically needed in the transitional period from middle school to high school (Campbell, 1990; Gilligan et al., 1990; Kahle et al., 1993; Nightingale & Wolverton, 1993; Kahle, 1987, 1989). Role models also can provide students with personal connections to possible futures that they would not otherwise believe to be within their reach. This may be especially important if parents do not or cannot provide such role modeling. While several projects have connected high-school girls with women in the workforce, less is known about the benefits that can result when middle-school girls have high-school girls as mentors, in addition to adult mentors.

Context

The "Eyes to the Future" program began with a pilot in the fall of 1997 in collaboration with one middle school and one high school in Somerville MA. The first phase of the pilot included one month of recruitment, training, and website design and three months of communications among the fifteen middle-school girls, five high-school girls, and five adult women who took part. Middle-school students were selected on a "first come" basis and represented a wide range of academic achievement as well as broad ethnic diversity. The HS students were selected with the help of the HS science coordinator who sought students known to be responsible, engaging, and strong in math, science, and technology (MST). The adult mentors were selected by following students' interests and included a boat builder-engineer, an ecologist, a veterinary technician, a pediatrician, and a geologist. TERC and school staff met weekly with the middle-school girls to facilitate activities. Over the course of three months, the middle-school girls and the high-school and adult mentors communicated frequently through the website, and every member participated.

The success of this pilot led to the program's expansion in the 1998-1999 school year. This second phase involved the development of an interactive website that would facilitate communication, sharing of science projects, space for personal reflection and the creation on a collaborative book that would document the students experiences on the project. The project was implemented during the second year in two middle schools: the West Somerville Neighborhood School in Somerville, and the Devotion School in Brookline (MA). It involved 30 middle school students, 10 high school students and ten adult mentors.

The current paper will focus on results of our first year's experience in the fall of 1997 and the subsequent design of an interactive website that emerged from this work.

Data Sources

Data used for this study were drawn from several sources. All network conversations between participants were archived as text files. In addition, there were focus groups with the middle-school and the high-school girls, face-to-face and electronic conversations with the participating teacher and mentors, and background questionnaires from the middle-school and high-school girls. Qualitative data were read and coded by two researchers, seeking themes and patterns within and between groups. Themes that emerged were discussed with the participating teacher.

Our findings address the following research questions:

- What were important themes that emerged from the mixed-age dialogues?
- What were the relative contributions of high-school and adult mentors?
- In addition we present the main features of the interactive website which emerged from this initial round of work.

Results and Discussion

Themes that emerged from dialogue between middle-school girls and high-school mentors

Middle-school students communicated for a period of approximately twelve weeks with their high-school mentors. The messages were often complex, containing many topics. It was common for a message to contain personal information, some questions about high school, a funny vignette that occurred at school, as well as a request for help on a science project.

The middle-school girls represented a broad range of academic ability and several were doing poorly in school. In contrast, all the high-school mentors were selected because they had pursued math and science in high school. Further, the high-school girls had different ethnic backgrounds from those of the middle-school girls. Initially, we questioned how these two groups would relate. Our fear was unfounded, as all five groups of middle-school students (three middle-school students were paired with each high-school mentor) related well to their mentors.

The following themes were most salient in the dialogue between middle-school girls and their high-school mentors.

Providing affective support

The tenor of the conversation between middle-school students and their high-school mentors was very personal and friendly. On each team three middle-school girls communicated with one HS mentor and one adult mentor. Even though the middle-school girls knew that all five people could read each message, they were surprisingly not self-conscious about the content of their messages. Frequently, the middle-school students shared their success, failures, and fears about high school with their mentors. Middle-school students wrote when they did well on their report cards and sought advice when they received poor grades on report cards or tests. The middle-school students wrote about subjects that were difficult for them and shared fears that they had about the transition to high school. The high-school girls showed remarkable sensitivity in answering personal queries and provided a great deal of affective support.

The high-school girls sent many messages that seemed to invite a personal dialogue.

From C++ (high school mentor): Now it's your turn to talk about yourself. Tell me anything you want me to know, anything you feel comfortable with, no pressure. Our main subject is SCIENCE & MATH, but we can bend the rules a bit. We can talk about anything (appropriate). If we do get off track too much, I'll steer us back.

In turn, middle-school students felt free to share their fears.

In a sense I am a little scared to go into the high next year. Even though this school is pretty big, the first school I went to was only one floor and one room per grade. It was called the Conwell. I hope at the High that I can join lots of clubs and stuff to keep me busy like I am now.

Learning about High School: the culture, the classes, the clubs, and the teachers.

When the middle-school girls began to converse with the high-school students it became apparent how important it was that these students came from the same district. Many messages helped to demystify the high school for the middle-school girls. The high-school students provided details about life in Somerville High School. They described the school's physical layout, interesting classes, supportive teachers to look for, and a wealth of knowledge about clubs that would support peer interactions as well as continued involvement in science and math. Furthermore, they passed on lessons they had learned about how to succeed in challenging classes, or with difficult teachers.

...High-school is actually not that intimidating....It's big, but very accessible. Room 100's are on the 1st floor (basement) 200's on the second floor...And the rooms are in numerical order. English has its own english wing...science has its own section. There are lots of clubs in the high-school. Science Club is definitely one club you should consider....

Providing a positive image about hard working students

The high school mentors often talk about working hard but reaping the benefits of their effort. They were clear that they balanced work with other interests such as dance, tennis, and socializing, but that they took their work seriously. One middle school student writes of being self conscious of doing "too well."

Sometimes I feel stupid when I get my report card. I get A's and B's, mostly all A's. Sometimes I feel stupid because other people call me a geek and say I'm too smart. I'm proud of my accomplishments, but I feel really bad when people make fun of me.

Her high school mentor is able to reassure her: Before I go I want to answer the question to J.T.S. about her grades. I think that you shouldn't worry about what other people think of you. Most of them are just jealous because they can't get the grades you do. When you get to high school, nobody really has problems with people getting good grades.

Positive view of Math, Science, and Technology

Perhaps one of the most valuable contributions of the high school students was their genuine enthusiasm for math and science. They were unabashedly excited about these subjects and very expressive about why they thought middle school girls should pursue them.

Well, I think science is THE most interesting subject, because it is infinite, but my absolute favorite is bio. There is no end to biology. Everything will always evolve into something totally different. However, other science are also neat. Because I like bio so much, I plan on taking pre-med in college. There are so many interesting things in the scientific world. Opportunities are endless. Even computer science is an expanding field.

Middle school students appealed to the high school students for help in selecting science projects. Here too, the high school girls showed good judgement, giving suggestions but not doing the work for them. A little bit of advice and encouragement seemed to go a long way.

(From HS mentor): Like I said to Micaela, tell me what you're interested in and I'll help you think of a topic. It's no use for me to suggest a topic that you have absolutely NO interest in. Tell me what areas you like. Hey, you should be proud that you won first in the 7th grade division. You did better than I did. What was your project on? Maybe you can expand upon it. Hint: When you get to high school, judges ABSOLUTELY LOVE long term projects that you've been doing for years. Have to finish homework.. talk to you later.

Themes that emerged from the dialogue between middle school girls and high school mentors

The dialogue between the middle school girls and the adult women was a bit more stilted than the one between middle school and high school students. Middle school students did not know how to begin the conversation. During an after-school session they "brainstormed" the following questions:

- What was the scariest case you ever experienced?
- What was the rarest disease that you've ever experienced?
- Do you use math and science when you work?
- When did you decide you'd like to do this job?
- What made you want to do this job?
- How does it feel to be a woman in a man's field?
- What kind of boats do you build?
- Are physics and engineering closely related?
- Aren't boat builders usually men?
- What's the worst environmental problem you've every dealt with?

- What skills do you need for your job?

Theme: math and science in careers

Whereas the high-school girls were able to realistically depict challenges that the middle-school students would face in the near term, the adult mentors broadened students' visions of possible long term futures. The adult women were able to relate why math and science were important for their jobs. This practical, real world application of these subject matters gave these subjects a different focus other than good grades or school success.

Some answers to your questions...I use math and science at work all the time. Some examples: When we have to figure out how much medication to give an animal we have to use math and base the dose of medication on how much the patient weighs. Just yesterday I helped to give medication to some salamanders and we had to use math to decide how much to give them. We do lots of tests using the microscope to diagnose a problem. For fish, we can see if they have any parasites...

Discussions about Gender issues

In terms of the teams, the girls raised the question of gender roles with their women mentors. The women were able to acknowledge the reality of role-stereotypes, while offering their own experience of success despite the difficulties:

Message: So, what is it like in a man's profession? I have to say it is a little strange... I am pretty certain that I am the only woman in the US that makes her living repairing this kind of boat... Why did I decide to get into the 'boat business?' Well, as an engineer who studied Aeronautics and Astronautics, my job choices involved a lot of Defense Industry positions. I was not comfortable with the idea of building better jets to better bombs or anything connected with wars and killing people. As a boat builder, I could still be creative as an engineer and work on something that I enjoyed..

Relative contributions of high-school and adult mentors?

The HS girls provided a concrete perspective on the MS girls' immediate future, in HS, which the women mentors did not. Because of their closeness in age, they were able to function as role models in a way that the women couldn't. They thus emerged as very powerful mentors, whose contribution was unique and complementary to that of the adult women. The MS girls had a harder time initiating conversations with the adult mentors than they had with the high-school students. There were instances where slang used by MS students was not immediately understood by mentors, and instances where mentor's writings seemed too dense or complex. Once the conversations got rolling, however, the women's real world experience provided great opportunities for middle-school students to reflect and question "Why do you need math and science anyway?" Middle-school students were able to see that both HS students and adults continue to struggle with conflicts, uncertainties, time constraints, and difficult decisions.

Design of an interactive website to serve an expanded implementation

Whereas our first pilot version of "Eyes to the Future" was implemented using a very simple software tool that served the small group of participants, but was not structured to be scaled up, and was seen to lack functionalities needed for the full implementation of the program. During the fall of 1998, a fully interactive website was developed. The site is user-friendly and extremely intuitive for middle-school students who may have no prior experience with the Web. The site provides a way for middle-school students to communicate with each other, with HS mentors and with adults in the workplace, without needing an e-mail account. It supports collaborative writing, and the formation of school "electronic books" to be shared with other schools. It also provides support for collaborative science projects. It allows for district-wide participation, and for participation from more than one school district.

The site had six main sections:

- An interactive database that can be updated by the users. The interactive database allows girls to find out more about each other while also serving as a research tool for TERC staff. The database allows us to archive all submissions and to track them by individual, class or school.

- An area for mixed age discussions for teams composed of three middle school students, one high school student and one adult mentor
- An area for peer discussions. Since each group has both shared and discrete issues and interests, we created private discussions for middle school girls only, for high school girls only, for adult mentors only and for teachers.
- A personal scrapbook where middle school students annotated particular messages that were meaningful to them.
- A collaborative writing area, where teams of students contributed to a school wide electronic book that recorded their experiences. The school “book” was organized into chapters that included: initial reflections, role models in math and science, getting around in high school, math and science in high school, science projects, adult mentors and careers, and final thoughts.
- A collaborative research area where students can share ideas, writings, and products of science projects and get feedback, encouragement and comments from their high school and adult mentors

Summary:

The middle-school girls showed significant anxiety about entering high school and lacked knowledge about clubs, peer groups, and supportive teachers that could support their Science, Math and Technology learning and achievement. High-school girls provided encouragement and valuable information about navigating high school while staying engaged with Science, Math and Technology, such as study tips, ways to cope with academic problems and find supportive teachers, consequences of course choices, and ways to locate math and science clubs and other supportive peer groups. Their advice was particularly valuable because they attended the high school which the middle-school students would be attending in the near future. High-school girls helped facilitate the conversation between middle-school girls and adult mentors, effectively bridging a “generation gap.” The high school girls also benefited from rich dialogues with adult mentors as they sought advice on their academic and career goals.

Adult women provided middle-school girls with valuable insights into careers involving Science, Math and Technology by discussing how they decided on their professions, how they used science and math at work, what schooling was needed to pursue such a profession, what challenges they faced, and what it felt like to be in a male-dominated field.

Our findings suggest that a network-supported mentorship program can provide important content and motivation in math, science and technology for middle-school girls. The pilot suggests important complementary roles for high-school and adult mentors in the program, and several salient themes arising from discussions among the participants. Discussion and presentation of the interactive website addresses how the technology can enable, and enhance facilitated conversation and collaboration among these three communities of middle school, high school, and the work place.

Abstract The purpose of this paper is to share our experiences in developing a unique all-in-one virtual university. The Defense Acquisition University virtual campus is a unique model for web based instruction because it integrates all aspects of managing a corporate university while providing myriad dynamic layers of access privileges. The OSS provides functionality in 16 main areas: DAU Public Website, Registration, Enrollment , Login , OSS User Types, OSS Collaboration Tools, Search , History, Logs, Reports, Canned Email, Feedback, Help, Courseware Interfaces, Test Application , and Database Interfaces.. We are currently on the fourth build of the system and have since added many new features and functions since its inception. Given the conference's paper restrictions for length, we have attempted to squeeze as much information as possible regarding the DAU's Virtual Campus. However, the information is best conveyed through a live presentation and a demo of the site. We welcome additional comments and questions regarding the site and our presentation.

Introduction

The purpose of this paper is to share our experiences in developing a unique all-in-one corporate university with the hope you will prevent non-desirable occurrences and glean the positive attributes in your own development of a virtual campus. The Operational Support System (OSS), <https://dau.fedworld.gov/dau/index2.htm> is the web-enabled GroupWare based administrative infrastructure used by the Defense Acquisition University (DAU) to support its effort in migrating its teaching approach to embrace distance learning concepts in a virtual campus milieu. Several commercial products were examined and failed to perform all of the functions contained in the OSS. Consequently, Booze Allen & Hamilton, Inc developed the OSS under contract. The OSS supports student registration, tracking, courseware distribution, scheduling, and a help desk. Other functions include the ability to maintain course schedules and information, schedule classes at various schools, allocate quotas, manage class registration, maintain class rosters, maintain a grade book, and historical training information. The OSS has 16 main functions and is dynamically layered according various roles and access privileges.

Why is DAU Transitioning to the OSS?

The Defense Acquisition University is a consortium of Department of Defense education and training institutions and organizations that provides mandatory and assignment-specific courses for military and civilian personnel serving in 11 acquisition career fields. The DAU's mission is to educate and train professionals for effective service in the defense acquisition system.

The DAU is anticipating a number of changes in the makeup of the DoD acquisition workforce. Over the next several years, the DoD acquisition workforce will increase in number from approximately 105,000 to 180,000 or more. Although the DAU student population will increase significantly, DAU will not experience an increase in funding. In response to this situation, the DAU Board of Visitors has recommended that DAU apply technology to its training and educational curriculum. Additional guidance on moving to technology-supported education and training has been provided by the Under Secretary of Defense (AT&T) and the Vice President of the United States.

To meet these directions and to permit maximum access and most efficient use by the acquisition workforce, DAU chose to use the latest educational technologies to design an integrated and accessible distributed education system. The overall objective of DAU's distance education system is to provide a more easily accessible, high quality program of instruction that will help the acquisition workforce acquire the skills and information necessary to keep pace with today's changing world. Specifically, the development of the system is guided by the following DAU educational requirements: provide access to all DAU education and training through a single portal, support materials developed using any DAU selected authoring tools, manage all delivery modes for all courses, maintain an open system for sharing of data and course materials (i.e., support the sharing of information/training modules with all who have a need for them), and provide centralized administration with distributed management of university functions.

As part of this distance education system initiative, DAU is migrating its teaching strategy to embrace distance learning concepts. The effort includes the analysis, design, and implementation of courseware to be delivered using web-enabled technology as well as extensive application development for the web-enabled administrative infrastructure. This administrative infrastructure is the Operational Support System (OSS).

The DAU Public Website serves as the DAU home page. The DAU Public Website is displayed when a user initially accesses the OSS. Visitors to the DAU Public Website include DoD personnel; authorized non-DoD personnel authorized to formally take DAU courses, and visitors (non-DoD personnel). The DAU Public Website provides users with the ability to register for DAU accounts, and log in to access full OSS functionality and on-line courses, and has an online catalog containing general information about DAU.

The DAU Virtual Campus serves as the user's Home Desktop within the OSS. The user's DAU Virtual Campus Desktop is displayed when a user logs in to the OSS. Access to the DAU Virtual Campus is limited to authorized users with OSS accounts, including DoD personnel and non-DoD personnel authorized to take DAU courses. The OSS collaboration tools and other functions available at this level include Task, News, Library, Glossary, Forum, FAQ, Email, Chat, Calendar, Utilities, Feedback, Search, Reports, User Directory, Site Map, Help, and Logout. The functions available to a user at the DAU Virtual Campus vary depending on the user's role. Depending on their user role, approved users of the DAU Virtual Campus can access specific DAU online training courses, administer courses and users, manage course enrollment, access the Help Desk, register for online training courses, view their course enrollment history, and generate system reports. All users have the capability to maintain their personal information including password and personnel information from the DAU Virtual Campus. The OSS automatically logs out any user that has been logged in with no system activity after 4 hours.

What is the Purpose of the OSS?

The purpose of the OSS is to provide system users such as instructors, students, schools, registrars, etc. with the tools necessary to deliver computer-based training (CBT) courses over the Internet, enroll in training courses, schedule training courses, manage course quotas and registrations, collaborate with others, etc. The OSS contains all the functionality necessary to provide a uniform delivery of courseware. The OSS operates as the student management infrastructure to present web-enabled courseware as well as all DAU necessary operational functionality. To support DAU, the OSS supports the following components.

Student Registration - The creation and maintenance of user accounts. The student registration function verifies that users are DoD authorized users and provides different templates depending on the users roles. User roles are defined in Section 2 and are based on the privilege model.

Course Enrollment - The access of on-line course and registration in any DAU onsite course. The system maintains a course schedule and allows students to register based on certain prerequisites. Course enrollment verifies prerequisites as well as provides a waiver process to allow a student into a course.

Test Delivery - The course administrator can centrally set up the test delivery engine to the specific course needs. This includes course, lesson, and terminal learning objective level tests generated at random from a question pool. The test engine selects one question per enabling learning objective for each test. Questions are not repeated until the student has used all questions in the pool. Answers and distracters are also presented at random. The test function supports multiple choice, all that apply, sorting, matching, and fill in the blank questions. Images can also be used as questions or distracters or to enhance the test. Test item analysis is also conducted as a report feature in the system.

Course Evaluation - A survey is available during and after the course to provide feedback on the students feeling on the course and course delivery. The course evaluation is based on a survey engine that supports dimensions and categories.

Student Tracking - User progress as well as bookmarking is provided by the system. The student or instructor can see student progress and analyze course material. The grade book feature allows instructors to compile evaluation material for non-self contained courses.

Report Generation - The system has a number of pre-canned reports to support student tracking and management.

Problem Resolution - A trouble ticket system exists to support students having problems, tracking issues, and determined enhancements. Trouble tickets are routed to second tier help desk personnel. Tickets are resolved or forwarded to a party that can resolve the tickets in an expeditious manner. The tier 1 help desk is supported at The National Technical Information Service (NTIS) with tickets generated from the on-line feedback or calls made to the help desk. The National Technical Information Service is the federal government's central source for the sale of scientific, technical, engineering, and related business information produced by or for the U.S. government.

Site Collaboration - A host of collaboration tools such as forums, IRC's, news, library, tasks, and calendar, are available for asynchronous and synchronous communication. The tools can be used for homework, teams, or to present site-specific information.

DAU's Approach to Developing Courseware

The DAU web-based learning environment is designed to support both procedural training and more complex cognitive training related to decision making and problem solving. Simple HTML-based lessons are used when presenting basic procedural information. In other courses requiring students to responding to complex cognitive stimuli encountered on the job; AuthorWare lessons, video teletraining, web conferencing, or other methods are combined with the HTML environment to address these more complex learning outcomes.

Performance outcomes refer to the task and performance levels desired of students during and after completing the course. Typically, a courseware developer would ask the following questions related to performance outcomes during analysis: What are the primary tasks to be trained? What are the characteristics of the desired task performance? Is the task primarily procedural or cognitive? What are the current and desired performance levels?

Learner interactions refer to the predominant learning styles, diversity and motivation of the student population. Typically, a courseware developer would ask the following questions related to learner interactions during analysis: Do members of the target student population have strong learning style preferences? How diverse are the members of the student population? What types of collaborative learning are desired? How motivated are the students to learn the course content?

In addition, DAU recommends that courseware developers address the following five areas related to learner interactions:

Layering Information – DAU students have diverse backgrounds and prior training experiences. Therefore, it is essential to allow students' access to layered or "popup information" for additional explanations of terms and concepts. By layering information, students who know the material have the option to bypass it.

Maximizing Student Control – Students are given learner control for the majority of the pathways through the lessons. A recommended sequence is provided, but students are allowed to select their own pathways after completing the first lesson.

Managing Web Surfing – Web links within lessons need to be managed carefully, since some students who are unfamiliar with the web environment may be unable to find their way back to the lesson after following an embedded web link. Therefore, students are offered selected web links after completing the core lesson materials. This is accomplished by providing web links on a lesson exit page, so students can complete the lesson before following the recommended links.

Encouraging Collaboration – Both synchronous and asynchronous forums are offered to students. Because most students are taking courses while on the job, asynchronous communication modes are preferred.

Motivating Students – Motivation can be addressed by creating simulated characters that reappear throughout the lessons, using appropriate humor, and sending personalized email messages from an assigned faculty member when milestones are accomplished.

Testing and Evaluation

Testing and evaluation refers to the students' mastery of the course content after completing the course. Typically, a courseware developer would ask the following questions related to testing and evaluation during analysis: What types of testing will be administered? What types of test security will be required? What if students fail to demonstrate mastery of the course content? Will follow-up data be collected?

Currently, DAU suggests courseware developers consider the following three areas related to testing and evaluation:

Test Security Issues – DAU students are required to complete courses as part of job certification requirements. Therefore, testing is critical. DAU addresses test security using the following strategies:

- Random generation of test items from test item pools so that students get unique combinations of test items
- Random placement of distracters within test items
- Comparison of performance within lesson quizzes to final test performance
- Inclusion of test items that are difficult enough to be valid if the student uses references.

Testing as a Learning Activity – For most courses, DAU students are allowed three attempts to achieve 100% mastery on the lesson's learning objectives. If a student fails to demonstrate mastery, the student is told to contact his/her assigned faculty member. The faculty member also receives a notice that the student has failed to reach full mastery. The faculty member reviews the questions missed on each attempt. Based on this item analysis, the faculty member develops an individualized plan for helping the student improve his/her performance. When the faculty member is satisfied the student has mastered the test material, he/she can automatically override the student's tests results.

Student–Faculty Interactions

Student–faculty interactions are an important component in the development of courseware. Typically, a developer would ask the following questions related to student–faculty interactions during analysis: What types of interaction are required between students and faculty? What is the anticipated faculty-to-student ratio? Will students be assigned to faculty in cohorts?

DAU recommends that courseware developers address the following three areas related to student–faculty interactions:

Individual Faculty Assignments – Each DAU student is assigned to a faculty member. After registering for the course, the student receives an email message with a greeting from the assigned faculty member. Subsequent communication with faculty are based on the course being presented and the student's needs. The environment provides for: synchronous and asynchronous private conferences between faculty and students, customized and automatic email messages, an instant feedback button present on most screens to create a trouble ticket (Note: If the feedback is course related, it is usually assigned to the appropriate instructor.)

Faculty-to-Student Ratios – The first step is to identify the critical types of faculty interactions to be offered and then to determine the demands those interactions will place on the assigned faculty. DAU estimates the faculty-to-student ratio during the course design. During the operational trial of the course, the ratio may be adjusted based on the actual demands on faculty time. If an instructor needs additional support, a second instructor and section can be established. It is critical to designate backup instructors so those assigned instructors can take a day off without impeding the progress of the course.

Cohorts vs. Rolling Admissions – The DAU environment allows courseware developers to set up courses in cohorts (all students within a section start at the same time) or rolling enrollment (students are enrolled in a section at any time as long as the faculty member has an opening). Cohorts are used when it is critical to keep students progressing through the lessons at the same pace. For examples, cohorts are used when web-based training is combined with video teletraining and students must be prepared for scheduled video teletraining broadcasts. Rolling admissions are used when quick access to course materials is more important than keeping students moving at an assigned pace.

Defining the Course Structure

The OSS includes a hierarchical structure to support courseware delivery through the OSS. The course hierarchy contains the framework for the courseware. Currently, DAU has defined the default courseware hierarchy to contain Course, Lesson, TLO, and ELO levels. The courseware developer has the ability to configure lesson dependencies. The OSS supports only serial dependencies. Therefore, access to Lesson 2 can be dependent upon successful completion of Lesson 1. The ELO is designated as the question level where all test questions are entered. Currently, the OSS supports the following question types: multiple choice, all that Apply, matching, sorting, fill in the blank. The OSS provides the capability to create, modify, and delete tests. Tests can be defined at the course, lesson, TLO and ELO levels. The OSS supports the following test types: Normal Test – The normal test can exist at any level in the course hierarchy. Successful completion of this test generates a pre-defined email and marks the level at which the test is taken as complete. The courseware developer can define the number of attempts allowed and the passing grade. A test may be created at the course, lesson, TLO and ELO level of the course hierarchy. Only one test may exist at a given level. When defining a test, the courseware developer must provide a unique test number along with a unique title, passing grade, the number of attempts allowed, predecessor/required node, and predecessor/required test. The courseware developer has the ability to configure test dependencies. The OSS supports only serial dependencies. Therefore, access to the Lesson 2 test can be dependent upon successful completion of the Lesson 1 test. The courseware developer is restricted from creating a circular dependency. For example, the courseware developer cannot designate Test 1 dependent upon Test 2 if Test 2 is already dependent upon Test 1. By selecting a dependent test, the courseware developer indicates that the student cannot take the defined test until the predecessor/required test has been successfully completed.

Test Questions

The OSS provides the capability to create, modify, and delete test questions. The OSS supports the following question types: multiple choice, all that apply, matching, sorting, and fill in the blank. The system supports the inclusion of images within the test question or test choices. Images are integrated into the test application by embedding the image tag within the actual question or choice.

Deciding Which OSS Tools to Integrate

In deciding which of the OSS collaboration tools to integrate into the courseware, the courseware developer should be guided by the principle that student-to-faculty and student-to student interaction of all types is desirable in order to increase the potential means for learning. Therefore, DAU courseware should be designed for interactivity, i.e. to incorporate multiple methods of interaction. The following OSS collaboration tools are available for integration into courseware: News, Library, Forum, Calendar, Task, Glossary, FAQ, Email, and Chat.

Each course can include the following set of functional modules: News, Library, Forum, Calendar, Task, Glossary, FAQ, Email, and Chat. Feedback (email to the OSS System Administrator) is available at any time from the left-hand button bar. To prevent duplication of effort, access to the OSS course functional modules is available from within the courseware. The user will populate these modules using the administrative screens as described in Populating OSS Tools below. The courseware will then include links that allow the student to access the functional

modules from within the courseware. A coding example for integrating the Glossary functional module within the courseware is as follows: <code><cfoutput> Glossary </cfoutput></code>

Populating OSS Tools

To support population of collaboration tools, bulk uploads are available at both the course and section levels. Bulk uploads are an alternative to manually populating the OSS tools using admin screens and forms. Course level uploads are used by the course administrator to provide course materials to all sections and by course instructors for their individual sections. Once course level entries are made, all sections that are created or started after the upload will inherit the information at the course level. Sections that already exist can inherit newly uploaded material by checking the inherit box. Section level loads are used by the instructor for providing information that is specific to their section. Section level uploads will be appended to the course information that was inherited by the section. Course and section uploads follow similar procedures and can be done for glossary terms, FAQ items, and library links.

There are five levels of privileges for each collaboration tool or function.

0 = No Access – No access to the associated function

1 = View Only – Access to view items within the associated function

2 = View & Edit – Access to view, create, and edit own created items within the associated function

3 = Limited Admin – Access to view, create, and edit items created by all users with View & Edit privilege, and to edit own created items within the associated function

4 = Admin Rights – Access to view, create, and edit any item within the associated function, regardless of the creator

The OSS contains multiple levels of information, including the DAU Public Website (public site), DAU Virtual Campus (private site), course level and section level. The reason for having multiple levels is to allow for information security and compartmentalization. In this way, users can only see the data to which they have been granted access. The course level is displayed when a user (other than a student) clicks on a course title link from the Home Desktop. The course level provides a course template for all sections of the course, and serves as the repository for course information. Course-related data is usually entered at the course level, in order to provide consistent information to all sections. At this level, instructors, course administrators and other authorized users can interact within the course environment. The section level is displayed when a user (other than a student) clicks on a section number link from the Home Desktop, or when a student clicks on a course title link. New sections inherit OSS data specified at the course level. Section-specific data is entered at the section level. At this level, all members of a particular course section (instructor and students) can interact within the section's virtual classroom environment.

Summary

The Defense Acquisition University virtual campus is a unique model for web based instruction because it integrates all aspects of managing a corporate university while providing myriad dynamic layers of access privileges. The OSS provides functionality in 16 main areas: DAU Public Website, Registration, Enrollment, Login, OSS User Types, OSS Collaboration Tools, Search, History, Logs, Reports, Canned Email, Feedback, Help, Courseware Interfaces, Test Application, and Database Interfaces. This paper has attempted to describe the functionality of the DAU's virtual campus. However, the virtual campus is best communicated through active demonstration and interactive dialogue.

Acknowledgements

We would like to thank Ric Cadenas and his staff at Booze Allen and Hamilton for their excellent support and service to this project. Also, certain aspects of this paper were modified and adapted from various user support manuals developed by Booze Allen and Hamilton.

Management and Workflow of Electronic Documents using a 2nd-Generation WWW-server

Dieter W. Fellner, Marco Zens
{d.fellner,m.zens}@tu-bs.de
Digital Library Lab, Computer Graphics, Braunschweig University of Technology
Rebenring 18, D-38106 Braunschweig, Germany
<http://www.cg.cs.tu-bs.de>

Abstract: With the advancement of DTP and Digital Libraries a workflow exclusively based on electronic documents has started to become a viable alternative for a continuously growing community. Information is entered into a computer, forwarded to other people, reviewed, modified and finally stored, without ever using paper (as a transport medium) during this full life cycle.

In most cases dedicated software (Document Management Systems) is used to accomplish this digital form of information management. However, these systems are typically expensive, either too specialized or too complex, or they lack the ability to support their users in an Internet environment (ie. not connected to their home intranet).

We present a new approach to use a second generation WWW-server (*Hyperwave Information Server*) to manage access, storage and workflow of electronic multimedia documents. We achieve this goal by a combination of Hyperwave and other components that are available in most offices: office-tools, WWW-browsers and the Internet.

This design, presented in more detail later in this paper, is being implemented and evaluated in cooperation with the German Research Foundation (DFG), where our existing prototype is being used for the electronic submission and the subsequent handling of research grant applications.

1 Introduction

Today, the scientific community faces a lot of situations where the use of electronic documents (opposed to paper) bears a lot of advantages, for both the sender and the receiver of information.

Considering the paper submission process to conferences we frequently experience that, even in case of electronic submission, printouts are made and sent to the reviewers. Their (sometimes handwritten) comments are typed into a computer and finally the paper is printed and sent to the publisher. Another example (which is the focus of our research project *GoldenGate*, see Section 5) are applications for research funding. Grant applications are prepared and sent – typically on paper – to a funding agency. There, copies are produced for the reviewing process and for internal use. Additionally the key parameters of the grant proposal (such as the amount of funding) are extracted and stored in a database. At the end of the application process, several printouts are made, one informing the applicant(s) about the approval, others informing various departments of the funding agency (e.g. finances or public relations), to name just a few examples.

Of course, paper has some important advantages over a simple electronic file. These advantages have to be modeled as accurately as possible whenever attempting to replace workflows similar to those described above by their electronic counterparts. We will describe some of the key features and their typical implementation in Section 2. Section 3 introduces the Hyperwave Information Server, a second generation WWW-server, that combines several ideas from the worlds of databases and the World Wide Web. It is the basis for our new approach (described in Section 4), which is the central issue of this paper: combine Hyperwave, existing “standard” office-tools and Internet technologies to form an Information and Workflow Management System. In Section 5 we briefly present our research project “GoldenGate” as a proof of concept for our approach. We finally deal with some results and some future steps of this project in Section 6.

2 Common Features of Information Management Systems

A piece of paper with some important information sitting on a desk can only be read by a person present in that room. If the paper is locked away even that is impossible. What is even more important: only a person actually holding the paper in his hands can make changes or add comments.

On paper one can leave a signature to prove that the information has been processed or to authenticate approvals. Of course, both can be forged, but techniques and rules to (at least) minimize this risk are well known and well established.

Especially in administrative environments, predefined actions are associated with each document. When it is passed on, the next person in the process chain typically knows about the following actions to be performed before passing it on again or returning it.

These three features – access control, authentication, workflow – are the most important ones (besides storage) that Information Management Systems (IMS) have to implement. A transition from traditional work processes to their digital equivalent cannot be implemented with any of the above key features missing. Even more critical, experienced users will recognize problems in these areas well before starting to appreciate the advantages of electronic workflows.

Of course, electronic information management systems also include some – hopefully many – of the advantages that an electronic environment can offer: simultaneous access to shared documents from distributed locations, the automatic creation of full-text indexes including new documents at insertion time, (full-text) queries, to name just the most prominent ones.

The point we are trying to make is that a system implementing the key features discussed above resembles an Information (or Workflow) Management System, even if is not marketed or easily identified as such. In the following sections we describe such a system, its prototype implementation and first results of a typical real-life application.

3 Hyperwave Information Server

The *Hyperwave Information Server* [Kappe et al., 1993, Maurer, 1996] can be described as a second generation WWW-server combining a database and a web-server. It is based on modern concepts of database design and information retrieval as well as multimedia storage and Internet access.

Some of the relevant features exploited by our approach are:

- The integrated database stores any kind of (multimedia) data-object in one or several hierarchies of objects and collections of objects (which can contain collections themselves). In any case, the data is stored only once, several instances are modeled by reference.

These references or “links” are database objects themselves and they are robust, meaning if you move or rename an object, all links remain valid.

- Any object can be described by arbitrary metadata, called “attributes”. You can build indexes over these attributes to execute boolean or ranked queries.
- Every database object is access controlled with read, write and delete rights for single users, groups or everyone, similar to UNIX file-system rights.
- All these features can be used and even administrated via conventional WWW-browsers from anywhere of the world (given the proper access rights).
- Additionally, the full functionality can be used from other programs with the help of a TCP/IP protocol (Hyper-G Client-Server-Protocol [Hyperwave GmbH, 1997]).
- A full-text engine of Verity Inc. is integrated allowing full-text queries not only for “readable” data, but also for popular formats like Adobe Portable Document Format (PDF) [Bienz and Cohn, 1993], PostScript [Adobe Systems Inc., 1990] and several formats from the Microsoft Office suite.

In addition to the above, Hyperwave includes programmable (server-side JavaScript) layout templates, support for multilinguality and sequences of objects, stored queries, and gateways to other databases or user identification systems.

Hyperwave Information Server runs on several different hardware/software platforms, including such common ones as Microsoft Windows NT, SUN Solaris and SGI IRIX.

4 Modeling Information Management with Hyperwave

If modern Information or Workflow Management Systems (like *Lotus Notes Domino* [Lotus Devel. Corp., 1999], *InConcert* [InConcert Inc., 1999], *Texcel Information Manager* [Texcel International, 1999],... to name only a few commercial ones) already do implement the features described in Section 2, why follow a different approach? The answer in our case is that these software packages often have disadvantages, which are severe in some situations (and may be negligible in others).

Each current IMS consists of several components or interfaces, which can be grouped according input, output, access, storage and workflow. If these components are integrated into one complete system, everything works smoothly and efficiently together. However, problems arise when applications require the use of special input components that are not included in the integrated system.

Another problem often is individual worldwide access (Groupware, collaboration, communication), especially using the complete functionality, possibly without special client software.

Many research groups are working in these fields, stressing one or the other aspect. For example, the *Open Hypermedia Systems Working Group* (OHSWG) [OHSWG, 1999] tries to combine existing tools as components and to extend them with Hypermedia functionality. The *Basic Support for Cooperative Work* project (BSCW) at GMD [Bentley et al., 1997] concentrates on cross-platform group collaboration services based on existing WWW technologies. Also Web-based is *Endeavors* [U.C. Irvine, Information and Computer Science, 1999] from U.C. Irvine, which is a flexible lightweight workflow infrastructure that provides support for process specification, distribution and integration of third party tools.

Our approach can be characterized best by: take the software you already use for the input, output and handling of documents plus a Hyperwave server for the storage and workflow as the basic components and combine these using the Internet technology.

As a consequence, users continue to use their favorite office tools (e.g. Microsoft Excel and Word) to enter information and store it in the applications' native formats into the Hyperwave database, which can handle them as any other type of data. Everyone with an Internet connection, a web-browser and a tool to handle the data format can access the information in the database (from everywhere), provided proper access rights have been granted. As the information is stored in the tool's native format, users can use the same tools to extract, modify or output the documents.

Storage and access control is one of Hyperwave's basic features. Personalized users, in contrast to anonymous ones, hold an account with username and password. Fine grain access control allows detailed tuning of document access at the read, write, modify, or hyperlink level, with anonymous users only having access to public information.

A major advantage of the use of single standard components is that each improved version immediately improves the complete system. For example, input tool A can be replaced by the new release A+ most of the time without (expensive or unreliable) update of the overall system.

It is important to note, that, due to being fully programmable, common office tools are very flexible today. As a consequence, customization to individual demands with regard to user functionality or user settings can easily be accomplished. Such customizations will enable the various components not only to download or upload data but also to interact with Hyperwave servers. Components could store/modify metadata about documents, query for additional information or collect data from a hierarchy to build a new document (e.g. a statistical analysis within Microsoft Excel).

This feature is the key to the implementation of the final part of an information management package: the workflow. The basis for workflow management are processes and use cases. Someone enters a new document and opens a case for a specific process. A second person modifies the document, a third returns it to the second or perhaps closes the case. Such a process can easily be modeled by passing along proper access rights: while the first user creates the document this person is the only one with full access. When the document is passed on ("checked out"), a tool adapts access rights such that only the second person can work with and modify the data and so on. Hyperwave's collections and reference links can be used to have such tasks show up in special locations of the hierarchy with the recipient informed about the arrival either by email or by the result of a stored query (a Hyperwave feature).

This sounds like a lot of work. In fact, there is work to do, but significantly less compared to building a full system from scratch. According to our approach we only need to build the interfaces between the existing components, similar to inserting an integrated system into an existing environment. Considering that we build on top of office components already in use training with the new system can be kept to an absolute minimum and productivity won't be reduced by an adaption period.

In the next section we will describe an actual application of this approach that shows how the concept works in the “real world”.

5 Proof of Concept: GoldenGate

GoldenGate is a joint research project of the German Research Foundation (Deutsche Forschungsgemeinschaft, DFG) and our group over a period of 3 years, that deals with the electronic submission, the managing and the approval of research grant proposals. DFG is the largest research funding agency in Germany and supports several thousand projects per year with a funding volume of about 1.2 billion US \$.

The goal of this project is the design and prototype development of a complete electronic workflow for the handling of research grant proposals and subsequent funding. Proposals are submitted in electronic form by researchers and are stored and managed (e.g. made available to reviewers) in a database until the final approval. Up to now the DFG interacts with the outside world only by paper documents. Internally they currently use a monolithic and proprietary system (called “All-in-One”) that has been installed about 10 years ago and that can only handle ASCII-documents.

The DFG acknowledges the need for a new, modern system, that can handle multimedia documents, is open to external users (e.g. reviewers) and is applicable for all departments. It also has to provide a modern user interface.

After carefully looking into DFG’s internal structures and approval processes, we made the design decision to implement a new system based on the ideas described in the previous section.

The hardware basis are conventional PCs running Microsoft Windows NT. As software components – besides the Hyperwave Information Server – we chose Microsoft Office’97, because it is already used within the DFG for various office tasks, it is very common and it is complete as well as flexible. These components are combined using the Hyperwave TCP/IP protocol [Hyperwave GmbH, 1997], the Microsoft Component Object Model (COM) [Microsoft Corp., 1999] and a scripting language (Python [Rossum, 1995], but also Java and Perl were used). See Figure 1 for the structure of the complete system. All components are centered around the Hyperwave server which acts as address and application database. It is accessed by TCP/IP either directly (e.g. with a WWW-browser) or through our so called TCP/IP – COM interface which allows access from office tools.

We should also mention that a significant number of employees at DFG are not satisfied with the currently available system (based on ‘dumb’ VT-220 type terminals) as they have computers at home and have reached the level of computer literacy which enables them to compare available tools in the MS Office environment to the system running in their office. Considering the already available skills of these employees (a continuously growing group) the choice for MS Office was an obvious one.

Figure 1: The structure, components and communication channels of the current prototype implementation of GoldenGate.

The final system will allow a potential grant applicant to download (via HTTP) a template for his favorite word-processor (Microsoft Word, L^AT_EX, Adobe FrameMaker...) which includes support and help (e.g. by “wizards” and selections lists) when creating the application. The resulting (electronic) document is uploaded (again, via HTTP)

to the GoldenGate server at the DFG, where it is converted into an internal format (XML [W3C XML WG, 1997]) and stored in a special collection of the database hierarchy. Security can be easily guaranteed by the use of techniques like Secure Socket Layer (SSL) and/or Pretty Good Privacy (PGP). Of course, this list is likely to change over the lifetime of this project. As we base our design on standard components, we can easily exploit new features or new components as they become available.

At the DFG, the receiving side of grant proposals, a funding officer in charge is informed that a new research proposal has arrived. From this application, a "dynamic view" (a Microsoft Excel sheet) is generated automatically and also stored in the database. It is automatically referenced from other locations within the hierarchy of the DFG's intranet server, according to several thesauri. The electronic version of the proposal is also supplemented with metadata automatically extracted from the application. Those dynamic documents can then be checked, manipulated or passed on with Excel'97.

Many features of Excel like pop-up menus or forms support the user in a well known and intuitive way, e.g. during access to the agency wide address database or in the selection of standard entries in predefined lists. During this whole process, so called "static views" (currently Adobe PDF documents, but any other format can easily be supported) can be generated at any time to take a snapshot of a particular state of the process or to act as read-only documents for other departments or reviewers.

All the time, the document remains stored in Hyperwave's database hierarchy. This database can be browsed or queried with each individual's favorite Web-browser thereby granting non-standard retrieval procedures. For example, all proposals by person X or all approved applications in research field Y can be viewed (provided access rights do match) without explicitly supporting these types of retrievals as dedicated user functions. In case someone clicks on a dynamic view to work with it, the document is checked-out by granting the read/write access exclusively to this user until it is checked-in again.

Hyperwave's programmable templates, its internal locking mechanisms and CGI scripts are used to implement this behavior. In a nutshell: all this could easily be accomplished by features of the 2nd generation WWW-server Hyperwave (see Sec. 3).

6 Preliminary Results and Future Work

First evaluations at the DFG are very promising and show that the system meets its design goals with respect to flexibility and efficient extensibility. As a conclusion, our approach of combining Hyperwave and office tools by Internet technologies fulfills our expectations (see also below).

The larger part of the GoldenGate system as described in the previous section has already been implemented. A specific template for Microsoft Word'97 has been developed. The document that is created from this template is structured (and looks) like a conventional grant application when printed on paper. But when saved in *Rich Text Format (RTF)* and sent to the GoldenGate server, the essential information is automatically extracted and converted (via XML) to a Microsoft Excel'97 sheet. This is made possible by using some hidden markup in the template, that is parsed during the conversion step. We have created a XML DTD that allows us to check well-formedness and validity of the incoming data and possibly reject the input automatically. The Excel sheet allows the people in a DFG department to fulfill all typical tasks.

During first demonstrations and iterations we learned quickly that we had to increase our systems' abilities (which was not planned in the beginning) to provide a complete electronic workflow: support for letters and mail merges, storage for "other" documents and statistical analysis of elements in the database became necessary.

As a proof of concept – and without implementing additional modules – we could support the additional tasks by merely activating (i.e. giving users access to) built-in functionality of the underlying office tools. Now, Microsoft Word'97 is used to generate mail merges by accessing the address database on the Hyperwave server and to store arbitrary documents (another basic feature of Hyperwave). For the data analysis we just use the statistics components of Microsoft Excel (tables, bar graphs, pie charts...). Data has just to be grabbed from the attributes of the database hierarchy filtered through appropriate retrievals.

By the way, during this improvement process we made one of DFG's currently used software packages superfluous. Its whole functionality basically consisted of running mail merge. With the help of our approach several thousands of lines of code were replaced by something that – at least today – is already there and just had to be used.

The resulting prototype in its current form has, over several demonstrations and evaluations, shown that it works efficiently and reliably. Several departments at the German Research Foundation are interested in using it, because they are convinced that the amount of routine work can be significantly reduced with the help of GoldenGate.

We are now preparing the installation of the first operational system in one of DFG's departments to gather

important information for our research. Of course, commercial partners will take care of the training, support, and running the hot-line.

At the moment we are still learning and analyzing the conventional processes and workflows at DFG. As those, like in most other large organizations, were never written down and nobody knows all of them, we have to use an iterative approach. Whenever we implement something new, people at DFG have new ideas and discover new possibilities how GoldenGate could help them. Up to now, we were able to realize those extra demands quite effortlessly.

Our future tasks are the systematic extension of the system to cover more steps in the process chain of reviewing and handling of grant proposals. Of course, the biggest challenge seems to be the automated assistance of end users in the desire to customize (or radically change) the look-and-feel of the individual user interface layouts ...

Abstract: In the post-capitalism era, the success of an organization lies more in its knowledge and system capabilities than its physical assets. Knowledge creation has become indispensable to industrial innovation and the improvement of the learning process in an organization. Therefore, this study reviewed the literature on knowledge creation and learning organization, and then drew on the "Knowledge Creating" model (Nonaka & Hedlund, 1994) for integrating it with the "processes of knowledge management", which was a new concept from this research. Furthermore, this research proposed a framework of a Digitized Learning Organization (hereinafter referred to as DLO) to further explore how to enhance the capabilities of learning and knowledge creation in a DLO. The ultimate goal of DLO is to become an environment with the atmosphere that would facilitate the learning activities of knowledge workers.

INTRODUCTION

The proper role of management is to ensure the application and performance of knowledge, that is, the application of knowledge, to knowledge itself. The creation and use of knowledge is a particular organizational challenge (Drucker, 1993). The purpose of this study is to depict the situations where an organization would make the most of knowledge. A conceptual model "Processes of Knowledge Management" is also developed, which is applied to the framework of DLO for facilitating dynamic changes of the environment. The section of implication deals with applying Knowledge Management to the DLO, introducing the basic framework of Knowledge Management as well as the concept of Knowledge Agent.

LITERATURE REVIEW: THE CONCEPT OF KNOWLEDGE

1. The definition of Knowledge

Drucker has called knowledge we know now consider proves itself in action. What we now mean by knowledge is information effective in action; information focused on results. These results are seen outside the person in the society and the economy, or in advancement of knowledge itself (Drucker, 1993). Hedlund and Nonaka have distinguished between three aspects of knowledge: cognitive knowledge in terms of mental constructs and precepts, skills, and knowledge embodied in products, well-defined services or artifacts (Hedlund and Nonaka, 1994).

First, the model distinguishes between tacit and articulated knowledge. The former is defined by Polanyi (Polanyi, 1962), as a type of knowledge that is non-verbalized or even intuitive and unarticulated. The latter can be found either verbally or in writing, computer program, patents, drawing or the like. Second, the model distinguishes between four different types of knowledge carriers: the individual, the small group, the organization, and the inter-organizational domain. Tacit and articulated knowledge exist across all levels (Hedlund and Nonaka, 1994).

2. The Concept of Learning Organizations

Senge has warned that many organizations are unable to fully function as knowledge-based organizations, suffering from learning disabilities (Senge, 1990). To prevent such disabilities from happening, a number of organizations initiate a self-organizing network that is called as "a spider's web". Typically speaking, a spider's web brings people together as quickly to solve a particular problem as they disband once the job is done. Quinn indicated that this power of networking is so great that even with a modest number of collaborative independent professionals, a spider's web can leverage knowledge capabilities by hundreds of times (Quinn, 1996). The ultimate goal of the spider's web is to develop knowledge and information in continually generative and adaptive learning. The learning organization of the spider's web possesses information and knowledge that provide learners

with a superb environment to maneuver with intelligence and creativity.

THE PROCESSES OF KNOWLEDGE MANAGEMENT

In this section, we attempt to present a conceptual model, an inductive one based on the observation we have made so far. It is also a model that we will employ to test more relevant hypotheses henceforth in our future research. The purpose of the model is to develop knowledge in continually profitable articulation and manifestations. To be more specific, the Processes of Knowledge Management include knowledge acquiring, knowledge transforming and knowledge distribution. (See Figure 1)

The knowledge acquiring process is about the interpretation of news and messages received from the environment. People must choose information that they consider is significant to them, and base their explanation on the past experiences. Eventually they would negotiate on different views in order to arrive at a unanimous interpretation.

The conversion of knowledge accounts for the knowledge transforming process. People share their personal knowledge with each other through training, drill and apprenticeships. They articulate what they know intuitively through informal exchange as well as more official channels.

During the knowledge distribution process, the key activity is the processing of information about the available alternative in order to weigh their relative advantages and disadvantages. Nonaka and Hedlund claimed that an effective model of knowledge was developed. It builds on the interplay between articulated and tacit knowledge at four levels: the individuals, the small group, the organization, and the inter-organizational domain. People typically follow the sequence of steps and adopt a set of criteria to collect and manage knowledge (Hedlund and Nonaka, 1995).

All the processes--knowledge acquiring, transforming, and distribution --are being dynamic and subject to interruptions and iterations. The processes lead to changes of the environment, generating particular outcomes for the organization to adapt to. Another cycle has thus begun. The Processes of Knowledge Management offers a special advantage, allowing organizations to maneuver with intelligence and creativity.

Figure 1: The Processes of Knowledge Management

THE FRAMEWORK OF KNOWLEDGE MANAGEMENT IN THE DLO

Employing Knowledge Management (hereinafter referred to as KM) on the move of constructing a DLO has been given an unprecedented dimension especially in this knowledge-dominated era. As an overwhelming intelligence reservoir beyond doubt, a DLO is obliged to giving fuller play to its stored invaluable knowledge. Furthermore, it should enable users to be involved in the management level, and to share with each other any available feedback. Hence, the target mission of this implication is to elaborate on the concept of KM in terms of establishing a DLO with three distinct to-dos in mind. Firstly, to provide the audience with an open and interactive learning environment. Secondly, to allow room for the audience to perform management-related tasks. Lastly, to ensure the audience to be able to share with the DLO their knowledge, while offering their feedback.

The three most essential components of this framework include knowledge workers, knowledge repository, and they are able to interact with the other only through knowledge activities, as shown in the below Figure 2.

Figure 2: Framework of KM in a DLO

1. Knowledge Workers

Those who carry out learning and management tasks are regarded as Knowledge Workers in a DLO. Being the sole active component in this infrastructure, they can be subdivided into three categories: learners, operators and officers.

2. Knowledge Repository

Being regarded as a passive element in the KM activities, it is in charge of compiling all the knowledge accumulated throughout the learning and management tasks by knowledge workers. Knowledge repository can be divided by their distinct nature further into three groups: the external knowledge, the structured internal knowledge and the informal internal knowledge (Davenport, 1998). On the other hand, in meeting the immediate demands of knowledge workers during any knowledge activities, this study distinguishes between learning knowledge repository and management knowledge repository, in the hope of enhancing the effectiveness and efficacy of the launching of learning and management tasks.

Learning knowledge repository refers to the knowledge that DLO has collected from knowledge workers in the course of their learning activities and can be categorized further into “feedback” and “service”. The former has to do with opinion postings and open discussions, while the latter involves record-keeping on customers’ behavior of inquiries, the in-person referral help offered by the instructors, the manufacturing of knowledge mapping, etc. The below figure 3 can be referred to for more details on this subject.

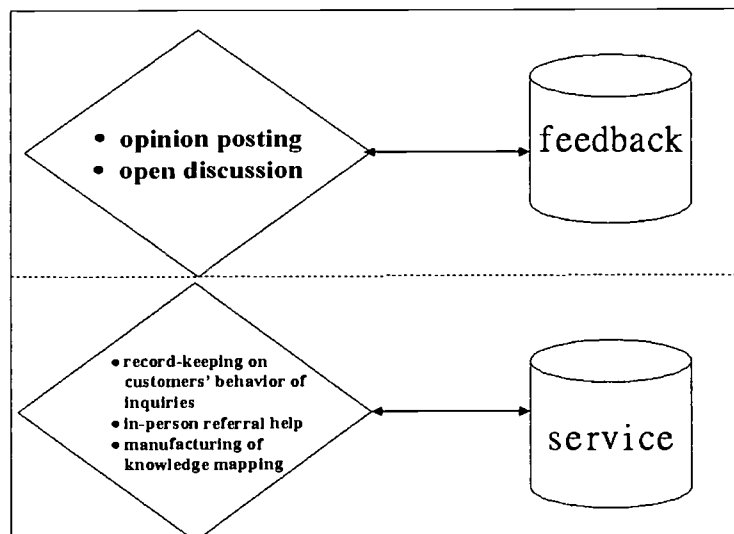

Figure 3: Learning knowledge repository

On the other hand, management knowledge repository is related to the accumulated knowledge to which knowledge workers contribute what they learn from their management activities. It can be categorized further into “standard” and “collection”, as shown in figure 4 in the below.

Figure 4: management knowledge repository

Standard has to do with the limits of one's authority, analysis/policy making, and management-related activities, while collection deals with ample room for recommendations, regular database update and maintenance, and announcements making, etc.

3. Knowledge activities

Can be divided further into "learning activities" and "management activities" by the nature of activity involved. The former has to do with the type of activity that is inspired and generated by knowledge workers' demand and interest. The latter is related to what knowledge workers dedicate themselves to for supporting and managing learning behaviors.

In addition, a term has been especially coined to propose proper proceeding entailed in any knowledge activity, which is "Processes of Knowledge Management" (Liou & Feng, 1998). The Processes of KM go from acquisition of knowledge, transformation of knowledge, and eventually, to the distribution of it, as exemplified in the previous Figure 1.

The acquisition of knowledge results from the collecting and sampling of knowledge for learners by any DLO. To enable learners to make inquiries and to launch meaningful searches, the transformation of knowledge refers to classify and store knowledge in a systemic and consistent way. The final stage of this process of KM, namely the distribution of knowledge, makes clear that learners can eventually be assisted to apply their knowledge better and to conduct discussions as well as sharing of knowledge; meanwhile, learners also get to contribute their knowledge to the DLO in return.

In order to further clarify the framework of KM in a DLO, an Analysis Model is put forward to help formulate the initial stage of setting up a KM system in a DLO. This Model consists of Knowledge Agent, Use Case Model and Object Model. Herein we prioritize the discussion of Knowledge Agent rather than the other two. The reason for doing this is because it is a new concept introduced by this study and it has everything to do with knowledge workers (Fig.5) whose behaviors would in turn bring about a huge impact on the aforementioned framework of KM in a DLO.

Figure 5: Relationship between Knowledge Agent and Knowledge Workers

More on knowledge workers

Prior to delving into the subject of Knowledge Agent, it is prerequisite and essential to develop the concept of knowledge workers better and introduce the knowledge structure in a DLO. According to Figure 6, it is self-evident that more sub-groups can be derived from the previous three types of knowledge workers, i.e. learners, instructors and managers.

Figure 6: Derivation of three types of Knowledge Workers

Note that knowledge workers work as a team, members of which are those that hold same or similar views toward certain things, and those whose knowledge work possess similar properties. They don't necessarily come from the same department in a DLO in order to be a team. Knowledge workers, before moving from one team to another as job demands, must know how to distinguish in the first place what job they are dealing with that suits the characteristic of the target team. This idea coincides with what Recipe Knowledge(Sackmann, 1991) has to offer.

Knowledge structure

Therefore, to analyze the knowledge structure in any DLO, we must first bear in mind that knowledge workers work as a team. Then, we induce and systematize a variety of Recipe Knowledge with the assistance of information technology in order to fit the KM mechanism seamlessly into the daily functioning of a DLO. (see Figure 7)

Figure7: Systematization of Knowledge Structure

Knowledge Agent

The conventionally inflexible bureaucratic levels in a DLO are subject to ossification, which smother workers' ability of innovation and self-improvement, despite the fact that it is an environment suitable for conducting the activities of knowledge acquisition and transfer. By putting forward the concept of Knowledge Agent, we accommodate a task-oriented departmentalization of the DLO for supplementing the lack of flexibility that the activity of knowledge dissemination can in effect benefit from. Knowledge Agent renders their service to team-based knowledge workers, supporting workers by offering them the necessary information

and management tools demanded by work. In addition, the below Table 1 further explicates the attributes and varieties of function carried out by Knowledge Agent.

Knowledge Agent	Service/support receiver	Attribute	Method
Officer Agent	Decision officer & depart. Manager in the Officer Crew	<ul style="list-style-type: none"> • Learning activity management; • Knowledge repository planning; • Comprehensive Information provider 	<ul style="list-style-type: none"> • decision support system • on-line analysis tool • processes management tool • data access tool
Operator Agent	Subject Specialist, IT Expert & Knowledge Officer in the Operator Crew	<ul style="list-style-type: none"> • learning activity instruction • information framework development • standardized procedure establishment 	<ul style="list-style-type: none"> • development tool of information system • classification & compilation tool • tool for management of limits of authority
Leamer Agent	Registered & Unregistered readers in the Leamer Crew	<ul style="list-style-type: none"> • interactive learning • assistance in participating management tasks • sharing & feedback 	<ul style="list-style-type: none"> • means for inquiry- making • recommendation channel open for learners • means of discussion for learners

Table 1: Attributes & Functions in a Knowledge Agent

CONCLUSION

The impacts brought about by a DLO range from creative learning, cooperative learning, to constructive learning. Among the three, constructive learning is especially a crucial characteristic in learning organization. It highlights knowledge discovery and knowledge exploring, which is capable of converting articulated knowledge into tacit knowledge. A computerized system shall be proposed to support these three types of learning.

The only comparative advantage with the developed countries is in the amount of the supply of knowledge workers (Drucker, 1997). This in turn will enable new ways of learning, managing and creating knowledge. It will also lead to a generation with interconnected network, associated databases and technologies in collaboration.

The implication is about an attempt to have the KM mechanism connected with the day-to-day functioning of a DLO, in anticipation of a more open KM environment in this digital era by means of information technology. We have also explored in the first place how well the DLO is doing now to know where to improve on, prior to the use of the concept of KM.

On2broker: Semantic-based access to information sources at the WWW

Dieter Fensel, Jürgen Angele, Stefan Decker, Michael Erdmann, Hans-Peter Schnurr, Steffen Staab, Rudi Studer, and Andreas Witt

Institute AIFB, University of Karlsruhe, D-76128 Karlsruhe, Germany
dfe@aifb.uni-karlsruhe.de, <http://www.aifb.uni-karlsruhe.de/www-broker>

Abstract. On2broker provides brokering services to improve access to heterogeneous, distributed and semistructured information sources as they are presented in the World Wide Web. It relies on the use of *ontologies* to make explicit the semantics of web pages. In the paper we will discuss the general architecture and main components of On2broker and provide some application scenarios. We show how we can provide semantic based access to web sources described with HTML, XML, or RDF.

1 Introduction

Meanwhile, the World Wide Web (WWW) contains several hundred million static objects providing a broad variety of information sources. The early question of whether a certain piece of information is on the web has changed into the problem of how to find and extract it. Therefore, dealing with the problem of finding and maintaining information in the WWW has become a highly important topic and several initiatives exist that try to improve the current situation. Currently, most web sources rely on the use of *HTML* that describes structure (and layout) of documents, but not the semantics of the provided information. More recently, *XML* has been proposed that allows the definition of new tags (based on a DTD) that enable the semantic annotation of information (i.e., a tag *person* with subtags *name* and *telephone number* allows direct access to the provided information). Another web standard that is currently under development is the *Resource Description Framework RDF* [RDF] which allows the meta level annotation of web sources making their content explicit and machine processable. In addition to formalisms, standard vocabularies for describing information sources are developed by the *Dublin Core* and *MPEG-7* initiative.

In the paper we describe a tool environment called On2broker that processes information sources and content descriptions in HTML, XML, and RDF and that provides information retrieval, query answering and maintenance support. Central for our approach is the use of *ontologies* to describe background knowledge and to make explicit the semantics of web documents. Ontologies have been developed in the area of knowledge-based systems for structuring and reusing large bodies of knowledge (cf. CYC [Lenat, 1995], (KA)² [Benjamins et al., to appear]). Ontologies are consensual and formal specifications of vocabularies used to describe a specific domain. Ontologies can be used to describe the semantic structure of complex objects and are therefore well-suited for describing heterogeneous, distributed and semistructured information sources.

On2broker provides a broker architecture with four elements: a query interface for formulating queries, an info agent used for collecting the required knowledge from the web, an inference engine used to derive answers, and a database manager used to cache semantic annotations. On2broker uses semantic information for guiding the query answering process. It provides the answers with a well-defined syntax and semantics that can be directly understood and further processed by automatic agents or other software tools. It enables a homogeneous access to information that is physically distributed and heterogeneously represented in the WWW and it provides information that is not directly represented as facts in the WWW but which can be derived from other facts and some background knowledge. Still, the range of problems it can be applied to is much broader than information access and identification in semistructured information sources:

- *Automatic document generation* extracts information from weakly structured text sources and creates new textual sources. Assume distributed publication lists of members of a research group. The publication list for the whole group can automatically be generated by a query to On2broker. A background agent periodically consults On2broker and updates this page. The gist of this application is that it generates semistructured information presentations *from* other semistructured ones.

- *Maintenance* of weakly structured text sources helps to detect inconsistencies among documents and to detect inconsistencies between documents and external sources, i.e., to detect incorrectness (for example, a publication on a page of a member of the group must also be included in the publication list of the entire group). Again such a service can be provided by On2broker using its ontological representation language and inference engine.

The content of the paper is organized as follows. Section 2 discuss its core architecture and section 3 to 6 its elements. Finally, conclusions, related and future work are given in section 7.

2 The General Picture

The overall architecture of On2broker is provided in Figure 1 which includes four basic engines representing different aspects.

- The **query engine** receives queries and answers them by checking the content of the databases that were filled by the info and inference agents.
- The **info agent** is responsible for collecting factual knowledge from the web using various style of meta annotations, direct annotations like XML and in future also text mining techniques.
- The **inference engine** uses facts and ontologies to derive additional factual knowledge that is only provided implicitly. It frees knowledge providers from the burden of specifying each fact explicitly.
- The **database manager** is the backbone of the entire system. It receives facts from the Info agent, exchanges facts as input and output with the inference agent, and provides facts to the query engine.

Ontologies are the overall structuring principle. The info agent uses them to extract facts, the inference agent to infer facts, the database manager to structure the database and the query engine to provide help in formulating queries. A *representation* language is used to formulate an ontology. This language is based on Frame logic [Kifer et al., 1995]. Basically it provides classes, attributes with domain and range definitions, is-a hierarchies with set inclusion of subclasses and multiple attribute inheritance, and logical axioms that can be used to further characterize relationships between elements of an ontology and its instances. The ontology introduces the terminology that is used to define the factual knowledge provided by information sources on the web. A little example is provided in Figure 2. It defines the class *Object* and its subclasses *Person* and *Publication*. Some attributes are defined and some rules expressing relationships between them, for example, if a publication has a

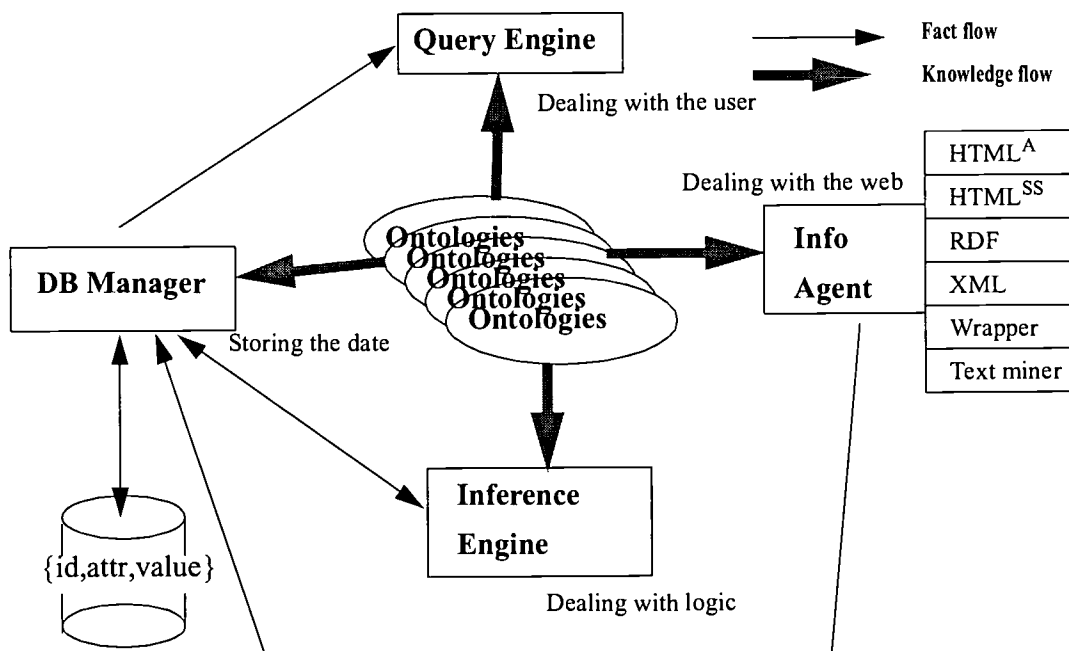

Figure 1 On2brokers Architecture.

Object[].	FORALL Person1, Person2
Person :: Object.	Person1:Researcher [cooperatesWith ->> Person2]
Publication::Object.	<-

year =>> NUMBER;	
abstract =>> STRING].	

Figure 2 An excerpt of an ontology (taken from [Benjamins et al., to appear])

person as an author, then the author should have it as a publication.

3 The Query Engine

The *query* language is defined as a subset of the representation language. The elementary expression is:

$$x \in c \wedge \text{attribute}(x) = v$$

written in Frame logic:

$$x[\text{attribute} \rightarrow v] : c$$

Complex expressions can be built by combining these elementary expressions with the usual logical connectives (\wedge , \vee , \neg). The following query asks for all abstracts of the publications of the researcher „Richard Benjamins“.

$$x[\text{name} \rightarrow \text{„Richard Benjamins“}; \text{publication} \rightarrow \{y[\text{abstract} \rightarrow z]\} : \text{Researcher}$$

The variable substitutions for z are the desired abstracts. Expecting a normal web user to type queries in a logical language and to browse large formal definitions of ontologies is not very practical. Therefore, we exploited the structure of the query language to provide a tabular query interface and a quick and easy navigation is provided by a presentation scheme based on Hyperbolic Geometry [Lamping et al., 1995] (see Figure 3, and for more details [Fensel et al., 1998a]). Based on these interfaces, On2broker automatically derives the query in textual form and presents the result of the query.

In the effort to create efficient search mechanisms in the WWW, information *mediators*, the like of Metacrawler, and softbots (cf. [Etzioni, 1997]) that access other search engines will become increasingly important. That is why in On2broker the decision was taken to implement the query interface as an JavaTM *Remote Method Invocation (RMI) Server*. This allows us to make the JavaTM interface publicly available and thus give meta search engines more efficient access to the knowledge base.

4 The Info Agent

The info agent extracts factual knowledge from web sources. We will discuss the four possibilities we provide in On2broker.

First, we developed a small extension of HTML called HTML^A to integrate semantic annotations in HTML documents. On2broker uses a *webcrawler* to collect pages from the web, extracts their annotations, and parses them into the internal format of On2broker. More details on HTML^A can be found in [Decker et al., 1999].

Second, we use wrappers for automatically extracting knowledge from web sources. Annotation is a declarative way to specify the semantics of information sources. A procedural method is to write a program (called *wrapper*) that extracts factual knowledge from web sources. Writing wrappers for stable information sources enable us to

Figure 3 The hyperbolic ontology view.

apply On2broker to structured information sources that do not make use of our annotation language. In fact, we applied On2broker to the CIA World Fact book [CIA]. This shows that it is already possible to exploit structure and regularity in current web sources (i.e., HTML documents) to extract semantic knowledge from it without any additional annotation effort.

Third, On2broker can make use of RDF Annotations (cf. [Lassila & Swick, 1998]). Manually adding annotations to web sources requires human effort causing costs in terms of time and money. However, this annotation effort may become less problematic by spreading it over the entire web community. Currently the Resource Description Framework (RDF) [Lassila & Swick, 1998] arises as a standard for annotating web sources with machine-processable metadata. *RDF* provides means for adding semantics to a document without making any assumptions about the internal structure of this document. The info engine of Onto2broker can deal with RDF descriptions. We make use of the RDF Parser SiRPAC that translates RDF descriptions into triples that can directly be put into our database. More details on how our inference engine works with RDF are given in [Decker et al., 1998]. The inference engine of On2broker specialized for RDF is called *SiLRI (Simple Logic-based RDF Interpreter)*. Actually, On2broker is the first inference engine for RDF.¹

Fourth, another interesting possibility is the increased use of the eXtensible Markup language XML. In many cases, the tags defined by a DTD may carry semantics that can be used for information retrieval. For example, assume a DTD that defines a person tag and within it a name and phone number tag.

```
<PERSON> <NAME>Richard Benjamins</NAME> <PHONE>+3120525-6263</PHONE> </PERSON>
```

Then the information is directly accessible with its semantics and can be processed later by Ontobroker for query answering. Expressed in Frame logic, we get:

```
url[NAME ->> „Richard Benjamins“; PHONE ->>+3120525-6263] : PERSON
```

RDF still requires the annotation effort for creating metadata but this effort is now shared by the entire web community. XML provides the chance to get metadata „for free“, i.e. as side product of defining the document structure. XML allows the definition of new tags with the help of a DTD and provides semantic information as a by-product of defining the structure of the document. A DTD defines a tree structure to describe documents and the different leaves of the tree have tags that provides semantics of the elementary information units presented by them. That is, the structure and semantics of a documents are interleaved. On2broker is able to read such DTD, to translate it into an ontology, and to translate XML documents into its internal triple representation. Actually, DTDs are serialized and simple means for describing ontologies. The above given example corresponds to a class

1. <http://www.w3.org/RDF>, RDF Software and Products.

Person with two attributes *Name* and *Phone*. Weaknesses of DTDs from an ontological point of view are:

- No inheritance is provided. Therefore attribute definitions need to be repeated. If classes like *Person*, *Employee*, and *Student* share the same attributes their definition must be repeated for each class making maintenance difficult. In our approach, they can be defined for *Person* and inherited by *Employee* and *Student*.
- DTDs do not provide means to define the range of attributes, i.e. to constrain the values a tag may have.
- DTDs do not provide rules that allow the implicit representation of data. All data need to be represented explicitly (i.e., materialized).

5 The Inference Engine

The *inference engine* takes the facts collected by the webcrawler together with the terminology and axioms of the ontology, and then derives the answers to user queries. To achieve this it has to do a rather complex job. First it translates Frame logic into Horn logic via Lloyd-Topor transformations [Lloyd & Topor, 1984]. Techniques from deductive databases are applicable to implement the second stage: the bottom-up fixpoint evaluation procedure. We have adopted the well-founded model semantics [Van Gelder et al., 1991] and compute this semantics with an extension of dynamic filtering [Van Gelder, 1993].

The inference engine is used to derive information that is implicitly present in web sources without requiring that all information is complete materialized by annotations. We will briefly illustrate this with some examples.

(1) *Employee* :: *Person*

This is-a relationship implies that each employee is also a person and each attribute that is defined for persons can also be applied to employees.

(2) $X[\text{cooperates} \rightarrow Y] \rightarrow Y[\text{cooperates} \rightarrow X]$

This rule ensures symmetry of cooperation. If it is known from an annotation that *Motta* cooperates with *Chandrasekaran* than we already know that *Chandrasekaran* cooperates with *Motta*, even if *Chandrasekaran* does not explicitly annotate his homepage with this fact.

(3) $X[\text{author} \rightarrow Y] : \text{Publication} \rightarrow Y[\text{has-publication} \rightarrow X] : \text{Researcher}$

The final example states that if in a publication file somebody is stated as author, we will get this publication if we query his homepage for his publications.

Without such an inference mechanism, the provided information is notoriously incomplete and annotation effort is unmanageable high.

6 The Database Manager: Decoupling Inference and Query Response

In the design of Ontobroker (cf. [Fensel et al., 1998a]) we already made an important decision when we separated the web crawler and the inference engine. The web crawler periodically collects information from the web and caches it. The inference engine uses this cache when answering queries. The decoupling of inferencing and fact collection is done for efficiency reasons. The same strategy is used by search engines on the web. A query is answered with help of their indexed cache and not by starting to extract pages from the web. Ontobroker refines this architecture by introducing a second separation: *separating the query and inference engines*. The inference engine works as a demon in the background. It takes facts from a database, infers new facts and returns these results back into the database. The query engine does not directly interact with the inference engine. Instead it takes facts from the database:

- Whenever inference is a time critical activity, it can be performed in the background independently of the time required to answer the query.
- Using database techniques for the query interface and its underlying facts provides robust tools that can handle mass data.
- It is relatively simple to include things like truncation, term similarity and ranking in the query answering mechanism. They can now directly be integrated into the SQL query interface (i.e., in part they are already provided by SQL) and do not require any changes to the much more complex inference engine.

The strict separation of query and inference engines can be weakened for cases where this separation would cause disadvantages. In many cases it may not be necessary to enter the entire minimal model in a database. Many facts are of intermediate or no interest when answering a query. The inference engine of On2broker incorporates this in its dynamic filtering strategy which uses the query to focus the inference process (cf. [Fensel et al., 1998b]).

7 Conclusions

On2broker is the successor system of Ontobroker (cf. [Fensel et al., 1998a], [Decker et al., 1999]). The major new design decisions in On2broker are the clear separation of query and inference engines and the integration of new web standards like XML and RDF. Both decisions are answers to two significant complexity problems of Ontobroker: the computational inference effort for a large number of facts and the human annotation effort for adding semantics to HTML documents. On2broker is available on the web and has been applied in a number of applications in the meantime. The most prominent one is the (KA)² initiative that provides semantic access to all kinds of information of research groups of the knowledge acquisition community [Benjamins et al., to appear].

The use of *one* ontology for annotating web documents will never scale up for the entire web. Neither will an ontology be suitable for all subjects and domains nor will ever such a large and heterogeneous community as the web community agree on a complex ontology for describing all their issues (like there will be not one DTD for all purposes). Therefore, work on relating and integrating various ontologies will become an interesting and necessary research enterprise which will also be addressed in the future course of the On2broker project.

Web Centric Education - a Challenge for Process Redesign

John D. Ferguson, George R. S. Weir and John N. Wilson
Department of Computer Science
University of Strathclyde
Glasgow
G1 1XH

e-mail {jf, gw, jnw}@cs.strath.ac.uk

Abstract: The fusion of computer and communications technology is giving rise to many novel developments in computer-based education and distance learning. Evolving web centric learning environments are challenging current modes of working in traditional universities. Over the last decade, higher education has been subjected to immense pressures for change. The massive increase in student numbers coupled with reduced levels of funding, lead many to the belief it is essential that new and innovative modes of teaching and learning are adopted. But how innovative are current uses of technology? Are present web centric environments not merely an electronic image of the traditional framework? As higher education finds itself moving towards a commercial market where it could be subject to commercial forces, it would seem reasonable to examine the impact of information technology on education using the same models adopted to evaluate its impact within commercial organisations. This paper draws together current developments in computer-based education with concepts from business process re-engineering.

1. Introduction

In the period from 400BC when Plato's Academy was established outside Athens to teach philosophy, mathematics and gymnastics, until the present day, the mode of the educational process has been remarkably stable. The idiom has essentially consisted of a small number of teachers delivering material to a larger number of students. This is true both for face-to-face learning and also for distance learning. As in Plato's time, there has been much more emphasis on the face-to-face approach while the numbers involved in the process – both teachers and students – have been strictly limited.

Distance learning approaches, and more recently computer based education (CBE) and computer aided learning (CAL) environments, have started to disturb the balance that has existed since Hellenist times. The introduction of IT and a business ethos to the educational process has given rise to pressures similar to those experienced in commerce, with a focus on customer needs and whether the organisation can efficiently meet these needs. Education is rapidly evolving from an opportunity that is provided mainly for an elite, to one that is available to a mass market and which is therefore prone to the forces generated by such an environment. Where, in the established pattern, commercial interest was limited mainly to the use of skills developed during the educational process, the future model of educational provision will involve extensive commercial activity in the production, delivery and marketing of material. Already there are a number of commercial companies offering framework products enabling "off the shelf solutions" for the construction and delivery of web based courses in any subject area. The commercialisation of education is underway and it is inevitable that entrepreneurs and customers will view it as any other commercial product. The commercial approach to education is emerging at a time when many business organisations are restructuring their operations to optimise use of IT. Such restructuring provides a clear pattern for changes within education.

2. Re-engineering - the models

Models for business change form a spectrum of approaches ranging from radical restructuring to evolutionary improvement. Their common purpose is that they aim to increase competitive edge by

aligning business organisation with communications and information technology. A combination of radical and evolutionary paradigms is used to characterise business process restructuring [Venkatraman 1991]. This incorporates the ideas of business process re-engineering (BPR) [Hammer 1993] and identifies several stages in the evolution of IT based organisations. These stages operate at two separate levels. At the progressive level, the changes are of limited consequence to the organisation of a business whilst at the radical level, changes are incompatible with pre-existing business structures [Figure 1]. In general, an organisation will complete the sequential steps at the progressive level before proceeding to the independent changes at the radical level.

The initial stage in the restructuring process is characterised as localised exploitation of IT developments. Exploitation may impact business activities themselves or the administrative operations that support such activities. The use of IT may be tactical or strategic. Examples of such activities include the use of knowledge-based tools to support diagnosis of faults in electronic systems and the use of data mining techniques to focus marketing exercises. The significance of development at this level is that IT is exploited in discrete niches that provide business advantage. There is no coherence across an organisation in its approach to the use of IT.

The integration of IT activities across an organisation using a communications network represents the second stage of process restructuring. This stage is dependent on the existence of several computerised processes of the kind characterised by the localised exploitation stage. The benefits of this stage include greater integration of different functions within the business process and ready access by management to data describing the performance of the operation. Intranet development provides an organisation with a capability to operate at this level.

Figure 1: IT capability dependencies in the stages of business restructuring (after [Venkatraman 1991])

Within the radical stages of restructuring, business process re-design encapsulates the developments required in the organisation of commerce needed to provide major gains in the efficiency of business enterprises in response to IT investment. The technique involves fundamentally restructuring the ways in which a business operates to replace rigid product orientation.

The input to the re-engineering process is a system of business organisation that developed between the industrial revolution and the middle part of the 20th century. The system was focussed on functional decomposition and dealt well with limited product demand. The desired output from the re-engineering process is an improved level of product or service achieved at an expense that is a fraction of the costs before re-engineering. Asynchronous communication supported by IT provides the means for ensuring that activities that could only be accomplished by specialists in the functional decomposition paradigm can be accomplished by generalists in the re-engineered process or can be avoided altogether.

Development of Internet capabilities has done much to simplify the business network redesign stage of process restructuring. The use of such technology provides a basis on which co-operative processes involving discrete organisations can be constructed. Typical of this is the process of a manufacturer providing its suppliers with access to inventory levels with the understanding that the supplier would be responsible for delivering materials to re-supply inventory items at appropriate times. Both parties gain business advantage in such an arrangement. The supplier is able to optimise production and at the same time, the consumer is guaranteed that inventory is maintained at the most appropriate level.

The fifth level of business process re-engineering comprises developments in the types of business activities that an organisation conducts in response to perceived marketing opportunities. Examples may arise from business-critical applications that are developed by the organisation to solve specific problems and which are, in themselves, viable products. A typical example of such a change in focus is the development of MRP by General Motors. Initially conceived as an in-house system for supporting manufacturing of vehicles, this was later marketed as a product in its own right.

Despite the promises of BPR, it is difficult to show improvements in productivity as a consequence of increased investment in information technology infrastructure [Brynjolfsson, 1998]. Traditionally, major advances in productivity have coincided with the development of general-purpose technologies but significant changes in organisation have been required to maximise the benefit of these technologies. The replacement of steam engines by electric power was most successful where a single large steam engine was replaced by several smaller electric motors that provided power where it was required. It is not surprising that given the difficulty of demonstrating consistent productivity improvements generated by IT investment, most managers cite improvements in customer service and quality above cost savings as motivation for making investments in IT.

3. CBE – evolution and revolution

Computer technology has made a significant impact in many areas of teaching and learning. The introduction of desktop computers, word-processing packages and presentation preparation tools have improved greatly the quality of the material presented to students and used in lectures. The use of simple database packages and spreadsheets has improved and simplified record keeping at all levels within education. However, perhaps the most significant impact has come from the use of supportive learning mechanisms such as CAL and computer based training (CBT). These technologies make use of various forms of interactivity to engage the student in effective, and often novel, learning experiences.

Viewed from a business process re-engineering model all of these activities fall within the early or progressive stage of IT implementation, characterised by the local exploitation of technology to improve, in the main, the efficiency of the traditional legacy activities within the organisation.

The introduction of high-speed communication networks in the early eighties followed by the development of simplified and standardised access and presentation software in the form of web browsers, in the nineties, has enabled the easy sharing of information within organisations (via Intranets) and externally (via the Internet). Arguably, educational institutions have grasped this phase of IT development more than industry and commerce. Academics were quick to see the potential of the World Wide Web and web technology as a means of retrieving and sharing information. Intranets and the Internet now form the IT platforms in many academic institutions for the integration of many teaching and auxiliary activities: access to publicity material, course records and regulations, minutes of committees, course notes, on-line assessments and CAL animated simulations. The list is extensive

and growing. Nearly all legacy activities offered by the faculty, or the institution as a whole, can be made available within and outside the organisation, using web-based technology.

At this stage of IT adoption, development has gone beyond individual activities exploiting their isolated IT applications and the integration of the institution's needs is now being handled through the shared IT platform. The fundamental processes however, remain basically unchanged: the university continues to carry out its basic activities - registration, lectures, assessment etc., as before but has made full use of the IT infrastructure. Completion of this stage marks the end of the progressive phase of IT adoption; the organisation has evolved, and through incremental change has adopted the use of the IT platform across its various activities.

The next phase of BPR development is characterised by a radical change in the way an organisation operates. In this phase, new technology enables a completely fresh approach to achieving the organisation's goals and does not simply provide support for the existing legacy operations. Business process redesign for education would involve not merely an improvement of existing practices, such as better CAL software or better multimedia presentations at lectures, but also, and more fundamentally, a reappraisal of the existing practice and a search for new and more efficient methods of achieving the organisation's goals [Mandviwalla 1998].

One area where teaching and learning practices are being re-examined is the implementation of distance learning courses delivered making use of technology based on the Internet, i.e. the Virtual University. Within this structure the technology is fully exploited to provide an environment where students can perform all their work remotely - accessing lectures from the home, tutorial discussions through news groups or on-line conferencing mechanisms, learning in a simulated environment, accessing a wide variety of information over the Internet. In the virtual university certain kinds of behaviour are encouraged and enabled. For example it is easy to communicate on a wide front, to search libraries and vast quantities of information, and to copy material. These capabilities have much to offer promoting student centred activity. However, they also have the potential to severely threaten aspects of quality as viewed from the conventional academic framework [Ferguson, McGettrick, and Smeed 1999].

While on the surface the virtual university concept might appear radical and a candidate for stage three in the BPR framework, close investigation does not show a fundamental shift from the basic legacy teaching and learning processes that are associated with traditional universities. The virtual lecture theatre, virtual coffee shop, assessment engines etc., are all parodies of processes within the traditional system.

4. Process redesign

Currently, traditional university learning is teacher centred. Within a virtual university the focus will shift from the teacher to the student. Inevitably, new approaches are required to produce materials that invite sustained study and examination. The role of the teacher will change to deal with the functions of evaluation and monitoring of distant learners as well as the author of material suitable for independent study. Incidentally, changes in the mechanisms of teaching delivery cast requirements for new techniques that ensure originality of work and protect against plagiarism and misuse of copyright.

Opportunities may develop for activities that have proven difficult to implement in traditional curriculum design. For example, many curricula seek to highlight common themes or lateral links between traditional, but separately taught topics or courses. It may be possible to ensure that these important keystones are highlighted to the student across what may appear to be totally disparate topics.

A number of emerging techniques offer radical enhancement to Web-based teaching. In particular, the need for dynamic control, annotation and interlinking of content can be addressed through recent developments. A key to all such ventures is a move away from manual organisational techniques toward automated management. The limited effectiveness of conventional Web-search and association facilities will soon be superseded by powerful context-sensitive trawling and data-mining approaches

(cf. [Brin and Page 1998] and [Chakrabarti et al 1999]). Localised control of dynamic annotation may be secured through use of a Web-based software intermediary (e.g., as proposed in [Weir and Lepouras 1998]). Finally, the existence of fellow learners in similar but remote contexts promises the prospect of new supportive and co-operative learning opportunities [Kumar et al 1998].

Whatever the impact of such developments, there is a need to re-examine the basic processes on which current education is based and to be prepared to re-engineer the system to make maximum advantage of the opportunities provided by new technology.

5. Conclusion

The development of a mass market in education is leading to the commercialisation of the process and a decreasing emphasis on face-to-face teaching methods in favour of distance learning and especially distance learning supported by CBE.

The parallels between business process re-engineering and IT investment in industry and the development of computer based education suggest that the fundamental benefit which can be sought by the introduction of technology is improvements in product quality and customer service. In view of the significant investment required to produce good quality educational material, it is important that there is some form of measurement of the improvement that such systems generate. Without this quantification of benefit, it will be increasingly difficult to justify continuing investment in CBE development

There is a lack of overwhelming evidence that business process re-engineering consistently produces commercial benefits although there are isolated cases where this is so. While re-engineering in business has been progressing for almost a decade, education is only now being drawn into the process. Both business and education face major challenges in attempting to capitalise on the opportunities presented by IT in re-organisation.

Estimating the Number of Defects at a WWW Site

John D. Ferguson, James Miller and George R S Weir
Department of Computer Science
University of Strathclyde
Glasgow
G1 1XH

e-mail {jf, james, gw}@cs.strath.ac.uk

Abstract: It is widely accepted that a high proportion of Web sites are poorly designed and suffer from a range of defects that affect both their usability and quality. Further, it has been postulated that failure to address this issue could lead to user rejection and a possible downturn in Web growth. The introduction of new Web authoring tools will help towards alleviating some problems at the design stage. However, despite these tools, any site of reasonable complexity will contain defects affecting its overall quality and usability. This paper presents an analysis that outlines several statistical models for estimating the number of defects at a Web site, providing a significant step forward in its appraisal and progress to improved reliability and quality.

1. Introduction

Recent forecasts have suggested that the current estimate of 4 million web sites will have grown to 200 million by the year 2003 [Nielsen 1999]. However, there is no indication that this rapid growth in site numbers will be accompanied by improvements in either their usability or quality. The profusion of badly designed and difficult to use sites is already prompting many to question the relevance of the Web for applications where quality is a major issue.

Education is one key area where quality is recognised as fundamental. The rapid growth in web-centric environments, characterised by the concept of the virtual university, have opened many new opportunities in student centred learning but have also raised concerns with the potential to severely threaten aspects of quality as viewed from the conventional academic framework [Ferguson, 1999].

Poor usability can arise from a number of factors: - bad design with over-complex graphics giving long download times, lack of search mechanisms on large sites, inconsistency in approach, broken and out of date links that fail to lead to the declared content, syntax or semantic errors in text, etc. New and improved Web authoring tools, encompassing templates, make it easier at the design stage to produce reasonably acceptable results avoiding many of the pitfalls. However, any Web site of reasonable complexity will still harbour defects.

One traditional approach used to evaluate a user interface, and increasingly common for the evaluation of web pages, is usability inspection [Nielsen 1994]. This technique comprises a set of methods that are all based on having evaluators inspect the user interface. Inspection methods include:

- Heuristic evaluation where each usability specialist assesses whether each dialogue element follows established usability rules.
- Feature inspection outlines groups of sequences used to perform tasks, checks for long sequence trails or difficult steps that would not be normal for users to try.
- Cognitive walkthrough where a detailed procedure is used to model a typical user's problem solving activity at each step, checking if they lead to the next correct action.
- Standards inspection to ensure that the interface meets a published standard.
- Consistency inspection to ensure that the interface is consistent with other products forming part of the same family.

Regardless of which techniques are applied only a partial set of defects existing at the site will in general be found. Hence the need exists to construct an estimate of the remaining defects. This

estimate would allow us to produce a fundamental measure of the quality of the Web site and can subsequently be used as a managerial aid on decisions with regard to increasing the quality of the site.

2. Process for estimating remaining defects

The characteristic used in constructing the estimate is a partial estimate of the number of defects in the site. Hence, unfortunately, we cannot attempt to construct the full estimate without undertaking an initial defect detection stage. Although this initial stage is straightforward, it obviously requires manpower and hence incurs cost. In fact this initial process is the major cost of deploying this technique. The initial defect detection process is simply a matter of deploying a number, say between 3 and 5, of individuals to explore the web space noting defects as they proceed. This exploration process should last for approximately 2 hours, during which the participant notes any defects they find.

The suggested duration is derived from other similar activities [Fagan 1976], as no information is currently available for the WWW sites. If the site is extremely large, then the participants should be asked to search the space repeatedly, in two-hour blocks, until they believe that they have fully explored the space. No specific instructions, information or process are required to be followed. In fact it is desirable that the participants search through the web space in a natural and uncontrolled manner, as the diversity helps to ensure that that different participants will find different faults. Further, additional techniques to increase the diversity are also desirable, such as selecting participants with different backgrounds or different interests with regard to the information space. Not only does this diversity increase the number of unique defects found, but it also simplifies the subsequent analysis; as the diversity helps us argue that each set of defects are found by a process which is completely independent from the processes deployed by other participants.

This argument, in addition to the fact that by definition the defects are mutually exclusive and all inclusive, allows us the use of a multinomial likelihood function to construct an estimate from this initial data. The final step in the initialisation process is for an individual or the team of participants to work as a defect oracle and decide which proposed defects are in fact false defects, which are duplicates and which are unique. Armed with this information we are now ready to construct our estimate of the total number of defects at the Web site.

3. Constructing a generic estimator

The multinomial distribution is the generalisation of the binomial distribution, and is introduced to most people as a model of the probabilities of dice throwing. The likelihood function, or sometimes the log-likelihood function, links the data (derived by the above process) with the unknown parameters (total number of defects) through a model that makes implicit all the assumptions (behaviour of participants; complexity of defects) underlying a process. Likelihood functions are the basis for rigorous inference in statistics.

Let N be the unknown number of defects; and k be the number of participants. Hence we can construct a binary matrix x ($N \times k$), which indicates if the j^{th} participant found the i^{th} defect¹. Further we can associate a probability of this event occurring p_{ij} . Note that we are unable to observe this entire matrix as N is unknown. If we further define n to be the unique defects found during the initial process, then we can define a further matrix x ($n \times k$) which is observable and is clearly a subset of x .

Given these definitions we can define the likelihood function as²:

$$L(N, p | x) = \frac{N!}{\prod_k f(n, x_i)!} \prod_N \prod_k p_{i,j}^{x_{i,j}} (1 - p_{i,j})^{1-x_{i,j}}$$

¹ This relationship is assumed in the rest of the paper and will not be repeated for the sake of brevity.

² Note that the indexing has been removed from product symbols to aid readability. Formally: $j=1, \dots, k, i=1, \dots, N$.

where $f(n, x_i)$ is the number of defects found by participant i and no other participant. Likelihood theory now implies that the correct estimate of N is found by finding p such that this function is maximised, i.e. the maximum likelihood estimate has been found.

4. Constructing estimators based upon differing P_{ij}

The probability function as defined above can vary according to two sources of variance: the ability of the participants and the difficulty of finding defects. The joint probability model of these two effects represents the most complex formulation of this model. In this section we will discuss other simpler formulations (by limiting the number of variance parameters), which can also be used as estimators.

The simplest model is when the ability of all the participants is considered equivalent and the complexity of finding any defect is considered equal, i.e. $p_{ij} = p$. Hence the above equation greatly simplifies and although the maximum likelihood estimator is straightforward (see [Darroch 1958] for a derivation), it is still not possible to describe it in a closed form and hence an analytical solution is not possible. This does not pose any great problems, as log-likelihood functions³, by definition, are monotonic, and N is an integer value, hence nearly any simple iterative method will quickly find a solution.

Unfortunately this formulation is likely to be conservative, and, in general, will underestimate in the presence of variation in the two sources. If variation between the defects is the dominant feature then adding variation in this direction provides a more accurate model. For this model, $p_{ij} = p_j$ is substituted into the equation yielding (after some re-arrangement):

$$L(N, p | x) = \frac{N!}{\prod_k f(n, x_i)!} \prod_k p_j^{n_j} (1 - p_j)^{N - n_j}$$

Unfortunately the authors are unaware of any public defect data for web sites, and hence direct evaluation of this model is currently impractical. Evidence exists in other fields [Chao 1987, 1988; Miller 1999] that the other source of variation (participant performance) is more important, but it is impossible to judge if that evidence transfers into this context. Again, as with the above model, the numerical solution to this formulation is straightforward. One possible addition to the model is to parameterise the probabilities with a confidence parameter indicating the certainty of assigning probabilities to individual defect 'types'. In the limiting case, no confidence, the model collapses to become the simpler model. The parameter allows the investigator to conduct a sensitivity analysis upon the assigned probabilities.

To model the performance of the participants we simply set $p_{ij} = p_i$. Again substituting and re-arranging yields:

$$L(N, p | x) = \frac{N!}{\prod_k f(n, x_i)!} \prod_N \binom{k}{g_i} p_i^{g_i} (1 - p_i)^{k - g_i}$$

Where $g_i = g(k, x_i)$ and denotes the number of participants to find the i^{th} defect.

As noted above, evidence exists in other fields [Chao 1987, 1988; Miller 1999] that this source of variation (participant performance) is dominant (in these other fields), but again it is presently impossible to judge if that evidence transfers into this context. This formulation is more difficult to evaluate, due to the lack of knowledge of the size of the vector of probabilities (N). This difficulty can be overcome by the application of resampling methods, for example Burnham and Overton [Burnham, 1978] show how models of this type can be evaluated by constructing a Jackknife estimator, other resampling techniques, such as bootstrapping [Efron 1993], can equally be applied to this type of estimator. As above the probabilities here can be parameterised to allow sensitivity analysis.

³ Log likelihood functions are simply the log of the likelihood function and are extensively used to simplify problems, while retaining the characteristics of the initial formulation.

The final estimator is where variation in both dimensions is allowed (the generic case). Here the evidence from other fields is that, although theoretically this model should provide the best performance, trials suggest that it does not significantly outperform the participant's performance variation only model, due to its dominance over the defect variation in these other fields. Additionally this model has been found to be highly unstable for limited numbers of participants, and hence may be difficult to apply to this problem [Chao 1987, 1988; Miller 1999]. Again judging the value of this evidence within the context of this problem is difficult, but the unstable nature of this estimator suggests at least caution. An example of the use of models in this type, for 'large' numbers of subjects can be found in Chao [Chao 1992].

This leaves us in a situation of having multiple models, which are likely to produce differing estimates of N , and limited evidence for the selection of the correct model and hence final estimate. In fact the position is even worse than this, as three of the models require prior hyper-parameters (probability functions or parameterised probability functions) for estimation. Hence each potential combination of hyper-parameters represents a different model for the selection mechanism to consider.

The following section will outline one potential method of model selection [Carlin 1996]; unfortunately it is impossible to provide specifics without data from the problem at hand.

5. Model Selection

Selecting from competing models is a difficult, but essential undertaking. Many fields, using statistical models, ignore the model uncertainty. Data analysts typically select a model from some class of models and then proceed as if the selected model had generated the data. This approach ignores the uncertainty in the model selection process, leading to inappropriate inferences and over-confidence in the derived estimates. Bayesian model selection and averaging provide a coherent mechanism for addressing model uncertainty, and hence providing more reliable estimates.

The Bayesian solution to this problem is to compute the posterior probability for each model. For model selection, simply choose the model that maximises this conditional probability, if several models provide similar values then the probabilities can be used as weighting functions in an averaging process.

Suppose that two models exist, $M1$ and $M2$, then we simply compute $p(M1/x)$ and $p(M2/x)$. To estimate the significance of the difference between two probabilities, then we simply form the ratio of the two conditional probabilities. This quantity is known as a Bayes factor⁴, and can be interpreted as the support for each model from the data. Unfortunately the interpretation of a Bayes factor is not exact, see Jeffreys [Jeffreys 1961 and Kass [Kass 1995] for slightly different interpretations, and hence the decision as to when one model is 'best' and when to average across several 'good' models is difficult. Again, the model selection mechanism requires empirical investigation within this context. When one model is a subset of the other, simpler likelihood ratio tests can be deployed, see Burnham [Burnham 1978] for an example of the use of likelihood tests with multinomial models.

Alternatively the model selection mechanism could attempt to use techniques for artificial intelligence, see [Kerans 1994; Chan 1996] for examples of techniques which could be adapted.

6. Conclusion

Given the explosion in the number of Web sites and the accompanying failure to increase their usability, the credibility of the Web to provide quality, easy to use sites is threatened. This problem is particularly acute within developing web-centric educational environments and products. If these are to succeed then the development of high quality products is essential.

Estimating the number of defects present at a Web site can lead to an important measure of its usability and will form a significant stage in its appraisal and overall progress to improvement of quality. This

^[4] This is an approximate definition and assuming that the prior probability of equal model is equal, and hence can be omitted from the formulation.

paper has presented a number of statistical models that could be used to obtain an overall measure of the number of defects at a site. It is believed that such measures and models of quality are essential for the Web to mature into a domain where appropriate quality standards can apply.

To progress the work further, the authors would like to learn of suitable data collected from Web sites that would allow testing of the analysis and selection of the most suitable model.

Abstract: The purpose of paper is to examine user feedback and usage patterns of the Course Submission System, a web based environment for the facilitation of online multimedia seminar classes. Three courses were taught in succession using the same online seminar system. Each course increased enrollment and thus overall use of the system. Students in the first test semester participated in a completely web-based course. The second and third courses utilized the same software but were web-assisted: while the course met "in person" each week, some classroom interaction and all of the presentation of student work was mediated by the seminar courseware. This paper assesses the strengths and the deficiencies of a model for web-based collaborative courseware in the context of the seminar and the larger course and details improvements to the software based on assessment.

1. Introduction

The Course Submission System was initially designed to address the needs of students participating in multimedia production seminars. The system facilitated the submission of on-line projects via an easy to use graphical interface. The system also provided facilities for the instructor and the students of the course to view submitted multimedia projects. In addition, the system also provided facilities for students to critique other's work through an asynchronous comment area bound to the multimedia content [Flanagan 98].

The prototype Course Submission System, renamed as the courseware "Integrated Online Seminar System" (IOS), represented a technological solution to a common problem – successfully addressing students with diverse backgrounds through courseware design. It provided an easy to understand user interface, a simple upload model, and an outlet for dialog and critique that was fundamentally different from that of newsgroups in that conversation was centered around the media content posted on web pages. The IOS system has been utilized over a period of three semesters at the university level. Over this time, the system's user interface and other aspects have been studied through surveys and usability testing. We have also monitored server usage patterns in order to correlate them with user's comments to the system. Although the technological solution has provided a strong first step in the development of the application, social aspects in the usability of the system had to be highlighted in the next version of the courseware. In order for the application to be useful, it had to combine technological advances with sociological models to support co-dependent work [Grudin 91]. We will examine some of the more problematic areas in the use of the system, and how technological and sociological solutions were addressed to overcome these issues.

2. IOS System

In order to describe the assessment and subsequent adjustments of the IOS system, we must examine the architecture. The IOS system consists of two applications: an administrator component and a student component. The administrative component is a database application that allows a class instructor to create record entries for courses, students, and projects. The administrative application can monitor the progress of a student in a class by reporting on the current submission status of their project, level of participation within the comment area, and monitor the student's usage patterns within the system. The class instructor can use the administrative application to dynamically change items within the class, such as adding or deleting assignments, changing due dates, and locking

student work as scaffolding examples for future classes. Finally, the administrative system is responsible for maintaining a file structure capable of storing student submissions and critique text.

The second half of the IOS system is the web-based student interface. The web approach was chosen since it offered the flexibility for cross-platform operation and for allowing students submit their work from both school and home. The IOS system utilizes Java Servlets [Davidson 98], which can be best categorized as server-side applets, for several system tasks. The servlets are responsible for accessing database information and for dynamically generating HTML content pages. The servlets are also responsible for facilitating the upload service. When a student participates in an IOS session, they are presented with a link-based navigational interface that allows for the selection of a course, student, and project. These navigation pages are dynamically generated by the servlets. When the student navigates to a project area, several frames are displayed which allow space for commands, multimedia content, and critiques. The student then has the option to either post a comment or to submit multimedia content. The system is protected through an authentication mechanism such that only class participants can post comments, and only the owner of a particular page can submit content. All student comments are tagged with the poster's name and the time of posting.

3. Assessment

Over the last year and a half, the IOS system has been utilized in three digital media university classes: a production course for the design of multimedia interfaces and two media theory courses. The production course required that students create interface designs as images, while the theory courses allowed students to explore a wider range of web-accessible media content. The courses also differed in that the production course was geared for a limited number of advanced students with working on multimedia design, whereas the theory courses contained more students and a wider range of diversity.

Each group of students who used the courseware were surveyed twice--once eight weeks into the semester and once at the end of the semester--in order to assess usability and acquire other kinds of feedback. Thus far, we have surveyed three class groups in three succeeding semesters. The first group, an upper level undergraduate and graduate seminar, involved 6 students. The second course was a media theory course with a mixed enrollment of 22 advanced undergraduates and graduates, and the third was a similarly structured course with a total of 26 students. Some of the benefits of the courseware cited by students were the efficiency of the system, the disuse of paper, the accessibility of the student work to other courses and friends of the participants, and increased possibilities for participation. One student noted that the interaction between "both shy and loud, outgoing people" was enhanced by the system. In addition, the administrator was also surveyed.

Although the IOS system proved to be an asset in providing these classes, user feedback noted some obstacles in interacting with the system. The data proved that we needed a revision of the original IOS on both the administrative side and the student side of the application. We grouped the obstacles into five categories: *administration, navigation, group management and participation, naming convention/posting, and representation.*

3.1 Administration

A central issue from an administrator's point of view was that the courseware had to be administered *on* the server. This is because the original database was tied to a specific application--Microsoft Access. The security model presented to users on the server prohibited remote administration of the database. The solution was to separate the application from its dependence on Microsoft Access and create a platform-independent web-based interface for administration.

3.2 Navigation

One of the primary student concerns was the navigational model. The system design required that a student navigate from course to student and then from student to project in order to view submitted content. The reason for the original design was to create a uniform navigational space and to create a strong relationship model between the

class components. In classes conducted using web technology before the use of IOS, students often posted their media content to their own web page; this ad-hoc structure generated confusion and frustration when trying to find student work and resulted in inconsistent navigational models. Content location varied widely.

Although there is a great deal of importance in maintaining a uniform navigational model, it is also important to have different methods of access and filtering for content. In the original IOS, students spent a great deal of time utilizing the navigational interface instead of viewing and critiquing content. We designed two navigational structures to provide unique and variable access to content: a portfolio mode, which organizes the navigation into particular "student sets" (looking at work which belongs to a particular student), and a project mode, which organizes the navigation around a particular class. We are also experimenting with navigational control panel to allow quicker access to the next student and next project within a particular set.

3.3 Group management and participation

Group management and participation were also surveyed. When IOS was initially deployed, it was used in a relatively small class of advanced students. Students could easily monitor the progress of their classmates and could critique all of the work presented because of the scale of the course. As the IOS system was used in larger classes, it became more difficult for the students to keep track of who had submitted work. In addition, students tended to cluster their comments around particular individuals in the class, leaving other students out of the communication process. In order to address this particular problem, we had to look at two issues: social mechanisms to report the status of individual work, and mechanisms to enforce equity in the comment process. The first problem was the easier of the two to address. In order to provide stronger feedback mechanisms, we now are providing two-part indicators in the project mode to indicate the submission status of a project. The first indicator reflects submission changes on the system. A class participant can view the class list involved in a project and quickly assess who has submitted new work and when. The second indicator is a student self-assessment. The student is able to provide commentary and an indication of the state of his or her work. By incorporating both indicators, it is possible to quickly access the status of individuals for a particular project. The indicators are incorporated into the navigational model to allow quick access to work that has changed. The second problem was more difficult to address. Although it is desirable to have a degree of freedom when choosing which work to critique, the equity issue of distributing comments and increasing overall participation is equally important. Although it would be desirable that students comment on every piece of work, this is not often feasible in larger classes. In order to create a degree of balance, we added a comment requirement to the system. The comment requirement manager is housed in the administrative section of the system, allowing an instructor to set a requirement per project as to the number of comments expected of each student. When this requirement is set, the system generates a list of participants per student for which he or she will have to comment. Status of both submission changes and student self-assessment is represented graphically. Of course, students can comment as much as they wish once they have met their "comment quota". One question we encountered in the design of the commentary requirement section: "What if one student must review another student who has not yet submitted work?" In the event that a student does not submit work by the due date, those dependent on the delinquent student are reassigned to other individuals.

Comment management also presented difficulties to students. As part of the old IOS model, graphics or multimedia content was displayed in a frame separate from that of the critiques and comments. In this manner, multimedia content did not have to be reloaded for each comment viewer by an observer. However, as the comments increase in frequency, the viewer was responsible for noting where he or she left off in the viewing. We have designed a new view model that will allow a user to either see the entire comment list, or view only the most recent additions. We have also considered adding automatic archival systems in order to automatically sort comments and generate navigational links.

The upload servlet also had to be addressed. Initially, we used a generic upload servlet to perform media transfer. Unlike the download process within a web browser, the upload servlet did not indicate the current percentage of transfer nor the transfer data rate. Although many of our students used the on-campus facilities connected through an Ethernet network, home users were often unsure as to the status of their transfer. Systems such as BSCW (Basic Support for Collaborative Work) approach the problem by creating separate helper applications for the upload process [Bentley 97]. To simplify the transfer process, we extended of the servlet model to create a low-priority feedback mechanism within the server that can be used to relay upload status information to the browser. We also

plan on extending the upload model to support multiple file and directory submission procedures so students will not have to submit content as individual files.

3.4 Naming Convention/Posting

Because of the naming conventions established by commercially available server software, we were restricted to using specific filenames. According to our survey results, submission was not easy at first, and the naming convention was most frequently cited as the problem. The larger the course size, the more common this problem became. Students became confused as to the types of specific files allowed on the system and had difficulty remembering that "index.htm" was the specific name that had to be included in the post, not "index.html" or "studentproject.htm." In addition, the interface did not easily indicate the way in which multiple items (such as a web page and graphics) could be posted successfully. In fact, the html page had to be submitted prior to the images on the page. Students also had difficulties with authentication. The IOS system requires a user name and password when the student wishes to submit media content or to participate and critique work. Authentication used to be requested each time one of these operations were performed. To address the authentication and re-authentication issue, we had considered using cookies to maintain password information, however many of our students use public access labs and often forget to close their browser sessions. We considered different active timing techniques to monitor activity and to close the session when a student is idle for a fixed amount of time. This issue remains open. To help students with naming and posting, we decided to use automatic page generation and framing techniques to mask the specific process of naming, thereby allowing students to submit with a variety of inconsistent file names.

3.5 Representation

In response to respondent requests, we developed a servlet handler for image data, capable of generating thumbnail images to assist in the navigational process. While this aspect also pertains to navigation, it makes the system more colorful and "lively", as imagery is immediately accessible for review purposes in small, easily downloaded file sizes. Another representational element incorporated into the system was a whiteboard image review and processing area. As the saying goes, "a picture is worth a thousand words", and it is often advantageous to suggest a media alteration through graphic changes to the content. It is equally as important to markup images to prevent ambiguities about the critique. At first, we examined mechanisms used in anchored collaboration schemes [Guzdial 97]. However, after examination, we decided the system needed something more than text anchoring, as students wanted the ability to perform simple editing to each other's images. In order to accommodate the request, we are in the process of developing an asynchronous whiteboard applet to be used in conjunction with the IOS system. The system will extend the anchored text model by allowing anchored media changes. Alterations will take place in the form of layers. We chose to implement a layers approach to maintain the integrity of the original submission and to minimize transfer time. As a student views a comment, the layer will be superimposed on the original work. Follow-up comments can either utilize the original media image or a combination of previous layers when formulating a response. The actual whiteboard application will provide simple editing tools such as lines, fills, and color maps, along with pre-defined objects such as arrows and shapes to facilitate the markup process.

4. Conclusion

When assessing the success of IOS, we examined to examine user feedback and usage patterns with the application. We found that we needed to rethink the initial implementation of the courseware. Our student surveys indicated that although our initial implementation addressed certain key technological issues, there were several social issues that needed to be considered. We explored techniques to integrate new mechanisms into the IOS system as a whole. We also leveraged the technology to integrate sociological solutions in the design of the application. The improvements to the IOS system address each of the documented student concerns. We plan to continue testing to see if these ways of redesigning the courseware prove effective. Through assessment, we are also looking at new paths to follow when expanding the use and capacity of the application.

The Critical Position of the Internet in the Creation, Development, and Maintenance of the Bronx-Wide (New York) Superintendents= Instructional Technology Leadership Forum

David C. Fletcher, Ph.D.
Department of Specialized Services in Education
Lehman College, The City University of New York
United States
fletcher@alpha.lehman.cuny.edu

Abstract: In 1998, the Bronx-Wide Superintendents' Technology and Learning Leadership Forum was created to investigate effective ways to support students' learning and achievement with instructional technology. The formation of the Forum is critical at this time because of the pressing urgency to build a firm educational foundation needed to support Bronx students development as creative and critical thinkers who must live and compete in the global communities that will characterize their 21st century world. Our effective use of the facilities of the Internet brings the possibility to significantly alter how Bronx students are being educated to prepare them for the 21st century by allowing for the articulation of curricula across PreK-16, by allowing for productive communication between and among shareholder representing multiple perspectives, and by allowing for Bronx-wide long-range instructional technology planning to take place.

Introduction

In this presentation, I will provide a to-date summary and review of the activities and progress of the development of an urban long-range instructional technology planning initiative in the Bronx, New York. A major goal of this initiative is support systemic educational reform with the development of Leadership Teams composed of superintendents, principals, teachers, students, parents, and community members. The ongoing and critical link between all participating members will be maintained through the facilities of the Internet.

Long range instructional technology planning, implementation, and evaluation are complex and involved processes that require the proactive participation shareholders within a school, across a school district, and, in this project, across the borough of the Bronx. A basic belief of this Bronx-Wide project is that educators, families, and not-for-profit and commercial community members hold a shared responsibility to ensure that instructional technology is infused effectively to support students learning and achievement. The Bronx pre-kindergarten child entering school in 1999 must be fully prepared upon graduation in 2013 to be a participating member of the global communities that will characterize her world.

The vision of the 21st century that we are determined to create into a reality is composed of students who are problem posers, problem solvers (Dede, 1998), effective users of telecommunications and information technologies (Ramirez & Bell, 1998), and literate information users (Breivik, 1998) in the evolving global communities that will characterize the 21st century. Jones et al (1995) has made it clear that our students must be prepared for a world different than the one their parents graduated into:

Today=s workplaces and communities B and tomorrow=s B have tougher requirements than every before. They need citizens who can think critically and strategically to solve problems. These individuals must learn in a rapidly changing environment, and build knowledge taken from numerous sources and different perspectives. They must understand systems in diverse contexts, and collaborate locally and around the globe (p. 5).

The New York City Board of Education and the Bronx

In order to understand the potential role the Internet can play in the future of education in the Bronx, it is necessary first to build an understanding of the history and structure of the New York City public school system and governing Board of Education. The New York City Board of Education is the largest school system in the country, with a student population of nearly 1.1 million, a budget in excess of \$8 billion, and more than 1,533 facilities. Its policy-making body is the seven-

member Board of Education, comprised of two mayoral appointees and one appointee selected by each of the five borough presidents (Bronx, Brooklyn, Manhattan, Queens and Staten Island). Responsibility for the day-to-day administration of the schools is vested in the Chancellor, who is selected by the Board. Throughout the five boroughs, there are 32 semi-autonomous PreK-8 community school districts, each serving each serving 12,000 to 40,000 students. The high schools of each of the five boroughs is governed by a Borough-level high school superintendent and staff (NYC BOE, 1999).

Following the appointment of Chancellor Crew in 1995, the structure of the NYC BOE has begun to be systematically changed in order to address problems arising from ineffectual administration both at the individual school district levels. In December 1996, the New York State Legislature passed a landmark school governance reform bill that established clear lines of authority and responsibility necessary to ensure a system fully accountable for the educational achievement of all children. The governance law gives the Chancellor direct responsibility for the selection and renewal of the 32 community school district superintendents, and the authority to intervene in any district or school for persistent educational failure. The law also provides for greater parental involvement and the opportunity to strengthen the focus of community school district boards on educational policy matters and promotion of student achievement (NYC BOE, 1999).

Unfortunately, one of the consequences of the structure created by 32 community school districts and the separate high school divisions has been the lack of articulated and coordinated curricula from PreK through high school. When decentralization began, no formal structure was put into place to provide for either a deliberate or planned articulation of curricula within Prek-8 districts, between Prek-8 districts, or between the 32 community school districts and the high school division. There are no structurally effective or efficient means to support students' academic movement from their Prek-8 school environments into the high schools.

An additional significant challenge has arisen in the past two years with by the New York State Department of Education's mandating that all graduating 2002 high school students must pass the new NY State Regents. A range of predictions have been made regarding the number of students prepared to pass these far more rigorous tests, ranging from fewer than 10% to 50%. Students are placed in an alarmingly precarious position in an educational system in which curricula is not being articulated across the grades and in which the professional development of teachers is not being conducted between the PreK-8 community school districts and high school division.

In the borough of the Bronx there are many significant educational challenges to be addresses. There are currently 228 schools serving approximately 223,437 students PreK through high school. Approximately two-thirds of Bronx students are identified as low-income. Approximately one-third of the students are English language limited, and one-third are first-generation immigrants.

Building a Bronx-Wide Superintendents' Technology and Learning Leadership Forum

The decision to build a Bronx-wide initiative began April 1997. At that time an advisory group of Bronx school district technology coordinators requested that the College take the lead and initiate a program to assist schools in the Bronx begin the complex task of long range instructional technology planning. All the school districts face numerous problems and challenges in determining how to allocate resources to a majority of students who live at or near the poverty level and do not have home access to up-to-date technology. However, there were several complications that prevented my becoming the initiator of such a daunting challenge. Since I was the newly appointed and only Educational Computing and Technology faculty member, I felt I needed to learn my way with the districts and my own Division before beginning. Also, at the time, our Dean of the Division was not yet appointed, and we needed to locate additional sources of support and collaboration.

By the Fall of 1998, the picture had changed and the earlier problems had been partially solved. The Dean of Education was appointed and had accepted the challenge to move the Division into a 21st century vision of education supported by instructional technology. I had had many discussions with the school districts and had managed a number of successful instructional technology projects in the College and in the district schools, thus proving my credibility. The BUSI (Bronx Urban Systemic Initiative) had agreed that long range instructional technology planning was necessary so that schools would have a clear plan to follow to support student learning, particularly in the areas of mathematics and science. Also, the development of effective instructional technology plans had recently been identified as a major goal of the BEA (Bronx Educational Alliance, one of the National Centers for Urban Partnerships sponsored by the Ford Foundation). NetTech (the Northeast Regional Technology in Education Consortium, funded by the US Dept. of Education, Office of Educational Research and Improvement) had agreed to support a Bronx-wide major collaborative initiative and to bring to the table their many regional resources. Also, the faculty had decided to move toward NCATE (National Council for Accreditation of Teacher Education) certification for our education programs. The time had arrived to move forward.

Why are we emphasizing the critical role of the Superintendents in the development of this Bronx-wide initiative? In the *Buckeye Association of School Administrators: Technology Ad Hoc Committee Report* (1998) the significant and necessary role of the superintendent as a technology leader has been duly noted by superintendents:

The Superintendent is a key player in a school district developing a high-quality, technologically literate learning environment. As the district's leader, the Superintendent sets the expectation for technology being an integral part of the instructional program as well as daily district, school, office and classroom operations. The Superintendent serves as a catalyst, sharing a vision and plan which supports educational goals that incorporate emerging technologies and allocates adequate financial and staff resources.

Leadership Forums - April 28 and May 8, 1999

On April 28 and May 8, the first two Bronx Superintendents' Technology and Leadership Forums were held to bring the Leadership Teams together to begin planning a Bronx-wide initiative. Five of the six Bronx PreK-8 community school Superintendents, the Superintendent for Bronx high schools, and the Superintendent for alternative high schools brought their designated leadership teams to meet for two-full days of collaboration to develop a more informed understanding of long-range instructional technology planning. Also participating in the Forums was Lehman College (CUNY), the United Federation of Teachers (UFT) Professional Development and Teacher Centers, Bronx Community College (CUNY), Hostos Community College (CUNY), the Bronx Educational Alliance (BEA), the Lehman Center for School/College Collaboratives, the Bronx Information Network (BIN). Guest speakers were from the Bronx school districts, New York State, and the region, including participating organizations collaborating with NetTech, presented components of a 21st century school. Their presentations addressed a number of important issues, including: alignment of the National Education Standards for Students (NETS) and curricula, Bronx-wide instructional technology assessment, funding, home-to-school electronic linkages, corporate partnerships, professional development of teachers and administrators, student achievement, information literacy, and infrastructure planning.

Feedback from the Leadership Teams on the two Forum days indicated that the time is at-hand to move a Bronx-wide initiative ahead. The opportunity for participants to network and share information across districts/schools was cited by well over half of the respondents as the best thing about the day overall. *"This forum will provide us with opportunities to formalize our discourse re providing the best education that we can for the students that we serve."* Other comments from participants about the best thing about the day included:

- § "...a united commitment to work on technology."
- § "...seeing the way technology is being integrated in the curriculum."
- § "Learning about collecting data across the state."
- § "A smart, focused effort about technology and our students is long overdue."

A majority of the participants agreed the Forums helped them to identify Bronx-wide PreK-16 topics for future development. Some of the concerns raised by the participants concerning PreK-16 were: how to reach out to the entire educational community; expanding technology in classrooms at reasonable cost; identifying resources and alternative funding arrangements; developing a vision of the classroom five years from now; disseminating professional development websites borough-wide; providing effective professional development activities; bridging the gap to full integration of technology in the classroom; training future teachers for teaching with technology; and how borough-wide planning will benefit the schools and districts.

Participants were prepared to take steps concerning PreK-16 such as continuing to be involved with the Forum (planning sessions) and getting others involved, debriefing the district and drawing up action plans for replicating strategies, sharing district best practices with a larger audience of teachers and parents, and adding a parent page that includes distance learning for parent involvement.

Several barriers to moving ahead on PreK-16 were identified. They included the need to involve more people, time for staff development, ongoing costs associated with the installation, maintenance and upgrading of equipment, political issues, fear of technology that hinders implementing technology in the classroom, teacher lack of competence in the use of technology, and student lack of access to technology.

Despite these roadblocks, participants had suggestions about what the group should do next to further the uses of technology in the Bronx:

- Involve more teachers and college faculty in the Forums;

- Create an Intranet;
- Continue to hold Forums and update the web pages;
- Develop guides to instructional models;
- Connect with current programs;
- Explore existing software and hardware applications;
- Identify exemplary classrooms where technology is integrated into instruction and videotape them for inclusion in a video library so others can view them;
- Model technology projects already accomplished in Bronx districts; and,
- Organize a borough-wide "share fair" to have each school display exemplary work.

During the Fall 1999 and Spring 2000, Bronx-wide action teams will be formed and will begin the work of developing, implementing and assessing proactive plans to address these several identified areas. The teams will be composed of shareholders representing multiple perspectives and interests with the goal for all to support students' achievement and success.

The Multiple Roles Intended for the Internet

The Internet has been selected as the organizing structure to ensure the success of the development and articulation of the pro-active goals of the Bronx-Wide Superintendents= Technology and Leadership Forum. Realizing that one of the keys to the successful implementation of this Bronx-Wide initiative will be communication between partners, electronic connectivity is one Internet tool that we are making use of and intend to make as accessible and equitable as possible. The extensive planning to design the forums is supported by electronic discussions and on-line video-conferencing. Many important WWW resources have been identified to support the superintendents and principals' work. Through the use email and listservs the superintendents' teams can share ideas and proposals, debate issues, present data and information, and pose questions for ongoing consideration. The many shareholders (educators, parents, students, community organizations, government agencies, and commercial investors) who are involved will be kept informed and involved. Action teams that are developed to address specific topics, issues, and questions (several identified above) will be able to identify and share resources, formulate plans, and assess their progress (<http://www.lehman.cuny.ed/bronxsuperpage>).

In addition to the areas listed above, actions teams will be supported with Internet-based facilities and resources to address additional areas:

- the creation of a *Bronx-Wide Virtual Teaching, Learning, and Research Center* to support life-long learning of students, families and educators;
- the dissemination of guidelines and the provision of on-site support to assist superintendent-lead and principal-lead leadership teams to develop, implement, and assess long range instructional technology plans;
- the formation of pro-active plans and proposals addressing Bronx-wide instructional technology issues and problems;
- the coordination of instructional technology services across the Bronx;
- the development of a plan to address the significant problem of equity and access for Bronx students;
- the participation of the Bronx Superintendents= Technology Leadership Teams in regional and national technology and computing organizations and forums;
- the articulation of PreK-16 (pre-kindergarten through college) student learning goals to be supported by identified forms of instructional technology in alignment with NETS;
- the development of long-range instructional technology plans that include seven identified components (student learning goals, assessment, professional development, infrastructure, hardware and software selection, staffing, and funding);
- the location and effective use of resources for grant development;
- the development of specialized collaboratives and partnerships between districts;
- the identification of additional resources to support the implementation of long range instructional technology plans; and,
- the development of additional collaborative and partnerships with the Division of Education and Lehman College to support the ongoing preparation of preservice education students and inservice teachers to effectively integrate instructional technology into the curriculum to support student learning.

Abstract: The Military Career Transition Program (MCTP) at Old Dominion University is the primary alternative certification program for teacher licensure targeting military personnel who are transitioning into education careers. Beginning Fall 1998, the MCTP added distance learning to its existing course offerings at five of its fifteen sites. These courses follow a hybrid instructional model, which include VTEL and web assisted instruction. Broadcast instructors and instructional facilitators at each distance learning site are utilized to facilitate collaborative, problem-based learning. This paper describes the evolution of the MCTP distance learning effort and examines the progression of strategic decision making involving the issues of course integrity, exemplary instructional methodology, and student accountability.

Introduction

In designing distance learning instruction the “garbage in, garbage out” tenet holds true as it does in any other kind of instruction. Quality distance learning depends upon: 1) sound curricular design, 2) exemplary instruction and 3) proper support, whether defined as technology resources or finances. These three variables do not carry equal weight in distance education; no amount of money or technology compensates for a lack of instructional skill or attention to curricular design. We maintain, based upon our experiences, that a hybrid instructional model which combines synchronous, asynchronous, and web based instruction supported by a team approach to goal setting and curricular design maximizes exemplary distance instruction, and therefore distance learning. This paper describes the curricular design process involved in broadcasting the core courses of the Military Career Transition Program (MCTP) at Old Dominion University. The development process detailed herein chronicles an ongoing effort that began in October 1998 involving three phases: creation of the instructional model and course technical support, instruction and broadcast delivery, and course and production refinement. The first six core pedagogical courses have been broadcast during Spring and Summer of 1999. Six additional courses, four instructional methodology courses and two educational electives, are slated for broadcast in Fall 1999 and Spring 2000, completing the MCTP degree program.

Background

Since its inception in 1988, Old Dominion University’s MCTP has been extraordinarily successful in preparing and placing its graduate teacher candidates. More than 1200 graduates are teaching in 47 states, over 1400 students are currently in the program, and about 150 new teachers are graduating and being certified each year. The MCTP now offers one baccalaureate program, three master’s programs, and a collaborative Certificate of

Advanced Study with the Educational Leadership and Counseling and Educational Curriculum and Instructional departments. Teacher licensure is offered at all grade levels, with additional endorsements available in Special Education and Technology Education. The MCTP offers standard semester courses as well as a compressed curriculum designed to meet the needs of deploying active duty military personnel.

In 1998 it became apparent that the MCTP alternative certification program possessed great marketability, both within the existing MCTP sites and through the established Old Dominion University distance education delivery system (TELETECHNET). No alternative paths to teaching licensure existed through distance learning prior to MCTP broadcast courses; traditional licensure methods almost always excluded active duty military personnel due to residency requirements. The MCTP distance education program broadcasted its first courses in January 1999 to a waiting constituency of students at five sites in Virginia, the District of Columbia, and the state of Washington.

Developing the Hybrid Model of Instruction

The current model for distance learning generally involves simply broadcasting existing live courses with little or no thought to reinventing instruction or selecting faculty best suited to broadcast. The major difficulty with this model is that it effectively ignores every available piece of reliable research on effective teaching (Hunter 1982, Joyce & Weil 1986, Fisher & Berliner 1985) which speaks to the delicate balance between sound planning and execution of instructional strategy. To say that it suffices to take mundane pedagogy that few people see and broadcast it for the multitudes negates our commitment to distance learning students; in effect we are saying that students pay for convenience with acceptance of mediocrity. Even with the more masterfully taught courses, there tends to be a lack of reinvention of instruction or curricular redesign— existing syllabi, course requirements, and instructor notes are simply posted to a course web site. Delivery of instruction is generally relegated to the “talking head” or “talking head in a box” superimposed over transparencies or electronic presentations. Current distance learning faculty tend to see themselves as presenters of material rather than facilitators of learning.

Confronted with these issues, we began the design of the Exemplary Teaching for Distance Learning (ETDL) Model. During the previous year, the MCTP elected to commence a comprehensive examination of existing curricula and redesign course competencies and requirements independent of any distance learning concerns. In order to accomplish this, teams of faculty members gathered in curricular groups to assess course outcomes, discuss strategies, and essentially “slash and burn” the curriculum with an eye toward what truly makes our students successful in the educational workforce. The resulting curriculum is a competency based course guide that ensures quality of instruction and consistency among the fifteen sites at which the MCTP is offered. Once the concept of offering the MCTP through distance learning was fully explored, a commitment was made to proceed with the new delivery methodology using the revised curriculum. A selected “team of experts” began program goal setting and logistic decision-making. It is this step which concretely began the MCTP distance learning effort and the construction of the ETDL Model.

An examination of the MCTP distance learning team is essential to understanding the importance of curricular redesign as a contributing factor to quality distance learning. The team consisted of College of Education instructional technology faculty, a curriculum design specialist, staff from the University Center for Learning Technologies and Academic Television Services, and potential broadcast faculty who were teaching MCTP courses. The advantages this approach gave included the ability of each team member to bring to the effort their own unique area of expertise, ensuring that exemplary input would yield an exemplary product. This team made decisions that included broadcast dates, times, locations, and program sequence. It became apparent that the curricular revisions of the previous year would not adequately ensure quality distance teaching. What followed was a process that can only be described as curricular reinvention. Courses taught over the normal 14 week semester had to be condensed into blended synchronous/asynchronous/web-based instruction with 50% less direct contact between broadcast instructor and student. In addition, course competencies had to be translated into web-based activities that would ensure student learning and provide critical assessment information for the instructors. Each instructor submitted a conceptual framework of requirements that they felt would lead to mastery of course competencies. The curriculum design specialist converted the original course competencies into problem-based learning and collaborative action projects that would increase student accountability. The instructional technologist then made logistical decisions regarding which activities were conducive to web based instruction. Based on those decisions, the course web site was developed. The breadth of experience represented on the design team played an important role in the development of blended courses that retain the integrity of the original course goals.

Course Reinvention

The MCTP reinvented rather than redesigned its core courses to better meet the needs of distance education students. Most distance education courses were previously taught with a traditional, teacher-directed approach. Students expressed dissatisfaction with this method of instructional delivery and disillusionment with their inability to customize course content and requirements according to their needs. Based upon these observations, the MCTP team decided that distance education courses should place the responsibility of problem solving and discovery upon the individual who desires the learning, thus allowing for greater customization of coursework. This concept alone created the need and the basis for the complete reinvention of curriculum, and more importantly the retraining of faculty who would need to take the leap of faith necessary in transferring accountability to students. Courses were designed with opportunities for students to customize content issues through threaded discussions on the web site and collaborative projects. Rather than creating increased student accountability by assigning more work, faculty were encouraged to adopt a problem based learning approach which would create motivation among students to acquire competencies. For example, in the core lesson planning course, MCTP students were required to work with classroom teachers in a school of their choice to design and teach problem-based learning units for pupils in grades K - 12. In the educational foundation course, teams of MCTP students attended and presented potential solutions to current problems with block scheduling, alternative schools, and national standards at school board and school faculty meetings. MCTP special education students developed an Individualized Education Plan (IEP) and case studies for the purpose of providing classroom remediation and intervention strategies.

Design Chronology

Three basic areas of learning were identified: broadcast instruction, web assisted instruction, and individual student-centered research. The initial decisions made by instructional faculty concerned the placement of course competencies in one of these three categories for course design. Concepts which needed to be communicated via "talking head" or which contained large amounts of overt information were relegated to the broadcast instruction category. This allowed faculty to retain control over the amount of content, depth of content, and the pacing of instruction during each broadcast session. Retaining a small portion of lecture format helped alleviate faculty fears that they would not be able to cover an appropriate amount of material in the reduced teacher-student contact time. Web assisted instruction consisted of a course website designed to clarify requirements, chronologically organize content and assignments, stimulate threaded discussions on controversial course topics, and provide space for on-line collaborative work across sites. Web assisted instruction was reserved primarily for application of course concepts taught via "talking head" and demonstration of contextual transfer of knowledge beyond the examples provided by the instructor. Student-centered research opportunities (collaborative projects, field research, and article analysis) were designed with the goal of creating motivation to delve deeper into content, customize the learning to meet individual need, and bring reality into the classroom discussions.

The bulk of course design then centered on the categorization of course concepts into three categories: those that would be introduced, those that would be taught, and those for which mastery would be expected. This filtering process was necessitated by the reduction of teacher-student contact time, previously mentioned. Modeling the tenets of effective teaching, faculty made critical but difficult decisions regarding depth and sometimes omission of content. In order to facilitate this process, a matrix was developed for each course, in which competencies were listed and catalogued by all MCTP faculty who taught core courses in any venue. Faculty were required to re-evaluate the critical attributes of their courses and determine what was relevant and what was related but less critical information. We were unprepared for how excruciating this consensus process would become. The tendency of instructional faculty to become proprietary regarding course content nearly overshadowed the concrete production parameters, i.e. time slots, equipment compatibility, taping capability, and presentation of visual aids. Ultimately, course visitations were made by a curricular committee to observe for each course, across sites, how the presentation of concepts differed. Consistency was critical because all MCTP students would be administered general comprehensive examinations at the end of their program. Where consensus seemed impossible regarding emphasis, final decisions were made by broadcast faculty in conjunction with the curricular specialist, and the official course syllabi were altered accordingly. These decisions were necessary, but rarely popular.

After concept categorization, faculty decisions were made regarding student accountability for each of the competencies. Prior distance learning experiences indicated that geographic distance contributed to a difficulty in assigning student accountability. The anonymity distance education students have tends to make them more passive and therefore less likely to invest in initiating and developing course goals and objectives. Additionally, distance

education faculty indicated a reticence among students to be fully accountable for their learning. Generally, their solution to this has been to utilize traditional forms of summative evaluation more frequently than in their traditional classrooms. Prior research among TELETECHNET courses indicated that anonymity potentially reduces motivation among students in initiating and completing course tasks. Because the MCTP broadcast classes were two-way video as well as audio, students felt more connected and less anonymous but this issue remained a concern. Solutions to this problem were generated through alternative assessment.

Alternative Assessment

Alternative forms of assessment were perhaps the most difficult manifestation of student accountability. Both faculty and students seemed instinctively drawn to traditional course requirements (i.e. papers, tests, presentations), despite the fact that these methods of assessment did not accurately test mastery of the higher cognitive level course objectives. The move toward more alternative forms of assessing student learning (i.e. teaching vignettes, threaded discussions, inter- and intra-site collaborative projects, problem-based learning activities) provided better assessment information and offered students the opportunity to customize learning. In the specific examples noted above, students teaching problem-based learning units videotaped classroom instruction. These tapes, along with additional demonstration lessons in class, were analyzed and critiqued by peer coaching teams. The course competencies regarding effective teaching research (Bloom et al. 1981) were used as guidelines for assessment. The efficacy of solutions developed by the Educational Foundations class was critiqued by area school personnel as well as instructors and classmates with regard to realistic use of resources and the potential for positive impact on the school. More traditional forms of assessment were applied toward basic knowledge/comprehension level concepts taught during broadcasting. The special education class combined both traditional and alternative forms of assessment by requiring written Individualized Education Plans (IEPs), and detailed analysis of vignettes, as well as the nontraditional, more thought provoking threaded discussions posted to the course web site, encouraging student development of philosophy regarding controversial special education issues.

In all cases, the intent of curricular assessment redesign was to promote not only critical but creative thinking of students related to course competencies. Ultimately faculty decided that outcome based assessment required mastery of both course competencies and a higher level of metacognition with the material presented. The critical question in course planning became "What do I want my students to do ten years from now?" This lens assisted instructors in defining both critical attributes of the course and survival skills embedded within the content. It should be noted that all broadcast courses both required and valued student self-evaluations; commitment to formative as well as summative assessment was an important paradigm shift.

Conclusions

The resulting course quality has been equal to or better than the original traditionally taught courses, as evidenced by student demonstration of course competencies, student evaluation of instruction, and subsequent student performance in advanced courses. Any negative feedback from students concerning the distance learning courses has centered on access to the technology and the resulting steep learning curve required to use the related web sites. Although the students in this distance learning program are experienced using technology, there has remained a wide range of ability levels that affects their early success with course requirements. Aside from the technology factor, all broadcast instructors have compensated for the geographic distance through creativity in instruction and assessment. This creativity is evident in previously cited examples of: 1) problem-based learning projects which allowed students to impact local educational concerns, 2) collaborative grouping students across distance learning sites, 3) students' involvement in community research on the trends and issues affecting educators, 4) partnerships with school districts providing clinical experience, 5) peer observation and feedback of practice teaching sessions across sites, and 6) student-to-student evaluation of online coursework in workshop formats.

As a result of our distance education experiences, we would like to propose the following points for consideration when creating or improving a distance learning program:

1. The distance learning planning process should begin with a carefully selected team representing educational technology, curriculum development, teaching faculty, and broadcast production technicians. Team dynamics definitely correlate to broadcast course quality. The "team of experts" approach insures that the quality of input is exemplary, requiring no individual to venture outside their area of expertise in designing or producing the final

product.

2. The foray into distance education at the program level requires a significant institutional commitment, both financial and conceptual. Garnering support at the institutional or departmental level is a critical step that must occur before course design commences. Otherwise, unexpected expenditures of time and money will assuredly derail the project. For example, one week before broadcasting our fourth course the MCTP discovered that the anticipated free military network time was unavailable, requiring broadcast time to be purchased. Many such unexpected support problems arose; our distance learning effort used significantly more of time and money than was originally anticipated. We could have made concessions along the way but opted instead to place quality and longevity of course offerings as the priorities.

3. Selection of distance education faculty for broadcast should center on the criteria associated with effective teaching research (Berliner, 1996), not by the usual mechanisms which often involve seniority, tenure or workload. Unfortunately, we found a high degree of mediocre instruction among the faculty who were teaching TELETECHNET courses for the University. The MCTP faculty (mostly adjuncts who are practitioners in public schools) presented a much better quality pool of teaching and presentation skills for broadcast instruction. However, they required a significant amount of technological training in order to operate the broadcast equipment. During the first airing of MCTP classes, our much anticipated new technology and broadcast facility was not complete; the first four VTEL classes were broadcast out of one of the University's off-campus graduate centers in a makeshift virtual classroom. Instructors were required to operate all of the equipment without the aid of technicians. Despite this, instructional quality was good, although tape quality suffered due to human error and much editing was needed.

4. Specific synchronous and asynchronous components of distance learning should be analyzed for the purpose of supporting the idea that all quality distance instruction need not fall like pearls of wisdom from the mouths of broadcast instructors. Course web sites, along with their associated URL's, should be reviewed for clarity and support of course goals, objectives, and requirements. Discussion databases (threads) should stimulate meaningful student participation. Non-traditional, authentic assessment using web based resources should be a topic of considerable faculty research. Course instructors must be pushed toward valuing both formative and summative kinds of evaluation in order to support increased student accountability.

5. Issues concerning student support, while not fully explored here, are as essential to the design process as are the course competencies and assessments.

6. Most importantly, courses previously taught in traditional classroom settings cannot simply be "converted" into broadcast instruction; reductions in contact time and the addition of geographic distance require creativity in instructional and evaluative design. It is critical that students show application and mastery in ways that mirror reality. To accomplish this, students must actively take charge of course objectives that present opportunities to interact with the community, practitioners in the field, and the populations they will ultimately serve.

Summary

Distance education presents unique opportunities for faculty, staff and students to impact the learning environment and individualize learning. This process challenges the instructional paradigms that have become familiar and comfortable to most faculty; it also rests the burden for learning squarely on the shoulders of the distance education student. Instructional mediocrity is not an acceptable exchange for locational convenience. Heretical though it may seem to the ivory tower, only those faculty who are capable of the exemplary instructional technique of the master teacher should be allowed to present to the multitudes. Committing to high quality distance education means that we select the individuals with the most potential for improvement in the broadcast arena for intensive training. Additionally, evaluation methods for faculty should undergo close scrutiny and revision in order to emphasize effective teaching skills. Resources must be available to cover both anticipated and unanticipated instructional and production concerns. Distance learning opportunities have literally changed the face of education and opened educational doors to untapped student markets. Distance education programs that satisfy critical student needs have become the cash cows of colleges and universities world-wide, encouraging new for-profit players in the distance education market. The lure of organizational financial gain makes it tempting to quickly and haphazardly broadcast or post existing courses to the web without regard to effective technique. The conversion of courses from traditional to blended distance instruction requires monumental institutional, faculty and student commitment in order to maximize learning, retention and transfer.

Abstract: The Department of Community Nursing and the Open Learning Centre of Technikon Natal, and the community owned Community Development Programme are collaborating to provide online learning to rural and urban community nurses. The project involves the development of a multimedia pharmacology course, a virtual Internet class and the provision of information points (tele centres) in factories, rural police stations, refitted containers, and the like. This is a response to the acute need for training of community nurses operating under difficult conditions, with few resources, in primary health care settings in Kwa Zulu Natal.

Background and Problem Statement

The Natal Technikon's Department of Community Nursing, in association with Open Learning Centre at the same institution, has initiated an on-line certificate course, in a joint venture with the Community Development Programme.

In keeping with the larger objectives of the new South African National Qualifications Framework, i.e. to facilitate access to, and mobility and progression within, education, training and career paths, these departments support the rationale for restructuring South African education by the South African Qualifications Authority (SAQA). They recognise that telematic learning lends itself to Outcomes Based Education (OBE) in both style and philosophy.

“One of the saddest achievements of widespread public education in the twentieth century was the embedding of an attitude that education was about certificates and status but had little relationship to the way one lived one’s life or did one’s work. The attitude was intensified in apartheid education. This could even be reflected in critical and radical action, where we still find supposed change agents who know all the words about critical pedagogy and empowerment, but cannot suggest one practical way of enacting these abstractions in real places and lives of real people.” (French 1997)

Therefore the Community Nursing project, which involves developing in-house courseware and a virtual classroom on the Internet, to meet the needs of the nurses stationed in remote areas - this in addition to the more usual teaching methodologies reflected in the existing pharmacology course. Urban community nurses based in factory clinics and urban primary health care points would also gain much from this distance course with regard to recent advances in distance education.

It is relatively easy to involve urban post-graduate community nurses in vital training required to equip them for significant changes in their roles - changes brought about by recent access for all South Africans to primary health care. Nurses in the rural areas, however, where there are few doctors and even fewer facilities, have little or no access to the information they need to carry out duties for which they have not been adequately prepared.

Apart from the problems of distance and suitable times usually associated with the need for online learning, there are few telephones, a rudimentary electrical power infrastructure, and a lack of computer literacy on the part of the nurses out in the rural areas. Access to service and repair of equipment is non-existent.

Crucial considerations are:

- the rural communities are fiercely suspicious of projects which they do not initiate themselves, for obvious reasons,
- once accepted and put in to place, the projects need to become self sustaining, and
- each project should contribute to the development of the community holistically.

The Community Development Programme Involvement

The Community Development Programme (CDP) operates a system whereby people with identified needs are formalised into small groups, and are then assisted to meet their needs by training, business mentorship and/or other forms of practical help. (Further details on the CDP can be found at <http://cdp.co.za>)

The CDP enjoys large-scale support by rural communities and CDP community facilitators will ensure acceptance of the Department Of Community Nursing's distance learning programmes.

Furthermore, the CDP is in a position to involve Telkom (telephone and Internet services) and ESKOM (electricity) at post offices, army bases and police stations for suitable placement of training centres.

Therefore, the CDP has been commissioned to identify and prepare suitable facilities for training the nurses, using already identified community information centres such as schools, post offices, police stations, factories and municipal offices. Each centre would be need to be equipped with a phone line, modem and computer and funding for Internet operating costs by the community itself with loans from the CDP National Trust Fund. These will be known as CDP telecentres.

Where there is extreme need and severe lack of facilities, the CDP is seeking corporate social responsibility funding to equip large shipping containers, already donated to the CDP, with necessary

technology - a generator and cell phone, if needs be - as an information/training centre. The use of wireless Internet technology and cell phones are being investigated as a practical solution to the absence of telephone lines.

The Community Development Programme (CDP)

South Africans of European origin often find it difficult to relate to the concept of community life. They tend to be trained to be independent and self-sufficient. To rural Zulu's the concept of community based life style is obvious and normal. They share facilities, work together towards the common good, share a common identity and tend to be transparent with each other. This often creates a culture of rejection and suspicion when Western business practices intrude into rural life in the form of social corporate responsibility initiatives.

The Community Development Programme tries to bring the two philosophies together, so that communities can benefit from corporate involvement, and develop their own forms of commerce and trade without being disempowered. The CDP aims to educate and train participants to meet self-identified needs, and to provide access to corporate resources and infrastructures, so that communities and, ultimately, individuals can become financially independent and self-sustaining.

The programme endeavours to set in motion a process of economic and social empowerment by stimulating the creation, and equal distribution, of wealth by using participating communities' resources, abilities and consumer buying power to their own advantage. The participants are managed at a highly competent level, consulting with and being guided by qualified leaders in specific areas of expertise, employed in the geographical areas of the local communities.

The Open Learning Centre's Involvement

The Open Learning Centre at Technikon Natal, Durban, South Africa, has embarked on authoring the pharmacology course. The course will be made available to registered nursing students via the Internet, and on CD-ROM with accompanying work books.

The pharmacology course is the first of the in-house multimedia courses being developed, together with a course in basic physiology for the Human Biology department at Technikon Natal - also for the Faculty of Health. Both multimedia courses will undergo alpha testing in the first six months of 1999 with the help of currently registered students.

Currently, two virtual class sites exist on the OLC Web server, with several others in preparation. The Technikon Natal Community Nursing homepage will be in operation by early next year as corporate sponsorship has been found to run it. (Find the OLC homepage at <http://olc.ntech.ac.za>)

The Open Learning Centre's Operations at Technikon Natal

The mission of the Open Learning Centre (OLC) is to offer services, training and support that enable the academic departments of Technikon Natal to develop, implement and research their own telematic teaching and learning resources

Current services comprise:- on-line learning and computer aided instruction for students in key subject areas; development of courseware for academic departments; training and workshops on how to write and develop courseware; and telematic consultative services.

Lecturers from academic departments accompany their students and act as facilitators during weekly computer-assisted learning tutorial sessions. All sessions are time tabled and compulsory (i.e. attendance remains high throughout the year). Most of the sessions are credit bearing (i.e. academic departments allocate marks for completion of lessons on computer).

The OLC multimedia training room is used to prepare academics in the use of telematic teaching and learning technologies. For example, the training room is used by computer studies lecturer Parivash Khalili to teach the subject Operating Systems IV. Her B.Tech Information Technology students make use of the training room in order to access their virtual class on the World Wide Web. First year Residential Childcare students make use of multimedia resources on CD-ROM for the completion of a credit-bearing project.

The OLC's approach to courseware design is to train academics to become involved in "low level" courseware development that is easy to learn and do. OLC staff members co-ordinate the development process and are involved in "high level" development requiring scripting and other specialised skills. The OLC also provides access to courseware development resources such as scanners and software.

A number of workshops were delivered to lecturers during 1998, primarily on designing and managing virtual classes, and on using the World Wide Web as a teaching and learning resource.

The Department Of Community Nursing's Involvement

The Community Nursing Department is providing the learning material, evaluating the students and managing the pharmacology course. The Department has organised subject expert, Beverly Gold, to write the courseware content and accompanying literature. A full time staff member will operate the virtual class, workshops and online student assessments from the inception of the course in July 1999.

There are no successful distance-based programmes in this discipline in South Africa. There are a number of registered nurses working in varying sizes and types of occupational settings throughout the country, and further north, who are unable to access formal education and training in community health nursing.

If the pharmacology course proves successful, other primary health care courses will be developed along these lines. Nurses in the field are experiencing great problems with the introduction of free primary health care to all South Africans under the age of six. There is a severe shortage of skilled health professionals in the field and nurses have no access to the information they need on a daily basis, and little time or opportunity for upgrading their skills.

The Department Of Community Nursing At Technikon Natal

Courses are offered in occupational health nursing and primary health care.

In addition to Internet-mediated learning, video technology is also a medium that is being explored by this department. Plans have been put into place to translate one specific programme - a post-graduate course in occupational health nursing - into video and supporting workbook format by the end of 1999. While video material seems to be much more accessible as a means of delivery in the United States, the dollar/rand exchange and the different cultural context, makes it necessary for the department to produce its own video material. Extracts from these videos will be used in the interactive and online courses. The occupational health nursing course, recognised by the South African Nursing Council, has been chosen as it is not dependent on clinical instruction, nor does it necessarily require synchronous lecturer/student contact.

A small but comprehensive studio is being adapted in, and for, the department. Computer technology will be incorporated in the making of the videos. While only 50% of the target group is likely to have access to video machines, the programme is planned so that the workbooks will be sufficient to sustain the learning process. The videos will enhance the concepts and serve to motivate students and provide video clips for the CD-ROM courses. I

The Department of Community Nursing is extremely flexible and intends to exploit all the forms of communication to which students have access.

In Summary

It is our belief that we do not need to repeat previous technological learning curves. While we have our own unique learning to do in this field, we can simply plug in to the opportunities afforded by the expertise, wide experience and effective telematic technologies, developed by the United States, and simply get on with the urgent need to train our nurses. Our country's training and health care problems are truly desperate. This collaborative multi-modal project by the Department of Community Nursing, the Community Development Programme and the Open Learning Centre at Technikon Natal is one attempt to reach into the rural communities themselves and to bring equality of opportunity and equal access while providing health care.

Fortunately online learning/teaching technology is relatively cheap, suitable for our needs and readily available. From the point of view of experience in the field of telematic learning and teaching, we consider ourselves to be "barefoot", technologically speaking. By firmly directing our "barefoot" teachers and lecturers, and their students, on to the information super highway, we may be able to address some severe problems. Lack of training has lead community nurses to dispense antibiotics to children, which has resulted in them becoming deaf. We need to reach community nurses with the information and support they require in order to operate effectively under difficult and trying conditions as soon as possible.

e-mail: {fulantelli, rcorrao}@itdf.pa.cnr.it, munna@indy1.itdf.pa.cnr.it

Abstract: Interaction with the information on the Web pages has been often reduced to the selection of links. This is a serious limit to all the Web applications that require an effective interaction with the information. Among the others, educational applications suffer from this limitation. Recent technologies, such as D-HTML and Java, are changing this, and opening up new interactive solutions on the Web. In this paper, we report on the design strategies and technical solutions we have adopted to increase interaction in a Web-Based Instruction system. In particular, but not exclusively, we have focused on the learning needs of university students on the subjects of Urban Planning and Architecture. Specifically, the developed system allows authorized users to modify the informative hypertext network dynamically; in addition, users can handle and re-elaborate the information published on the web pages through specific "working tools". The paper mainly focuses on these tools, from functional and technical points of view.

Introduction

The World Wide Web is fast emerging as one of the most popular technologies for education, since it allows educational institutions to potentially reach millions of people located all over the world [De Bra 98]. Specifically, Web-Based Instruction systems, based on the integration of a rich hypermedia information system with powerful communication tools [Ibrahim et al. 95], have proved the instructional effectiveness of teaching and learning through the Web [Alexander 95].

However, some important features required for an effective use of the Internet in education are still missing from the Web. Limits concern many aspects of the Web, from presentation to interaction, from navigation to structure. Amongst the limits, we point out:

- The hypertext feature of the Web is extremely author-centered: users can only follow the hypertextual paths established by others (the page authors), but are not allowed modifying the existing links or adding new ones. Even if the available hypertextual navigation is a very important educational activity by itself, the impossibility of interacting with the information structure is a limit for educational applications.
- Information provided by the servers is usually in the form of web pages identical for all the students of on-line modules, rather than personalized pages.
- In html, information and its attributes (i.e., html tags) are mixed in the same document, thus making it difficult to work with automatic procedures aimed at elaborating the pure informative content [Andrews et al. 95].
- Interaction with the content of the pages is really poor, even though recent technologies provide interesting solutions.

More generally speaking, accessing a rich information environment -even if it is integrated with effective communication tools- is not a sufficient condition for expanding knowledge and stimulating learning. In fact, from a pedagogic point of view, learning requires "a deep understanding of the subject content" [Alexander 95] through a cognitive re-elaboration of the information [Colbourn 95].

Some design strategies can be adopted to overtake some limits of the Web. Research in this direction covers many aspects: from the hypertext organization of the information for individual learning paths [Oliver et al. 96] to the use of multiple media sources; from the publishing formats to the design of interfaces to reduce the cognitive overload; from the possibility of planning collaborative activities, to adaptive hypermedia [Brusilovsky 96] [De Bra 98], to the integration of tools which have proved particularly effective for stand alone educational hypermedia systems; and so forth.

In this paper we report on the design strategies we have adopted and on some specific tools we have developed to improve the interaction in a Web-Based Instruction (WBI) system. The system is aimed at supporting new

didactic approaches to the subjects of Urban Planning and Architecture through the activation of on-line modules at University level.

Brief Introduction to the Developed WBI System and Innovative Features

The Web-Based Instruction system is organized in two “work areas” respectively named “Analysis Area” and “Design Area”. The Analysis Area organizes-in a hypertextual way- the “external” information necessary for design activities in Architecture and Urban Planning (data on the town and on particular areas, the urban context for a new building, building regulations, administrative laws, formal and bibliography references, and so on).

The Design Area is directly aimed at some important phases of the design process in Architecture; it integrates Internet synchronous and asynchronous communication tools (e-mail, electronic discussion forums, video-conferencing, chatting) and tools to support the “control” of the project (virtual galleries, shared blackboard).

The Analysis Area represents an information repository for on-line educational modules activated on and managed through the system. The information in this area concerns, as a case study, the city of Palermo (Italy) and the design activities focus on, in particular, the sea front, in view of its future refurbishment.

In this paper, we do not present the Design Area in more details [Corrao et al. 99]; rather, we focus on the Analysis Area, by highlighting the interaction mechanisms implemented on it and their benefits in the educational field.

Actually, the system has been developed in such a way to provide different classes of users with different access facilities. Specifically, “students”, “teachers” and “expert guests” can extend the information network interactively, by adding new pages and new (internal and external) links to the Analysis Area. “Students” can handle and re-elaborate the informative content of the pages; to this aim, we have implemented the “Working tools” which allow students to mimic effective traditional study activities. Changes operated on the Analysis Area can be “public”, which means that they modify the original structure and content of the information network, and will be shown to all the classes of users; otherwise, changes are private to their author, so that they modify a “personalised” version of a web page in the Analysis Area (in addition, personalization can take into account some user’s preferences, such as visualization preferences). Finally, “students”, “teachers” and “tutors” can review the “study activities” performed during a specific study session (visited pages, operations on the page content, new added pages and links, and so on). We consider a “work session” as the set of operations performed by the user during two consecutive logs into the system.

Users gain access to the system through their Home Page [Fig. 1], corresponding to a personalized access point to the Design Area as well as to the Analysis Area.

Following, we report on the strategies we have adopted in order to implement the system.

Extending the Information Network

From a methodological point of view the possibility of extending the information network can improve learning through the construction of knowledge. This real interaction between students and the knowledge representation in the hypertext network is an important point towards a real and significant implementation of the Constructivist theory on the Web, by allowing for the development of personalized in-depth research sections [Schank 94]; the possibility of extending the information network allows teachers and expert guests to enrich the content of the system too. Finally, the privileges accorded to specific classes of users prevent guests from arbitrarily adding information to the system.

The possibility of extending the information network rises important theoretical and technical questions about the parameters to be fixed in order to guarantee a consistent growth of an on-line informative hypertextual network. Firstly, we have focused on a very precise model of the information domain, and imposed an a-priori organization of information; in such a way, new nodes can be immediately classified in some pre-defined category (and added to the right place in the network). Secondly, we have imposed some limits to the extension mechanism, both at information node and link levels; particular attention has been paid to the types of links users can add to the system. These constraints have been fixed in such a way to preserve the original structure of the network, yet allowing people to add new pieces of information. Moreover, it is extremely important to keep information about each node and link author, in order to guarantee source reliability. Finally, it has been necessary to provide system known users with mechanisms showing modifications to the network since their last access.

Fig. 1: The user Home Page is the personal entry point to system.

Specific tools have been developed to allow users to add nodes and associative links. By selecting a “New Page” button [Fig. 2], the user can add the content of the new page through a preformatted form; afterwards, s/he is guided to identify the category of information the new node is to be classified. Through the “New Link” button, the user can select the link anchor by interacting directly with the text on the page, through a common click-and-drag operation on the text; then, she is guided to select the link destination.

New added pages and links are public to all the system users, and not only to their authors, thus providing for learning activities based on cooperative production of knowledge.

Working on the Information Pages

The “working tools” sustain the user’s attention at high level and develop his/her critical sense and his/her abilities to search for, extract and synthesize information. Specifically, we refer to the tools that allow the users to mimic traditional activities, through a series of stationery items like “Marker”, “Foot-Note” and “Page-mark”. These tools, together with the “Note-book” and the “Kit bag”, enable the user to handle and manipulate the information in the web pages. Changes to the page content are private to the user who makes the modification. The philosophy of these tools is, in fact, the provision of mechanism for individual study strategies. In addition, making private modifications available to all the users could produce a chaotic representation of the information. The “Marker” tool allows parts of the text on the pages to be highlighted. The selected parts remain highlighted until the end of the on-line module; in addition, the user can decide whether and when to transform these selected parts into real informative documents by putting them into the “Kit bag”. The “Foot-Note” tool allows the user to add notes, reference-marks and other information to the text of a page. The notes, which are for the private use of the user who created them, remain “attached” to the pages from one on-line work session to another. During first reading, the user can “mark” each page of the system s/he considers relevant to his/her studies by using the “Page-mark” tool (activated through a specific button [Fig. 2]); the user can navigate back

Fig. 2: A screen shot of the system while the user is adding a note; the upper frame contains the “working tools” buttons and the buttons to extend the information network.

to the marked pages through the “Iter” tool (refer to [Controlling Oneself Study Path]) to study these pages in more detail. The “Note-book” tool works like a real note-book enabling the user to write down reflections, critical notes, and so on; for this reason it represents a collection of writing sheets. It is activated through the Note-book button [Fig. 2]. The user can access the Note-Book in the Design Area and pass through the different notes taken during the navigation across the Analysis Area. The tool “Iter” highlights the presence of footnotes on the pages. Finally, the “Kit bag” tool represents a kind of catalogue that the users carry with them during navigation through the system, and where they store pieces of information collected on this way around. The pieces of information in the “Kit bag” retain the reference to their original web page; therefore, it is possible for the user to go back to the page, and choose links to other parts of the system. Furthermore, users carry the “Kit bag” with them in the “Design Area”. The user interaction with the “Foot-Note”, “Marker” and “Kit bag” tools is extremely easy and rapid: once the corresponding button has been selected [Fig. 2], the user selects (through the click-and drag mechanism) the chunk of text which is, respectively, the anchor for the note, the text to be marked or the piece of text to be inserted into the kit bag.

Controlling Oneself Study Path

One of the most effective tools to help the users navigate through the information is the “Iter” tool: it shows the list of pages visited during each work session or since a date specified by the user. Unlike the “history” tool available in commercial browsers, the “Iter” tool keeps track of the operation performed on the pages through the tools described above. In particular, next to the name of every page, there are symbols to indicate the operation carried out by the user, so s/he may locate the information s/he considered important and return there directly. The same information can be accessed by the teachers and the tutors of the on-line modules, thus controlling and assessing the students’ activities in the system. Non-technical teachers can, therefore, work with the system and perform assessment activities in a very easy way.

BEST COPY AVAILABLE

It should be noted that some of the described activities could already be performed by using features of the browsers and of the most popular operating systems. However, these solutions are unsatisfactory because the mechanisms are not integrated into a single environment, they are usually separated from the learning/reading context (the informative content of the Web pages), and require a cognitive overload on the part of the learner/reader.

System Architecture and Implementation Overview

The implementation of the system is strongly centered on Java™, both on the client-side and on the server-side. Specifically, Java Applets are used to host the text and to handle the user interaction; on the server side, the system is managed by a set of Servlets; to be more precise, servlets handle the mechanism necessary to provide the personalised pages to each registered user and to log all the user's operations. To this aim, an SQL-compatible Data Base is used to store information about the registered users (login, password, visualization preferences, and so forth), specific information belonging to each user (references to the file containing the personal notes added during the navigation, references to the information stored into the kit bag, and so on) and information on the modifications that each user has made on each page of the system. In particular, the system stores four different files for each page in the Analysis Area: the html page, containing the page layout, the file containing the pure text, the file of the public attributes (html formatting tags, link tags) and the file of the private attributes (to be more precise, there is one "private" file for each registered user). The separation between content, layout and attributes greatly improves the management of the personal versions of the pages. Finally, a Web Server, used to deliver html pages to the browser completes the system architecture.

When a registered user logs into the system, a specific servlet sends the user's Homepage to the client. As told before, the Homepage represents the personal entry point to all the parts of the system, included the Analysis Area; in order to guarantee the deliver of the personal pages of the Analysis Area to each user, all the URLs contained in the HomePage are modified in such a way to include its owner's ID. The ID will enable the servlets to identify the origin of each request. Specifically, when the client requires a page of the Analysis Area, an applet sends the modified URL to a specific servlet (ReqDocument), together with indication of the file containing the text as parameter; then, the applet sets up a *channel* which is used by the servlet to deliver the document. The particular servlet to be activated and the parameters (if required) are also included into the URL sent by the browser. The ReqDocument servlet builds the document by merging all the information contained in the four files reported before. When the document is received by the client, the applet interprets the tags included in the document, divides the text into the lines which will appear on the page, builds two arrays for each line containing the pure text (*line_text*) and the text inclusive of the tags (*line_tag*), and finally displays the document. The two arrays are necessary to handle the click-and-drag operation on the text.

The set of tags, which the applet is able to interpret, is a reduced sub-set of html tags together with new proprietary tags defined by the authors to encode the user changes to the text.

The selection of chunks of text on the page through the click-and-drag mechanism (which is central to many operations) is handled by the applet that hosts the text.

When a chunk of text is selected and the user operates on it through one of the tools described above, a communication process between the applet which handles the operative buttons [Fig. 2] and the applet hosting the text is started, so that the selected text is modified according to the operation selected by the user. In addition, the notification of the user action and of the words affected by it is sent to the server, so that the DataBase and the specific files are modified.

Some examples of the working mechanism for the most significant tools are reported. By selecting the Marker tool, the system modifies the background color of the selected text and communicates the event to the server; by activating the Foot-Note tool, the system opens a Java frame external to the browser, thus allowing the user to add the note [Fig. 2]; afterwards, it adds a symbol at the end of the selected text in order to anchor the footnote, and passes the event (including the note content) to the server; finally, by choosing Link button, the applet opens a Java frame external to the browser, allowing the user to select the page to be linked to the new created link, or directly writing the URL (internal and external URL's can be specified by the user); the new link is passed to the server.

The developed prototype is running on Windows NT platform equipped with Apache Web Server and Microsoft Access Database.

Conclusions and Future Developments

In this paper, we have proposed some design and technical solutions to improve interaction in a Web-Based Instruction system. Specifically, we have introduced the design strategies which allow users to extend the information network, and some "working tools" which can maximize the learning and reading processes and facilitate the recognition of the phases of knowledge acquisition. Even if the presented system concerns a specific subject, and is aimed at University studies level, the working tools should be considered as general solutions for educational systems. The Analysis Area can be substituted straightforwardly, thus widening the use of the system to different application fields. Anyway, a rigorous definition of the knowledge domain is necessary to allow for a consistent growth of the Analysis Area. Finally, the communication tools in the Design Area can be easily adapted for different educational contexts, and new tools can be integrated into it. The main limit of the Java based implementation is the restricted number of html tags the system recognizes in order to reduce the complexity of the interpretation work; consequently, an appropriate tradeoff between complexity and effectiveness should be investigated further. There are some other important developments we foresee for the presented system: firstly, it is possible for the servlet mechanism to work with distributed data base; secondly, some operations on the text which have been defined "private" can be straightforwardly made public, and vice versa, according to the user's decision and to the use context of the system. Finally, division between pure text and text attributes makes it possible the implementation of effective automatic procedures on the text.

Ephemeral Paths on the WWW: The Walden's Paths Lightweight Path Mechanism

Richard Furuta, Frank M. Shipman III, Luis Francisco-Revilla, Haowei Hsieh, Unmil Karadkar, Shueh-Cheng Hu

Abstract: Walden's Paths provides a mechanism for overlaying linear paths over World-Wide Web material. The path structure does not alter the pre-existing structure of the original material, but provides a means for organizing and contextualizing the collection of material. This paper first reviews the design of Walden's Paths and our experience with it. It then presents a new mechanism that enables ephemeral "lightweight" paths, which may be generated by a computer process.

1. Introduction

Walden's Paths provides directed paths over the World-Wide Web. It permits the specification of a *meta-structure* over the Web—a structure that brings together materials from widely-separated locations on the Web into a single, cohesive unit that leaves the original structure and content untouched and accessible. Although the function provided by Walden's Paths is somewhat similar to that provided by bookmark lists, the path provides the reader a stronger dynamic sense of context. Navigational context is provided through addition of user controls that enable traversal through the path while representing position within the whole. A path's author can add annotations that can be used to help the reader understand the page's material in the context of their own environment and experience.

The usefulness of paths (particularly linear paths) in organizing and contextualizing hypertextual material has been long-recognized [Bush 1945], and stand-alone implementations have existed since the 1980s [Trigg 1988, Zellweger 1988 and 1989]. Even so, implementing paths over the Web has required addressing novel issues, particularly issues related to Web materials' heterogeneous ownership and decentralized administrative control.

For some years we have been supporting K-12 classroom use of Walden's Paths in collecting, contextualizing, and communicating Web materials. We have reported on these experiences in earlier papers [Shipman et al. 1996, Shipman et al. 1997, Furuta et al. 1997, Shipman et al. 1998, Shipman et al. 1999]. Another project with similar educational goals has been described by Nichol [Nichol 1996].

These activities, in support of teacher-student, student-teacher, and student-student communication, require long-lived artifacts. Consequently, the publicly-available version of Walden's Paths supports temporally persistent paths—explicit authoring and annotation of paths are required; paths are "published" and appear in a centralized site directory; and issues of sharing and of path maintenance are topics of our current research.

Paths, however, have additional uses beyond that of supporting interpersonal communication. For example, they can be useful to an individual as a means of organizing inspection of discovered resources. Such applications require paths that can be reconfigured dynamically—paths that perhaps are generated initially by a computer process and then are manipulated and pruned as the reader inspects the results.

To increase our understanding of these applications, we have extended Walden's Paths to incorporate *ephemeral* paths—paths that provide a service upon creation but that are regenerated subsequently rather than retained. We consider this to be a "lightweight" path mechanism—lightweight not from the standpoint of implementation but from the standpoint of user expectation. Indeed, the implementation costs of lightweight paths are approximately equal to that of the earlier-mentioned persistent paths. Since they are not catalogued, no specific generally-available "handle" is provided; such paths are intended to be a personal, rather than public, artifact.

The next section of this paper contains a discussion of the relevant portions of the design, implementation, and use of Walden's Paths' publicly-available version. Following this, we return our attention to lightweight paths in section 3, presenting examples of their use in section 4. Section 5's discussion and conclusions complete the paper.

2. Walden's Paths (system view)

Figure 1 shows the Walden's Paths architecture, illustrating its major components (the WWW Browser and the HTTP Server are external to the Walden's Paths system). This paper will focus on modifications to the Path Server, so the other components will not be described; see our earlier papers or our Web site for their details.

The Path Server, implemented in C and invoked as a CGI program, takes the path information and produces a

Figure 1: The Walden's Paths Architecture

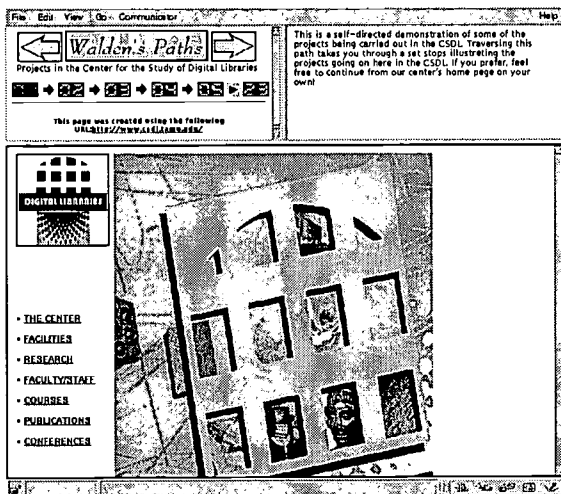

Figure 2: A stop along a path.

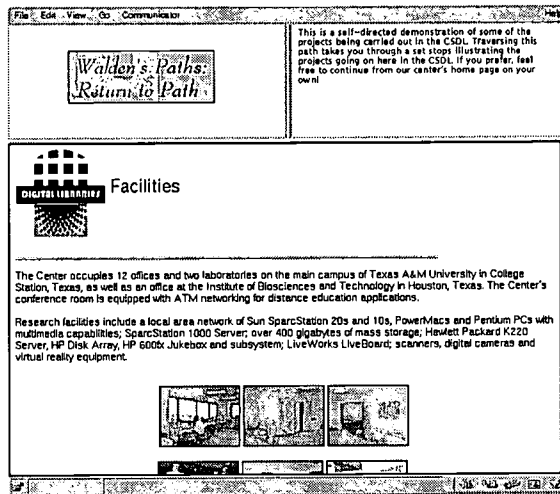

Figure 3: Going off the path provides reader with quick way back.

frame set with the control-flow buttons in the upper-left, the annotation in the upper-right, and the source Web page from the original site in the lower frame (see Figure 2). The control-flow frame provides the path reader with a sense of where they are in relation to the overall path, access to later pages in the path, and a pointer to where the source page comes from so the page can be viewed directly, without the Walden's Paths frames on top, if so desired.

Links in the source page remain active and, besides changing the contents of the bottom frame, change the upper-left frame to a "back to path" button so the reader can quickly get back to where he/she left the path. Figure 3 shows an example of this when browsing off of the page. Here, the reader has selected the "FACILITIES" link in the lower window shown in Figure 2.

The Path Server (as well as the other programs that make up the Walden's Paths system) is maintained in versions for Sun Solaris and for Windows NT. The paths displayed by the path server are not browser-specific or platform-specific, other than the requirement for frames support. In practice, current versions of Netscape and Internet Explorer are being used to access paths.

Early versions of Walden's Paths have been used by teachers taking part in summer teaching workshops and by teachers and students in eight high-school art and music classrooms. It is these experiences that have determined subsequent development, including the lightweight path mechanism.

In both workshop and actual classroom situations, one of the most striking outcomes of Walden's Paths use is how quickly the path technology fades into the background. Teachers and students find the path metaphor natural

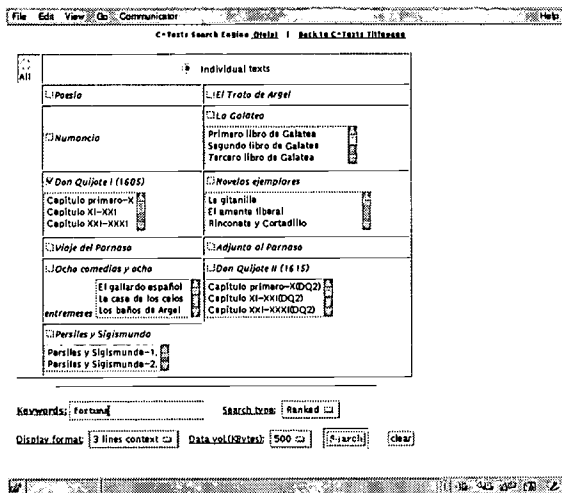

Figure 4: A query posed to the Cervantes search engine, seeking all occurrences of the term “fortuna” in the 1605 edition of *Don Quijote*, book one

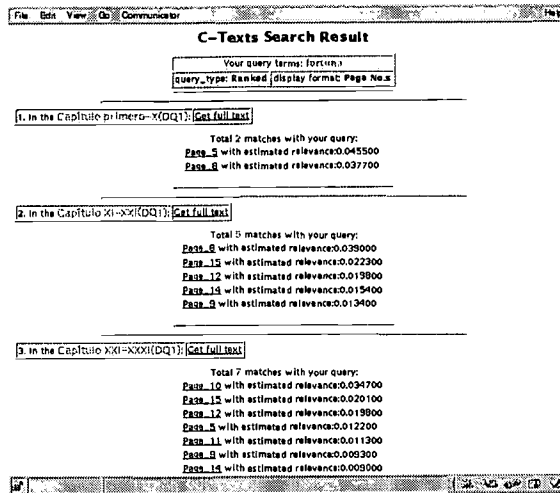

Figure 5: The result of the query, presented in traditional list format.

and, after a short period of learning about the system, quickly focus on the content within paths. This is a positive outcome as the ability for the technology to slip into the background in the classroom allows teachers and students to focus on what they are teaching/learning [Furuta et al. 1997, Shipman et al. 1999]

One observation from our experiences is that while teachers find paths easy to integrate in the classroom, they find it difficult to find time to author paths from scratch. Many of the paths used in the classroom were authored during training sessions rather than during the semester when they are spending most of their time in the classroom. It is this observation that has driven the need for greater authoring support for teachers and the more general notion of lightweight paths.

3. Lightweight paths

The persistent paths described in the previous section suggest entry specification, refinement, and annotation by a human author. The investment of time and effort is reflected in an expectation that such paths will be long-lived—that they will be catalogued, reused, shared, and maintained.

Generation of lightweight paths assumes the involvement of a computer process. They are intended to enable the application of Walden’s Paths representations to computationally-generated collections of resources—results from queries, subsets or supersets of previously-developed collections, and applications customized for an individual or environment. Since lightweight paths are ephemeral, it seems unwise to support their fine-tuned tailoring or other large-scale investment of human energy in their specification.

Our lightweight path implementation fits into the general architecture of Figure 1. Lightweight paths use the same internal description format as persistent paths, but their entries are flagged as ephemeral and include information about their creation and retention times. Lightweight paths are registered with the Path Server but are not included in the path directory (i.e., the Path Server does not publish the path). A handle is returned to the caller, in the form of a URL, that can be used to access the path. A CGI program creating a lightweight path, can, therefore, generate an HTML page containing a redirection to this URL (i.e., the ONLOAD attribute of the BODY element), or it can carry out further processing to use the lightweight path in whatever way it wishes.

4. Applications of lightweight paths

In this section, we will examine some scenarios of lightweight paths in use.

4.1. Organizing the results from a search query

A group in our Center is developing a resource for humanities scholars of Miguel de Cervantes Saavedra (1547-1616), the author of *Don Quijote de la Mancha*. Cervantes, a figure of immense significance in Spanish culture, is credited as the inventor of the modern novel. His works and his use of language receive careful scrutiny by scholars.

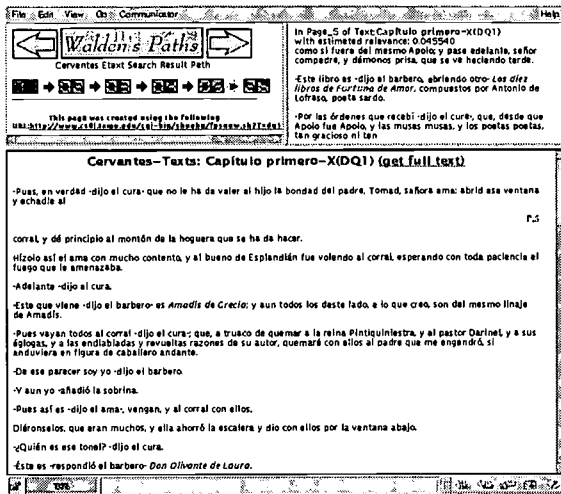

Figure 6: The first result from the query, presented as a Walden's Paths entry.

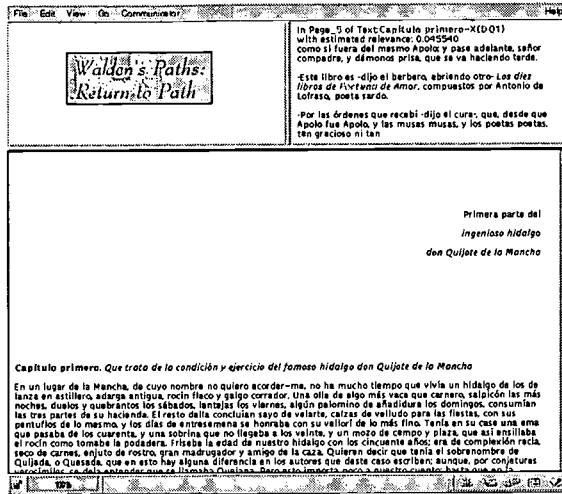

Figure 7: Traversing the provided link to see the entire text of the *Don Quijote* edition.

Figure 8: Selecting pages to retain from the path resulting from the earlier query.

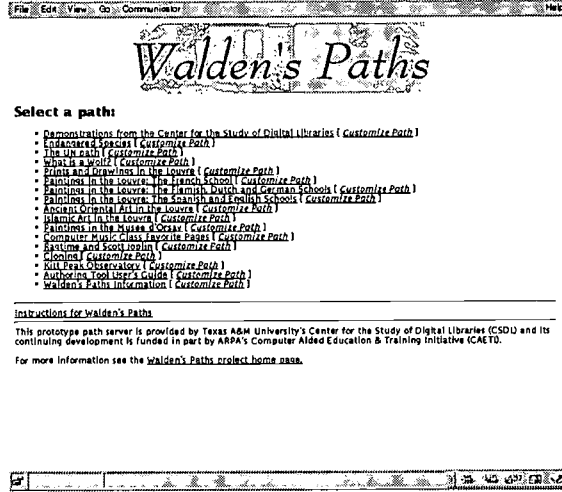

Figure 9: Choosing "persistent" paths for elision.

This project maintains a set of Web pages at <http://www.csd1.tamu.edu/cervantes/>. One of the important components of that site is an on-line, searchable, edition of Cervantes' complete works. A scholar seeking, for example, the uses of the term "fortuna" in the first book of the *Don Quijote* would pose a query as shown in Figure 4. The traditional result of such a query is a list of responses, as shown as Figure 5. It is likely in this case that the scholar will next examine the use context for each occurrence of the term. This requires selection of an element on the list, examination of the page that is then displayed (the page on which the match has occurred), selection of the browser's back button, and finally selection of the next element on the list. Each new selection requires reorientation within the list, to determine first which element had just been selected and then to choose the next in the list. When the list is long, the selection of each element in turn becomes an error-prone operation, as it is quite easy to re-select an element already visited or to skip an element accidentally.

Figure 6 shows the result of the query, implemented as a lightweight Walden's Path. In this implementation, each search result becomes a separate stop in the path; here we are at the first stop. A brief summary is shown as the path annotation and the complete details of the match is shown as the stop's content (the matching words are highlighted in both places). Selecting the "next" arrow will take the scholar to the next match. Following the link in the content

page results in an off-the-path traversal, shown in Figure 7, that displays the full text of the *Don Quijote* edition. Return to the path can then be accomplished using the standard Walden's Path mechanism with a single mouse click on the button in the navigation window.

Path elision

The previous scenario has assumed that all pages selected by the search are relevant to the questioner. What if irrelevant material has been selected, a likely outcome of an automatic selection process, and the researcher wants to pick and choose the items worthy of closer inspection? Path elision permits the selection of a subset of the path.

We view lightweight paths as the intermediary representation that permits implementation of a set of small "filters"—relatively simple bits of executable code that accept a path (either lightweight or persistent) as input and produce a modified (lightweight) path as output. One such filter permits a degree of path customization—allowing the selection of pages to retain and those to remove from a previously-generated path. As Figure 8 shows, this allows the modification of the previous search-generated lightweight path. The resulting path, also a lightweight path, would then be browsed with the standard Walden's Paths interface.

Such filters are useful when applied to persistent paths, as well. Figure 9 shows a modified directory listing for the persistent paths stored at a particular site. Application of the elision filter allows the reader to customize the path to be viewed. In this example, the reader might wish, for example, to focus on one of the projects of the several that are reported in the tour of our Center's activities.

4.2. Potential areas of application for lightweight paths

We are considering the development of additional, more sophisticated, path generators and path filters for applications that are inconvenient to implement with persistent paths. These applications of lightweight paths include those in which the dynamic nature of the underlying content make persistent paths impractical, those in which individually customized versions of a path are appropriate, and those in which the content of the path may vary depending on the specified or identified characteristics of the reader.

Paths over transient materials

Many forms of information are temporally-transient but persistently structured. The contents of a newspaper change on a continuing basis but the general form of the newspaper remains constant (e.g., the sections into which it is divided, the relative importance of the front and inner pages, the significance of placement of materials on a page). Weather satellite pictures provide a consistent set of information, but visible-light images are only useful for areas of the globe that are in daylight. We envision path generators that are able to locate the current versions of a set of resources, annotate them as appropriate to their context, and arrange them into lightweight paths for presentation.

Paths generated according to specified rules

Persistent paths have been used in creating on-line versions of course examinations (see [Shipman et al. 1998]). We envision applications that use lightweight paths to create customized tests from provided question pools using defined criteria. For example, some examinations for types of Federal licenses draw questions from a publically-available pool, with the distribution of the questions' subject areas specified by regulation. Other criteria might include randomization of order so that no two students had the same exact question sequence.

Paths generated in response to student strengths or weaknesses

A natural extension to testing mechanisms would be the use of the testing results to identify a set of tutorial material to aid the student in correcting deficiencies. We envision the presentation of such collections of material as being implemented by lightweight paths.

Template-generated paths

Customization of materials for students of differing skill levels may also be a possible application of lightweight paths. Here we envision a family of paths each with the same backbone structure, and with each drawing materials from a persistently-defined pool. However, the presentation of the specific topics along the path may be varied based on the individual student's age, grade level, interests, or other factors.

Randomly-generated paths

Finally, we envision applications that will benefit from randomly-generated paths. We have observed the use of persistent paths as a virtual "tour guide"—presenting an overview of an organization, perhaps. Randomized pages could be used, for example, to show selections from an art gallery's collection, or to show some tips about use of a software package.

5. Discussion and conclusions

Our experience with Walden's Paths has illustrated to us the strength and utility of applying meta-structures over the World-Wide Web. Our existing implementation provides a relatively simple linear path structure. This has had the desirable property of unobtrusively enabling the provision of guidance and context to readers.

While it appears that meta-structures have positive benefit, it is also clear that authoring meta-structure requires effort and attention. This observation is not surprising, as it is a characteristic of any creative and organizational activity. Nevertheless, it does suggest that the benefits gained from authoring should be in proportion to the effort expended.

In this paper, we have reported on a mechanism to allow application of paths in contexts in which the ephemeral nature of the application mandates against large-scale investment of an author's time. We have demonstrated that heuristic approaches to building meta-structure can be effective for some applications in this class. Our assumption is that the paths created using the lightweight path mechanism also will be ephemeral, and consequently will not be catalogued or retained for reuse. In applications suggesting reuse, therefore, the further assumption is that the resources required to rebuild a lightweight path should be similar to the resources required to locate a path in a persistent collection.

Consequently, we have provided mechanisms at two ends of the persistent-ephemeral spectrum. However, the categorization of many documents and structures ranges between fixed and fluid, influenced particularly by the application. Buckland [Buckland 1997] illustrates this clearly in surveying the differing notions of how to define "document". Levy [Levy 1994] considers similar issues in his discussion of literary hypertextual presentations, and Levy and Marshall extend these thoughts into the Digital Library domain [Levy and Marshall 1995].

We see similar influences in the future directions of our project and expect to extend our model of persistent-ephemeral paths as it develops. We are examining a number of such extensions, already. These include extension of the directory mechanism to reflect categorization of paths along multiple dimensions, one of which may be the required temporal persistence of the path. We also see potential for generalizing our model of the authoring process, using lightweight paths to represent intermediate versions of a path while under development.

Abstract: This paper presents a set of advanced network services developed to support the administrative operations and the collaboration of different scientific groups within the University of Patras. The system developed is exploiting Intranet technologies enabling asynchronous and synchronous cooperation, manipulation of information from heterogeneous sources, security and easy administration, providing in parallel advanced communication facilities. This is one of the first attempts made in national level in Greece, in order to support a campus to increase the effectiveness of workgroup, departmental, and cross-functional communication by giving the users the possibility to use advanced network services. More specifically, we describe the services developed, the whole system architecture and present the security issues faced in the implementation of the project as well as the introduction of the whole system to the users.

1. Introduction

Today, the Internet and the technologies it has spawned have altered the way people think and work and created a major new industry virtually overnight. For today's knowledge workers, the Web is a network of computers navigated with "browser" software that links them instantly to vast repositories. The result is a revolution in the way organizations communicate with the outside world and - perhaps more importantly in the near term - in the way they distribute and share information internally.

By using common Internet protocols, or core technologies, in conjunction with their own applications, corporations can easily communicate, distribute information and facilitate project collaboration across the entire organization while keeping unauthorized users out.

A recent study by NetworkWorld found that 89 percent of organizations sampled already have implemented or will implement an intranet strategy in the next 12 months. Internal webs have become so popular that installations of servers limited to internal use is outpacing that of external web servers by better than five to one.

Some of the key advantages of Intranet technology are the following [Bernard 96]:

- Web technology is inexpensive. The basic system configuration consists of a server hardware platform/operating system and WWW server software. On the user side, an inexpensive browser is needed to navigate the information.
- A second driving force behind the rapid growth of Intranets is that the technology is extremely intuitive and easy to use without much training. Users use hypertext links to search for and access text, graphics, audio or video, all organized into home pages.
- Another appealing feature of Intranets is security. Sensitive corporate data are protected from the outside world by security software known as firewalls. When anyone on the outside tries to get into an internal web, the firewall requests a password and other forms of identification.
- Finally, and perhaps most importantly, Intranets solve the problem of interoperability. Web servers are based on open technology and common standards, allowing Intranets to connect all the different types of computers on a network, whether they are PCs, MACs or Unix workstations.

In this paper, we present an Intranet-based, database-oriented CSCW system implemented around the 'shared workspace' notion [Grudin 94]. The workspace comprises asynchronous and synchronous cooperation and communication tools. The use of these tools is restricted (password controlled) and can be accessed via standard, unmodified web-clients using the login/password authentication scheme. Within the boundaries of a

workspace the user can manage and share with other members of the workspace different kinds of information, including:

- A folder-file repository, in which the users may transfer various types of files from their local store into a shared repository (uploading) or retrieve files from the workspace to their local system (downloading).
- A discussion forum (bulletin board). A shared location for posting announcements supporting follow-up messages (that is, replies to existing messages).
- A real-time Chat session. A synchronous communication, Java-based, client/server application integrated in the web-browser. The members of the workspaces can communicate in real time via a chat session belonging exclusively to the workspace, a session similar to the well-known IRC chat sessions.

This paper is organized as follows: Section 2 provides the details of the system architecture, specifically the construction of the databases and its functional modules. In section 3 the security issues for the smooth operation of the whole system is addressed. The last section summarizes conclusions elicited from our work and presents future work issues.

2. System Architecture

The university has various departments, laboratories and services that administer and maintain their own databases. These databases are completely independent of each other, in which case each can be treated as a single entity.

However, if multiple databases are going to be connected to each other through an intranet, then several issues of inter-connectivity, permissions, and administration arise. An intranet that contains inter-connected databases requires careful planning, considerable co-operation and co-ordination.

The most critical component of such an intranet infrastructure is the main server which is responsible for the co-ordination of the network. The selection criteria for the server platform in our case included:

- High performance
- Scalability (the ability to expand as needs change)
- Powerful operating system administration and management tools
- High throughput hardware systems for both networking and storage media
- Strong security features

The server platform houses a variety of modules to provide various services to intranet users. The main modules of the intranet are [Fig. 1]:

1. World Wide Web module
2. Database module
3. Communication module
4. Search module
5. Multimedia module

Each of these modules is installed on a single machine except from the database server, which has a distributed architecture.

2.1 The World Wide Web Module

This is the basic module [December et al. 96] that brings together the power of the intranet. This module is comprised of a WWW server which allows clients access to organisational information by facilitating information publishing, application execution, and data retrieval.

The Web server software package is Microsoft's Internet Information Server 4.0, a server that provides a comprehensive set of set-up, management and administration facilities. The Web server uses the HTTP (HyperText Transport Protocol) for the transfer of data (text, images and sound) to/from the network. The use of HTTP allows the communication between the server and the client (a WWW browser) via a socket connection established by the TCP/IP protocol. The ever-growing use of multimedia technology for the construction of web pages requires the adoption of several multimedia standards such as Active X and ShockWave. A number of plug-ins is also required for the browsers to have the capability to handle multimedia-rich files.

2.2 The Database Module

Most Intranet implementations are using flat files or proprietary systems for storing data and information. However, since the organisation already had many large databases installed and operational in different departments, it was necessary their integration to a larger management system with a distributed architecture.

A main database server is used to co-ordinate access rights to data through applications written to access the databases both from the WWW module and from existing in-house applications. Extensions to standards such as ODBC (Open Database Connectivity), and ISAPI (Internet Server Application Programming Interface) enable the Web Module to interface to the various databases.

Figure 1. Intranet Architecture

2.3 The Communication Module

The Communication Module [Stallings 88] facilitates information exchange between users of the intranet. More specifically it provides functionality for:

- *Multimedia Electronic Mail (e-mail)* - a messaging system for exchanging information between users. The mail services use a variety of protocols including SMTP (Simple Mail Transport Protocol), MIME (Multimedia Interface Mail Extensions), POP3 (Post Office Protocol) and IMAP4. These protocols deliver essential e-mail features including:
 - message tracking, return receipt, accurate attachments and in box synchronisation regardless of whether the users are located inside the Intranet architecture
 - HTML editors for creating rich, hyper-linked messages
 - support for messages originating from a variety of software packages
- *Bulletin Boards* - A "Post-it™ Notes" system for disseminating information to a group of users.
- *Discussion Groups* - A forum for exchanging ideas and engaging in discussions on various topics.
- *Chat Rooms* - A place where users can interactively "talk" to each other
- *Video-Conferencing*: the Local Area Networks is connected to hubs bringing sufficient bandwidth for multi-user conferencing. Furthermore, special protocols such as Real-time Transport Protocol (RTP) are used to facilitate real-time transmission of audio, video, and data. This framework incorporates several codecs including MPEG, H.261 and GSM.
- *Remote Access* - Allow users remote connection to the corporate intranet through dial-up networking.

The Communications Module works in conjunction with the WWW Module to provide a seamless means for users to interact with the intranet and with each other. The Module also provides secure connectivity through e-mail gateways to the outside world. Users can send and receive e-mail messages to people all around the world using their Web browser or other e-mail software package.

2.4 The Search Module

The Search Module is actually an advanced search engine that uses indexing mechanisms to provide users with a means for finding and retrieving information from the Database Module. The search engine catalogs and

indexes information being published on a distributed database system. As new information is added to the intranet databases, the search engine updates its indices to reflect these changes.

The most critical aspect of the search mechanism is the ability of the system to provide search results in a fast, efficient, and error-free manner. Speed becomes an important issue as the size of the intranet grows.

2.5 The Multimedia Module

The Multimedia Module provides support for high speed streaming media such as video and audio. It is comprised of a multimedia servers which uses high speed links to provide intranet users access to live or pre-recorded multimedia content.

One of the most compelling applications for the Multimedia Module was to provide support for live audio and video communications for the support of videoconferencing or collaboration tools. Users can interact with each other through sight and sound rather than using text-based messages.

Another application for this module was to provide on line and off line teletraining. Users can access video catalogs of seminars and training classes and view them using their browser software or other multimedia clients.

3. Intranet security issues

3.1 Basic Concepts

The transfer of confidential information through the Internet poses the need for advanced security measures from any unauthorized Internet user. The need for secure channels of communication and different levels of security is a major problem during the design of every Internet-based transaction system. This section will give guidelines on how to secure Internet connected systems from both inside or outside intruders.

There are four categories that security is applied [Schneier 96]:

- *System Security*

Is the operating system secure? Have all patches been applied to enhance the system's security? Are all security "holes" been closed? Do only authorized users log in to the system? Have guest accounts been disabled? Have directory and file read/write access restrictions been applied correctly? In our systems all the above questions are answered with "YES" in order to achieve system security.
- *Communications Security*

The data between computers are transferred from/to servers to/from clients and vice versa. If those data are transferred without encryption it is possible for anyone to sniff them, log them to a file and then use them in any hazardous or offensive way.
- *Data Security on End-Systems*

After the two above actions we should pay attention to secure the data that arrive to the end system and are stored to its hard disc. Those data should be encrypted by the receiver-program before being stored as a file to the hard disc. One common way of further enhancing the security on end systems is to firstly cipher the data and then store a piece of that information on the hard disc ciphered and the rest data be transferred by secure E-mail to another system.
- *Authentication and Authorization*

The authentication is the process of identifying which user wants to access a server mostly by a combination of username and password pairs [Tari et al. 97]. After successful authentication, the user can only use resources that are explicitly assigned for him to access. Roles or groups (e.g. operators, administrators, staff) have been assigned to all users so specific services can be accessed by specific groups.

3.2 The SSL Protocol Specifications

The SSL Protocol is designed to provide privacy between two communicating applications (a client and a server). Second, the protocol is designed to authenticate the server, and optionally the client. SSL requires a reliable transport protocol (e.g. TCP) for data transmission and reception. The SSL protocol is a protocol layer, which may be placed between a reliable connection-oriented network layer protocol (e.g. TCP/IP) and the application protocol layer (e.g. HTTP). SSL provides for secure communication between client and server by allowing mutual authentication, the use of digital signatures for integrity, and encryption for privacy.

The SSL protocol provides "channel security" which has three basic properties:

- *The channel is private.* Encryption is used for all messages after a simple handshake is used to define a secret key.
- *The channel is authenticated.* The server endpoint of the conversation is always authenticated, while the client endpoint is optionally authenticated.
- *The channel is reliable.* The message transport includes a message integrity check.

The protocol is designed to support a range of choices for specific algorithms used for cryptography, digests, and signatures. This allows algorithm selection for specific servers to be made based on legal, export or other concerns, and also enables the protocol to take advantage of new algorithms. Choices are negotiated between client and server at the start of establishing a protocol session. The SSL session is established by following a handshake sequence between client and server. Once an SSL session has been established it may be reused, thus avoiding the performance penalty of repeating the many steps needed to start a session. For this the server assigns each SSL session a unique session identifier which is cached in the server and which the client can use on forthcoming connections to reduce the handshake (until the session identifier expires in the cache of the server). The elements of the handshake sequence, as used by the client and server, are: a) Negotiate the Cipher Suite to be used during data transfer; b) Establish and share a session key between client and server; c) Optionally authenticate the server to the client; d) Optionally authenticate the client to the server.

3.3 Firewalls

An important component of an overall security strategy is the deployment of firewalls. Although they cannot prevent data-driven attacks, they provide control of traffic that enters and exits the corporate web site. Traffic can be accepted or rejected based on application type and source address. Some key features of a firewall are:

- Regulation of the type of traffic comes in and goes out of a network. At the most basic level, a firewall lets some traffic in and keeps other traffic out. How the firewall does this and what other security features it offers - differentiates it from other firewall products. Firewalls provide a single point from which to audit for intruders and log access attempts and dropped connections
- Hiding of the corporate Intranet. By making network address translation, a firewall system can hide the IP addresses and domain names of internal systems from the Internet. This provides benefits in keeping the private network, safe from public eyes and also enables users to use IP addresses internally that may not be valid on the public Internet.

There are three basic types of firewalls: packet filters, circuit-level gateways, and application gateways. Of course there are also hybrid firewalls which can be combinations of all three [Chapman et al. 95].

Packet filter gateways are usually comprised of a series of simple checks based on the source and destination IP address and ports. They are very simple to the user since the user will probably not even realize that the checks are taking place. However, that simplicity is also their biggest problem: there is no way for the filter to securely distinguish one user from another. Packet filtering firewalls can be router-based or bridge-based. In general, this type of firewall examines each packet as it enters the router and decides whether or not to allow it in to the network, based on administrator-defined rules. Because packet filters examine one packet at a time, they are best for filtering stateless protocols, that is, protocols that can be examined one packet at a time without relation to what has gone before. HTTP is stateless, whereas FTP is stateful.

Circuit-level gateways are very similar to packet filters except that they operate at a different level of the OSI protocol stack. Unlike most packet filters, connections passing through a circuit-level gateway appear to the remote machine as if they originated from the firewall. This is very useful to hide information about protected networks. "Socks" is a popular de-facto standard for automatic circuit-level gateways. Application gateways represent a totally different concept of firewalls. Instead of a list of simple rules which control which packets or sessions should be allowed through, a program accepts the connection, typically performs strong authentication on the user which often requires one-time passwords, and then often prompts the user for information on what host to connect to. Hybrid gateways are ones where the above types are combined.

One difficulty with packet filters is that, if they conform to the rules Internet packets are admitted to the internal network without modification. By contrast, application gateways often use proxies to translate packets, ensuring that no raw packets enter the internal network. Knowing how many packets are rejected and where they are coming from is important, so select a packet filter that provides these logging capabilities. While packet filters examine each packet for its source, application gateways provide finer-grained access control of each application type.

The strictest method for setting-up a firewall is to deny all access that is not explicitly permitted. A more liberal policy is to permit all access that is not explicitly denied. The strictest rule is also the most difficult to

live with, in the case of an application gateway. Each application that is permitted must have a proxy. A proxy is software that runs on the firewall and appears to internal users to be a host and appears to the Internet to be a client. The proxy translates packets between the two applications. In the case of E-mail a good proxy will strip out internal host names from mail headers and replace them with the firewall's host name, in keeping with the policy of hiding internal host names and IP addresses.

4. Conclusions & Future Work

One of the most critical stages of the whole project is the introduction of the services to the users. International surveys have shown that the gradual and easy introduction of the system to the users as well as its interactivity and functionality are some of the major factors that will determine its acceptance [Ponta 96]. Moreover, considering that the final system is used for most of the educational procedures within the campus, several pedagogical aspects are already taken into account.

The final purpose was to develop a highly interactive system to support efficient and effective user functionalities, taking advantage of the new Intranet multimedia infrastructures available based on a friendly and easy to use user interface. Our work showed once more that the introduction of new network services is not mainly a technological problem. The development of the services, their integration and introduction to the users has to follow a well-defined, user oriented implementation plan.

The implementation of the Patra's University Intranet has resulted in:

- Money Savings by offering a great potential for cost savings over existing networking and collaborative technologies.
- Time Saving: The timely implementation of a collaborative application is faster using Intranet techniques.
- Standardization of Data Access: The availability of web browsers on every major operating platform is making it possible to provide high impact graphics access to all users, regardless of their platform. By using the HTML coding, which is a common standard, collaboration is easier within such environments. TCP/IP protocols provide the means to transmit such uniform data to large number of dissimilar platforms.
- Wide area communications: Web-based Intranets are ideal for developing corporate communications among geographically dispersed locations.
- Improvement of the information flow from/to the University.

The target of the project is a pool of advanced services focused on the user needs for effective information retrieval and spreading, and the use of alternative education tools. An extensive statistical process on a per service basis shows the network use and utilization and reveals potential modifications for improving the Intranet network structure and its services.

E-commerce Across International Borders: A Personal Experience

Christos J. Georgiou
IBM T.J. Watson Research Center
P.O. Box 218, Yorktown Heights, NY 10598, USA
geor@watson.ibm.com

Abstract: E-commerce has gone beyond the stage of discussion and it is now being broadly implemented. Within the past year, a large number of companies in the US have become e-commerce enabled. Furthermore, a lot of networking infrastructure exists worldwide which makes possible the easy access of e-commerce services in the US from abroad. This paper presents an experiment in international telecommuting via the Internet. It discusses the current state of e-commerce solutions and Internet communications, and points out areas where improvements could be made.

1. Introduction

In the past few years, the use of the Internet has gained widespread popularity. According to a particular market survey, by mid-1998 there were 100 million Internet users worldwide [CommerceNet 1997]. The Internet is a global phenomenon that eliminates international borders. A user in New York City can access an Internet server located around the corner in the same city or across the planet in New Zealand in a matter of seconds without knowing (or really caring) where it actually is. This is the real power of the Internet: it can shrink the globe down to the size of a computer keyboard, making everything reachable in just a few keystrokes.

Along with the big growth of the Internet users, electronic commerce (e-commerce) has also begun gaining momentum, as a large number of companies have espoused this new paradigm of doing business. The belief is that e-commerce will improve overall profitability by increasing productivity and market penetration while reducing operating costs. As a result, e-commerce has evolved beyond a concept on the drawing board into a reality that can now affect the everyday life of each one of us.

The term electronic commerce has different meaning among different people. Some interpret it as a fully or almost fully digital commercial activity. Others prefer to view it as a traditional commercial activity supported more or less by electronic technology. We suggest that e-commerce encompasses both of the above. The commercial activity can be between businesses, between businesses and consumers, between businesses and government agencies, and between citizens and government agencies.

Of the 100 million current Internet users, more than half (i.e., 58 million) reside in the US and Canada [CommerceNet 1997]. The popularity of e-commerce seems to be much higher in this region of the world, as well. However, the vision of an electronically interconnected world where e-commerce is going to see explosive growth across international borders assumes a global adoption of e-commerce not only by the consumers of the highly industrialized nations of North America but also of Europe and many of the developing nations.

Most users of the Internet have communicated via e-mail and many have telecommuted or engaged in some form of e-commerce such as online banking, buying or selling stocks, purchasing books, placing an ad, and so forth. But how many have considered depending entirely on the Internet for an extended period of time to take care of all work related functions and every day personal business?

I have been a researcher at the IBM T.J. Watson Research Center, Yorktown Heights, New York, where for the past three years I have had the responsibility of managing a number of research activities in the highly competitive area of microprocessors. A department reorganization at the end of the year opened a window of opportunity for me to take a sabbatical leave for a few months and explore something different. I decided to go to the National Technical University in Athens, Greece, where my family and I could also spend some time close to relatives, and look into the subject of e-commerce.

While away, I did not shed all of my managerial responsibilities. There were a couple of projects I was particularly interested in and I suggested to the department director to continue managing these projects in a form of telecommuting via the Internet from 5,000 miles away, which he accepted. In addition, I wanted to find out how far I could go with the current state of e-commerce. The question that I wanted to answer was whether it would be possible to do via the Internet from far away all the mundane but necessary things that everyday life in a civilized world imposes upon us, such as manage bank accounts, keep track of credit cards, pay house bills, etc. My goal was to take care of all company and family business back in the US via the Internet, as if I was still physically there.

Armed with an IBM Thinkpad 760E laptop computer and with a lot of hope and excitement about the trip and the experiment, and admittedly with some fear in my heart that I might be betrayed by my overdependence on the use of high technology, I set out on this journey of exploration of the cyberspace capabilities, accompanied by my wife and baby child.

2. Preparations Before the Trip

My first concern was to make sure that I had the software needed to communicate over the Internet properly setup before the trip. My Windows 95 computer was loaded with some key software packages:

- Lotus Notes for sending and receiving e-mail, and accessing project and other internal company databases.
- Intuit's Quicken 98 for keeping track of finances, doing online banking, paying bills, making fund transfers between accounts, and keeping track of my stock portfolio.
- Netscape Communicator, for general Internet access.

These three packages contain 128-bit RSA encryption and are not allowed for export outside the US and Canada. However, government regulations allow American citizens to legally take them abroad and use them for one year, once they are installed in their personal computer.

My second concern was to ensure that I was setup for electronically accessing my various financial accounts so that I could monitor each account's activity. In the absence of the Internet, an old fashioned way would have been to change my mailing address and receive statements via regular mail -in this case surface mail- which usually takes one to two months to arrive, an unacceptably long period. In addition, it did not make much sense to do this for only a five-month period, and then have to change addresses again. Another old-fashioned way would have been to have an entrusted friend receive my mail, sort it out, and then send it to me via airmail. Again, that would have been an error prone and more expensive process with longer delays than direct access via the Internet and, more importantly, a burden on my good friend. So, I requested that my mail be forwarded to a P.O. Box I rent at my neighborhood Post Office, and did the following:

- My salary was electronically deposited into my bank account and corresponding statements were sent to me via e-mail on Lotus Notes.
- I had already made arrangements with Chase Bank for online banking via the Quicken software. This process took place over a period of a few months and required the set up of accounts, installing the software, and debugging the process. It involved making phone calls to Chase customer service and receiving passwords over the mail. Once I got everything to work properly, making a money transfer or writing a check over the Internet became trivially simple.
- I made arrangements by calling the Chase customer service so that I could download my Visa credit card transactions via Quicken. Transactions were usually available for downloading two to three days after they were sent to the Visa clearing house by the merchant, thus giving me a timely update of the use of the card and remaining balance.
- I also made arrangements with AT&T Universal Card to download my MasterCard statement over the Internet. This was a different process than the Chase setup. The Internet access setup was done directly from the web site www.att.com/ucs. I entered my card number and chose a user id. A few days later, a password arrived via the US mail to my home address. This setup allowed the downloading of the account statement, which was posted once a month.

Of the other preparations for the trip, an interesting experience was my efforts to sell the older of our two cars, a Toyota Celica, via the Internet. I just happened to hear in a TV news show that *www.autoweb.com* was becoming very popular with the public for trading used cars, so I decided to place an ad myself. It was a very easy thing to do. I visited the site, supplied the car information along with the desired selling price, my name and phone number, e-mail address, and an access code to use when I wanted to make changes to the ad, and submitted the request. For payment (\$19.95) I entered my credit card information. A few minutes later I received an e-mail message confirming the submission of the ad and the ad number.

The ad was active for a month. During the first two weeks, I did not receive any phone calls, so I visited the web site, entered the ad number and password and changed the selling price to a lower one. This time I received a couple of e-mail messages and a few phone calls, one of which was from a fellow in Endicott, New York, a good four-hour drive away. He seemed very interested in the car but wanted a picture of it to show it to his wife before driving all this distance to take a look at it in person. I promised I would send him one via e-mail.

I did not have a digital camera but I used, instead, my videocamera and Snappy, a video snapshot device, and generated a picture in JPEG format which I sent via e-mail from Netscape Communicator as an attachment file. My prospective customer received the e-mail but could not see the picture. I thought something must have gone wrong with the transmission, so I e-mailed it for a second time, again with the same results. I even converted the picture into an ASCII file using the UNIX program *uuencode* and sent it as a regular data file but that didn't help either. I was getting frustrated that I was going to lose my customer because of an unexplained problem in this complex communications software when, the following day, he called to tell me that the problem was solved. The culprit turned out to be a missing driver in his Windows-95 system. A friend of his discovered the problem and promptly solved it by installing the driver. After that, he was able to receive the picture and, most importantly, he told me that he was still interested in the car. But the next day, he called to say that his wife did not like the car and that they were going to pursue other alternatives.

Time was running out, so we decided not to sell the car and leave it in the garage. Since we were not going to use it for a while we thought that we could save some money by discontinuing the insurance coverage. A visit at the New York State's Department of Motor Vehicles (DMV) web page *www.nydmv.state.ny.us*, gave us good instructions on what to do. We could temporarily discontinue the insurance coverage but had to return the license plates to the DMV, which we promptly did.

Other preparations that were done via the Internet included:

- I needed to have my passport renewed. I found all the needed information along with application form at *www.state.gov*
- I made reservations for a car in Athens using *www.hertz.com*. This service was available for #1 Club members. After visiting the site, I only needed to enter my account number and details about the date, place, and type of rental car.

3. Living and Working 5,000 Miles From Home Base

Once we arrived in Athens, connecting to the Internet was very simple. First, I obtained a small cable adapter for the 220V power wall socket, which is a different type in Greece than in the US. The AC power adapter of the laptop automatically detected the voltage of the power source (i.e., 220V vs. the 110V used in the US) so I did not have to use an additional transformer. Then, I used the local dial-up number for IBM's Global Network (IGN) and connected to the Internet at 28.8 Kbaud without any problem. I also had Internet access from a workstation in my office at the University, which was LAN connected (via Ethernet) to the University's backbone network.

Greece has significant networking infrastructure that provides international connectivity. There is the academic network GRNet, funded jointly by the European Union (EU) and the Greek government, that connects universities, technological institutes, and government research centers. The backbone network connecting three major Greek cities (Athens, Thessaloniki, Iraklion) operates at 34 Mb/s. International connectivity is provided via a 10 Mb/s leased line (recently upgraded to 34 Mb/s). In the private sector, there are at least 7 Internet service providers (ISPs), one of which is IGN, and competition is fierce. As a result, monthly access fees are kept low (between US \$15-\$20).

The number of the Internet users in Greece has been quite small, despite the excellent networking infrastructure. As of spring 1998, the total number of the Internet users was estimated at 70,000, of which around 30,000 had accounts with commercial ISPs and the rest were at academic institutions [Maglaris 1998]. Thus, less than 1% of the

Greek population has had Internet access. This number is significantly below the European Union average (7% of the population) [CommerceNet 1997]. The currently low levels of the Internet use in Greece are not due exclusively to lack of personal computers (estimates as of 2 years ago place the number of PCs in Greece at about 500,000 or 5% of the population [ETD 1998]) but, instead, appear to be the result of educational and cultural reasons, as discussed in detail in [Georgiou 1998]. The current state of e-commerce in Greece is not any different from the low levels of the Internet use. The concepts of e-commerce are relatively well known to the academic community primarily because of EU funded initiatives, such as research projects, workshops, and presentations, but currently there are few local businesses with web sites supporting e-commerce. However, because of the global nature of the Internet, one can easily engage in e-commerce activities across international borders.

During my stay in Athens I was in constant contact with the office via my Thinkpad and IGN. I used the replicate mode in Lotus Notes that allowed me to download my mail, disconnect from the network, prepare responses, and then reconnect to the network to upload them for delivery. While connected to the network, I would also access accounting and purchase order approval software on mainframe computers in the US. Thus, I was able to do all the usual managerial things that project management entails, such as:

- Communicate via e-mail with the people reporting to me and with my own manager to direct project activities.
- Approve travel expense accounts and purchase orders.
- Give salary raises via e-mail. This is customarily done in person but under the circumstances I had to do it with the exchange of messages. I was glad to find out that it was equally appreciated.
- Work with the accounting department to determine budgets.
- Use the Internet to find information so that I could respond to technical questions.

Carrying out these activities electronically seemed like a natural thing to do because I used to do most of them in the same way at Yorktown Heights. What was missing at times, however, was a face-to-face discussion. A solution, here, would have been the use of videoconferencing but that would have required a high-speed network connection (e.g., ISDN line), as well as hardware (video camera, high-speed modem) and software installed both in my Thinkpad and at my colleagues' workstations. While this was possible to do, the complexity and expense of such an approach (considering that we were on different continents) quickly put any further thoughts to rest.

The communications with my home base seemed to be going on quite smoothly, except for a few minor problems:

- A digital certificate used for security purposes in my Lotus Notes account expired and I did not know where to send the request for recertification.
- While changing my password for accessing a mainframe system I lost the network connection and then I was not sure of which password to use. After a few unsuccessful tries the system locked me out and I had to contact the system administrator to be readmitted.

In both cases an e-mail message to the department secretary requesting her assistance provided a quick solution to the problem.

On the personal communications front, things did not go as smoothly. The bulk of my electronic activities took place via Quicken and my online banking accounts. I would regularly check to see the account activity and make necessary payments. Transferring funds between accounts was just as easy. It was a great thing, I thought, to be able to take care of all my financial matters in New York from so far away, as if I was there in person. Two transactions that would not have been possible just a few months earlier were the following:

- I would visit the web site of Con Edison, www.coned.com, the utilities company in the New York area, enter my account number and see the electric bill due. Then I would send in a payment order via Quicken and my bank checking account.
- I would visit the web site of my auto insurance company, www.geico.com, enter the policy number, find the new car insurance premium and likewise make a payment.

One problem that came up was that all of a sudden I stopped receiving credit card activity from Chase. I sent an e-mail message to the online banking customer service who began looking into the problem. However, after

many e-mail message exchanges the problem was not solved. Since I needed to know the balance due in order to send in a payment, the online banking customer service told me that I could get this information by calling the bank's 800 number for credit card transactions.

Calling 800 numbers from outside the US is not straight forward. The 800 service is designed so that call charges are paid by the called party and not the caller. This applies only to phone calls made from within the US or Canada. Furthermore, 800 numbers cannot be directly called from abroad. One has to go via the operator and this is usually a much more expensive phone call than a direct dial. Since most companies in the US provide access to their customer service via 800 numbers, I began exploring other possibilities via the Internet.

I tried using *net2phone*, an Internet phone program from www.net2phone.com that provides free 800 calls to the US from anywhere in the world, but I could not get it to work behind the firewall from my IGN connection. I tried the same from my workstation at the University but the connection was coming in with many interruptions that made it practically unusable, despite the high-speed lines connecting the country to the rest of Europe. I was told that the problem was most likely due to the fact that the European academic network connects to the US via a few 45 Mb/s lines, which, as one might expect, can become easily congested, thus introducing delays in the flow of the audio bit-stream.

The due date for the credit card payment was approaching fast and since I did not want to miss it, I was ready to surrender to the old-fashioned ways of operator assisted phone calls. But, quite unexpectedly, I was able to solve the problem on my own. It was a simple but tricky one, similar in nature to the year-2000 problem. It had to do with a change in my credit card account number that was scheduled in the bank's computer many months earlier.

After the merger of Chase bank with Chemical, new credit cards were issued to Chemical's customers but in the computer files the old account number was kept active for some period of time. My Quicken register entry had the old account number and, of course, everything worked fine until the change to the new number took place. Apparently, this change was not known to the support people at the online customer service who believed that I should continue using the old number, something that they had specifically told me to do. But then I remembered a conversation I had with bank personnel when the merger took place, that the old numbers were going to be deleted at some point in time. So, I entered the new account number, the problem was corrected, and I was able to download all the missing information.

Another problem that came up towards the end of my trip was that, all of a sudden, when I tried to log into my AT&T Universal card account at www.att.com/ucs, I was not allowed access but, instead, would receive the message: "*We've had a problem processing your request. You must first register, then activate an existing account before using this feature.*" This was a total mystery to me because everything had worked fine for many months. Re-registering was out of the question, as I would have to receive the password via the US mail at my home address. So, I decided to investigate this problem upon my return to the US.

It turned out that the problem was caused by the Post Office. When I forwarded my mail to the P.O. Box I was told that they would keep it there until I returned. But the P.O. Box overflowed and, after a month, they began returning the mail to the sender. When the credit card company saw that there was a problem with my mailing address, they froze the online access to my account (but not the account itself).

On the positive side, a problem that I always feared could happen but fortunately never did was catastrophic equipment failure (e.g., hard disk drive failure) or theft. Before leaving for the trip I made backups of all key Lotus Notes and Quicken files. But if any of the above happened, I would have had to find a way to replace the hardware, reinstall all the software and bring my system up to the most recently used state. I considered a tape backup, but that would have added up weight to the equipment I was carrying. Also using a backup tape to recreate from scratch an old system on a new computer seldom works 100% because of the different configuration files of the two systems. In other words, that would have been a nightmare that I was lucky enough to have avoided.

4. Lessons Learned

In the beginning of September my sabbatical leave was over and it was time to take the return flight back to New York. The experiment that I wanted to run when I set out on this trip to Greece was to see whether it was possible to take care of all company and family business back in the US via the Internet, as if I was still physically there. Without any question, I feel that the experiment turned out to be quite successful.

The experience that I had has shown that e-commerce has now gone beyond the stage of discussion and is being broadly implemented. Within the past year, a large number of companies in the US have become e-commerce enabled. Furthermore, a lot of networking infrastructure exists worldwide which makes the concept of international telecommuting a reality. Improvements in two areas of Internet communications, such as videoconferencing to the laptop (or desktop) and more useable Internet phone service could result in better person-to-person interactions when exchanges between humans are needed. Both would be greatly helped by higher bandwidth and better quality of service in Internet networks.

Two of the potentially biggest obstacles to the broad acceptance of e-commerce by the general public (and not only those technologically inclined) were highlighted by problems I had, i.e., one with the Internet delivery of the car photo and the other with the downloading of the credit card transactions. These are:

Complexity of current personal computer software and hardware. This is a problem that has been widely discussed and attempts are being made to solve it by various approaches (for example, development of Java-based network computers, and others). The device that carries out e-commerce transactions must have the same ease of use that the telephone or the television set currently have. In either case, the device has a simple user interface and it always works, for all practical purposes, without any delay. Of course, these technologies have been refined over a much longer period of time than the personal computer and Internet technologies. It is not, therefore, accidental, that they have reached a level of usability that has made them ubiquitous.

Poor end-to-end diagnostics and lack of feedback for problem determination. Carrying out an e-commerce transaction is a very complex operation that involves multiple computer systems, communications networks, and large application programs. When everything works fine, a transaction can be successfully completed. If, on the other hand, something goes wrong, it is very difficult to find out where the problem lies. For example, in the case of the credit card account change, the system could have come back with at least an error response of the type "Incorrect credit card account number received at the bank." Instead, there was no error indication whatsoever; only missing transaction data. This made any attempts at problem determination very difficult. What is needed is to have sophisticated diagnostics software at every stage of the transaction path. An expert system can then process the information extracted and present it to the end-user in an easily comprehensible way.

5. Summary

This paper presented an experiment in international telecommuting, in which all work-related and household matters in the US were taken care of by the author via the Internet while living in Europe. This was made possible by the rapid adoption of e-commerce by a large number of companies in the US and the Internet infrastructure that is available around the world. While the current state of e-commerce allowed this experiment to be quite successful, improvements are needed if we expect to see large numbers of consumers confidently attempt to depend so heavily on the use of these new technologies.

Abstract: The University of Hawaii at Hilo, on the Big Island, offers a B.S. in computer science to students on other islands in the state where a four-year institution is not available. This paper described the planning for this program and the first year experience in its delivery. Care was taken to use the Web to support course delivery in ways that exploit unique capabilities the web offers that are not so easily duplicated on the ordinary printed page. Outcomes, both objective and subjective, are discussed.

Introduction

The state University system of Hawaii includes a research-level campus on the island of Oahu near the state capital of Honolulu, the regional comprehensive University of Hawaii at Hilo campus on the Big Island of Hawaii, a two-year upper-division campus at West Oahu, and seven community colleges scattered throughout the state. The islands of Maui and Kauai are served by community colleges but no four-year institutions, and the rapidly growing West Hawaii area is 100 miles away from Hilo.

Within the past two years, community colleges at Maui and Kauai and West Hawaii have been empowered as University Centers. This gives them the authority to broker selected four-year degree programs or even graduate degree programs for which there is a demonstrated need. The University Centers may "contract" with any institution of higher education to deliver these programs.

The University Center at Maui has contracted with the University of Hawaii at Hilo to deliver a B.S. degree in computer science using a variety of educational technologies, including the World Wide Web. This paper discusses the planning and preparations leading up to this agreement, the experiences delivering the first year of the degree program, and the educational issues involved.

Planning

Once an initial "market interest" had been established for an undergraduate computer science degree, a long period of negotiation ensued to iron out many of the administrative details such as scheduling, delivery mechanisms, counseling, faculty workload, on-site responsibilities, etc. This was the first such program brokered through the University Center and was breaking new ground, so each of these questions, while seemingly routine, had to be addressed.

The following list indicates how these sorts of questions were ultimately resolved.

- Students apply to the B.S. in computer science degree program at UH-Hilo; if accepted, they become UH-Hilo students and pay UH-Hilo tuition.

- Students without a previous degree must complete the equivalent of an AA degree at the local community college. This satisfies the general education requirements for the degree (English, speech, humanities, and social sciences.)
- Students take the special supporting courses required for the degree at the community college (one semester of technical writing, one year of calculus, one year of physics, one year of chemistry). Calculus is prerequisite to admission, but the sciences may be taken later.
- Students complete the first year of computer science at the community college.
- UH-Hilo is responsible for delivering the computer science courses for years 2, 3, and 4, plus the three upper-division mathematics courses required for the degree.
- All courses are designed to duplicate, as much as possible, the on-campus educational experience as far as the content covered, the software and computing platforms used, what is required of the students, and the activities in which they engage.
- All courses are offered on an evening or weekend schedule to accommodate working students.
- Courses are part of the regular faculty workload, that is, a distance ed section counts for one course the faculty member teaches, just as an on-campus section does.
- Courses are scheduled as much as possible so that a faculty member teaching a distance ed section has an on-campus section of the same course at the same time.
- Courses are scheduled so that a student can complete the degree program in four years, including summers.
- The University Center staff is responsible for marketing the program, screening potential applicants, and providing on-site general counseling.
- The University Center/community college is responsible for providing, within reason, necessary computing laboratories and software to support the courses.
- The University Center/community college staff is responsible for handling any physical mailings between the two campus locations, i.e., collecting or distributing hard copy of any materials, exams, etc., as well as for monitoring on-site exams.
- The community college staff is responsible for on-site TV transmission.
- UH-Hilo is responsible for TV transmission in support of instruction.
- UH-Hilo is responsible for handling registration, maintaining student records, and providing academic counseling.
- A grant from Maui County, through the University Center, provided funding for faculty release time in preparation for teaching in a distance education mode and a multimedia center to produce web-based materials.

Table 1 shows the four-year course rotation agreed upon.

	Fall	Spring	Summer
Year 1	Discrete Math	Data Structures	Linear Algebra
Year 2	Computer Organization, File Management	Computer Networks, Database Design	Probability & Statistics
Year 3	Software Engr. I, Formal Lang. & Automata Theory	Software Engr. II, Programming Languages, Professionalism	Numerical Analysis
Year 4	Operating Systems, CS Elective	Computer Architecture, CS Elective	

Table 1: Course Rotation

The First Year

The first cohort of students was admitted in Fall, 1998. The majority of the students (19) were on Maui, and a small group (3) were on Oahu. During the academic year 1998-99, Discrete Mathematics and Data Structures were taught to these students via distance education from UH-Hilo.

A combination of interactive television and on-line, web-based instruction was used as the vehicle for delivering these courses. In addition, the instructor made several visits to the two distance ed locations to meet with students. The interactive television component used HITS, the Hawai'i Interactive Television System, for a class session every Monday evening from 7-9:45 PM. The web-based component used WebCT, a password-protected web-based teaching environment developed at the University of British Columbia. The instructor's original inclination to use entirely web-based instruction was discarded based on experience as an auditor in a 100% web-based course; it is too easy for students to fall into an "out-of-sight, out-of-mind" mindset when there are no regular checkpoints. Attendance at the HITS sessions was not required, but the students seldom missed this opportunity for face-to-face interaction. The TV sessions are recorded, and the tapes are also available for students to review later.

A brief description of each of these two courses will help clarify choices made in the use of these two technologies.

The discrete mathematics course is, indeed, a mathematics course, although laced with applications for computer science. The course is heavily based on problem solving, with students working in collaborative groups to develop and present problem solutions, and to critique the solutions of other groups. The advantage to this being the first course taught in this distance education degree program was that it is not a programming course, so the issues of hardware platforms, programming language, and software availability were postponed. However, there were disadvantages. First, this is one of our most difficult courses, and to hit these students right out of the box, so to speak, with both a very difficult course and an introduction to distance education all at once was a bit harsh. Second, as a mathematics course, there were problems with notation. While we all coped with questions and answers on text-based e-mail by inventing shorthand for various mathematical notation, I required Word documents to be submitted for homework, where the Symbol font covered most of what we needed to use.

The data structures course covers algorithms for searching, sorting, hashing, data compression, and graph algorithms, with a heavy emphasis on analysis of the efficiency of various algorithms. Work in the course is heavily programming-based. Assignments require experiments to measure algorithm behavior on test sets of data and reports on the results as compared with those predicted by the theoretical analyses we develop in class. This introduced issues of programming language and compiler availability. While students had completed one year of programming at the community college, their language was Java, while this course was taught in C++. The instructor had been contemplating teaching the course in Java, but one of the students, pressing this point, argued "We've already had a year of Java, if we work for four more years we'll really get to be expert in that one language and stand a better chance of competing in the job market." This had precisely the opposite effect from what the student intended, as we believe our degree program is designed to, among other things, give the students the intellectual tools to cope with any programming language that comes down the pike. Hence, the course was taught in C++, with a heavy language review at the beginning of the semester.

The HITS system has been used for distance education in the state for some years. The instructor assumed that this would be a tried-and-true technology with little cause for concern, whereas WebCT, a new technology, might be the more problematic medium. The opposite turned out to be true. HITS had previously been used for delivering lecture-based courses from site A to site B, with possibly one or two student questions at the end. In the mode we were using HITS, the instructor was at site A, students were at sites B and C, and the classroom sessions, particularly in the discrete math course, consisted primarily of problem presentations and solution discussions. A student on Maui presented a solution, a student on Oahu had a question or an alternate solution, the instructor had a comment, etc. Transmission was emanating from three sites, and all transmissions went to a fourth "master control" site on Oahu that was responsible for controlling which transmission all sites were receiving. Because of the interactive nature of the class, the master control site had to constantly monitor the transmission and make the necessary signal switching go quickly and smoothly. The quality of this service varied greatly, depending on the individual at master control. Indeed, one of the frustrations of the HITS component was that the instructor had to rely on the capabilities of so many technical people (at four different sites) and the fact that down-time in any of the equipment (or individuals) left the synchronous classroom session at risk.

WebCT proved to be a reliable and extremely useful environment for on-line course support. It provides a number of features, including bulletin board discussion groups, private e-mail, a testing capability (not used for

these courses), a grade management system, the ability to post HTML content pages, a chat room, and an electronic whiteboard. (There is also an on-line HTML editing capability in WebCT, but it is a rather cramped environment in which to work. It is much more satisfactory to develop the web pages elsewhere and then port them to WebCT.) These capabilities are wrapped in an easy-to-use shell wherein the instructor can upload files, arrange icons with links to content pages, set up forums for discussion within the bulletin board, attach files to e-mail or bulletin board postings, etc.

For both courses, the bulletin board and e-mail in WebCT (as well as "traditional" e-mail) provided a vital communications link between students and instructor. Particularly in the discrete math course, where the students worked in collaborative groups, the bulletin board - with a private forum for each group - was the basis for their collaboration. In both classes, the bulletin board provided a location for updates, questions and answers, and "are we meeting for a study session Saturday" postings. The chat room, which was regularly scheduled with the instructor for two hours every Thursday evening, also allowed some extremely lively and useful technical discussions. These communications served the place of the more frequent classroom meetings and the conversations in the instructor's office of the on-campus versions of the courses. Support for asynchronous communications among students, and between students and instructor, seems to be one of the most important components of any on-line distance education course. If this were the only part "the web" played in these two courses, it would still have been crucial.

Communication is pointless, however, without course content. Each class used a traditional textbook, which students were expected to read. For the on-line course content pages, then, there was no point in merely repeating sections of the text. The course content pages were primarily used for two purposes. One was to give the "value added" viewpoint that the instructor presumes to present over and above that which is in the textbook. As in a classroom setting, the instructor does not merely regurgitate the text to the students, but provides a larger context, relates new topics to what has gone before (or to other courses), fills in troublesome details omitted from the text, or gives alternative examples or explanations. However, this information, although it was posted as web pages, could have been delivered to students as a hard-copy handout, which would probably have been easier to read. The second use of the course content pages was intended to exploit capabilities the web offers that are not so easily duplicated on the ordinary printed page.

In the discrete math course, the course content pages consisted primarily of typical problem solutions. For each type of problem that the students were expected to learn how to solve, a typical problem statement was given (a different problem from any in their text). Succeeding pages developed the solution, much as the student would be expected to write it. As the student navigates the pages, the solution unfolds step-by-step. However, a compressed audio file was also part of each web page after the initial problem statement. The audio file contained a first-person stream-of-consciousness thought process about that step of the solution - why it occurred to the narrator to try this, why it looked promising, what knowledge was being called upon to suggest that this should come next, etc. The point is, students see perfect and complete worked-out proofs in the textbook, and often see them performed by the instructor. Yet when a student goes home and tries to produce such a solution by himself or herself, he or she is unsure where to start or how to think about the problem or how to see any pattern to enable a guess as to what to do next. Consequently the student gives up in frustration. The purpose of the audio narration is to share the "secret picture" that mathematicians use to solve problems. Several of the audio files even start the narrator down a dead end, recognize the dead end, and back up to start again. In a poll at the end of the semester, students rated these content pages the most helpful feature of the web site.

In the data structures course, students have to understand how various algorithms work. Simple gif animations that students access by links from the content pages illustrate algorithms at work on small data sets. This visualization capability is very important in talking about algorithms, and the gif animations are the natural successor to the sequenced overhead transparencies or PowerPoint slides of previous years. The animations are also features that the students love. Static graphics were also incorporated into web pages via electronic pen software that works on a graphics tablet.

Lessons Learned

Academic Outcomes

The distance education discrete math and data structures courses both had tests, homework, and programming assignments identical to what was given in the on-campus sections. As a "control group," the on-campus discrete math course in the first semester had no access to the web-based course materials. The outcomes as far as the overall average grade is concerned were virtually the same. Table 2 shows the first semester grades. The on-

campus class had greater variation in arriving at the final average, scoring higher on the homework but lower on the tests than the distance ed group.

Grade	On-Campus	Distance Ed
A	2	4
A-	0	1
B	4	3
B-	1	5
C	10	5
D	4	2
F	0	2
Semester Average	76	77

Table 2: Comparison of Grades

It is certainly possible, then, for a distance ed course to achieve levels of student performance comparable to those of a traditional class. If the grades in a course are indeed indicative of student learning, then we may say that the students in the distance ed program are "learning as much" as the on-campus group. But there are other, more subjective evaluations to the success of a course.

Student Opinions

The distance ed students were initially overwhelmed both by the course material and its level of difficulty, and by the fact that no instructor was physically present on their campus. As a result, the students engaged in a "negotiating mentality" for much of the first semester: Won't you do this for us, won't you do that for us, won't you give us extra credit work, won't you drop our lowest grade, won't you come over and visit every weekend, won't you increase the chat line with us to 4 hours per week instead of 2, ... Once the students gained more confidence with this learning mode and realized that the instructor was going to hold the line at a reasonable level of accommodation, a better working mode developed.

A survey administered at the end of the discrete structures course asked both on-campus students and distance ed students to give information on their academic background (do they already have another degree, for example), the number of hours they worked, the number of hours they studied, their expectations of the course beforehand, and their evaluation of the course afterwards. As expected, the distance ed students generally worked more hours and were taking fewer classes. Surprisingly, they also spent more hours per week studying for this class. They had less idea beforehand what to expect of the course (not being privy to campus gossip), but seemed equally satisfied with the course once it was over. Some expressed the opinion that a face-to-face course would have been preferable but they recognized that such a course was not available, and found this an acceptable alternative. Students expressed particular appreciation for the audio file pages in the course content on WebCT.

Instructor Opinion

The instructor shared the student view that a face-to-face class would be preferable. After all, college faculty teach because they love to teach, and personal interaction - particularly the ability to see the "Aha" moment in a student's eyes - is a large part of that. An "OK, I see it now" on the chat line or over a bulletin board doesn't carry quite the same thrill. However, these alternative forms of interaction lend themselves to an informality that may not exist in a classroom setting. And, again, when there is no alternative, a distance ed class comes to the rescue.

The challenge is to learn how to create educational experiences and materials to really make use of the new capabilities of the web. This seems particularly difficult in a technical course where the course content is more sequential in nature and it's not appropriate to assign students some research paper where they run off and search the web for lots of material or engage in on-line debate about points of view.

The instructor had been to a number of workshops and presentations on distance education, where all the presenters said the same things: it takes lots of time to develop course materials, you must have help in putting things together, you will spend a lot of time interacting with students via e-mail and bulletin boards, etc. Even forewarned, it was still astonishing the amount of time required to prepare for and manage these courses. An estimate of instructor time on various kinds of activities for the first semester appears in Table 3.

Activity	Time Estimate hours/week
Actual student contact hours (HITS plus chat room)	5
Answering e-mail questions, monitoring bulletin board	10
File management	5
Grading	12
Slide preparation	6
Course content pages	15
Total	53

Table 3: Distribution of Instructor Time

In addition, a student helper spent about 6 hours per week recording the audio files from the instructor's scripts and posting the results to the WebCT site.

This is a serious investment of instructor time, which may be amortized over future offerings of the course. The last two items in Table 3 should require much less time commitment as they will be revisions rather than original work.

Conclusion

The distance education B.S. in computer science offered by the University of Hawaii at Hilo seems to be off to a good start. It is clear that if both the instructor and the students are willing to make the effort, these students can succeed at the same rate as an on-campus class. It is gratifying to think that we are providing them with an opportunity for higher education they would otherwise not have at all. We hope to attract a second cohort of students for fall 2000 to start another rotation of courses.

Hawai'i was, after all, the originating site for one of the earliest network communication protocols (the ALOHA protocol for packet radio transmission between islands developed at the University of Hawaii in 1971). It seems only fitting that education via the web and other technologies should carry on this tradition.

Arthur: Adapting Instruction to Accommodate Learning Style

Abstract: The theory of learning styles states that people have different approaches to learning and studying (Dunn 1987 & Dunn 1978). Given a specific instruction method or environment, some people will learn more effectively than others due to their individual learning style and the grade distribution of the learning would be bell shaped, with the majority of the learners appearing in the middle of the distribution curve. Several studies show that there is "No Significant Difference" when technology is applied to instruction (Russell 1999), since either in traditional classrooms or in any of the technological environments, there is only one form of instruction, and usually from one source, yielding the familiar bell shaped grade distribution. This explains the "No Significant Difference" results and indicates that another instruction method needs to be investigated. An approach to achieve "A Significant Difference" is to provide several different instruction methods. This paper describes Arthur, which is a Web-based instruction system that provides adaptive instruction to achieve "A Significant Difference".

Introduction

Learning styles are approaches to learning and studying (Dunn 1987). We all have learning preferences, which enable us to learn more effectively. When introduced into a learning environment that supports our learning style(s), learners have a higher level of understanding the material. The learning styles theory implies that how much individuals learn has more to do with whether the educational experience is geared toward their particular style of learning. In a traditional classroom environment, there is one instructor and several learners, which is an one-to-many relationship. The instructor presents information with his/her personal style of instruction. The instructor may use technology such as overhead slides, computer animations, videos, or simply chalk and talk lectures. If the instructor's style of instruction is conducive with the majority of the learner's learning style, then the class as a whole will perform well. In the general case, the instructor's style is conducive with most of the learner's, but not a perfect match. In this case, the majority of the class will have an average performance with fewer people doing either very well or very bad, which establishes a bell shaped grade distribution.

There are several different learning styles and combinations of styles. Sarasin (1998) discusses auditory, visual, and tactile learning styles. Inquiry-Based Learning (Pasch 1991), Discovery Learning (Bruner 1966), and Expository Teaching (Ausubel 1977) are just a few other learning styles. There are several other learning styles and instruction methods. In fact, learning styles or instruction methods can overlap or be used in combination with other methods. When considering all the possibilities of instruction, it becomes clear why there is a bell shaped grade distribution in the traditional classroom. It becomes an impossible task to accommodate everyone's learning style. Therefore, instructors generally use what works best for them and on the average, most people get it, yielding a bell shaped grade distribution.

In the tutoring environment there is one instructor and one learner, which is an one-to-one relationship. This environment would appear to be an improvement on the traditional classroom because of

the personalized attention. This may be so, but there is still the limitation of the tutor's ability to adapt to the learner's learning style. If the tutor can not adapt to the learner's learning style, then the learner does not gain very much of an advantage over the traditional classroom.

Imagine a classroom full of instructors and only one learner, which is a many-to-one relationship. Each instructor is an expert in the same field of study, but each uses a different style of instruction. Hence, the learner's chances of doing well in this classroom would appear to be significantly better than in a classroom with one instructor because each learner would adapt to the instructor(s) that would facilitate his/her learning style. In the sections that follow, we will introduce an implementation of the many-to-one relationship.

Arthur: Adapting Instruction to Accommodate Learning Style

We have developed a Web-based instruction system that provides adaptive instruction, Arthur (Gilbert 1999). Arthur takes several different styles of instruction from several different instructors and makes them available to each learner, which defines a many-to-one relationship. A group of instructors from the same field collaborate to create a course map, which is similar to a syllabus, for the course content. The course map is divided into small sections that are called concepts. A concept is a basic unit of instruction or a fundamental concept that must be covered within the course. In Figure 1, there are 3 instructors. Each instructor has their own course module, which is identified as a row. Each module utilizes a different form of instruction. For example, instructor Gilbert's module utilizes an audio based method of instruction. Notice that each instructor's module adheres to the same concept map, where concepts are represented as columns. Each module begins with concept 1 and ends with concept 4. Each cell in Figure 1 represents a concept which utilizes a different form of instruction. This information is added to Arthur via Web-based forms.

Figure 1: Concepts and Modules

Submitting Content

Instructors will add their course module to Arthur via several Web-based forms. Each instructor will deposit URLs that point to the first page associated with each concept within their module. Arthur will reference concepts via URLs submitted by the instructor. This will allow each instructor to maintain his/her own course materials on their own Web servers. Instructors will also add their personal information into Arthur as well. This includes their name, affiliation(s), email address, etc. Finally, the instructors will submit quiz questions that will appear at the end of each concept. The quiz questions appear in the form of multiple choice or written answer. Once instructors have submitted their course materials and quiz questions to Arthur, the system is ready for learner use.

Learning Experience

When a learner enters Arthur using a login and password, Arthur will deliver the first concept of one of the course modules from the instruction pool. The courses are initially selected at random. Therefore, each student will be assigned their first course module by chance. Each concept is terminated by a short evaluation quiz entered by the instructor. For example, John Smith logs into Arthur. John is assigned the first concept for Calculus 101 using an Auditory (Sarasin 1998) Expository Teaching (Ausubel 1977) style, which was developed by instructor Carl Gilbert. This style uses audio to present a general explanation of each concept followed by examples. When John completes the first concept, he will be given a short quiz. The quiz is delivered through the Web using Arthur. The quiz will be graded by the instructor, Carl Gilbert, or automatically by Arthur, i.e., multiple choice. Instructor Gilbert will be notified via email that a quiz has been taken. After notification, instructor Gilbert will log into Arthur where the quiz questions and answers will be presented. The learner's name, John Smith, is never revealed to instructor Gilbert only the question and answers. After grading the quiz, instructor Gilbert will report a score for the learner. The student must pass each section with a score of eighty percent or better in order to continue within the current course module. This evaluation method introduces the term *Mastery Learning*, which is used by Arthur to adapt the instruction style.

Adapting Instruction

Mastery Learning is based on the assumption that, given enough time and proper instruction, most students can master any learning objective (Bloom 1968 & Guskey 1986). The normal distribution of scores learners exhibit on any performance test arise from the use of one instruction style given by one instructor and the practice of holding instructional time constant for all students and allowing learning to vary. Bloom (1976) suggest that learning should be held constant and time allowed to vary. To use the mastery approach, an instructor must break a course down into small units of study, which correspond to concepts within Arthur. Each unit might involve mastering several specific concepts or objectives. Mastery usually means a score of 80 to 100 percent on a test or other assessment (Woolfolk 1998).

Arthur uses mastery learning to adapt instruction for each learner. When a learner completes a quiz at the end of a concept, Arthur employs mastery learning to adapt the instruction based upon the learner's score for each quiz. If the learner scores 80 percent or better, Arthur will allow the learner to move onto the next concept using the current course module. In the Calculus 101 example, assume John Smith passes the first concept of Carl Gilbert's course module with a score of 90 percent. Arthur will present John Smith with the second concept of instructor Gilbert's course module. John Smith scores a 70 percent on the quiz following the second concept. Arthur presents John Smith with the second concept of Frank Howard's Calculus 101 course module, which uses a different instruction style from Carl Gilbert's course module. Therefore, when learners pass the quiz at the end of a section, Arthur assumes that the instruction style used in that section matches the learner's learning style.

Learner Models using Case-Based Reasoning

When a learner successfully completes a course using Arthur, the system creates a learner model, which is a learning map, of the learner's learning experience. The learner model contains each concept that the learner passed and failed. In the cases where the learner failed the quiz at the end of a concept, Arthur

records the questions that the learner missed. The missed questions at the end of each quiz are used to classify future learners when adapting instruction. This type of classification is called *Cased-Based Reasoning*. In case-based reasoning new problems are solved by adapting or matching previously observed cases. A new problem is matched against cases in the case base and one or more similar cases are retrieved. A solution suggested by the matching cases is then reused (Reisbeck 1989 & Kolodner 1993).

For example, when John Smith completed Calculus 101, he failed the quiz following the second concept of instructor Carl Gilbert's module. John missed questions 1, 2, 4, 6, 7, 8 and 9, which are used to create a case base for John. Also, note that John was reassigned concept two under Frank Howard's Calculus 101 course module, which John passed with a score of ninety percent. Later, Chris Hudson logs into Arthur to take Calculus 101. He is assigned instructor Gilbert's course module. Chris passes concept one and fails concept two, just like John Smith. When Chris fails concept two, he misses questions 1, 2, 4, 6, 8 and 9, the same questions John Smith missed. Using the knowledge of the John Smith's case base, Arthur will classify Chris as a learner with a similar learning style as John Smith and reassign concept two to Chris using Frank Howard's course module. Because John Smith's case base for concept two is similar to Chris Hudson's new case base, Arthur assumes that Chris Hudson has a similar learning style to that of John Smith and assigns Chris an instruction method based on John Smith's case base. Classifying new learners is not the only purpose of the learner model.

The learner model is also used when previous learners return to Arthur to take a new, yet similar course. For example, if John Smith returns to Arthur to take Calculus 201, then Arthur uses John's learner model to assign John instruction methods. Given our previous examples, Arthur will assign John to instructor Frank Howard's course module because John performed best within this module compared to the other modules. If John does not perform well within instructor Howard's Calculus 201 course module, Arthur will use any previous Calculus 201 case bases to adapt instruction for John as necessary. Otherwise, Arthur will reassign concepts to John at random with an emphasis on instruction styles similar to that of instructor Frank Howard's, since John scored so well under Howard's Calculus 101 module.

The random selection of concepts within Arthur occurs when there are no previously stored case bases available for the current learner. Each course module is placed into a course module category: auditory, visual, tactile or text based. When a learner fails a quiz at the end of a concept, Arthur searches for a matching case base. If there is no matching case base available, Arthur will randomly select a new instruction method from a different course module category. The random selection of an instruction method from a different category will increase the chances that a match will be obtained. In the following sections, we will describe the system implementation of Arthur.

System Implementation

Client Side

Each learner will use Netscape Navigator 4.x or Internet Explorer 4.x to use Arthur. Once the learner goes to the Web site that hosts Arthur, the learner will be forced to authenticate using his/her pre-assigned login and password. The interface to Arthur uses a Java applet in a HTML frame to provide all the navigation information from the Web server. Special client side software requirements may be necessary for particular courses upon the demand of the instructor. For example, an instructor may require that the learner have a particular programming language installed on their computer in order to compile and test programs. Another instructor may require that the learner's computer have a particular database package or word processor. These requirements depend on the individual instructors and the tools needed to successfully complete their course.

Server Side

Arthur uses a complex knowledge base (Russel 1995) to store information and relationships on the learner, instructor, courses and the learner-instructor interactions. The knowledge base is stored in a SQL (Elmasri 1994) database on the Web server. The knowledge base consists of database tables that contain facts gathered by Arthur from the learner and instructor. It behaves as a repository of facts that can later be used during decision making, i.e. adapting instruction. The Java applet in the learner's Web browser communicates with the knowledge base through a Java socket process. This provides fast and platform

independent access to data in the knowledge repository. Arthur handles frequently asked questions using an implementation known as Intelligent FAQ.

Intelligent FAQ

Arthur will also make use of Intelligent FAQ, which is an information retrieval (Salton 1989) system used to answer frequently asked questions. When the learners are going through the course modules, questions will arise about the concept being learned. In order to answer those questions quickly and effectively, Arthur utilize Intelligent FAQ. Intelligent FAQ accepts a question from the learner and creates a query string as seen in information retrieval systems. The query string is created by removing the stop words (Britanica 1998) from the original question. After the stop words have been removed, each query string will be categorized. Arthur categorizes questions by concept and question type. Each question that is asked will be assigned a concept. In other words, the current working concept that the learner is actively pursuing will be the concept assigned to the question asked. The question types are what, when, where, why, how, define, who and other. Therefore, the query string is composed of a concept, question type and the question with the stop words removed. When a question appears for the first time, it is sent directly to the instructor via email. The instructor will log into Arthur and answer the question. Once the question has been answered, the learner will receive an email notification that an answer has been submitted. The learner will log into Arthur and pick up the answer to the question. Arthur will store the query string and answer in the knowledge base (Russell 1995) for later use. When a different learner asks a similar question, Arthur will retrieve the answer from the previously asked query string and answer stored in the knowledge base. Intelligent FAQ is being developed as part of Arthur, but can be used on any Web site.

Conclusions

The theory of learning styles states that people have different approaches to learning and studying (Dunn 1987 & Dunn 1978). Several studies show that there is "No Significant Difference" when technology is applied to instruction (Russell 1999). The most commonly used instruction environments use an one-to-many or one-to-one instructor/learner relationship. We have developed an environment that utilizes technology to deliver a many-to-one instructor/learner relationship. Before the recent use of technology, this type of education experience would have been too expensive to implement. Using the world wide Web and supporting technologies, we can deliver a many-to-one instructor/learner relationship such that individual learning styles can be accommodated.

Arthur will be initially tested using Physics 101 and CS 1, computer science programming with C++. It is expected that other domains will work as well. In the future, Arthur will add new domains of instruction. For example, the arts, sciences, languages, mathematics and other engineering disciplines will be added to Arthur. In the short term, Physics 101, which is currently being taught to various degree tracks, and CS 1 will be used to gather initial data results.

The IN-TELE Project: Developing Internet-Based Teaching and Learning in Europe

Guinevere Glasfurd, IN-TELE Centre, University of Essex, Wivenhoe Park, Colchester, Essex,
guin@essex.ac.uk

Anthony Vickers, University of Essex, Department of ESE, University of Essex, Wivenhoe Park, Colchester,
Essex, vicka@essex.ac.uk

Abstract: The IN-TELE project, funded by the European Commission, is a two-year research project running from January 1998 to December 1999. This article focuses upon the design and implementation of the IN-TELE Teacher-Training Course in 1998, and its further development by researchers at the University of Essex, UK in 1999. We discuss the key challenges of developing a teacher-training programme for use within four European contexts and discuss experiences and early outcomes. Although the project has worked with sixteen secondary schools in France, Germany, the UK and Sweden, IN-TELE aims to design Internet-based teaching and learning solutions which are generally applicable to 'average' schools throughout Europe.

1. Introduction

'Our solutions are developed for average schools, dealing with the problem of low budgets, the difficulty of lacking experience among teachers and authorities and the problem of teachers' serious fears of new technologies. [IN-TELE, 1997]

The use and availability of information communications technology (henceforth ICT) in European schools varies considerably between, and within, each of the member states, [1]. That ICT is increasingly on political, commercial and research agenda is apparent from the *Review of research and development in technologies for education and training 1994-1998*, [European Commission, 1998] which lists some eighty-six collaborative projects, involving twelve European member states, and five EFTA countries. Nonetheless, the pattern of development remains uneven, if exceedingly dynamic, varying between national provision, [2] to regional, local or even private initiatives [3].

The IN-TELE Project, is a collaborative research project involving three university-based research groups and two independent research organisations from France, (Université Louis Pasteur), Sweden (Centre for Information Technology in Northern Sweden, Umeå), Germany (Friedrich-Schiller Universität, Jena; FAST, Munich) and the UK (University of Essex). These groups worked in 1998-99 to create, apply and test the organisational, technological, pedagogical and psychological conditions for the development of media competence of students and teachers in Europe. The project had the following objectives: to create a conceptually innovative technological basis for Internet-based learning and teaching between participating schools tailored to specific educational strategies; to develop an integrated working environment using the Hyperwave Information Server (version 4.1.1); to develop and implement a curriculum for training teachers in the use of the Internet for teaching and learning; to provide psychological, pedagogical and media didactic support for the participating schools; and to supervise joint thematic projects between schools on aspects of European Identity, [IN-TELE, 1997].

2. The IN-TELE Teacher-Training Course 1998-1999: Overview, and developments

'The emphasis lies on teacher training, with the aim of increasing Internet competence, supply of hard and software, the realisation of Internet teaching projects, schools of all countries are involved in, and the evaluation of the effects of these interventions. Objectives of the teacher training are improving abilities of well-aimed information research, communication by e-mail, newsgroups and chats and programming with HTML...Additionally, current developments in the field of the new communication technologies are discussed and the relevant educational and psychological theories and methods are introduced' [Suckfull *et al*, 1999]

Annex I of the IN-TELE Project programme specifies the general content of the teacher-training programme. The following general areas were considered to form a common 'core' curriculum:

- the history of the Internet;
- ways to get online;
- identifying, retrieving and using online resources;
- the differences between traditional teaching discourses and Internet-based teaching and learning: Scientific theories and results, practical experiences and pedagogical consequences;
- HTML authoring for designing Internet-based lessons across the curriculum;
- discussion of the problems of computer-mediated teaching and learning;
- how the Internet may be used as a means of European Identity construction. [IN-TELE, 1997].

Key objectives were for teachers to:

- identify, manage and use the Internet and Internet-based resources competently and effectively within the classroom to enable cross-cultural exchange;
- understand how the Internet may support and develop learning, and be able to *apply* this understanding to the specific subject being taught;
- understand and identify appropriate and inappropriate uses of the Internet, from examples identified by teachers and discussed within the training programme;
- understand and address issues of equality of opportunity; copyright, ethical, and other legal considerations. [Glasfurd & Vickers, 1998]

The IN-TELE Teacher-Training Course, designed by academics from the University of Essex IN-TELE team, had to be used in a variety of contexts, across differing national curricula, and be relevant to the learning needs of teachers working with the project - each with different levels of experience and competence. The course aimed to build key technical skills and competencies, to build teacher confidence in ICT use, and to provide clear examples of how the Internet might be used within the classroom to support and develop teaching and learning, and facilitate cultural exchange. The training, implemented in 1998, was structured through six 'learning through doing' sessions, each lasting between four to six hours, with additional in-school workshops and support available for the duration of the project in 1998-99. One hundred and fifty teachers, at sixteen European schools, participated in the training in 1998 on a voluntary basis, [4]. Responsibility for the implementation of the training and the in-school workshops rested with IN-TELE project partners in each of the four countries.

2.1 Designing for flexible learning

'flexible learning...provides students with the opportunity to take greater responsibility for their learning and to be engaged in learning activities and opportunities that meet their own individual needs.' [Wade, *et al*, 1994]

In designing the 1998 teacher-training course the research group at the University of Essex faced a number of challenges. The training could not exceed six training days because of limited project resources. The course

[4] The numbers trained are as follows: UK: 53; France: 30; Germany: 51; Sweden: 16.

had to be applicable to all areas of four differing national curricula, and address the very different levels of experience of ICT among the project teachers. It was essential, therefore, that the training should be flexible and provide a platform of core skills and competencies from which the teachers could progress as independent learners able to choose *when, where, how* and *how much* they learnt.

The six training days in each of the four countries were supported with a variety of course materials, which have been (or are in the process of being) translated into French, German and Swedish. The training materials included an HTML authoring course on CD-ROM; paper-based worksheets; and online resources. In addition, most of the schools working with the IN-TELE project were issued with a mobile Internet set [5]. A multi-media laptop computer forms an integral part of this, and enabled project teachers to work either on or offline from home or in school, this being of particular importance to schools with few resources.

2.2 Developments in 1999

Whereas the initial IN-TELE training was supported in each of the four participating countries by project staff working as trainers, the *final* training materials for commercial dissemination from the Autumn of 1999, are designed entirely for self-study. The revised IN-TELE Teacher-Training Course is browser-based, with fifteen supporting activities. Hypertext is used to enable users to follow the course in a variety of ways, working either on or offline. He/she may wish to work through the course from beginning to end, or just to dip into sections of specific interest: the path is not determined but flexible, again enabling users to progress as independent learners. The course includes relevant information for French, German, Swedish and English teachers, as well as more general information of relevance to European users. The course has a practical, 'hands-on' approach; the use of jargon is kept to a minimum. Throughout the course users are pointed to the most up to date information and to selective further readings. The course also includes experiences of teachers who worked with the IN-TELE Project in 1998-1999.

The revised course is comprised of seven sections. The structure is illustrated in Fig 2.

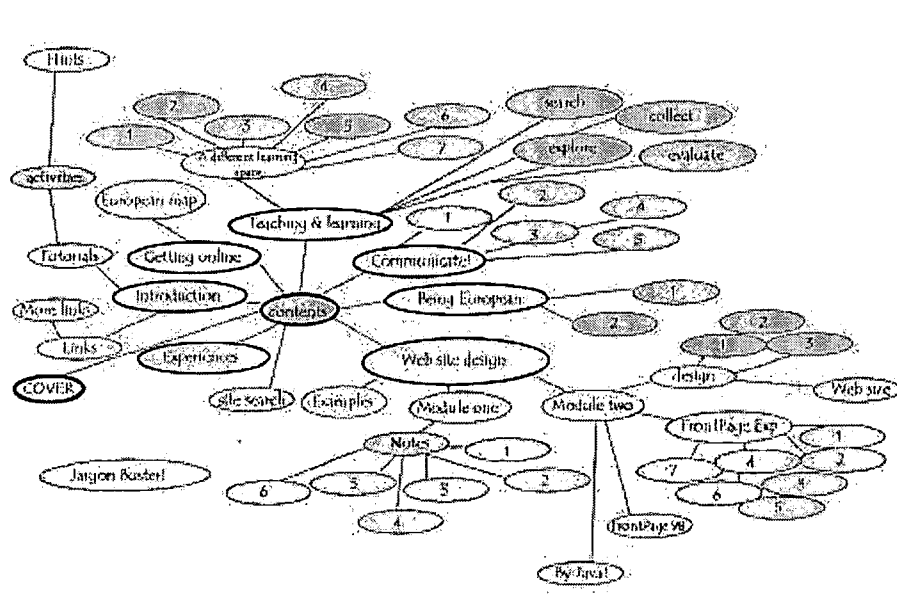

Fig. 2 IN-TELE Teacher-Training Course Site Map

[5] The mobile Internet set is comprised of a multi-media computer, a video projector and a cart or trolley. The set was to include a Radio LAN, but this was unavailable throughout the project.

2.3 Content of revised teacher-training course.

1. Introductory presentation and Introduction to the course
Introduces the history of the Internet and outlines the aims and objectives of the training course;
2. How to Get Online
Discusses the possibilities of getting online in a European context, including national educational initiatives; and how to make full and effective use of often limited school resources;
3. Using the Internet for Teaching and Learning
The section explores the Internet as a qualitatively different learning space, in particular the ways in which the Internet may be used to:
 - Encourage active and independent learning;
 - Test ideas and encourage critical reasoning;
 - Enable communication within and beyond the seminar or class room;
 - Encourage subject exploration, information retrieval and network literacy;
 - Develop student creativity with text, pictures and sound;
 - Link knowledge and promote cross-curricular learning through the use of Hypertext;
 - Enable differentiation (e.g. use of Hypertext within Web pages to provide different pathways through a particular topic for students of differing abilities, and/or with different learning styles);

There are four activities:

1. Search! Explains how to search the Internet effectively.
2. Collect! Explains how to save Bookmarks or Favorites for future reference.
3. Explore! Searching specific Web sites for examples of Internet-based lessons.
4. Evaluate! Evaluating the content of Internet-based lessons identified.

The activities are designed to build effective searching skills and to engage teachers from the outset as *critical* Internet users. Teachers have to consider how they might make use of or *consume* Internet-based resources, and also how they might *produce* resources themselves (in the shape of an Internet-based lesson) in the future.

4. Communicate!
Considers how e-mail may be used to expand the boundaries of a classroom and support inter-cultural exchange and language learning. There are five activities to follow which discuss some of the challenges and opportunities of using e-mail within the classroom:
 1. Who's online?
 2. Opening a Web-based e-mail account
 3. Discussion groups and lists
 4. Meeting others and using interactive Web sites
 5. Language learning
5. Being European
What does it mean to French, German, British, or European? What is our national identity comprised of? What makes us similar, what makes us different? How can the Internet help us to understand each other? Two activities support this section:
 1. Finding out about Europe
 2. Collaborate!
6. Designing Web sites for Student Learning
This section is comprised of two modules.

Module One: An HTML Authoring course: shows course users how to create a Web page with the minimum of resources. The activity involves users constructing a Web site on the topic Bangladesh Floods.

Module Two: comprised of four sections:

- Designing Web sites for student learning, with three supporting activities:
 1. Design Matters!
 2. Copyright
 3. Safety on the Web

- Creating Web Pages with FrontPage Express: shows how to use the free HTML editor FrontPage Express (supplied with the course) to create a web site in seven stages.
- FrontPage 98: introduces the main features of this sophisticated HTML editor.
- By Java, let's animate! Shows users how to create interactive Web sites using freely available Java Scripts on the Web.

7. Quotes from teachers who worked with the IN-TELE project reflecting upon their experiences.

3. Experiences

From September 1998 to June 1999, the teachers were asked to build upon the training provided by IN-TELE, to develop and integrate Internet-based lessons within the curriculum, and to work collaboratively with the project schools across Europe, considering European Identity themes and topics. Equipment in schools ranged from a networked computer room with sixteen PCs with Internet access, to use of the mobile Internet set: a single laptop computer with beamer.

All teachers who participated in the training were issued with a questionnaire, which asked them to reflect upon their learning experience with the IN-TELE project. In addition, teachers were asked to consider how their work with the project could be best supported locally (at their own school), nationally (by Government policy), and at the European level. Of questionnaires issued, just over a third were returned see Fig.1. Although the data is incomplete, and anecdotal, responses received illustrate several discernible trends and issues and these are discussed below.

Country	Teachers trained	Lessons produced by June 1999 [6]	Questionnaires returned
France	30	5 (including for WP4)	11
Germany	51	6	14
Sweden	16	9	9
UK	53	21, + 11 student pages	18

Fig. 1 Summary of participation

4. Conclusion

The Internet-based lessons produced by teachers working with the IN-TELE project demonstrate a rich and varied use of the Internet as a teaching tool and learning environment. The work produced by teachers can be accessed via the four IN-TELE Project servers (UK, <http://intele3.essex.ac.uk/>; Germany, <http://www.in-tele.org/>; France, <http://in-tele.u-strasbg.fr/>; Sweden, <http://intele.snic.se/>) and is discussed in *D3.3 Trainers and Teachers' Internet Pages*, [Glasfurd, 1999]. Some teachers created interactive Web sites, others used e-mail to support pupils with learning difficulties; some teachers used the Internet as a source for ideas for lesson plans and professional development, and others for engaging pupils as active and independent learners. Some teachers have invested considerable time and energy in the creation of sophisticated Web sites as a whole and *immersive* learning environment which allowed for extension and/or differentiated activities, whereas others have used the Internet in a highly selective manner, integrating it within existing teaching materials and techniques.

[6] This includes all completed projects. Responses to the questionnaire illustrate that there was considerably more activity than the figures above suggest. For example, there were many unfinished projects, which were not complete before the deadline of Deliverable D3.3, Trainers and Teachers Internet Pages.

However, the work for the project was frustrated to a greater or lesser degree by a number of constraints. Teachers in all four countries experienced difficulties primarily associated with a lack of free time, and access to, or the functioning of, suitable equipment. Many felt that their institutions did not support their work with the project sufficiently (by making free time available in school time for them to work with the learning materials; or by making available additional equipment and technical support). At the national and European levels many felt that there should be more effort to supply equipment and provide training to schools.

The IN-TELE mobile Internet set, whilst enabling the use of Internet-based resources within classrooms with no network connection, cannot be used effectively to support some of the desired student learning outcomes associated with Internet-based teaching and learning. Responses to the questionnaires show teachers reporting problems of too few computers among too many students. Active and independent learning needs to be supported by direct access to networked computers by students working individually or collaboratively in small groups. A central aim of IN-TELE was to encourage and engage students and teachers in cross-border communication. Open access to e-mail by both students and teachers is an important requisite in enabling full and open communication. At one UK school, where the only access to the Internet was via the project laptop linked to a telephone line in a secretary's office, concrete collaborative work was nearly impossible.

The IN-TELE training course is intended to provide teachers with a set of core skills and competencies; and provide a programme of study, which could be broadly applied to other European countries. The experience of the project has illustrated that although this strategy and approach has been relatively effective, successful outcomes do not rely just upon individual skills levels or the motivation of each teacher participating in the training. The context within which the teachers work - including the management culture of institutions, the priority given to ICT and their support by regional, national and European governments and educational authorities - plays a crucial part in determining outcomes.

Abstract: E-Commerce, when viewed as a network of multimedia data transactions, is a sophisticated application of multimedia information authoring, retrieval, searching, browsing, clustering, and navigation. This paper analyzes the role of each of these multimedia technologies in the context of E-Commerce.

1. Introduction

“Electronic Commerce” or “E-Commerce” refers to the use of computer networks to exchange information in commercial transactions, whether in form of prices, orders, advertising, authentication, or electronic goods. The computer networks involved can be private or public, local or global; the Internet is a prime example. Multimedia data in E-Commerce can be actual goods, such as images, sound or video recordings, but also be used as interface elements to facilitate the exchange of physical goods. Electronic Commerce depends on the transmission of information goods and services; viewed as a network of multimedia data transactions, this introduces new challenges to the field of multimedia. This paper analyzes multimedia interfaces from the E-Commerce perspective and describes how these technologies need to be adapted to benefit E-Commerce.

While many factors drive the growth of electronic commerce, equally many social problems inhibit it. Growth is accelerated by technological advances such as improved network infrastructure and data access that lower transaction costs and expand markets. It is stunted by the lack of standards and easy-to-use interfaces: for example, the format of Electronic Transactions is still fluid as digital certificates such as E-pass are still evolving and have not yet been standardized. Only basic mechanisms of digital cash and data protection have been accepted, as models and mechanisms that fit businesses are still in flux, lacking sufficient market analysis.

These problems reinforce the resistance of many companies to conduct business on the Internet. The lack of standards has been compounded by the changing nature of the Internet and the lack of a sufficient number of prototypes to serve as benchmarks. Various industry sectors respond and benefit differently; extensive research is needed to convince them of the potential revenue generated by this new type of commercial market, and to show that it can exceed traditional services. Research in various industry sectors like finance, pharmaceuticals, publishing, and retail sales can identify the driving forces behind each one.

Traditional forces still govern most manufacturers, distributors, and product designers who choose to base commercial success on face-to-face transactions. It is still not clear, from the limited applicability of existing multimedia technologies on the Web, how face-to-face transactions can co-exist and evolve with computer-based transactions. In fact, most business decision makers view E-Commerce as a non-effective tool to advertise their products because it is based on a non-push technology, the Web. Unlike television advertisement, which comes as part of a station's program, Web-based advertisement is server-based and therefore depends on where consumers direct their browsers, instead of being part of the data stream that consumers receive from their ISP.

Although the Web is at present a passive mechanism for selling products, it can offer both sellers and buyers other, more long-term benefits such as valuable consumer information, purchase opportunities, and educational experiences or interactivity. Once companies and consumers understand this better, E-Commerce will gain as a commercial platform. Furthermore, television advertising has a very high cost and non-lasting effect when compared to accessing product information on the Web. What is needed is a better understanding of how television and the Web can be combined for synergistic impact. For example, accessing

television advertisements via the Web, or accessing the Web by way of television advertisements, can give viewers new avenues of interaction and feedback.

Another significant issue is the background necessary to conduct E-business. New approaches and strategies are needed in training managers, consultants, and clients in communicating and interacting. This is a complex problem. As research is conducted on a set of key virtual communities in E-business, patterns will evolve which will become valuable insights.

2. Key Factors for Multimedia Interfaces

We believe that multimedia user interface technologies will play a key role in the development of E-Commerce. Therefore, existing multimedia tools must be reconsidered in the light of E-Commerce, and specifications drafted on how to adapt such technologies to provide significant additional benefits to the consumer. At the same time, traditional commerce parameters must be upheld, and concerns of security addressed. Only if these conditions are met, multimedia interfaces can help the growth of E-Commerce.

The Quality Factor

Since it is the business decision makers who drive E-Commerce, technology developers and multimedia experts must show the decision makers that the multimedia data access tools have additional, enriching features that make E-Commerce competitive. This "Quality Factor" may mean a variety of tool adaptations: for instance, image or audio servers may want to include watermarking or other authentication and copyright facilities. Ease of use and scalability are very important. To measure market compatibility, benchmarks and other mechanisms of comparison are needed. Retrieved or browsed data needs to be easily analyzed, assessed, or compared to other goods.

The Assurance Factor

To improve acceptance and productivity, E-Commerce is required to be compliant with legal, commercial, and financial principles. Automating part of this "Assurance Factor" is important, so multimedia technologies must incorporate measures that deal with non-technical constraints. Authoring tools would require ways to check raw materials prior to use and verify their proper commercial identification and credentials such as authenticity, copyright clearance, and market value.

The Security Factor

Since E-commodities may deal with sensitive information such as images, video, medical records, insurance records, or legal documents, "efficient data processing", traditionally describing speed and accuracy of transactions, must also measure robust and secure communication. Transactions must ensure customers' privacy and protect sensitive information, but also check for violations in privacy, security, access privileges, and data protection on both the customers' and the providers' side.

3. Authoring and Retrieval

The success of commercial information transactions is mostly based on two issues: how well the information can be retrieved, and how well it can be presented. The technologies that affect these issues the most are Multimedia Authoring (MMA) and Multimedia Information Retrieval (MMIR).

The goal of MMIR is the seamless access to heterogeneous types of data and the ability to retrieve specific, multi-modal information, as expressed in the form of a query, either by describing the target (text query) or giving similar objects as examples (media-based query). On the other hand, the goal of MMA technologies is to build or compose new multimedia documents or applications from existing or retrieved information. Authoring should be an integral part of any dynamic commercial venture that enables a consumer to express decision making, be it as simple as adding a check mark to a table to indicate interest, or as complex as designing an architectural draft of a new house plan. Authoring is integrally associated with retrieving information from a constantly changing knowledge database, whether the goal is to author for retrieval (to create a new knowledge database) or to retrieve for authoring (to use the database for creating new documents). It is important to avoid excessively large or complex documents that are difficult to manage or query ("authoring beyond retrieval"), and to guard against retrieval problems where results are in a form that is not easily assembled, classified, clustered or composed with other information into comprehensible self-standing modules.

Linking information retrieval with authoring can prevent "authoring beyond retrieval" and retrieval problems. In the case of authoring, mechanisms for automatic segmentation and indexing of multimedia objects capture or encode changes of document structure. One way to achieve this is by using "tagging" during the authoring process: a lecturer recording a talk on video could use automatic facilities to indicate changes of structure in his lecture, aiding later retrieval. Retrieved information "units" must be

of a size that is easily assembled and built upon, therefore the granularity of the information retrieved must be adapted for authoring.

Cross-Modal Information Retrieval

For practical E-Commerce applications, most MMIR tools are still in a primitive state and cannot derive accurate information. Text-based queries are far more mature than media-based queries which need to be translated into low-level attributes that the retrieval system can recognize and mechanically search for.

Computed Alignment is a method to align two diverse media streams of information so that a query in the “easier” media type (usually text) yields the corresponding segment in the other, more complex media type (such as audio or video data). An example is the transcript and the audio recording of a speech: by aligning the text with the audio, passages in the audio stream can be found with simple text queries. Computed Alignment is an intermediate solution to the difficult problem of retrieving information “across modalities” from multimedia databases.

By employing CMIR via Computed Alignment, E-Commerce applications can provide simple interfaces for serving stream-based multimodal information. Automated alignments allow frequently changing databases to be prepared easily, e.g. a news station can align transcripts to audio or video segments of interest to provide “custom news” for clients. Three potential E-Commerce applications of Computed Alignment are Text-to-Speech Retrieval, Slide-to-Video Retrieval, and Parallel Text Alignment:

- Text-to-Speech Retrieval, as mentioned above, synchronizes speech audio with its textual transcript that has been derived from a separate source. Queries for passages in the audio can now be formed as textual queries and located easily. Applications include court and other legal proceedings, language instruction audio tapes, entertainment materials, lectures and courses, etc.
- Slide-to-Video Retrieval: given a video presentation and the corresponding slides in digital form, a query might ask for the video segment corresponding to a particular slide. The slide images are aligned to the video images of the slides using fast image processing techniques and a discrete formulation of the general theory of cross-modal information retrieval mentioned previously. With large video presentation libraries, such a media-based query (i.e., by slide) can be very useful to retrieve video segments of interest, e.g. for employee training.
- Parallel Text Alignment (PTA) provides tools for the automatic alignment of two or more textual documents that have been separately derived from a shared source, such as different translations of ancient works. PTA can be used to retrieve points in these translations that relate to the same original source location, even when this source is not available. Applications include tracking different versions of product documentation or comparing translations from different languages that deal with the same event.

Computed Alignments can also serve to anchor various meta-notes and thus permit metadata queries. Cross-modal infrastructure of this sort can make multimedia data processing a valuable asset for future E-Commerce growth.

4. Searching and Browsing

Search engines are a primary means of locating new information on the World Wide Web today. Search engines evaluate the relevance of a user’s description (usually a string of keywords) to each item in a collection and present the results of this evaluation to the user. The standard for presentation of results in search engines is a ranked list of results, with order based on a calculated relevance score. Depending on the narrowness of the search, the size of the information pool indexed by the engine, and the search engine’s algorithm, typical results are a few to hundreds of thousands of matches. Search engine users typically browse these results in search of potentially good matches for their original queries. So far, we discussed retrieval and authoring. How about browsing?

‘Searching’ and ‘browsing’ are recognized as complementary but mostly separate approaches for information access. Browsing is like leafing through a magazine and searching is like turning to a specific article directly. Both are valuable information access ways especially needed for E-Commerce applications. “Browse engines” is a term coined at the DEVLAB (Dartmouth) to denote a class of information tools that permits convenient access (indexing) to World Wide Web resources. Browse engines work much like search engines to provide a useful summary of Web resources; they resemble search engines in being based on previous surveys of Web material, and not on active, on-line access to the Web. They differ in being designed to facilitate browsing instead of just searching of World Wide Web materials.

While search engines use search techniques to locate resources, the interface they present to a user typically requires browsing. Search engines have facilities for indexing text and providing URLs whose associated text matches search text. However, search engines do not make it convenient to assess the contents of Web materials quickly and interactively. Links presented by a search engine must be chosen for closer inspection or ignored based on incomplete text snippets; further, finding out if the material they link to is significant requires initiating and waiting for connections to Web sites.

Browse engines are like search engines in that they index Web material, but their presentation includes formatting, links, and reduced-quality graphics. This makes it possible to evaluate Web materials as they appear, and to browse search results by following links between documents—all without incurring the overhead of online connections to retrieve materials.

Because of the greater difficulty in storing images, links, and other content, browse engines are intended for topic-specific use or one-time scans. For example, one might establish a browse engine for a specific area like Macintosh computer maintenance that would be kept up-to-date by daily Web crawls. Alternatively, one might "launch" a browse engine daemon to run overnight and build a one-use browse engine for an interesting topic, permitting a convenient assessment of Web materials on the topic when its scans of the Web are done.

The idea of a browse engine is similar to that of pre-fetching: in anticipation of user need, pages are downloaded from the World Wide Web and archived. A difference is that instead of caching the few pages most likely to be requested soon, the engine stores all the pages it can find, using a reduced form, and optionally makes this information available to multiple users. This allows better presentation of results, with links, clusters, and summaries as possible features. For some tasks, it also makes possible a more effective and efficient World Wide Web information retrieval system than is currently available.

Yahoo and Infoseek incorporate categorization approaches similar to those used in library catalogs to make users' browsing easier. These systems require manual classification to make this approach feasible, however. The browsable catalogs are mainly links with small snippets of associated text, although new services like the Yahoo Image Surfer provide searching and browsing of images, along with links to access their source World Wide Web pages. The Yahoo Image Surfer presents a thumbnail picture and Web page title for each image entry in its browsing interface, but no further indication of the content of the page.

Results of searches can also be presented in more complex ways. The graphical visualization interface "Envision" makes two dimensional plots of icons representing publications along user-selected axes. Rankings can be by estimated relevance, publication type, index terms, author, or publication year. Estimated relevance is also used as a third dimension, expressed either through color or shape of document icons. Clustering results and displaying descriptions and representatives of each cluster is another potentially useful technique for organizing and presenting results.

Current work on improving speed in this area has focused on pre-fetching and caching using proxy servers. There is work concerned with improving caching strategies (Krishnamurthy, Reddy) and extending proxy servers to handle temporal media like audio and video (Tewari) and with reusing or "caching" network connections (Osawa) so that a sequence of requests can be serviced over a single connection. None of these approaches use new types of servers specifically targeted at browsing summary information. E-Commerce applications will require development of fast browsing engines which incorporate intelligent compression techniques for web pages, visualization of a degraded version of a web page during browsing, caching and proxy server techniques, and statistical analysis of Web usage patterns which feed into a browse engine system.

5. Clustering and Navigation

As the content of cyberspace grows exponentially, it becomes increasingly difficult to construct predefined tools that effectively support navigation and exploration of this information space. This means that the computer will have to become a much more proactive element in navigation by generating content- and context-aware navigational tools based on the user's current environment. Techniques based on automatic recognition of structure and content of the Web will become increasingly important. Unfortunately, today's implementations of these systems still need too much human intervention to be useful. Automatic organization of retrieved or authored multimedia information requires tools for clustering (grouping) related information in a multimodal sense: not just images that look alike but images and text segments that describe similar things. Multimodal clustering is an unsolved problem.

Cybermap is a new tool which automatically generates overview maps for textual documents. It creates a graph of a collection of nodes by clustering related documents by content into nodes as well as automatically generating links between semantically-related nodes. The resulting graph can be viewed in multiple representations, providing for quick access to information and data filtering in the Web. Cybermap incorporates the concept of hyperdrawers as a means for partitioning nodes into ordered sequences.

In addition to retrieval, browsing, authoring and clustering, E-Commerce requires easy navigation of the information space and a mechanism to track or keep a record of such navigation. Cybermap either complements existing navigational aids for hyperdocuments or provides a self-sufficient navigation tool for browsing the Web. In addition, it offers the capability of horizontal growth and easy hypertextualization of nonhypertextual documents without restricting the use of already installed browsing mechanisms.

Desirable Cybermap Extensions

Automatic clustering of multimedia documents is not only a valuable organizational tool but also important for retrieval, browsing and authoring. Cybermap is one of the first such clustering tools developed for efficient browsing and navigation, even before the Web was developed. Its clustering capabilities have been demonstrated with large databases of textual keywords, images and audio sounds. The following extensions to Cybermap represent work in progress:

- a) a filter that extracts keywords based upon which clustering can be performed.
- b) a map-drawing facility that develops a graphic of the history of searching or browsing performed.
- c) a security mechanism for checking authenticity of multimedia data item as they are added to a cluster; requests with certain traits fall into different categories and alarm systems go off when a particular situation is reached.

- d) a visual interface that allows private and public annotations next to each cluster or automatic linking to a commercial (such as medical/pharmaceutical) atlas.
- e) a help facility for altering the parameters based on which clustering is done or changing the average size of the cluster, or changing the types of data acceptable.

6. Sample Application: Courseware and Museum Content

Learning commodities is a familiar scenario in the case of distance learning. However, assessing the commercial value of courseware information in the context of E-Commerce is different as the quality, assurance, and security factors discussed earlier need to be taken into account.

For example, given a set of lectures in computer science, there are video, audio, textual and other components that are either in the form of aligned tracks or presentations, or separate documents, or both. Trading a whole course or a whole lecture is one way of segmenting the value of the exchange. Another way is to look at this from a digital library point of view, i.e. pay by access, pay by view, or pay by minute. Similar questions arise in other applications, such as viewing medical records for the purpose of training, investment portfolios, artistic images, etc. In all these cases, the technologies we mentioned earlier are involved. If retrieval is inefficient, any "pay by access" strategy will fall apart. Thus, commercial scenarios based on "pay by view" etc. depend on how robust the multimedia infrastructure is.

Consider museum content as an educational commodity. It can be viewed as a resource or service of artistic or cultural value that must continuously be enriched, managed, maintained and interacted with by a diverse set of users, both locally and distantly. Museum objects may include books, painting, statues, archived information, lectures, audio tours, etc. Providing the user with an automatic museum object management retrieval, requires effective workflow agents sensitive to constraints imposed by the content providers the employer or the donor of a collection.

7. Other E-Commerce Technologies

Workflows

Commercial workflow systems, mostly used in banking, describe business processes as service requests (the workflows) and service providers (institutions, individuals, and other components of a business). Workflows eliminate duplication of effort, exploit parallelism, and reduce costs, processing, and delays. In designing a workflow, a diverse set of components (such as organizations, individuals, documents, and deadlines) must be integrated over a wide area network connecting the participating institutions.

Agents

Intelligent software agents can automate transactions and reduce time and costs. In a networked marketplace, agents can represent customers who make selections, request information, or offer contracts; providers who offer services, features, or product choices, and assess buying capabilities and authentication; or goods and services being exchanged. There are a multitude of legal issues arising from the digitization of valuable materials which need to be disseminated widely and fast. Copyright management tools must be developed and built into the access mechanisms of retrieval and authoring. There are several security levels which one must consider:

- a) how to secure the actual documents by encryption of the materials to prevent malicious destruction or alteration or unauthorized access;
- b) how to provide document identities to possibly complex multimedia documents (such as a video that is annotated with music);
- c) how to keep track of materials usage, important in generating fees. Tracking materials usage is done by controlling access, using passwords, and a form of digital signature generation;
- d) how to generate payment, provided that there is a good way to measure or quantify the use of the materials.

Trading using a query language would enable customers to search for information based on a variety of parameters (duration of course, difficulty level, number of images, number assignments, etc.) Notification services can be used to notify customers of course or materials services. A transaction management system keeps track of all transactions for any one site. Repository services store information in different manners. Payment and banking services manage the transactions and complete the payment using a bank.

8. Conclusion

Thousands of organizations and millions of individuals will soon depend on a dynamic, heterogeneous market economy of multimedia transactions. Vast amounts of diverse data (animation, images, audio clips, tables, etc.) will need to be processed and

stored daily, in raw databases, digital libraries, websites, commercial databanks. The demands of the public are growing and must be met. New commercial applications are mushrooming in all fields: medicine, environmental studies, finance, humanities, and law are all seeking good retrieval methodologies to enable fast decision making.

THE CHALLENGE OF DESIGNING AND EVALUATING 'INTERACTION' IN WEB-BASED DISTANCE EDUCATION

Charlotte Gunawardena
University of New Mexico
lani@unm.edu

INTRODUCTION

The World Wide Web (WWW) is increasingly being used as a medium to deliver distance education at the post-secondary level. However, an examination of a significant number of web-based courses for adult learners indicates that they are predominantly designed to transmit information to the learner rather than foster the teaching and learning process in a dialogic manner. These courses disregard Knowles'(1990) principles of andragogy especially the principle of using the adult learner's experience in a learning situation, and lack the design of interaction that promotes collaborative learning. This view was confirmed by Boshier et. al. (1997) in their survey of web-based courses for adult learners. They note that while the web holds considerable potential for learner interaction, few courses use much of its interactive capability. Most do not provide opportunities for collaborative learning. They note that the chief difficulty is not technological, but conceptual, as many instructional designers or teachers are obsessed with objectives and the assessment of students and arranging information in a hierarchical order. They have unwittingly or naively endorsed a transmission model of learning similar to what happens in a traditional or face-to-face classroom.

If the web is to be used as a versatile medium for adult learning, then, careful attention must be paid to the design of interaction that can foster the negotiation of meaning, the validation of knowledge, and the construction of knowledge through social negotiation. Learner - centered learning environments based on constructivist principles where the focus is on learner initiated inquiry and exploration are far more suitable for adult learners than the transmission model of learning which is based on the notion that learners are empty vessels to be filled up with the teacher's knowledge. Constructivist learning environments provide multiple perspectives and real world examples, encourage reflection, and support collaborative construction of knowledge through social negotiation (Jonassen, 1994). Instructional design models based on behaviorist principles that are used to design and develop instruction for traditional classes do not offer much guidance for the design of instructional strategies for two-way interactive distance education systems. Instructional designs must address the complex interrelationships between learning task, media attributes and the learner's cognitive processes. The design of interaction that facilitates adult learning and the evaluation of the learning experience that occurred as a result of that interaction has been a challenge to many web designers.

THE PURPOSE OF THIS PAPER

The purpose of this paper is three fold: 1) to discuss issues related to the design of 'interaction' on the web using models of interaction developed for distance education, 2) to examine several techniques for the analysis of interactions and the quality of the learning experience in a computer-mediated group conference, and 3) to propose a model for analyzing the social construction of knowledge in such a group conference. The paper provides guidelines for both designers and evaluators of web-based instruction.

The paper will examine the definition of 'interaction' in a computer-mediated communication (CMC) environment as definitions of 'interaction' for interpersonal communication used by communication researchers to study face-to-face dialogue do not transfer well to the CMC context. The paper will point out the strengths and shortcomings of interaction analysis techniques that have been developed and will propose a model for analyzing the quality of CMC interactions and learning experiences. The application of this model for analyzing interaction will be discussed briefly.

DESIGNING INTERACTION IN WEB-BASED INSTRUCTION

The issue of 'interaction' has been an area of much debate in the practice of distance education. Often debated questions are: What type and level of interaction is essential for effective learning? How can we achieve interaction? What does synchronous (real - time) and asynchronous (time - delayed) interaction contribute? What type of interaction can the new interactive technologies provide? Is it worth the cost? Designers need to keep these questions in mind as they grapple with the task of designing 'interaction' for the web.

Examining instructional interaction in distance education, Moore (1989) makes a distinction between three types of interaction: learner- content interaction, learner- instructor interaction, and learner- learner interaction. This model serves as a useful guide for designing interaction in web-based instruction. Dinucci, Giudice, and Stiles (1998) discuss interactivity in web design as falling into three categories: users interacting with the web site itself, which is similar to learner - content interaction, users interacting with the site's publisher, similar to learner - instructor interaction, and users interacting with each other, similar to learner - learner interaction. They provide design guidelines for all three types of interaction using the unique technological capabilities of the WWW. The design issues related to these three types of interaction will be discussed in this section.

The interaction between the learner and content is the process of intellectually interacting with content that results in changes in the learner's understanding, perspective, or the cognitive structures of the learner's mind. This type of interaction could also be considered as 'system interactivity' when students work with a web-based instructional program where the system may adapt to their inputs or interactions.. Hyperlinking by which students navigate through the web, as well as web pages that interact with students by changing their form and displaying new information in response to the position of the cursor or to mouse clicks are ways in which learner - content interaction can be designed taking into consideration the unique features of the web. The multimedia capabilities and the hypertextual navigational tools of the web not only provide access to multiple perspectives but also provide some degree of control to learners as they try to make sense of the content.

The second type of interaction Moore (1989) describes is the interaction between the learner and the instructor, a type of interaction that is regarded as essential by many educators and highly desired by many learners. He states that the instructor is especially valuable in responding to the learners' application of new knowledge. Learners do not know enough about the subject to be sure that they are (1) applying it correctly, (2) applying it as intensively or extensively as possible, or (3) are aware of all the potential areas of application. 'It is for reality testing and feedback that interaction with an instructor is likely to be most valuable.' (Moore, 1989, pp. 3-4). In the web-based environment, this type of interaction can take place either between the individual learner and the instructor via private e-mail, or between a group of learners and the instructor in a group conferencing situation. The web-based environment is versatile in being able to provide for these types of interaction in a synchronous format (real-time audio, video, or text, or a combination of them), or in an asynchronous manner (time-delayed text).

Dinucci, Giudice, and Stiles (1998) observe that one of the most simplest and useful ways to open lines of communication between the learner and the instructor is including an e-mail feedback form using the 'mailto' feature built into HTML. However, 'mailto' only generates a message form and if the instructor requires more detailed feedback from the students, the designer may want to create fill-in forms. They note that creating such a form can be handled by standard HTML 2.0 code and by drag-and drop controls in most WYSIWYG HTML editors. Although you can create the form using HTML, in order to use the form interactively you need to use a programming language such as JavaScript. They note that JavaScript event handlers can be used with any form element to trigger interactions. Event handlers are commands that trigger actions whenever a certain event occurs - either an interactive event, such as the user clicking a button, or a noninteractive event, such as a page loading. When the event happens, the event handler can be used to run a JavaScript function in response to it. With new browsers, for example, those that support HTML 4.0 event handlers become really powerful. Any object on a page can react to user actions, as event handlers do things like trigger sounds and animation. Another method used to add interactivity is the use of plug-ins such as Shockwave for Director and Shockwave or Flash. However, the drawback is that learners have to have the plug-ins or be willing to download very large files. These more sophisticated techniques provide the combination of learner - content interaction and learner - instructor interaction. However, using more sophisticated technology on the web may prevent access for those learners who have a low end computer or internet connection. This is a factor that must be considered carefully by those who design web instruction for distance learners.

The third type of interaction, is the interaction that takes place between one learner and other learners, alone or in group settings, either in the presence or absence of an instructor. Moore (1989) notes that this type of interaction is a new dimension for distance education and will challenge our thinking and practice in the 1990s. It is also this type of interaction that would contribute immensely to a learner-centered view of learning, and provide the opportunity for the social negotiation of knowledge and construction of meaning. It is the evaluation of this type of learning that poses a critical challenge, and guidelines for this type of evaluation is presented in this paper.

It is the capability of the web to provide both chat sessions and forums for building communities, that is of most interest to adult educators who want to design instruction based on constructivist principles. These can be both synchronous or asynchronous. The 'Chat' feature allows learners to exchange text messages with other learners and the instructor in real time. The standard Internet protocol for chat is the 'Internet Relay Chat (IRC). Forums are asynchronous conferencing environments such as Netscape's Collabra or the WWWboard which are web-based, or stand alone online conferencing programs such as Lotus Notes or First Class. Most chat environments use a text-based interface, while some provide sound capabilities as well. As Dinucci, Giudice, and Stiles (1998) note newer systems offer graphic stand-ins called 'avatars' which users can use to represent themselves online. Others use VRML to create interactive 3D spaces in which your avatar can actually walk up to other users (or to their avatars) and exchange conversation, usually as text strings displayed in the window. However, these fanciful 3D environments may not be what the adult learner needs, and designers must carefully distinguish between the glitz and the goal of facilitating learning.

In order to enhance 'social presence' designers can add real-time videoconferencing such as CU-Seeme and NetMeeting. However, social presence can be facilitated in a text-based conferencing system without the addition of video by training the communicators involved in the communication transaction (Gunawardena, 1995). Gunawardena and Zittle (1997) have shown that social presence is a predictor of satisfaction in a text-based conferencing environment. Videoconferencing applications are not part of the web yet, but can be launched as helper applications or as browser plug-ins. One of the aspects that the designer needs to keep in mind is the limited bandwidth available for videoconferencing and issues related to access.

The design of asynchronous learning environments that facilitate interaction among learners and between the instructor and learners in a virtual group, is discussed elsewhere in detail (Gunawardena, 1998). It is the evaluation of learning that takes place in such an environment that is of interest to this paper and is discussed in the following sections.

Hillman, Willis, and Gunawardena (1994) argue that Moore's (1989) three types of interaction do not account for all aspects of interaction in technology-mediated distance education. They point out that the addition of high technology communications systems necessitates the conceptualization of an additional type of interaction: learner-interface interaction. They note that a facet of distance education that is increasingly overlooked is the effect of high-technology devices on interaction. Instructors and learners have to interact with the technology and manipulate interfaces in order to be able to communicate with each other. They state that it is important to make a distinction between the perception of interface as an independent, fourth mode of interaction, and the use of an interface as a mediating element in all interaction. In distance education, the interface itself is unlikely to be relevant to the subject being studied; it merely acts as a confounding intermediary between the three previously mentioned modes of interaction. The interface in this case has become an independent force with which the learner must contend. The web is a new medium for many adult learners and instructors and therefore designers must pay careful attention to training both instructors and learners to use this new medium if effective instruction is to take place. In order to address the learner-interface problem, Hillman, et al. (1994) suggest three types of activities to make the learner and instructor at ease with the technology. These include in-class exercises, orientation sessions, or technology credit courses.

In summary, the previous section has discussed issues that web designers need to consider if they are interested in facilitating the teaching -learning process for adults. It has provided guidelines for the design of three types of interaction discussed by Moore (1989), and the fourth type of interaction discussed by Hillman et. al. (1994). The following sections discuss several techniques for the analysis of interactions and the quality of the learning experience in asynchronous group conferences that facilitate learner - learner interaction, and propose a model for analyzing the social construction of knowledge in such a group conference.

EVALUATING INTERACTION AND THE QUALITY OF THE LEARNING EXPERIENCE IN GROUP CONFERENCING

A number of models for the evaluation of quality in computer conferencing are available. Hiltz (1990) describes analysis of the use of computer technology along four dimensions: 1) characteristics inherent to the technology, 2) social and psychological characteristics of users, 3) characteristics of groups adopting the technology, and 4) interaction of the preceding factors. Levin, Kim and Riel (1990) describe a method of analyzing the structure and content of interactions by the creation of 'message maps' which display graphically the interrelationships among the messages submitted to a conference. Levin, et al. use this analysis to identify 'threads' within a conference and to display the 'multithreaded' nature of conference interaction. They also practice identifying messages which are particularly 'influential' in producing numerous responses or lengthy sequences of responses and they diagram message flow described as the ebbing or flowing volume of messages in the conference. Henri (1992) proposes a system of content analysis which involves breaking messages down into units of meaning and classifying these units according to their content. Henri includes a quasi-quantitative 'participative' dimension of analysis in her scheme for content analysis which the authors feel is more properly considered as a separate issue from the more qualitative analysis of message meaning units. Henri's other four broad categories of content are described as 1) content which reflects the social dimension of conference interchanges, 2) content relating to the interactive dimension of the conference, 3) content indicating the application of cognitive skills, and 4) content showing metacognitive skills.

These models serve as a useful starting point for analyzing group interactions but one of the shortcomings of these models is that no specific criteria have been established for determining the quality of those interactions. Moreover, the definitions of interaction these models present are either unclear or not very applicable to the pattern of interaction observed in group conferences. Ravitz (1997) notes that the assessment of social interactions that occur online must use ethnographic approaches such as discourse analysis of messages that tell more about the interactions that occurred. He focuses attention on the importance of assessing questions such as 'How did the interactions change the participants?' and proposes one methodology described as the Interactive Project Vita.

The following section describes the development of an interaction analysis model by the author and her colleagues for examining the social construction of knowledge in group-based computer conferencing (Gunawardena, Lowe, and Anderson, 1997).

AN INTERACTION ANALYSIS MODEL FOR EXAMINING SOCIAL CONSTRUCTION OF KNOWLEDGE

The study undertaken by Gunawardena, Lowe, and Anderson, (1997) was interested in finding appropriate interaction analysis techniques that help address the following two evaluation research questions:

1. Was knowledge constructed within the group by means of the exchanges among participants? And
2. Did individual participants change their understanding or create new personal constructions of knowledge as a result of interactions within the group?

They examine the definition of 'interaction' in a computer-mediated communication (CMC) environment, explore strengths and shortcomings of currently available interaction analysis techniques, and propose a model based on grounded theory building for analyzing the quality of CMC interactions and learning experiences. The interaction analysis model was developed by analyzing the interactions that occurred in a professional development exercise; the ICDE95 global online debate conducted through asynchronous computer conferencing. The authors contend that the debate forms a particularly good example of collaborative construction of knowledge through social negotiation, a key feature of a constructivist learning environment. Fortunately, the computer provides a transcript that enables discourse analysis or interaction analysis.

In order to address the research questions posed above, a number of interaction analysis models were examined, and Henri's (1992) model selected as the most promising starting point. Three dimensions of this model, the interactive,

cognitive, and metacognitive, were selected as a framework for detailed analysis of the debate. However, it became clear that three aspects of Henri's (1992) model; its basis in a teacher-centered instructional paradigm, its distinction between the cognitive and the metacognitive dimensions, and its treatment of the concept of interaction, were unsuited for application to the debate. The authors therefore, developed a framework of interaction analysis that would be more appropriate for analyzing the debate transcript.

Gunawardena, Lowe and Anderson (1997) believe that the metaphor of a patchwork quilt better describes the process of shared construction of knowledge that occurs in a constructivist learning environment. A quilt block is built up by the application, one after another, of small pieces of cloth, which when assembled form a bright and colorful pattern. The pieces, according to this analogy, are the contributions of individual participants. Each participant contributes to the whole his or her own texture and color of thought, just as every scrap of fabric forms a distinctive element in the overall pattern. The pattern may not be complete during a single conference, but individual responses can contribute toward the formation of a pattern. The process by which the contributions are fitted together is interaction, broadly understood, and the pattern which emerges at the end, when the entire gestalt of accumulated interaction is viewed, is the newly-created knowledge or meaning. Interaction is the essential process of putting together the pieces in the co-creation of knowledge.

Based on this new definition of interaction, the debate was analyzed for the: 1) type of cognitive activity performed by participants (questioning, clarifying, negotiating, synthesizing, etc.), 2) types of arguments advanced throughout the debate, 3) resources brought in by participants for use in exploring their differences and negotiating new meanings, and 4) evidence of changes in understanding or the creation of new personal constructions of knowledge as a result of interactions within the group.

Grounded on this analysis an outline was developed of the process of negotiation which appears to occur in the co-construction of knowledge. The outline led to the development of the model which has five phases, reflecting the complete process of negotiation which must occur when there are substantial areas of inconsistency or disagreement to be resolved. The phases of learning outlined in this model occur at both the individual and social level and can be described as:

- Phase I: Sharing/Comparing,
- Phase II: Dissonance,
- Phase III: Negotiation/Co-construction,
- Phase IV: Testing Tentative Constructions, and
- Phase V: Statement/Application of Newly-Constructed Knowledge.

In applying the model to the analysis of the debate it was evident that the debate format influenced the process of co-construction by sometimes supporting and sometimes hindering the efforts made by participants to reach a synthesis, a Phase III operation. The debate format supported Phase I by soliciting agreement on propositions, and Phase II by introducing inconsistencies between statements and helped to move the arguments to Phase III. However, the debate format hindered the desire of participants to reach a compromise or a synthesis at Phase III and above, as the debate leaders tried to keep the two sides apart.

Two major themes were observed. One was the progress of certain strands of argument from Phase I to Phase V which can be described as an exercise in the co-construction of knowledge, moving from lower to higher mental functions. The other was the evidence of more than one and sometimes three phases within a single message posted by one participant, which usually progressed in sequence through the phases, showing progress from lower to higher mental functions, showing how individuals contributed toward the co-construction. Detailed discussion of the application of the model to the analysis of the debate is found in Gunawardena, Lowe, and Anderson (1997). The efficacy of the interaction analysis model described above was tested in a second online forum (Anderson & Kanuka, 1998).

This paper has discussed the issues that web-designers must consider as they approach designing interaction that facilitates the teaching - learning process. It has also discussed issues that evaluators must consider as they begin to evaluate the learning that occurred as a result of that interaction. The paper has provided models for designing interaction and for evaluating the social construction of knowledge in web-based distance education.

Abstract: The impressive boost that the WWW has received have turned this platform to a very important candidate for the deployment of various kinds of applications in the Internet and in corporate intranets. An area where the WWW had considerable impact is that of DBMS applications. A distributed architecture for RDBMS gateways is presented. Such architecture is based on the Sockets mechanism which allows the client and server parts to operate on different platforms. The Microsoft ISAPI specification has been adopted for the gateway's interface towards the WWW server. Additionally, the gateway takes provision for the reduction of the rate at which connection rejections are experienced at the server part. This approach proves very assisting under periods of heavy workload as users obtain, at a very small time expense, the desired service with high probability. A proprietary protocol for the communication between the client and server parts is also introduced.

1. Introduction

Since its introduction, in the early '90s, the WWW has become the defacto standard for the deployment of telematic applications in wide area networks. Furthermore, WWW is adopted as the basic technology for the introduction of intranet applications. WWW greatly owes its success in the standardisation of the communication between WWW servers and browsers. The three open and well established standards which are involved in such communication are: the Universal Resource Identifiers (URI) addressing scheme, the HyperText Transfer Protocol (HTTP) and the HyperText Markup Language (HTML).

WWW servers carry specialised software, called HTTP demon (hereinafter to be referred to as httpd), which receives and dispatches HTTP requests issued by browsers. The need to incorporate information sources other than static HTML files (e.g., DBMSs, information retrieval systems) motivated the standardisation of the communication between httpds and legacy application programmes. Such efforts led to the specification of Common Gateway Interface (CGI) [Coar & Robinson 98] which is supported by all httpds. The CGI standard though, proves highly inefficient during periods of heavy workload. Throughout the evolution of the WWW, key industrial players like Netscape and Microsoft introduced their own, proprietary mechanisms (e.g., NSAPI, ISAPI) as enhanced and elaborated alternatives for performing similar tasks (i.e., dynamic generation of pages, extension of basic server's functionality). Such specifications are also the "building blocks" of contemporary server functionality extension frameworks like Microsoft's Active Server Pages (ASP).

RDBMS gateways (i.e., software for interfacing legacy RDBMSs to the WWW service) have always attracted the interest of the WWW community. Such connectivity has been a trendy research issue since the early stages of the service [Eichmann et al. 94], [Perrochon 95] while many relevant tools emerged in the software market. Issues-problems associated with the deployment of database gateways encompass: portability among systems, generality [Hadjiefthymiades & Martakos 96], compliance to standards, high performance [Hadjiefthymiades & Martakos 97], stateful operation, transaction support, etc.

In this paper we discuss issues associated with the development of a software prototype of a generic database gateway which is compliant with the Internet Server API (ISAPI) specification [Tracy 96]. Such gateway has a client/server architecture and thus, may operate in a distributed way.

The server part of the gateway (GSP: Gateway Server Part) is installed and operated in a database server, receives SQL statements through the BSD Sockets inter-process communication (IPC) mechanism, executes them on the designated database and returns the generated results' set back to the client part. The client part

(GCP: Gateway Client Part) operates within Microsoft's Internet Information Server as an ISAPI compliant dynamic link library (DLL). Its principal role covers the formulation of SQL statements on the basis of input transmitted to the httpd by the interacting browser, composition of messages intended for the GSP, retrieval or the respective responses and transmission of results back to the browser.

Our intent is to find solutions for eliminating problems in different intranet uses. Some of the technical issues faced hereinafter have been encountered during the development of intranet servers for tele-teaching [Metaxaki-Kossionides 97] where a significant volume of data needs to be provided to the user in very short time.

This paper is structured as follows. Section 2 presents the protocol designed for the interaction between the GSP and the GCP. Section 3 discusses the internal structure of the two modules in the software prototype. The GSP, due to the requirement for the execution of any SQL statement submitted by the GCP, is based on the X/Open compliant Dynamic SQL API that many of the contemporary RDBMSs offer (e.g., Informix, Oracle). The GCP has a multi-threaded structure but the execution of individual threads is controlled to avoid potential overflows in the Socket queue of the GSP. In Section 4 we present certain results from the pilot operation of the gateway. To evaluate the efficiency of the thread controlling mechanism we have tested the gateway prototype through a HTTP pinger program which simulates the traffic caused by a population of WWW users. We conclude this paper in Section 5 where we summarise the presented work.

2. Gateway Client - Server Interaction Protocol

One of the most crucial aspects of the architecture presented above is communication between the GSP and the GCP. The specification of such communication encompasses the design of a database oriented protocol as well as the selection of an IPC mechanism suitable for its implementation. The protocol is presented in the following paragraph while the selected IPC mechanism is BSD Sockets [Comer & Stevens 93].

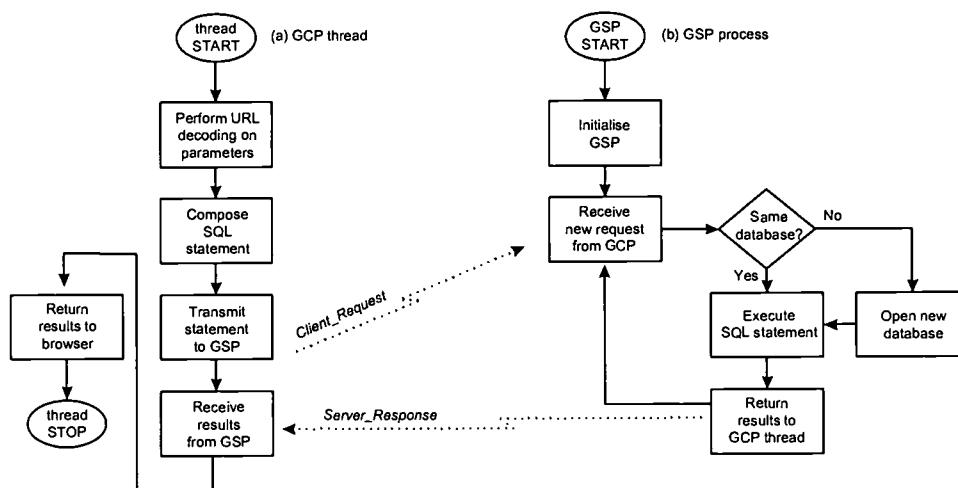

Figure 1: Flowcharts for GCP and GSP.

The protocol comprises two message structures; has the form of a typical request-response protocol. The first structure refers to requests transmitted by threads of the GCP. Such threads, as show in [Fig. 1], are responsible for URL decoding the activation parameters (contents of QUERY_STRING, name-value pairs, etc.), compose a request (*Client_Request*) intended for the GSP and proceed with its transmission. Such message indicates the database to be accessed, the SQL statement to be executed as well as the layout of the anticipated results (with respect to the HTML). In [Fig. 2] we provide the Backus-Naur Form (BNF) of *Client_Request*.

In [Fig. 2], **OCTET* denotes a sequence of printable characters and thus, represents a string field. Results are communicated back to the GCP threads by means of the second message of the protocol which will be referred to as *Server_Response*. The *Server_Response* is a plain byte stream (i.e., *Server_Response* = **OCTET*)

containing the results of the executed query. Such information is returned to the client, embedded in valid HTML commands. The type of commands used is the one specified in the *results_layout* field of *Client_Request*.

```
Client_Request = database_name + sql_statement + results_layout
database_name = *OCTET
sql_statement = *OCTET
results_layout = "TABLE" | "PRE" | "OPTION"
```

Figure 2: BNF of Client_Request.

3. Internal Structure of GSP and GCP

3.1 Gateway Server Part

The GSP is a standard UNIX demon process developed in conventional C and operated in a Sun Solaris workstation. Due to its generic orientation, GSP should be able to dispatch any SQL statement irrespective of the database-table and field combination it addresses. In this respect, query execution is realised through Dynamic SQL. Dynamic SQL allows applications to interact with database tables and fields without prior knowledge of their structure, data-types, length etc. [Date 95]. In our software prototype data retrieval was realised through the Dynamic SQL API of the Informix RDBMS [Informix 96] and more specifically, through the *sqlda* C structure (not standardised by X/Open but providing quite similar functionality). The use of Dynamic SQL, though, could undermine the performance of the proposed architecture. As the database management system needs to generate an access plan at runtime for Dynamic SQL statements, Dynamic SQL is generally slower than static SQL (static SQL is used when conventional Embedded SQL programs are built). To diminish the associated overhead, we have adopted an optimised form of Dynamic SQL execution, named *prepared* execution.

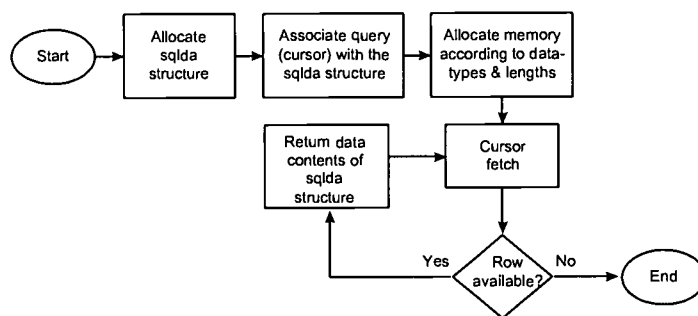

Figure 3: Information retrieval through the *sqlda* structure.

The *sqlda* structure indicates, similarly to the X/Open System Descriptor Area, the number of columns fetched as well as their particular characteristics (datatype, length, name, precision, scale, etc.). Furthermore, *sqlda* contains pointers to the actual data. As the database access through 3-GLs (i.e. C, COBOL) is cursor based, pointers to data are updated each time a new row is fetched by the system. In our case, the server process scans the overall *sqlda* after each invocation of the cursor FETCH command and prints its contents according to the *results_layout* field of the *Client_Request*. The dynamic mechanism for database access is presented in the flowchart of [Fig. 3]. The *sqlda* structure rendered our prototype capable of accessing any database table, without the need for hard-coded definitions, system tables lookup etc. In addition to the above, through the functionality of the DATABASE command (Embedded SQL) the prototype could access the whole range of available databases. Results are returned by the database agent in three different formats which are specified in the *results_layout* field of *Client_Request*. HTML Tables ("TABLE") and preformatted text ("PRE") are mainly used for the tabular presentation of query results. The "OPTION" alternative is used for the population of combo boxes intended for Query By Example (QBE) forms [Hadjiefthymiades & Martakos 96]. Regarding its

BEST COPY AVAILABLE

communication with the GCP, the GSP behaves as an iterative connection oriented server [Comer & Stevens 93].

3.2 Gateway Client Part

As already discussed, the GCP was built as a dynamic link library (DLL) compliant with the ISAPI specification. ISAPI DLLs can be loaded and called by an HTTP server and provide similar functionality to CGI applications. The competitive advantage of ISAPI over CGI is that ISAPI code runs in the same address space as the httpd and has access to all the resources available to the httpd. Additionally, ISAPI extensions, due to their multi-threaded orientation, have lower overhead than CGI applications because they do not require the creation of additional processes upon reception of new requests and do not perform time-consuming communications across process boundaries. ISAPI DLLs may be unloaded if the memory is needed by another process. Interaction between the ISAPI extension code and the httpd is performed through a memory structure called Extension Control Block. Each request addressed to the ISAPI extension causes a new ECB to be instantiated and filled with information like the `QUERY_STRING` parameter encountered in common CGI applications.

In the prototype, the GCP consulted an external file where the mapping of databases to specific database servers (hosts) was held. Additionally, this external file contained the TCP port of the database server to which the GSP was bound and the GCP should address its *Client_Request* messages. [Fig. 4] presents the distributed operation of the gateway where one GCP is capable of relaying users' requests to multiple database servers. The TCP network can be the Internet, a LAN. Alternatively, the loopback interface of the WWW server machine could be used (Windows NT hosted RDBMS).

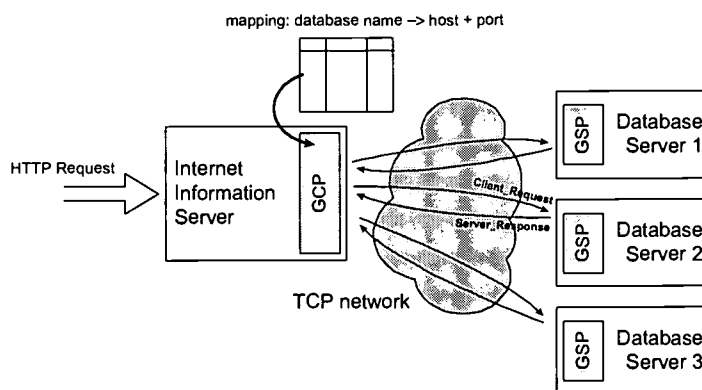

Figure 4: Distributed operation of the gateway.

For its communication with the GSP, the GCP uses the Windows Sockets (Winsock) library [Boner 96]. Although the Winsock interface supports the "Asynchronous notification", through which several Winsock primitives can be executed in non-blocking mode, we based the internal structure of the GCP on the blocking mode of operation (i.e., primitives like `connect()`, `accept()`, `recv()` and `send()` remain blocked until the respective network task is completed). The same model applies to the UNIX Socket interface.

One important issue that affects the design of the GCP is the possibility of excessive loads in the GSP which may result in connection rejections. When the size of the demon's incoming queue exceeds the specified maximum, new connections are dropped (more accurately, the TCP SYN packets - used in the 3-way handshake - are dropped). To cover this case and apply a pro-active strategy which could eliminate connection rejections, the GCP employs a Windows *semaphore* [Schildt 97]. Through this semaphore, the simultaneous operation of multiple requesting threads of the ISAPI extension can be controlled. The semaphore allows one or more threads to concurrently access a specific resource which in our case is the capability to issue a socket connection request towards the designated GSP. The maximum number of threads that can simultaneously gain access to the resource is specified in the `CreateSemaphore()` primitive. When the maximum number of threads allowed within the semaphore is reached, new threads, that try to obtain control of the resource remain blocked. The time, during which, new threads may remain blocked is controllable and may extend to infinity. The

semaphore is released by a non-blocked thread as soon as the latter receives the *Server_Response* from the GSP. In our prototype, the maximum number of threads allowed to simultaneously communicate with the GSP is 6 while the maximum waiting time for a thread has been set to INFINITY, (i.e., all threads are eventually allowed to transmit).

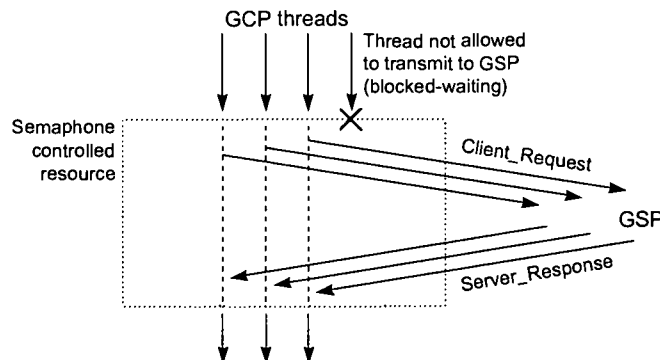

Figure 5: Semaphore controlled transmission of *Client_Requests*.

4. Gateway Performance Measurements at Increased Workload

A series of trials were performed to demonstrate that the connection rejection avoidance mechanism discussed in Section 3 substantially ameliorated the behaviour of the gateway. The relevant testbed consisted of two workstations connected through an Ethernet LAN. The LAN was isolated by other workstation to exclude unwanted traffic which could endanger the accuracy of our measurements.

From the two workstations the first was executing Windows NT while the second Solaris 2.5.1. In the Solaris workstation we have installed and configured an Informix Online Dynamic Server Ver. 7.1. Attached to the RDBMS was the GSP which was programmed in ANSI C and Embedded SQL. The Windows NT workstation was executing Microsoft's Internet Information Server (httpd) and the GCP. The latter module was programmed in MS-Visual C++ ver.5. Additionally, the Windows NT workstation was equipped with a HTTP pinger application capable of generating the traffic caused by a population of WWW users. The pinger application directed its requests to the httpd through the TCP loopback interface. This architecture is shown in [Fig. 6].

The pinger was configured to emulate the traffic caused by up to 10 simultaneous HTTP clients. Cumulative statistics were collected and recorded for each hypothetical HTTP client after the repetitive execution of 40 HTTP requests. Two series of trials were performed: one in which the connection rejection avoidance mechanism was not activated in the GCP and one in which the considered mechanism was brought into effect. In the former case, after the 6 users limit, we observed a considerable connection rejection rate. The percentage of successfully completed requests as a function of the HTTP population is plotted in [Fig. 7].

When the connection rejection avoidance mechanism was applied (i.e., the semaphore prevented multiple threads from simultaneously accessing the GSP), the total time required for the completion of experiments was increased. GCP threads incur an additional delay due to the fact that they are blocked waiting for the semaphore to be released by another thread which has already established communication with the GSP. Connection rejections in GSP are not experienced in this scenario. The additional time overhead is calculated at 2.7% and 2.1% for the 8 users and 10 users scenarios respectively (i.e., an HTTP user is guaranteed to provision of the service - database browsing - if he is willing to experience an additional time overhead in his queries for information; the mean value of this overhead is estimated at 2.1% for the 10 user workload).

5. Conclusions

In this paper we have presented the design and implementation of a client/server WWW-DBMS gateway. This gateway adopts the ISAPI specification for its interface towards the WWW server. Additionally, the gateway employs the BSD Sockets mechanism for the communication between its client and server parts. The BNF of a proprietary protocol introduced for the communication between these two components of the gateway has been

presented. To reduce the connection rejection phenomenon at the server part of the architecture, throughout periods of heavy workload, the client part applies a pro-active strategy through the introduction of a semaphore structure. The benefits from the introduction of the semaphore has been quantified through a series of trials.

Abstract: The following contribution describes our present approach to the development of hypermedia materials for and by the help of students. The interactive JAVA learning and teaching environment *mechado* intends to illustrate the idea of developing a mixture of highly interactive animations and simulations, so called *explorations*. Explorations form a digital laboratory, which allows students to create, modify, calculate and describe complex problem settings in an interactive manner over the net. *Explorations* are more than common animations, since they give the student a most direct feedback and operate more as an interactive learning environment dealing with a special topic. As a second fact explorations do not only provide a constructive net-based workbench for students, but allow teachers to define tasks and respective constraints that have to be worked out by the students. Furthermore, explorations are means to structure the teaching materials, because they represent complex multimedia models which are centred around important themes and issues in the respective curriculum.

Introduction

On the one hand the rapidly growing number of conferences, books and articles dealing with computer-based concepts and methods for teaching and learning exemplify that new media may soon become a natural and integral part of all kinds of learning processes. On the other hand, the vast amount of publications shows that multimedia still has not reached this goal, because we are teaching about means and technologies to support learning rather than discussing what should be learnt and why. In our view two deficits have to be overcome:

Viability of every day use (Alltagspraxis) [see Brennecke & Keil-Slawik 1995]: Tools and infrastructures must be designed in such a way that they support the day to day activities of students and lecturers and ease their burden rather than demonstrate outstanding and unparalleled single accomplishments.

Electrification of the Nuremberg Funnel (Nürnberger Trichter): Multimedia and networking should be used to enhance the lecturers ability to communicate what they have learnt and to decide how to accomplish their teaching goals rather than increasing the lecturers means to control the learning process by supporting them with an ever more refined mechanism for instructional design [see Brennecke et al. 1997].

Both deficits are by and large caused by an engineer's exclusive concern to only demonstrate the flexibility of a new innovative technological idea (what Ted Nelson coined *cybercrud*), and an pedagogue's continuous attempt to control the uncontrollable, the self-organising process of learning. Finally economists' attempt to cut down costs by replacing expensive labour processes by way of using multimedia technology.

In contrast to a technology centred approach, we have set up during the last 5-6 years an infrastructure for computer supported cooperative learning, which allows us to study the production of teaching material and its use under the constraints of routine teaching in a university.

Everyday viability by setting up a complex learning environment comprising networking and special server technology, electronic course materials, multimedia laboratories, new concepts of teaching as well as especially designed furniture is our innovation [see Keil-Slawik & Selke 1998].

Everyday viability, however, is not restricted to the configuration and adaptation of existing tools and technology, but it includes the development of innovative technology as well. The only difference is that the design of such projects is not primarily based on an analysis of what can be sold in terms of innovative contributions to a specific scientific community and what might be applicable in a couple of years from now. It is rather based on

an analysis of today's pitfalls and shortcomings and an assessment of what can be integrated in today's infrastructure to create a sustainable learning environment.

To avoid misunderstandings, we would like to add that this is not a question of innovation versus every day viability – we need both. The point is that integrating both is not just a matter of developing and applying technology at different instances of time. Many facts of this integration require intertwined activities of design, use and evaluation where sometimes only hard demands and requirements of every day teaching and learning activities (situated actions) provide the necessary feedback needed to decide which mixture of technological and non-technological means will finally lead to a sustainable learning environment.

Our entire approach to learning, our education and character are geared more and more towards active participation in the learning process. Students write their own texts in school from their first year on, in mathematics problems must be solved independently for a deeper understanding which results in the creation of new problems to be discussed. Modern didactical concepts aim at a self-exploring process of learning. Therefore, the students should be enabled to develop new knowledge independently and “learn how to learn”. They should be encouraged to discover and solve problems in their everyday environment on their own. Following this philosophy, learning is not simply the transfer of materials into the students heads. Rather it is the art to awake an interest and to simplify and to illustrate the acquisition and compilation of knowledge in new ways. To this end the objective of new media is to develop an active and open organisation of knowledge transfer. Multimedia cannot be a high-tech solution for the old problem of transferring knowledge as easily as possible from books or from the head of the instructor into the head of the learner.

Our metaphor of “the quarry of learning” [see Keil-Slawik 1998] describes learning with the support of multimedia as a collection of most different aspects and styles. Each student breaks his personally relevant “stone” from this “quarry”, i.e., he/she learns individually. We see the realisation of this idea of the “quarry of learning” in the development of most different representations of knowledge by hypermedia working environments and multimedia databases. The main target is to provide the students with a surrounding that makes perceptive and active learning possible. The stimulation and the willingness to experiment with objects, to try them and to explore them in a playful manner will lead to active interaction and to the discovery of teaching subjects. Learners should understand and commentate texts, diagrams, animations and visualisations in hypermedia working environments and relate them to each other. Personal structuring, processing and compression of contents permits new forms of compilation of contents, particularly in a group.

Explorations, The Next Dimension of Learning

The integration of new media in engineering education and the “in-field test” of advanced future learning and training concepts can be characterised as the main interest of the project *mechANIma*¹. The didactical concept as well as the underlying theory of the establishment of learning supportive infrastructures and the everyday practice of hypermedia configuration has already been described in details in a number of publications. Specific implementation concepts of the project *mechANIma*, the editing of basic mechanical problem representations, the development of interactive animations and visualisations has already been documented in detail at different conferences.² The present paper intends to illustrate the idea of developing a mixture of highly interactive animations and simulations, so called *explorations*. The main goal of such *explorations*, as realised in one early example, the statics tool *mechado*, are their possibilities to explore certain facts and to interact individually with the system. *Explorations* are more than common animations, since they give the student a most direct feedback and operate more as a interactive learning environment dealing with a special topic.

Another important feature of *mechado* is the fact, that it was developed by one of our students at the University of Paderborn, Michael Rüter. This supports our idea of an engineering student who is able to create his own sophisticated multimedia applications by the help of an adequate mixture of powerful and easy to use tools and applications.

¹ The acronym *mechANIma* symbolises a synthesis of the terms mechanics and animation. The idea of introducing multimedia to form everyday teaching practice characterises the endeavour to integrate all audio-visual media like lecture records, lectures, instructional films, simulations and animations into a data base oriented hypermedia system for information and documentation. Main focus of the *mechANIma* project is the development of the necessary infrastructure and a pedagogic concept for a meaningful use of new media teaching. The *mechANIma* project is an interdisciplinary cooperation between the Laboratory for Technical Mechanics, and the Working Group Computers and Society at Paderborn University.

² See [Ferber et al. 1996], [Hampel & Ferber 1998], [Hampel et al. 1998a], [Hampel & Keil-Slawik 1998] and [Hampel et al. 1998b]

The Need for Explorations- *mechado*

One of the subjects of technical mechanics is statics, i.e., mechanical systems, such as bridges or cranes, which are loaded by forces and yet stay at rest [see Pestel 1989], [Gross et al. 1990], [Assmann 1993]. From the viewpoint of engineering science these systems play an extremely important role. It is the art of engineering to describe real objects, such as bridges and cranes, from a more abstract point of view and not necessarily consider every detail, but all the essential mechanical features. Especially components, which have a relatively simple structure and can be simplified to meet the features of a truss system are of interest. Bridges, cranes or scaffolds are suitable examples for such systems.

Despite the simplicity of the concept of a truss system the calculation of its internal forces and its reaction forces usually requires a substantial amount of algebraic manipulation as well as calculation time. The calculation of the example shown in [Figure 1] would require the solution of a system of equations with 18 unknowns. Since a by-hand calculation is very time-consuming, students cannot experience creative learning by changing and developing the best design for the crane possible. In this case common teaching methods fail, because there is no room for "creative play" with this type of problem. Realising this, the interactive framework-simulation of *mechado* was developed. The individual generation of frameworks with *mechado* particularly allows a creative design study. The editor offers the possibility to generate a framework step by step. Bars can be separately sketched, bearings and loads can be placed at various positions of the framework. During the interactive creation process of the crane the students get a good insight into the features of a truss system in general and will find answers to questions, such as:

- How does a framework react if the bearings or loads are changed?
- How does a framework react if bars are deleted or added?
- How have the bearings to be rearranged, so that the framework is stable?
- Which bars are free of forces?

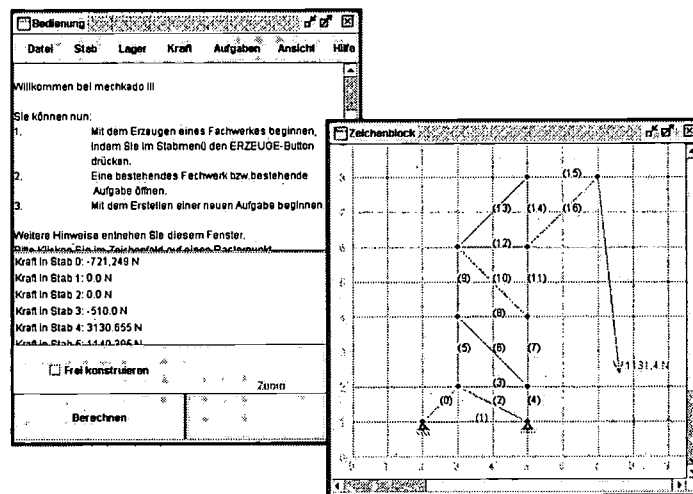

Figure 1: Example of a framework, which was created and solved in *mechado*.

The Development of *mechado*

The definition of fundamental elements and features of a truss system simulation was a necessary pre-requisite before implementing it in a programming language. In *mechado* simple truss systems can be created, to which many engineering problems can be reduced. Simple truss systems have to meet the following requirements:

- The bars of the truss are connected in central joints ignoring friction.
- Loads are to be applied to the system only at the joints. The forces in each bar are assumed to be either tensile or compressive in nature.
- The bars of the framework are straight-line structural elements.
- Single or double valued bearings are applied suitably which ensure static equilibrium of the truss system.

BEST COPY AVAILABLE

- For simple frameworks the connection of bars has to be reproduced by the following rule: Start with a triangle of bars and extend it by adding two new members which intersect in a new joints until all bars and joints are used up.

Besides the interactive construction of frameworks with the above mentioned characteristics the creation and solution of problems is a further key feature of *mechado*. With the assistance of this functionality *mechado* is particularly useful in first and second year lectures which deal with the subject of statics. Some valuable teaching assistance is easily implemented [Figure 1].

The software package VisualAge for Java from IBM was chosen as the development environment for the first version of *mechado*. Due to the usage of the VisualAge package it was possible to create a large part of the user-interface by visual programming.

Besides its object-oriented approach, Java is the dominating programming language for applications in the internet. Thus, *mechado* can easily be started out of the internet and offers the opportunity to provide a wide range of users with the program.

Creation Of a Problem Example With *mechado*

A fresh start of *mechado* will result in a divided user-interface. The first window shows the drawing surface [see Figure 2] and the second window depicts all menus and text fields [see Figure 3]. If a menu point is selected, additional information will be displayed in the information field. Consequently, further explanations of each of the menu points is superfluous.

The important feature of *mechado* is the solution of truss frame problems which will be described next. In principle only two types need to be distinguished. The first type of problem consists of only one task, the student herself/himself has to generate the solution to a given problem. The second type of problem contains two tasks, the creation of a truss system as well as its numerical evaluation.

Creation of a Problem

After clicking *Start* in the menu *Erzeuge Aufgabenstellung (generate problem)* a truss system can be created which starts in the menu *Aufgabe (problem)*. The mode for drawing the truss members is activated by clicking on *Erzeugen (generate)* in the menu *Stab (member)*. If required, bearings and loads are applied to the framework (Fig. 6).

Figure 2: Example of a framework for a task.

Figure 3: User-interface of *mechado*

Afterwards the description of the task can be typed in the text area [Figure 3(1)]. When the task is done, the menu item *Aufgabenstellung beenden (finish problem)* in the menu *Aufgabe (problem)* is selected [Figure 3 (2)]. The so far generated problem is saved by clicking on *Fachwerk (truss system)* in the menu *Speichern (save)* [Figure 3 (3)]. After this step a problem has been created which only contains one task.

Generation of a Solution to a Problem

After a task has been created the solution to the task can be started immediately. Alternatively a file with an existing task must be opened. This is done by clicking on *Aufgabe (problem)* in the menu *Öffnen (open)* [Figure 3 (5)]. The generation of the solution is started by activating the menu item *Erzeuge Aufgabenlösung (generate problem solution)* in the menu *Aufgabe (problem)* [Figure 3 (6)]. The menu *Ansicht (view)* renders it possible to switch between the actual state of the solution and the task by clicking on the items *Aufgabenstellung (problem)* and *Aufgabenlösung (solution of the problem)* respectively [Figure 3 (7)]. Supplementary text for the solution may be typed in the text area [Figure 3 (8)].

If the solution to the task is completed as required, the forces of the framework will be calculated by clicking on the button *Berechne* (compute). After the computation the forces in each bar becomes apparent through colouring.

Figure 4: Different views on a calculated framework.

Figure 5: Output of the calculation for the internal and reaction forces.

Blue coloured bars indicate tensile forces, red coloured bars are loaded by compressive forces. Green bars are so called null bars, i.e., they are not loaded at all. By clicking on *Stabkräfte anzeigen* (display forces) in the menu *Ansicht* (view) it is possible to show the result of the calculated forces directly at the members in the drawing plane [Figure 4]. The internal forces of the bars and the reaction forces can also be read into the output window of the calculation. When the final solution to the task is found, the generation of the solution is finished by clicking on *Ende* (end) in the menu *Erzeuge Aufgabenlösung* (generate solution). The whole problem can be saved by selecting *Aufgabe* (problem) in the menu *Speichern* (save).

Class Structure in *mechado*

Classes, meaning independent program segments, are important components of object-oriented programming. The following classes can be found in *mechado* [Figure 6]. The development of classes, which obtain data and methods for the specification of objects, can very simply be handled in Java and clearly reflects the object-oriented approach. The features of the desired objects, which should be represented in the class, simply have to be defined and transformed. For example Objects of the type “member” have the following characteristics:

- a beam member has a start and end point as well as a number,
- a member has one internal force,
- the geometric position of the member is determined by the angle to the horizontal, the gradient, and its x- and its y-position, respectively.

Figure 6: Class structure of *mechado*

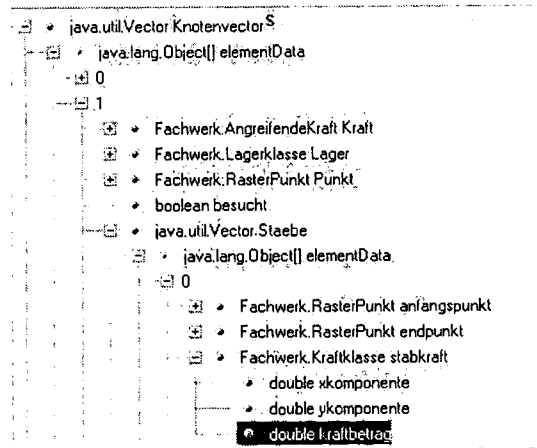

Figure 7: Detail of the *Knotenvector* in the debugger.

Objects of the type “bearing” are clearly defined by their position, the bearing coordinates, the type of bearing and the forces it is required to hold. Objects of the type “force” are defined by their magnitude and the x- and y-components of the force.

The above listed detail of the VisualAge debugger makes the object-oriented approach quite clear [Figure 7]. In the vector “nodevector” (*Knotenvektor*), which contains all joints of the actual truss system, all features for each joint can be found: an applied load, a bearing, the position of the joint as well as all bars that are added to the joint.

Conclusions

By creating explorations like *mechado* we will not try to compete with advanced technological solutions for single purposes. The notion of “Alltagspraxis” - “every day practise” that provides the necessary background for the integration of different tools and environments into a sustainable infrastructure is a research goal on its own. It is not sufficient that technology works in principle, but it must work on a day to day basis. Accordingly *mechado* and other explorations are evaluated by our students at the moment. We hope that these studies will support our idea of students getting a better insight and deeper understanding of mechanics by the constructive view on statics presented by *mechado* and other *explorations*.

sTEAM - Cooperation and Structuring Information in a Team

Thorsten Hampel

Heinz Nixdorf Institut, Computers and Society
Fürstenallee 11, 33102 Paderborn, Germany, E-mail: hampel@uni-paderborn.de

Abstract: Setting up infrastructures for computer-supported cooperative learning requires an integrated design approach which covers a range of different aspects, such as networks, servers, teaching concepts and tools. Cooperation is an integral part of the learning process and not just the complement to individual learning. Learning requires the flexible combination of the cooperative and the individual as well as synchronous and asynchronous activities. The research project "sTEAM" (Structuring Information in a Team) combines the experiences of our research group in the field of learning supportive infrastructures, with novel technological concepts to explore new ways of computer-supported cooperative learning through virtual environments. The aim of sTEAM is to allow groups of students and lecturers to construct and organise their individual and cooperative learning space. Both teachers and students should actively participate in the process of building knowledge. Students assemble in virtual rooms and rearrange the semantic structure of the learning room by simply moving or exchanging documents while communicating with each other. The sTEAM system consists of a highly efficient object-oriented sTEAM-server, connected to a database and flexible Java-clients. The server is event-driven and manages all user-objects as well as the communication between the connected clients. Clients are flexible Java components that adapt easily to individual needs. One important feature of the sTEAM system is that users are able to program objects during run-time.

Introduction

The Paderborn "DISCO" (Digital Infrastructure for Computer-Supported Cooperative Learning) is an elaborate multimedia environment for teaching and learning. It comprises of interactive teaching theatres (see [Norman 1990] and [Shneiderman 1993]), production facilities for multimedia documents, work places, and different kinds of networks, servers and software tools.

Setting up the DISCO was a combined effort of several research groups from five departments, under the guidance of our research group. One of our primary research goals is to evaluate the everyday viability (Alltagstauglichkeit) of multimedia-based learning environments (see [Brennecke, Schwolle, Selke 1997], [Brennecke & Keil-Slawik 1997] and [Brennecke & Keil-Slawik 1995]) and to provide a platform for exploring new ways of teaching and learning. Thus, the "Interactive Teaching Theatre" supports many-to-many communication replacing the traditional one-to-many, in-silence communication.

Networked personal computers supported by an interactive control panel enable students to be the sender as well as the receiver, the speaker as well as the listener, and the presenter as well as the viewer. Interaction takes place between people and not between computer and human. In order to accomplish this, new furniture even had to be designed to allow us to work in the most flexible way, with or without technology.

Together, special web server technology (sTEAM and Hyperwave, see [Andrews et al. 1995]) as well as additional self-developed cooperative tools, provide means for creating, accessing, annotating, and maintaining multimedia documents wherever and whenever learning takes place. In turn, we are able to conduct lectures fully via the Internet and evaluate the trade-off between the increase in resources needed and the effectiveness and quality of the teaching and learning process. This gives rise to the development of new concepts and methods, and the exploration of their viability under the constraints of day-to-day teaching and learning activities. As a result, we are able to specify requirements for setting up a sustainable multimedia infrastructure.

This infrastructure contains components relating to software as well as hardware. In particular, the connection and the variety of tools available to individually design teaching materials, text and graphics; as well as the cooperation and

network tools applied at the working environment and other learning environments, give new inspiration to the ways of modern teaching. Particularly the connection of tools, such as CSCW systems that are equipped with learning supportive infrastructures, that support cooperative activities, are a healthy and fruitful mixture. In this sense, we do not so much intend to envision learning suggestive infrastructures as an independent set up or institution, but rather as being a necessary requirement for everyday use of new media in teaching. The idea of sTEAM is based on the fact that students need to create their own entry points to, and paths through, the material as part of their learning process; rather than follow pre-defined paths only which will more likely lead to the what's known as "lost in hyperspace syndrome". However, today, students lack appropriate means to create their own access structures to the quarrel and use trails [see Bush 1945] as well as entry points as objects of cooperation.

"Why We Decided To Built sTEAM."

So far, a classical client-server architecture (Hyperwave) is used to manage all documents for three courses in our institute. Our experiences show that in daily teaching and learning practice, three main problems arise:

very flexible, but pre-defined document structure - In normal teaching practice students learn with the help of a, in a sense, static document structure defined and written by lecturers and teaching assistants. For the learner this hypertext structure allows different ways through the material by following various links in alternative orders. Hence the flexibility lies in the link structure. In most cases this link structure is relatively static, students only have the possibility to build their own structure through bookmark lists or private collections in the Hyperwave system [see Andrews et al. 1995].

The "lost in hyperspace" syndrome - When building quite a large document space, covering an entire lecture or even three quite different lectures, the possibility of the so called "lost in hyperspace" syndrome arises. Our experiences dealing with standard WWW-technology show that structuring a large amount of documents only through the link structure, without an underlying structuring philosophy, such as the room or folder metaphor [see Henderson & Card 1985], is nearly impossible. When considering different types of learners it is considerably impracticable to guide each user through the document space. The danger and frequently the result is a loss of orientation in the linkage structure of the documents. Even from the point of view of a lecturer or author of document structures, the complex problem of maintenance and restructuring often leaves them feeling disoriented and confused.

no combination of productive and communicative facilities without discontinuities in the use of media - One field of our research is to evaluate the scientific interrelationship between information and communication technology and its usage context. Therefore, the main focus on the study of human learning processes, lies in the integration of new media and methods into the daily learning and teaching practice — particularly the integration of new media into present learning and group environments. Up until now, we have not found any hypermedia system which copes with this particular teaching environment. Common hypertext and multimedia systems are in most cases closed systems concerning the interaction of various learners with the learning materials. As a result, learners use different tools and media to communicate and work with the learning materials. We call this gap of integration and change between the media, out of technical reasons, "*discontinuities in the use of new media.*"

Due to the aspects listed above there is an inherent lack of integration of communication supporting technologies and document structuring systems. For our particular teaching situation, it is significantly important to develop systems which support asynchronous as well as synchronous communication between the users, and allows one to structure documents and link the structures of the learning space individually as well as in groups.

sTEAM is our platform for the evaluation and research of new forms of human communication through virtual environments.

In consideration of existing products, we are not free to study the aspects of sociology and didactical concepts of learning. Meanwhile, it is possible to simply modify our own system. With this flexibility we may even consider studying the social structures of virtual learning communities in order to learn more about how students learn cooperatively [see Becker & Mark 1998]. Additionally, we are easily able to adapt and develop innovative user interfaces and add additional functionality needed for a specific experiment or course. Finding innovative design solutions for cooperative learning requires the evaluation of different approaches; for example, various forms of integration of the student's own work. A precondition of our supposition is the ability to easily design and implement special learning supportive infrastructures. The sTEAM system is designed to fulfil our particular needs in this area, concerning the flexibility to create prototypes and models quickly and to evaluate them with the help of our students under everyday learning and teaching conditions.

sTEAM Architecture

When commencing to describe the sTEAM architecture in detail, it is necessary to step back to the beginning of the history of the internet. With the emergence of local area networks and the massive growth of internet communi-

cation games on such networks, the so-called MUDs (multi-user dungeons), were developed.¹ While many of these were text-oriented, recent games of this type also support graphical user interfaces. MUDs are based on real-time communication and interaction of multiple users moving through a "virtual world" organised in "rooms" or "places". MUDs are based on a client-server architecture, allowing players with different computer systems to participate in these games from different places. On the one hand, MUDs are multi-user capable, on the other hand authorised players, the so-called wizards, can restrict access to the game. They are able to grant or deny a certain group of players access to specific "rooms" and are also able to extend the "world". In such games direct real-time communication and interaction are the main objectives. Groups of players can communicate directly and mutually influence each other in their game actions, as the communicational flow is unrestricted. Given that the architecture of MUDs is open, the games can be modified and adapted to new situations during the current session even while the system is running. Therefore, at any time during the game new situations could arise, which groups of players have to contend with.

In order to be able to modify MUD worlds in real time, it was necessary to develop very powerful interpreted object oriented script languages, e.g., the LPC language². The idea to use this efficient architecture for non-game purposes is not new. A number of "serious" applications usually called "collaborative virtual environments" (CVE) - have been developed on top of the MUD architecture. By using techniques like MUD, IRC (Internet Relay Chat) or even newsgroups, social cohesion is supported or set up between users; a phenomena which is called "virtual community" [see Rheingold 1991], [Rheingold 1994].

Since our commencement in 1997, our goal has been to combine the advantages of both classical MUDs, and Hypermedia database systems, with each other, allowing users to share documents in a virtual world and to communicate with other users while working with certain documents [see Bollmeyer 1997]. The system developed is called sTEAM and uses the paradigm of virtual rooms to represent document space. People can meet in virtual rooms, interchange documents and communicate with each other. These forms of synchronised communication are particularly important when considering cooperative working conditions.

Similar to other approaches (e.g. [Huxor 1998], [Wessner et al. 1998]) the rooms can be seen as areas of interest or as given subjects of a lecture. We believe that the room metaphor [see Henderson & Card 1985], which is of course a directory metaphor, opens the gateway to serious research fields; namely, the question of awareness or presence. In these rooms (areas of interest) the stored objects are documents, all of which share a common topic or subject. Exits connecting different rooms represent hyperlinks. A prime advantage of this connecting technique is that hyperlinks represent a semantic context, without having to show a planar layout of the rooms illustrated by a planar map. We therefore believe the choice of a semantic oriented structure enables the user to create individual and powerful navigational concepts [Bush 1945], [Nelson 1980], [Klemme et al. 1998].

Among the system's main new features is its ability to easily construct new rooms. As virtual rooms can be created by any user on-the-fly, document collections can easily be individually or collaboratively structured by the students. If students, for example, wanted to discuss different approaches to a certain topic during a tutorial or lecture, let's say, on user interface design, they could create a new room and meet there. They could then search for examples of different user interfaces on the web and collect them (as hyperlinks or as copies of the documents) in the new room. After they have finished their work, they could either leave this room and make it accessible for other students interested in the same topic, or just take a few objects back to their private rooms and delete the temporarily required room. With regard to the learning environment, the room, metaphorically speaking, gives rise to an interesting concept for structuring the learning process. Rooms may represent miscellaneous topics or different learning groups; at all times allowing groups of students to meet and work together on a specific topic. For every course there is one room designed to hand in one's exercises to the tutors. We are even considering the scenario of letting students mutually evaluate their exercises that are being presented in exercise and evaluation rooms.

¹ Essex Computer Science graduates Richard Bartle and Roy Trubshaw wrote the world's first Multi- Dungeon (MUD) game when they were students at the University of Essex, U.K. the end of the 1970's.

² LPC is a small, object oriented type C language developed by Lars Pensjö for LP-MUD, a Multi-User Dungeon environment under many UNIX systems.

Figure 1: sTEAM architecture

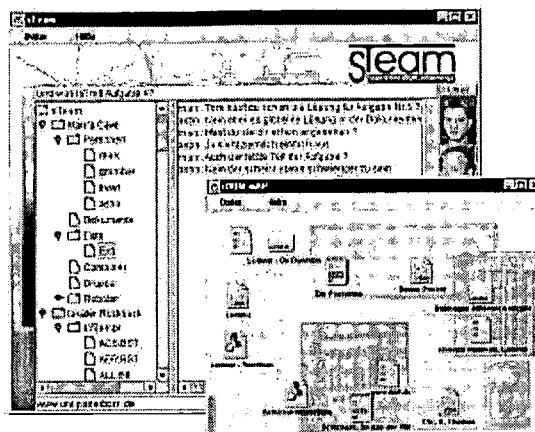

Figure 2: sTEAM client – prototype (design study)

Messages and attachments can be readily stored in such learning places and, most important, the learners would be able to meet in groups within the system. The system could either be used within a scenario where students meet “in real life”, using the rooms in the way described, or within a scenario where students do not meet but rather make use of the integrated facilities that enable them to synchronously communicate with each other. Currently, only a text-based chat tool is integrated, however audio or video connections may be implemented in the future. Thus, collaboration is enhanced through a powerful CSCW-system regardless of whether people meet in the same place or work from different places.

We are currently in the process of developing a mechanism that creates, quick and easy, special robots that behave as autonomous tools or users in the sTEAM system. This technology allows us to create individual search engines, helping assistants and wizards to attach individual functionality to rooms or groups of users. Following the example above, users can create a guided tour through their materials or even a small helping assistant for new learners entering the respective learning space. Another potentiality is to create an open whiteboard for comments notices, etc., which are automatically posted to the author of the material, correcting their mistakes or to inform them of new proposals.

Groups of students and teachers can thus build and structure their individual and cooperative learning spaces. Students are given the possibility to actively participate in the process of constructing knowledge. Hypermedia documents can be transported easily between the various rooms. The underlying philosophy is that users meet in virtual rooms and rearrange the semantic structure of the learning room simply by using drag and drop, or exchange documents while communicating with each other — naturally using sTEAM.

The sTEAM system currently exists as a prototype, consisting of a client written in Java and a web server implemented in the MUDs own object-oriented programming-language LPC, using the Dworkins Generic Driver (DGD), a modified well-known MUD server [see Fig 1]. This system allows runtime modifications of all objects in the environment. Users can employ the predefined objects to create their individual environment inside of sTEAM, derive their objects from existing ones or create new ones by implementing them in LPC. As you would expect, many different new objects may be created over a long period of the system’s use. Even though the predefined object-types are sufficient for our current needs, the creation of user-defined objects will be an essential key feature in the future of sTEAM. Setting up learning supportive infrastructures means adapting electronic media and communication to the specific environment and context of the learner, not to adapt the learner to the medium. Therefore, it is essential to design a technology which allows one to adapt the CSCL (Computer Supported Cooperative Learning) system, simply and frequently to the particular needs of the learner. By using sTEAM learners may create and modify individual objects of unique appearance and behaviour, allowing them to adapt their individual learning space within the system to their special requirements.

The sTEAM Server

All data management is currently covered by the sTEAM server; data-objects are stored in a MySQL database [see Axmark 1999]. By using an open JDBC/SQL-database interface still under development, it will be possible to connect sTEAM to various databases in the future; thus allowing the use of multimedia documents stored in a particular database or of hypermedia objects stored on a standard Web-Server or Hyperwave server. By these means, sTEAM can easily be integrated into existing web environments.

All objects such as hypertexts, images, links, users, etc., have a number of common attributes that are used to control the objects details: such as name, access rights, owner, creation date, expiration date, etc., and its methods. In addition, some objects have special attributes and methods such as an associated MIME-Type with a download method for documents, or a method "talk to" for user objects. Users can also add their own generic attributes to objects. By default, the user object has a "virtual" container object, that is shown as a "suitcase" carried along by the user. Any objects intended to be taken along, even exits, can be stored in this suitcase and held there until being taken out.

sTEAM features a sophisticated security scheme resembling that of Hyperwave with one significant difference: User groups can be defined by any user, as they are just objects on the server which have attributes. Just the same as rooms, user groups can thus be created on-the-fly. Therefore, if any team of students decides to form a group which needs to share access rights, they can create a group object. (this concept is similar to the BSCW system see [see Hinrichs & Koch 1999], [Trevor & Koch 1997] or [Bentley & Appelt 1997].

Entry Point Into The Virtual Community -The sTEAM-Client

The client serves as the interface between the user and the functionality given by the server and thus has to be easy-to-use and platform independent. Due to this requirement it was implemented in Java. In order to create an easy-to-use interface in the current development [see Fig. 2], we restricted the view of the virtual environment to a simple 2D-representation. However, we are researching for an innovative 3D-representation of the document link structure or for the visualisation of elements of the room structure. We believe that 3D-representations may enhance the capability to display a large amount of nodes and documents or help learners to orientate themselves inside the document space. Interesting approaches are the adaptation of cone-trees or cam-trees and various similar concepts. (see [Robertson et al. 1993], [Young, 1996], or [Munzner 1998]).

Following this idea, we place great demands on the usability aspects of these representations and for them to run without the need of special virtual reality hardware, such as head mounted displays or eye trackers. The integration of these technologies would inhibit the flow of communication in group learning environments such as tutorials or lectures.

A brief description of our current sTEAM clients is as follows; the display presents three areas; one showing the users currently in the room; another showing the interior of the room, i.e., the objects including exits to other rooms; and the other the communication area. Here, the user is able to chat by typing text and talk or communicate in other text based ways.

All of these objects, even the users, are subject to direct manipulation. For instance, you can "talk to" other users, "download" documents, or move to other rooms with just a mouse click on the respective object. More sophisticated functions including the creation of new objects and file upload can be accessed by menus.

Conclusions

sTEAM is not our answer, but rather a new hypothesis embedded in teaching, allowing us to shape technology according to the needs of students and teachers. Thus sTEAM is used to study various concepts such as presence or awareness. Other interesting aspects are the sense of avatars [Damer 1998], or other concepts for 3D user interfaces such as special metaphors that visualise interaction patterns, etc. However, in doing so, our purpose is not to produce advanced technological solutions for single purposes. The notion of "Alltagspraxis", that provides the necessary background for the integration of different tools and environments into a sustainable infrastructure, is a research goal all on its own. It is not sufficient that technology works in principle, it must work on a day-to-day basis. Accordingly, DISCO as well as sTEAM are our approaches to supporting teaching and learning, but more important they are technological hypotheses which will help us to study the best way to support their processes in the future.

Web Based Intelligent Tutoring System for Collaborative Learning

SunGwan Han, GeunSik Jo
Inha University, Department of Computer Science and Engineering, Incheon, South Korea
Email: fish@eslab.inha.ac.kr

Abstract: This study suggests the design and implementation of ITS study by knowledge level for distance collaborative learning in a Web situation including the diagnostic agent examining the group agent and the students involved in the program. The students involved in this learning need to have a situation whereby many are simultaneously interested in the same subject and the same type of lesson. The similarity of their knowledge and ability level enhances the effectiveness of lessons on the same subject. The diagnostic agent examines the students and the results of the examination are added to the knowledge of the group agent thereby the group agent may be able to recruit the students based on their personal characteristics and requirements. The teacher module is composed of a tutoring module and an expert module as in the basic ITS structure. Dynamic resource scheduling that uses time as a resource has been used to make a model of the students based on their requirements, knowledge level and availability of time for learning, all of which are considered important in recruiting the students for collaborative learning.

1. Introduction

Today, the advent of the Web that can easily be connected through the "Internet" is known to be an easy and popular method for teaching and learning, moreover the Web provides us with a new horizon for an attractive tutoring system. This type of model is called a Web based tutoring system. This particular way of tutoring can be defined to mean that it is an activity that transmits intentional interaction by way of the Web to promote the student's ability to develop his knowledge and competence[8].

The tutoring system now in use however is centered on a type of tutoring system stressing the power of memory in most of the lessons. Such a system, relying on memory, does not take into account the cognitive information treatment process. Therefore, it is not only difficult to stimulate the thinking process but also fails to help students make a meaningful connection between the new information they have acquired and what they already have, thus failing to produce true understanding. In order to overcome this problem, the intelligent tutoring system, called ITS, came into being. ITS is composed of four different modules – the student module, the tutor module, the expert module and the interface module[7].

The ITS in a Web situation can be dispersed and each model is called an agent capable of communicating with each other. The agent is an independent computer program capable of acquiring knowledge and reasoning and capable of automatically solving a student's projects in lieu of the student. In this study, an arrangement has been made so that the diagnostic agent and the group agent may help the students freely exchange lesson-related information and their knowledge through KQML by connecting the tutor module with the students. In addition, the students on the same level are grouped together to allow them to pursue the same category of study with individual students engaged in chat rooms, discussion groups, bulletin boards, multi-media learning and detection lesson[5]. ITS is designed in this study to allow a multitude of students to engage in collaborative learning based on the Web with the computer tutor. A diagnostic examination was made to find out the knowledge level of the students. The dynamic resource scheduling using time as a resource was also made to ferret out student who can share time with others at the same time to ensure the effectiveness of the lesson. Finally, an attempt has been made to prove the validity of ITS in connection with distance collaborative learning.

2. Structure of Web-based ITS for Collaborative Learning

2.1 Basic structure

The structure chart of this system is shown in [Figure 1]. Each client has an interface module and a student module with a server containing a tutor module and an expert module. The diagnostic agent estimates the intelligence and knowledge level of the students through a diagnostic examination based on the basic data and requirements. Information obtained will be transmitted to the group agent. The group agent then examines the

other students in a Web situation based on the information. When it finds students with similar intelligence and interest in the same subject, it offers them a suggestion. When they accept the offer, they participate in the collaborative learning at a time they choose.

Figure 1. Structure of System

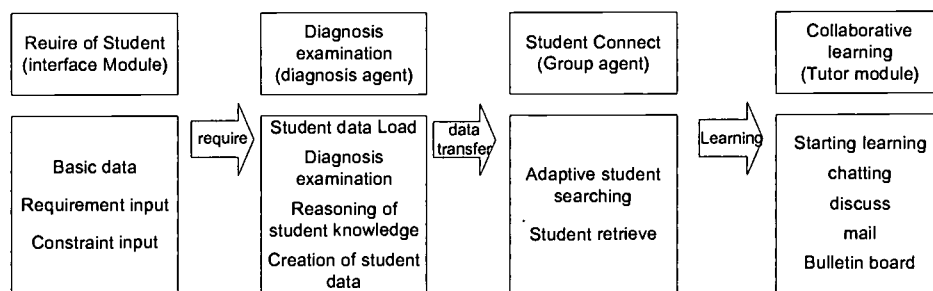

Figure 2. System Scenario

2.2 Tutor and Expert module

The tutor module containing the lesson program and strategy provides assistance on matters related to a suitable tutoring method and any mistakes the students make based on the data from the expert module[7]. The expert module is a knowledge base storing a detailed lesson program. The tutor module and the expert module are capable of providing a variety of services and prevent the server from being overloaded by changing the server depending on the type of lesson. All the servers exchange information through the group agent and connect the students to the lessons, exchanging information about the lesson program and the server's schedule. The tutor module connected to the student module should be able to assess the student's ability dynamically and predict a new lesson program by consolidating the knowledge obtained. In addition, it should have the ability to solve stereotypical problems by using stored plans and design a new lesson program through revision and adjustment[2].

The portion to be expanded and restructured is the mutual sharing of the knowledge that can be achieved by connecting the outside "Internet" to the knowledge base. The expert module and the tutor module may be supported through various multi-media material such as graphics, music, voice, animation and various communication methods such as mail, chatting, web board and monitor conferences[5].

2.3 Student module

The individual student model structured by the student model. The student model is composed of all the facts obtained through interaction between the students and the expert module and the basic information of the students are placed into it by the interface module. The student's basic input data and requirements for lessons are as shown in <Table 1>.

The student module is stored in the form of knowledge of frame and managed in three categories - the basic student data (limiting conditions and requirements), information about the diagnostic evaluation, assessment of the student's intelligence level with lesson environment. Information for the student module is inserted by interface. Diagnostic evaluation and lesson assessment results are stored with other student information file for future use in lesson scheduling.

Classification	Item	Instance
Basic Input Data	Name	Han sun gwan
	Sex	M
	Age	11
	Grade	5
	Language	Korean
Requirement (Constraints)	ID	Fish
	Study Course	Math

	Relation of Study	Interest: high
		Endurance: good
		Relation course: Science
		Study Manner: Very good
		Evaluation: 90 point

Table 1. Student Module

2.4 Diagnostic agent

The diagnostic agent composed of diagnostic rules for the student maintains and controls a student model by analyzing the student's behavior. A library list of mistakes students are liable to make is made and indicates the level of the students. The diagnostic agent indicated degree of understanding for each item of the Bug Library and records its history. For flexibility, the diagnostic agent delays a decision - making a student model with inaccurate knowledge might attempt to make on interaction with the students. A few limiting factors such as the required time and the number of interactions are applied to filter a student's mistakes and errors on time difference. It also revises the student model when it recognizes a student's misconception and estimates the student's intelligence level based on the revised numerical values, basic data and input material. Such numerical values are stored back into the student's module for use by the group agent in recruiting the students.

Figure 3. Levelled Diagnostic Process Model

The diagnostic process includes checking answers to the questions for correctness, solution time, degree of difficulty, Weight rate and is expressed in the form of a Rule Base System. Information regarding the assessment may be converted and updated according to the learning area.

2.5 Group agent

The group agent is an agent evaluating and recruiting students based on their intelligence level showing basic data (limiting conditions) and diagnostic assessment. The communication between the student module and the diagnostic agent is made possible through KQML. The information transmitted by KQML should be filtered and inter-mediated according to the lesson hours, subjects to be studied and intelligence level. In particular, scheduling for a lesson in the same area at the same time with a large number of students will complicate the scheduling.

At first, the students who can participate in the lesson is sought by taking into account the limiting conditions and checking the availability of time. The server is divided into “full”, “common” and “empty” and the student's time is divided into “good”, “yes”, “no”, carefully comparing the time availability between the server and the students and removing improper times (“no” or “full”) one by one. When the lesson hour is the same, the students are given a certain amount of time and a proper amount of time is allotted to the inappropriate students by loosening (“common” or “?”) the limiting condition.

Having too many students at one time poses another problem. In this case, the time could be given to the students by using an evaluation function. The evaluation function can be evaluated based on the student's behavior as supplied by the diagnostic agent. As such, each agent selects the best students through competition.

2.6 Communication agent

The communication agent provides various multi-media services in the lesson environment by connecting the students and controlling them. The type of service that can be provided includes chatting, a white board system, a multi-media player, mail management, user management, VOD and bulletin boards used in the existing Web.

3. Implementation and Consideration

The ITS designed and implemented in this study showed the interface and communication service by utilizing JAVA and C++ and diagnostic examination and preparation of lesson contents were made with the use of KAS(Korea Authoring System). JESS(Java Expert System Shell) was used for engine pattern matching and KQML was used to exchange messages between the agents. Users basic data and requirements placed through the interface module are shown in [Figure 4] and the numerical values inserted through the interface module are used for the student module.

Figure 4. Basic data input interface

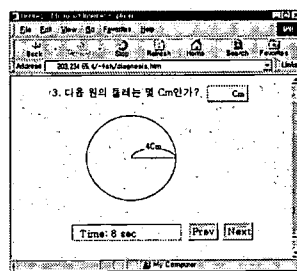

Figure 5. diagnostic examination by level

Time	S	Mon	Tue	Wed	Thu	Fri	Sat	Sun
A		N	N	N	G	G	N	
B		N	N	Y	G	G	G	N
C		N	N	N	Y	Y	G	N
D		Y	Y	G	N	G	N	N
E		Y	Y	N	N	N	G	Y
F		N	N	G	G	G	Y	N
G		G	G	N	N	G	G	Y

Figure 6. lesson hour scheduling

For diagnostic examination, the student's intelligence level was checked by using the KAS program which includes 20 questions as shown in [Figure 5]. The questions are all related to each other with 10 questions for reliability and another 10 questions for checking the student's level. Each question has a time limit with a weight rate and a degree of difficulty added to it, which makes it possible to determine objectively the student's knowledge level. The problem solving process of the student's behavior, number of interactions made and their intelligence level were put in the student module following the revision and adjustment.

Figure 7. Over-all scheduling results

The scheduling for lesson hours implemented in this study included 7 students as shown in [Figure 6]. The students transmit their preferences for time and day of the week. Group agent initiates the scheduling by

obtaining the numerical values as shown in [Figure 6] and show the server's itinerary and arrange the student's schedules in a line. Next, it removes the server's "full" and the time the student selected as "no" and extract the server's empty portion and the time students selected as "good". In a case where there are too many students, time is given to the appropriate number of students, using evaluation function. In a case where there are few students, the server's "common" and "good" or "yes" which students selected are extracted by loosening the limiting conditions. As shown in [Figure 6], scheduling has been made so that students A, D, E and G join the lesson between first and second hours on Monday, with B, C, and F joining the lesson between the 2nd and the 4th hours on Thursday. Over-all scheduling results obtained from the scheduling of the lesson hour implemented in this study are shown in [Figure 7].

4. Background

4.1 ITS based on Web

An ITS structure suggested to overcome the shortcomings of CAI - a static and across-the-board lesson - is shown in [Figure 8-a].[7]

Figure 8. Basic ITS and Web based ITS

The model of the traditional ITS was a "stand alone" type allowing a single user to pursue knowledge as the single computer contains all kinds of modules. The disadvantage this type of structure has is that the knowledge of a variety of students can not be accumulated and shared. In addition, the inability to provide a variety of learning methods makes it impossible to share the multi-media information and interaction between the human-computer interaction (HCI) and human-human interaction(HHI). However, ITS enabled us to share the knowledge with the development of the Web environment through the "Internet" and ITS itself followed its course of development in a dispersion environment as shown in [Figure 8-b]. If we look at the ITS structure based on the Web, the student module and the interface module are situated as clients and the tutor module and the expert module as servers allowing many students to share the knowledge. The peculiar dispersion environment produced the need for a communication agent and an adjustment agent for proper communication between the clients and servers.

4.2 Agent system and KQML

The agent is a program with intelligent characteristics to help the users with the use of computers and take the user's place. The intelligent agent perceives any dynamic stimulation or condition and interprets the data collected for a solution to the problem and exercises reasoning for a final decision. It also act to change the conditions within its environment in order to perform assigned duties[1]. It has autonomy, social ability, reactivity, pro-activeness and a cooperative relationship and falls under the three different categories listed below[6].

-A *single agent* provides service to the users in its unique area such as assistant agent system, the user interface agent and the intelligent agent system.

-A *cooperating agent* is also called a multi-agent and provides necessary service for mutual cooperation in order to achieve the common objective.

-A *society of agent* is also called a mobile agent and provides necessary service by moving to an area wider than the cooperating agent.

The dialogue between these multiple agents is exchanged according to the established language agreement. The message takes the form of data, logic information, command and script. The ACL(agent communication language) - a common communication language - is normally used among the programs shaped with different languages. Representative language is called KQML(knowledge query manipulation language) developed by

DARPA. KQML not only provides words with grammatical structure for first order logic messages based on a speech-act theory but also contains a communication agreement, including the structure to allow the agents and programs to exchange information and knowledge[6].

4.3 The problem of dynamic resource scheduling for lesson hours

Scheduling the lesson hours should be prepared in such a way as to satisfy the limiting conditions such as the preferred lesson hours, the existing individual schedules and the plans to alleviate the burdens of the server for effective learning. The students have a certain time they prefer for an effective lesson and they prefer using a certain time for lessons due to their previous schedules. The preferences, however, vary according to the student as do their current schedules. Furthermore, even when collaborative learning is started, it is difficult to achieve effective lessons due to the noticeable reduction of wireless transmission speed caused by the server being overcrowded by many users at one time. It has to spend a lot of time and effort using a systematic method in order to alleviate and satisfy the limiting conditions[3]. The problem of adjusting these problems belongs to the dynamic resource scheduling which has the following limitations:

-The individual students have their own schedules and it is possible that these schedules cannot overlap each other.

-The students have a certain time they prefer for more a effective lesson.

-Their level of intelligence may vary.

-The server has its own schedule and is not in a position to accommodate large numbers of users.

Many of the students may attempt to use the lesson hours in their favor for better lessons. Since they manage their own schedules, the information and the knowledge related to the lesson hour scheduling are dispersed, leaving everybody unaware of the over-all lesson activities. This is characteristic of the dispersion system and the students may clash with each other because of this phenomenon. In order to avoid this kind of clash, the agent should find negotiating tactics to select appropriate students and a good scheduling method.

5. Conclusions and future work

In this study, the diagnostic agent and the group agent that realizes collaborative learning have been implemented based on the ITS student module for student's distance collaborative learning. It has presented a more expanded Web-based ITS by overcoming the shortcomings of the existing ITS. The diagnostic agent helped realize the lessons by level by supplying the results of the student's intelligence level assessment to the group agent and the group agent helped with the lesson by assigning a suitable time based on the student's requirements and limiting conditions. Scheduling has been made so that student may have a chance to learn with the most suitable students by competing with a multitude of students.

The teaching tactics module and the expert module are capable of sharing and expanding the knowledge together, creating a variety of student models through mutual communication with the help of KQML. In the future, a study to improve the insufficient portion of the tutor module and an expert module including a variety of exchanges in tutoring methods are urgently required. More study is required in structuring an accommodative student model. The research and rectification of the difficulty in assessing the intelligence level of a group often found in collaborative learning and the misconception held by the group as a whole are a must. Structuring a new student model by assessing a multitude of student models is also considered to be another area of research.

Abstract: This paper discusses examination, focusing on the possibilities available in asynchronous learning networks (ALN) based education. An ALN supports anywhere/anytime collaborative learning and this research has explored suitable examination forms in this setting. The notion of mandatory participation in learning activities is argued to be more viable in ALNs rather than traditional classrooms. Mandatory participation as the primary examination criteria was used and evaluated in a higher education ALN based course, resulting in several key experiences which are presented and discussed. These experiences contribute to a richer understanding of problems and difficulties involved in ALN based courses.

1. Introduction

It is often argued that the post-industrial society requires skills and abilities that are different from what traditional education focuses on, for example regarding teamwork, systems thinking and communication. When information is abundant in society the goal of learning is no longer memorization of facts. Instead we learn to learn, and engage in a life-long learning process. As a result, learner-centered education has emerged as a contender for the dominating learning philosophy [Norman & Spohrer 1996].

Constructivism and collaborativism are two related learning models which are learner-centered. Constructivism denies the existence of an objective reality; reality is a unique world-view related to each individual's mind. Rather than passively absorbing transferred knowledge, knowledge is actively constructed by each learner. The collaborative model of learning differs from constructivism by focusing on learning as a result of interaction among individuals. Learners construct an individual understanding through reflective discussion and confrontation with others' understandings, and also improve communication and listening skills. See for instance [Leidner & Jarvenpaa 1995] for an in-depth discussion on different learning models.

Constructivism and collaborativism stress active participation in the learning process. Passive individuals do not learn, so learners must be motivated and engaged, and instructors should support rather than control the learning process. Course organization and incentives must facilitate and promote active participation. It is easy to assume that students naturally should participate actively, but reality is complex and students often choose other learning strategies.

Perhaps the most important influence on learning strategies and outcomes is the examination procedure. Courses have an official curriculum, but the examination procedure constitutes an unofficial hidden agenda. For meaningful learning to occur, examination, i.e. the hidden agenda, must be congruent with the learning philosophy [Ramsden 1992]. If examination procedures in practice promote different learning strategies than intended, official curriculums have little, or no effect.

This research attempts to explore suitable examination forms for net based collaborative learning. Net based learning environments offer possibilities unavailable in traditional classrooms, possibilities which are discussed below, and make active participation a realistic option for examination criteria. We propose mandatory participation as the primary examination criteria in net based collaborative learning. The idea of mandatory participation guided the design of a higher education course which was realized and used for the evaluation. 85 students participated in the course, where the authors were teaching assistant and course coordinator respectively. Key experiences from the evaluation are presented to give a rich understanding of problems and difficulties involved in net based collaborative learning.

2. Asynchronous Learning Networks

For the remainder of this paper, instead of using the term net based learning environment we will adhere to the established concept of asynchronous learning networks (ALN). An ALN is a net based learning and teaching environment where possibilities and problems are different from traditional classrooms. A distinct characteristic of an ALN is the notion of anywhere/anytime learning. ALNs are often built using different tools for computer mediated communication, for example email, bulletin boards and newsgroups, synchronous chat systems, computer conference systems, group decision support systems, and most recently, the World Wide Web [Hiltz & Wellman 1997].

In an ALN, learners form a community engaging in collaborative learning at the time and place of the individual learner's convenience [Bourne et al. 1997]. By slowing down interaction, learners are given time for reflection, and ideas, questions, comments, etc. can grow and mature before being shared with other learners. Articulating and making understandings explicit is a learning process in itself, and knowing that ones work will be available for other learners is motivating and brings out high efforts. Active participation in learning activities, for example discussions, is crucial for successful learning; this is proclaimed in most research on ALN based collaborative learning.

Learning processes and the role of educators and learners in ALNs can be radically different from traditional classrooms [Harasim et al. 1995]. An important issue to remember is that ALN based learning is a social process, or in other words: "though the classroom is virtual, the relationships and the learning it supports are real" [Hiltz & Wellman 1997]. Social skills, status, preferences, traditions, etc. affect the success of individuals and groups. See for instance [Wegerif 1998] for a discussion on the social dimension of ALNs.

The next section will discuss the relation between participation and presence, after which we suggest an integration of learning and examination relying on the unique possibilities offered by ALNs.

3. Participation Versus Presence

A somewhat controversial discussion about participation versus presence highlights some weaknesses of traditional classrooms and strengths of ALNs. To be present is simply to passively attend group sessions, and to participate is to actively contribute to group sessions. Attendance does not imply active participation and this is where traditional classrooms are, we claim, weak. In a traditional classroom learners can attend, not be active participants, and seemingly participate. In an ALN one cannot just attend; lurkers are invisible and to be visible participation, that is interaction with other learners, is necessary.

Participation versus presence is more than an issue of control; it is also an issue of equality. Learners who try to actively participate can be hampered by various social factors. Whereas in traditional classrooms learners must be allowed into the discussion before speaking, in an ALN learners are part of the discussion at all times; there is no slow turn-taking which keeps ideas and comments on the sideline. Time passes quickly in real-time discussions and many learners have difficulties to find ideas under such extreme time pressure. In ALN based discussions ideas can grow over a longer time period and also, considering that contributions are situated in a discussion context, the moment where the contribution is suitable is longer. In traditional classrooms discussions change direction rapidly and the right moments are brief. Other social factors are for instance gender issues, nervousness and self-confidence, and language differences. ALNs do not always have a positive impact on equality, for instance the permanent nature of text in discussions can be considered uncomfortable and limiting as opposed to casual talks.

Considering the importance of active participation for collaborative learning the discussion of participation versus presence leads us towards a starting point for the evaluation: The notion of mandatory participation in learning activities is argued to be more viable in ALNs rather than traditional classrooms.

4. Mandatory Participation

ALN based courses are well-suited for active participation in learning activities. This makes it viable to consider active participation as the criteria of examination. Current educational practices intend for examination forms to support, or at least not hinder, learning, but in practice the examination forms are often unaligned with the learning philosophy. An alignment of learning philosophy and examination, thus making examination an

integrated part of the learning process, is suggested: Collaborative learning stresses active participation; ALNs support active participation. Therefore this paper proposes mandatory participation as the primary examination form in ALN based courses.

Mandatory participation seems to offer an almost seamless integration between examination and learning, which is in line with the notion that one cannot separate examination from learning. Demanding active participation is a bold and radical move considering that in most cases participation in ALN based discussions is optional and examination consists of assignments such as essays at certain times. However, considering the characteristics and demands of collaborative learning, it seems a very natural move.

As discussed above anywhere/anytime learning is a key issue for ALNs. Participate wherever and whenever you want but participation is mandatory. Learners are used to mandatory attendance in physical spaces but mandatory participation, not only attendance, in virtual spaces is new for learners. As it is accepted with mandatory lecture attendance, we say: If you cannot participate, then why are you taking this course? Certainly voices will be raised about inequality concerning computer access. We however consider the time has come when computers are widely available. Large investments have been made to increase the number of campus computers and many people have computers at home.

This of course sounds harsh and perhaps naive but it is a main ingredient if participation is to be mandatory. In the next section we will discuss the evaluation of the concept of mandatory participation in an ALN based course.

5. Evaluation

The concept of mandatory participation guided the design of an introductory course in Informatics. Mandatory participation is a continuous form of examination where learners must be "reasonably" active throughout the course. Therefore, learning activities must be evenly spread over the course duration; learners can be more or less active over time so the total participation determines examination outcome, not large assignments at certain times. In order to achieve this flexibility in participation the course was structured using thematic modules (TM).

TM is a structuring philosophy which divides the course into several self-contained units [Nulden 1999]. This is different from traditional modular structuring where a large topic area is divided into subtopics small enough to digest for learners, like chapters in a book. In TM each module introduces a separate issue or problem, like tiny islands in a vast ocean of knowledge. Every module has a well defined beginning and ending. Because each module is self-contained learners can be more or less active in different modules according to interest and outer circumstances, as long as the total participation is satisfactory.

The introductory course in Informatics was given for undergraduate business administration students. Each module was initialized with a, hopefully inspiring and challenging, two hour lecture. The rest of the week-long module consisted of discussion in groups in the ALN and an end-of-module summary provided closure. The course lasted for 10 weeks, that is covering 10 modules, and awarded 2 credit points. 85 students were entered in the course and they were divided into five groups, each having a teaching assistant (TA) to facilitate and support online discussions. One of the TAs' responsibilities was to inform the course coordinator about students who were not fulfilling examination requirements. The course coordinator would then review the students effort and be fully responsible for any final decision to fail the student. Deciding if a student's participation fulfilled the examination requirements was in some cases difficult. Some limited tools, i.e. visualizations, were available to make it easier to understand each individuals participation level but these were apparently not enough. However, the issue of technology support for TAs is beyond the scope of this paper but has been discussed in a previous paper by the authors [Hardless & Nulden 1999] and is an important area for future research.

The main part of the ALN used for the course was a conference system that was hierarchically structured. [Fig. 1] shows screenshots of the interface. Each group had a separate area, i.e. folder, and within the group folder there were 10 folders, one for each module. During a module the group would create appropriate discussions in the current module folder. Discussions were containers for messages and, as we can see in [Fig. 1], new messages were appended to a vertical list of existing messages. New messages were also sent to the students with e-mail as a notification service. In this case the ALN was highly-structured but this is not a requirement for TM in general. TM is a flexible structuring philosophy and can be adjusted to different settings and intentions.

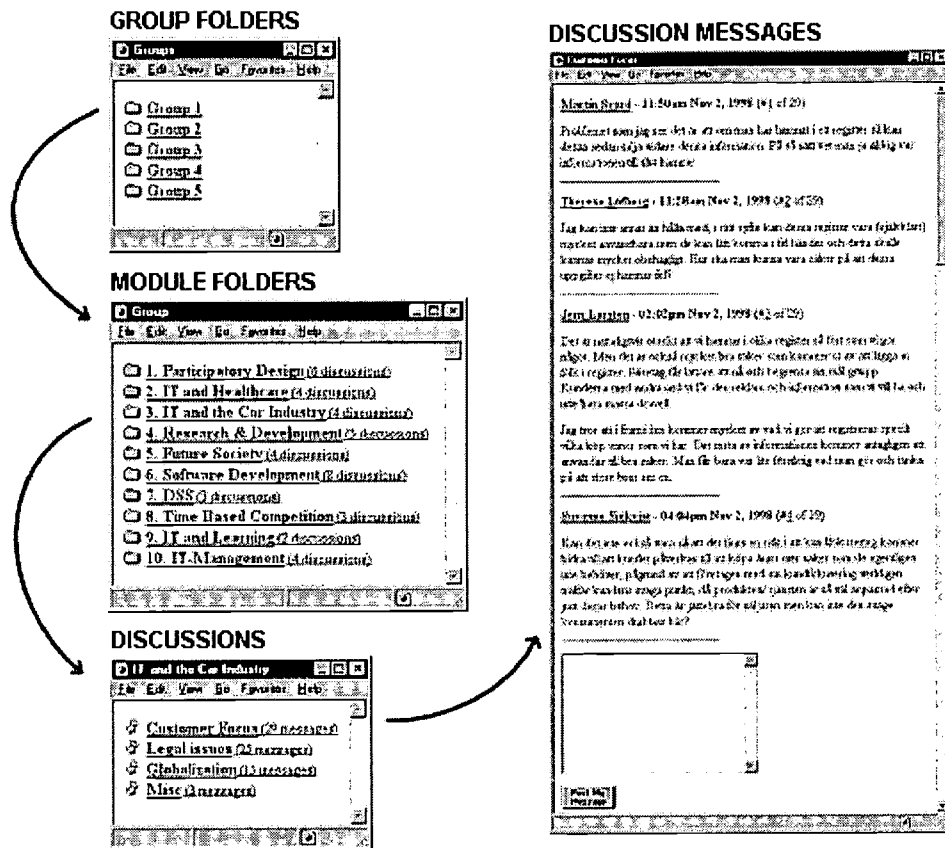

Figure 1: Screenshots of the highly structured conference system used as the main part of the ALN.

Halfway through the course the course coordinator and TAs thoroughly discussed students' participation and five students were judged to be non-participant and as an effect of being failed they were no longer allowed to access the ALN. It should be noted that the learners were judged leniently; only very apparent cases of low participation were failed. This does not mean students passed for free; only that, because determining reasonable participation is difficult, we decided to rather pass than fail the uncertain cases. For the second half of the course none of the remaining students neglected participation and so they all passed the primary examination. Having passed the primary examination they were allowed to complete the secondary examination which was an end-of-course assignment determining the final grade.

In practice, mandatory participation as the primary examination criteria turned out well. There were some complaints on problems in accessing computers, as expected causing a conflict with the mandatory participation demand, but this was a minority of students and they managed alright despite this problem. Many students wanted us to reserve campus computers for them regularly but we did not since this conflicts with the notion of anywhere/anytime learning.

6. Experiences

We will share some of our experiences, or anecdotes if you wish, from the evaluation which are broadly related to mandatory participation. These experiences serve to give some depth in the understanding of problems and difficulties involved in ALN based learning and mandatory participation. Some of the experiences might seem irrelevant at first but participation depends on many factors and thus a broad account gives a better understanding of success and failure.

6.1 New and Different

The ALN based course proved to be in sharp contrast with regular courses which the students had experienced previously. The shift from teacher-centered to learner-centered education was somewhat of a revolution.

Technology-wise it was certainly a change in that the course was ALN based but students were relatively familiar with computers and the Internet. The students were given a brief manual for the system, a short demonstration, and an optional half-day workshop. The few computer novices learned quickly and some of them remarked afterwards "oh, was it that simple...".

The revolution concerned the learning philosophy. Students were not used to collaborative learning, unstructured tasks, open-ended discussions, and the notion of producing knowledge for themselves rather than the teacher. They were hampered by a textbook focus and lack of initiatives. Roughly they were asking: "What are the exact examination criterias and where is the final written exam?"

Many of the lecturers, especially those who were teachers, were also stuck in the traditional view on learning. Their lectures were not perceived by the students to serve as a motivating starting point. Understanding the lecture as a starting point instead of an overview or summary is a difficult change process. Interestingly, the most appreciated lectures were those performed by professionals from the industry.

For the course coordinator and TAs it too was a new and challenging situation. We had little previous experience of this new form of learning and knew it would be a difficult process, for us and foremost the students. Therefore we decided to have a very positive and generous attitude, by for example having extended office hours. Introducing the ideas to the students was not trivial. Convincing them to commit and engage in collaborative learning was problematic and is a key issue for the success of ALN based courses.

6.2 Off-Topic Discussions

We identified two cases where students engaged in off-topic discussions. The first concerns non-serious discussion, i.e. topics not related to the course. The second concerns students posting to serious discussions but with the intent to pass examination, not contributing to the learning process.

Examples of non-serious discussions were sports discussions, tv-show discussions, and music discussions. Each of the five groups created about two such discussions and, unlike the serious discussions, these lasted throughout the course. These discussions were popular judging by the volume of messages they recieved, for instance one discussion about icehockey recieved 140 messages. The tone of voice was different compared to serious discussions; more relaxed. One, unintentional, problem was that all messages were also sent as e-mails to participants. The volume of e-mails was already high enough without off-topic messages so this became a source of annoyance. This leads us to claim that non-serious discussions should be kept totally separate from serious ones; not so much where they are placed but more importantly avoiding interference issues such as ours.

The second type of off-topic discussions concerned students feeling the pressure to say something in order to pass the examination. Because we had an open-minded and friendly attitude towards the examination many students dared to admit posting not to contribute to discussions but to meet examination criteria, that is they posted just for the sake of it. Some joked about the need to say something serious quickly in the beginning of the module before everything was said. Especially during the first modules students tended to post similar messages, rather than building on each others contributions. Another reason for low-quality messages was the problems in accessing computers. The affected students simply had to do everything at once when they found a computer, that is read, think, and post. There was no room for reflection since leaving the computer and coming back later to post was unthinkable.

6.3 Mature and Evolve

Above we discussed how new and different ALN based collaborative learning was for students. During the course we also noticed how students changed attitudes, learning strategies, etc. We feel that at first many students had difficulty seeing the point in collaborative learning but over time some students revised their attitude to this way of learning and realised that one can learn from interaction with other learners. Of course, not all students were convinced and 10 weeks is a short time to change ones perception of what learning is. We do however believe that the new experience will have started a thinking process within most students which will

lead to critical and reflective examination of the learning they participate in later. Even if they did not see the point of collaborative learning directly, they might think differently in a year or two.

Also, students at first had trouble with the mandatory participation criteria. As one TA expressed it: "Initially my students thought mandatory participation meant they had to be constantly present in the ALN. This caused frustration and they said: 'Be there all the time? This can't be? We have other things to do!'. Gradually they realised what we meant and eventually they started working as intended with about one visit per day to update themselves, reflect, and post messages."

6.4 Teaching Assistant Frustration

One of the TAs' responsibilities was to stimulate students who were inactive and not participating in a satisfactory manner. The first difficulty was to decide when a student was not reasonably active. All TAs had different personal styles but none wanted to appear bossy or bad tempered, so pushing students was difficult, especially when faced with a borderline case of inactivity. This gives us the second difficulty; how to approach students and give them a friendly push. Another practical issue is being able to contact students. Sometimes reaching inactive students was impossible because they did not participate in the discussions and we did not always have their email address. A TA should always be able to reach all of her students.

The TAs mainly tried to facilitate discussions and help students reach higher levels of understanding. Sometimes a TA might say something really interesting and challenging, only to be disappointed when no reaction was triggered. Either the students were not interested in the new discussion option or they simply lacked the experience to build on feedback which was too advanced. Giving appropriate feedback is a very complex issue and it is further complicated by the fact that the students all have different backgrounds, experiences, and preferences.

7. Conclusion and Future Work

In this paper we have discussed the idea of mandatory participation as examination in ALN based courses. The evaluation indicates that it is a viable examination form for ALN based collaborative learning. However, our experiences show that the alignment between learning and examination was not complete since many students took on learning strategies purely focused on passing examination. This was our first evaluation of mandatory participation as examination so of course further research is needed. A multitude of issues need to be explored further, such as facilitating learning processes, technology support for participants, other ALN based examination forms, and how to further integrate learning and examination.

Exploring Electronic Media and the Human Mind - a Web-Based Training Module

Joachim Hasebrook

Bankakademie e.V., Oeder Weg 16-18, D-60318 Frankfurt/Main (Germany),

URL: <http://www.bankakademie.de>, email: hasebrook@bankakademie.de

Abstract: Effective Web-based training (WBT) has a need for adaptation and contextual information, but most WBT modules provide not more than some simple help pages or hypertext facilities with keyword indices. Help pages mostly provide information how to access functions but not how to apply them - and why. Therefore, we designed a generic Web-based Performance Support System (PSS) that can be used as a stand-alone training course about 'Learning in electronic media' or as an integrated help system supporting other WBTs. The PSS provides four modules, a comprehensive glossary, a keyword and a full-text index as well as a graphical overview with brief summaries of all modules. In order to motivate users to apply learning strategies we integrated about fifty so called brain tests: Each test consists of short psychological experiments which can be easily conducted within a few seconds and illustrate important features of human perception and human memory. First experiences ascertained that it is highly motivating for students to test their own perceptions and learn about human cognition.

Introduction

Learning effects of multimedia in education are disappointing, quite frequently. Van den Berg and Watt (1991, pg. 119) compared multimedia in competition to a classroom lecture, multimedia supplementing a lecture and multimedia replacing a lecture. They drew the conclusion: 'Objectively the academic performance of (multimedia) users was not different from those attending classroom lectures [...] Although, positive about (multimedia) technology, they indicated that they would prefer to use it as a supplement to lectures and books.' Meta-analyses support statements like these. Kulik and Kulik (1991) examined 248 research studies about computer-supported learning. 150 studies failed to show any significant effects. The other studies showed only a slight advantage of multimedia over textbooks or lectures. Considering all studies included into the meta-analysis, multimedia produced only a small effect (Hasebrook, 1995). Although, multimedia seems to save some time and reduce simple errors, it has not been found to be very effective as a problem solving tool (Mayer & Anderson, 1992).

There are some promising studies, however, showing that multimedia could potentially facilitate the learning processes. The Software Publishers Association (1995) reviewed the effect of instructional technologies in 133 school studies from 1990 to 1994. It was stated that there were better test results, an increase in self-reliance and a closer interaction between students and teachers. Many other studies have confirmed that multimedia applications enhance learning, only if the individual skills and abilities match the demands of the learning task and the functionality of the multimedia system (e.g. Barba, 1993; Mayer & Sims, 1994). Therefore, it is necessary to teach users strategies and concepts to use multimedia applications. Additionally, it is necessary to adapt the system to individual abilities and the overall learning environment (Schulmeister, 1996; Larkin & Chabay, 1992).

Many vendors and users prefer a stepwise migration from 'old' to 'new' technologies. For instance, Bank Academy has implemented a multimedia CBT in charge of the financial department of an international automobile manufacturer and dealer (cf. figure 1) which was implemented in five different languages and delivered on CD-ROM. One of the challenges of this project was to produce off-line and on-line training courses in a single production process. Therefore, we implemented the different CBT versions using the Hyperwave Information Server (Maurer, 1998) in order to maintain the multimedia elements. Hyperwave directly delivers Web-based training, because it includes a complete Web server, and allows to produce a 'snapshot' of the database which can be delivered on a CD-ROM. Up to now, the training course does not provide more than a traditional multimedia CBT. But in the year 2000 the course will be put on-line and therefore integrate Hyperwave's on-line features, such as note taking, discussion forums and bulletin boards.

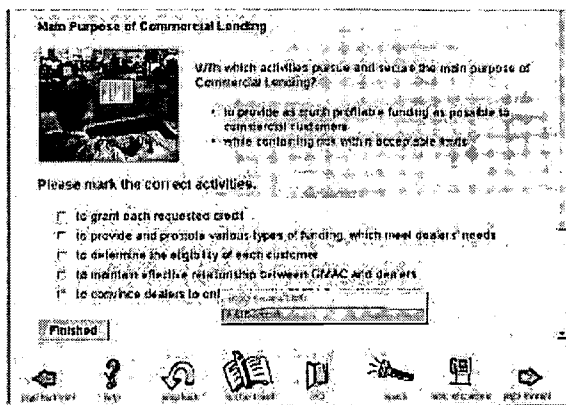

Figure 1: Advanced Web servers like Hyperwave allow to introduce Web-based training starting with off-line multimedia CBTs; this approach has been chosen in an project of Bank Academy in charge of an international automobile manufacturer.

From Help Pages to Performance Support Systems

Duchastel (1992, pg. 69) claims: 'Adaptation is essence of what is known as pedagogical knowledge'. Many researchers aim to make their multimedia systems more adaptive – and therefore more 'pedagogical' (e.g. Cox & Brna, 1995). Expert systems and Intelligent Tutoring Systems (ITS) adapt to the learner's demands, abilities and knowledge – especially in subjects which can be described in formal structures (Bastien, 1992). There is an increasing number of adaptive computer programs which are equipped with media like videos and photographs. As of today, a diverse spectrum of techniques, approaches and philosophies impede the progress in intelligent learning environments (Self, 1992). There are promising results, however, supporting positive effects of intelligent learning environments teaching mathematics and programming (e.g. McGraw, 1994). In general, effects of adaptation and system-controlled tutoring have been small or medium sized, yet (e.g. Schulmeister, 1996).

Despite these insights about the need for adaptation and contextual information many Web-based training modules provide not more than some simple help pages or hypertext facilities with keyword indices. Help pages mostly provide information how to access functions but not how to apply them in different learning contexts - and why to apply them. Effective learning needs a good deal of verbal and visual literacy, whereas computer literacy seems not to be the most influential factor (cf. Mayer & Sims, 1994; Mayer & Anderson, 1992). Thus, most help systems do not support learning strategies to cope with linked multimedia elements, and they do not motivate to use electronic media as an serious learning tool. Effective help systems should support the user to overcome his or her weaknesses and take advantage of her or his strength. We therefore designed a generic Web-based training system that can be used as a stand-alone training course about 'Learning in electronic media' or as an integrated help system supporting other Web applications (cf. figure 2). Thus, it can be used as a Performance Support System (PSS) to enhance utilizing electronic media in an learning and in working environment (McGraw, 1994). The PSS provides four modules, a comprehensive glossary, a keyword and a full-text index as well as a graphical overview with brief summaries of all modules. The table of contents comprises the following topics:

- Learning with multimedia: Advantages and disadvantages of computer-based training - Appropriateness of multiple media - Learning strategies for multimedia - Combining dynamic and static media - Self test 'Multimedia expert'.
- Information from the Internet: Basics about the Internet - Addresses in the Internet - Search engines and search strategies - Self test 'Internet expert'.
- Email and Computer Conferences: Basics about email - Writing emails - Mail and list server - Asynchronous and synchronous computer conferences - Video conferencing - Self test 'Email expert'.
- Learning strategies for CBT: Browsing hypertext and multimedia - Using navigational tools - Using bookmarks and note taking - Graphical browsers, maps and overviews - Strategies for learning and re-learning - Self test 'CBT expert'.

Learning to Learn

Many authors suggest that deeper understanding means that sequential verbal information is highly interconnected with analog pictorial information (e.g. Mayer & Anderson, 1991, 1992). Supporting understanding, then, demands the construction of semantically connected pieces of text and pictures, activating

appropriate pre-knowledge, providing learning strategies for multimedia, and changes of media and learning perspectives to support the construction of comprehensive mental models (Albrecht & O'Brian, 1993). Research (e.g. Mayer & Sims, 1994) support the consideration of individual differences in abilities and interests in order to enhance the understanding processes.

In two studies with 75 subjects we were able to confirm that individually adapted information enhances motivational and learning processes within computer-supported learning environments: Audio-visual media produced only a small effect, individual generated information, however, was very effective and was independent of subject variables like computer experience and usability judgements (Hasebrook & Gremm, in press).

Glowalla and Hasebrook (1995) conducted studies with 52 students which participated in a hypermedia learning course, all of them were novice hypermedia users. In the first lesson they are "unskilled learners", in the last lesson they were "skilled learners". Four month later, 43 of these students attended a relearning course. All students received exactly the same course materials and configuration of features of the hypermedia system as in the learning sessions. Therefore, in the first lesson they were skilled learners, but "unskilled relearners", and in the last lesson, they were "skilled relearners". The results show that browsing tools, such as paging and hypertext links, were used most frequently by skilled relearners, informational tools, such as a glossary and a keyword index, were used more often during learning than during relearning.

In conclusion, multimedia information is first encoded in simple text and image bases; using more sophisticated elaborating and inferring processes mental models can be generated based on the information in the text and image bases (Hasebrook, 1999). Information selection and encoding from short term memory leads to separated encoding of verbal and pictorial information in the long term memory (Baddely, 1990; Paivio, 1986). There is a tendency to understand pictures 'at a glance' resulting in a simple representation that is not linked to verbal information (Weidenmann, 1994). Deeper processing of images can be elicited by teaching appropriate learning techniques (Drewniak, 1992) and by obvious links between pictures and verbal explanations. These higher levels of processing can help to generate appropriate static and dynamic mental models (Hegarty, 1992).

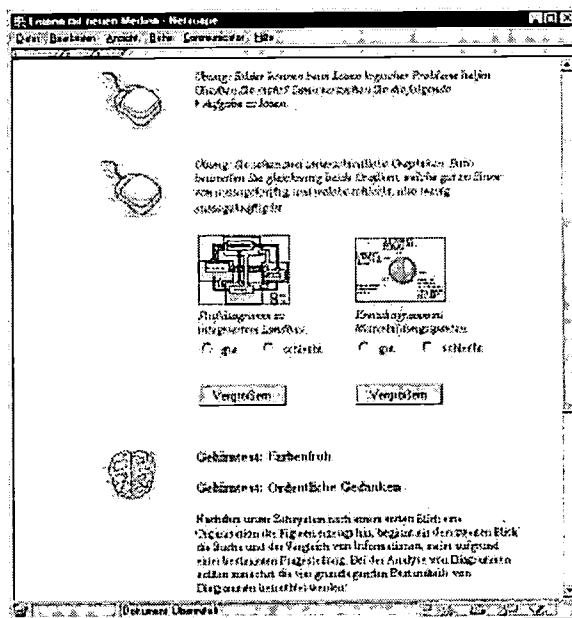

Figure 2: A content screen of the Web-based training course 'Learning in electronic media' provides brief explanations, interactive exercises (indicated by the mouse icon) and psychological self assessment (indicated by the brain icon).

The role of Meta-Cognition

Self-regulated learners govern a broad variety of cognitive and metacognitive strategies to fulfill their learning tasks. They monitor and - if necessary - modify their learning strategies. They are motivated, independent, and metacognitively active controllers of their own learning processes (Zimmermann, 1990). It is not easy to

acquire knowledge about knowledge acquisition, but it is even more difficult to transfer this knowledge to every-day learning tasks. Therefore, it is essential to practice how to apply study techniques and to motivate the use of sometimes time consuming learning strategies. Otherwise, the learners most likely prefer simple study techniques, such as accessing all pages in sequential order.

Our aim is that is to use 'the computer as a tool for learning through reflection', as Collins and Brown (1988) put it. We tested the correlation of pre-knowledge and acceptance of software tools using an on-line expert system for vocational guidance. There is a positive correlation between the students' judgements about (1) how well the information provided by the system match their interests, (2) how well they know subject, (3) and how well they can imagine important aspects of the subject matter. However, there is a negative correlation between all these variables and the actual state of information: That is, the more information the students have got, the less they are willing to accept system advisory – and the less they have got a notion of knowing. Therefore, information leads to more skepticism and critics (Hasebrook & Nathusius, 1997).

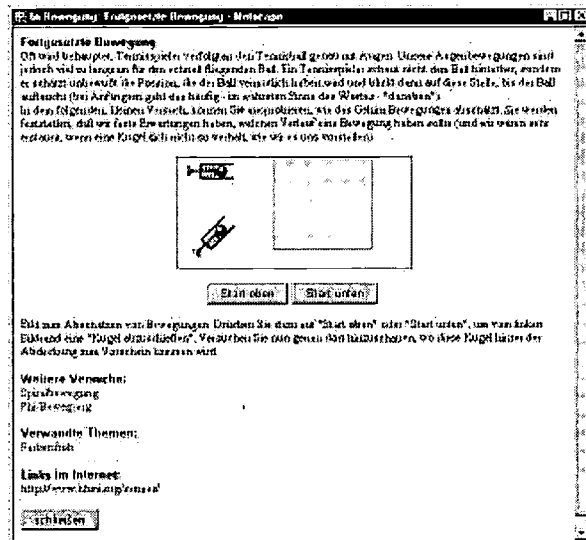

Figure 3: 'Brain tests' enable the user the participate in brief psychological self tests and learn about her or his perceptual and memory system; the screenshot depicts an experiment about the perception of movement.

In order to motivate users to apply learning strategies we integrated about fifty so called brain tests (cf. figure 3): Each brain test consists of short psychological experiments which can be easily conducted within a few seconds and illustrate important features of human perception and human memory. First experiences ascertained that it is amazing and highly motivating for students to test their own perceptions and learn about human cognition. The list of the brain tests comprises the following subjects: Specialization of the brain hemispheres - Grouping visual stimuli - Processing visual features (angles and distances) - Processing three-dimensional scenes - Perceiving colors - Perceiving movements - Acoustical illusions - Short-term and working memory - Memory sets and schemes - Cognitive illusions - Mood and memory - Social influences on cognition - Illusions of awareness and consciousness - (Very) long-term memory - Unconscious and implicit learning. Additionally, self tests for each module help the users to check their expertise on each topic and enables them to review directly the parts of the course which are linked to the questions.

Integrating Performance Support in Learning Systems

Web-based learning systems combine various advantages: access to huge amount of data, up-to-date information, and guidance provided by (self) tests and expert systems. This does not necessarily mean that students enjoy working with electronic media. This is the lesson we learned when comparing four media for vocational guidance (Hasebrook & Wagner, 1997): two of them are multimedia applications and the other two products are printed matter. We measured individual acceptance ratings after having used the four different products with 75 students participating in this study. The results show that printed matter are preferred. This result is statistically independent of sex, education, and experience in using a computer. Thus, the students enjoyed using electronic media, but they rely on printed matter.

Expert advice provided by the system, however, clearly increases acceptance and performance of electronic media: Users pick up more information and they consider this information to be more valuable. The more information they have gathered and elaborated the more they lose their notion of knowing and develop a critical

approach to expert advisory. Multimedia applications should not be designed to provide "something for everyone", but they should provide exactly that piece of information which is needed in a particular stage of the decision making process. The effects were enhanced, if individual preferences were regarded.

A major German bank uses a special version of the PSS 'Learning in electronic media' as a kick-off course and motivational aid to introduce Web-based training in the bank. The aim of the PSS here is not to achieve pre-defined learning objectives but to avoid a 'learning culture shock' by helping the user to become a self-regulated learner. We aim to fully integrate the PSS as a background library and help system for any specific Web-based training course (cf. figure 4). Therefore, we develop an interface that uses keywords from the current HTML pages of the specific course and search terms entered by the user to search the glossary, the keyword and the full-text index of the PSS for relevant explanations and exercises.

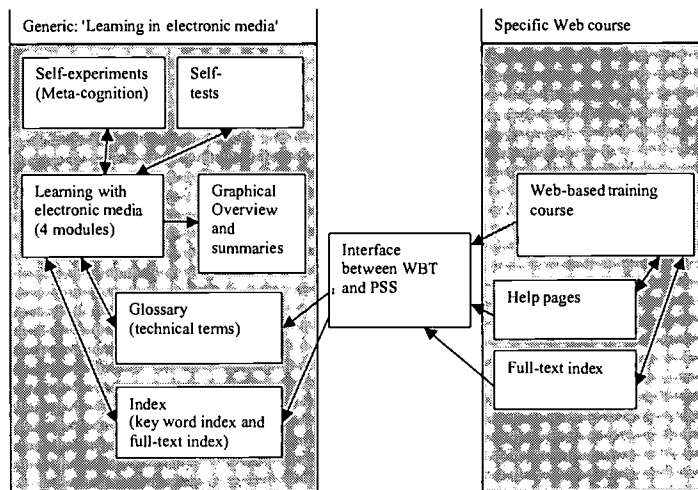

Figure 4: Architecture of the Web-based PSS 'Learning in electronic media' - generic topics and exercises can be linked to specific on-line courses by an interface using the search and the index facilities of the PSS.

The entire system can be stored on an ordinary 'open' Web server, such as Apache. New browser version allows for minor adaptations of colors and fonts using style sheets. Additionally, the system runs on a Hyperwave server which adapts the complete graphical user interface of the PSS to the user interface style of the target system: All buttons of the target system are active, styles guides concerning font, color, and navigational tools such as table of contents, are applied automatically. In this way the PSS becomes an integral part of any specific Web-based training course without re-implementing or modifying its contents.

Conclusion

The learning effect of multimedia has been disappointing, so far. This seems not to be based on a lack of computer literacy but on general deficits in media literacy and in learning strategies that support the integration of knowledge from different sources. Simple help pages are insufficient to cope with these deficits and to strengthen users' ability to become self-regulated learners. We therefore suggest to design and implement generic Web-based Performance Support Systems (PSS) that help the learner to understand and practice appropriate study techniques. Such an PSS has to enable the users to transfer the use of general learning strategies to their actual learning tasks - and it has to motivate this additional learning effort.

The PSS 'Learning in electronic media' comprises explanatory texts, pictures, and animations as well as interactive exercises, self tests, and brief psychological self experiments which give an vivid impression why and how elaborated learning strategies should be applied. Furthermore, the PSS discussed here can be integrated into specific Web-based courses by using style sheets, advanced Web servers, and an interface applet that browses the search facilities of the PSS and automatically points the user to appropriate information.

Abstract: In this paper we present the current situation at the field of hypermedia data modelling. We list advantages and disadvantages of the most primitive hypermedia data model, i.e. the node-link data model and the models of the second generation hypermedia, such as the Hyperwave data model and HM-Data Model. We believe that an introduction of a semantic hypermedia data model, called the HC-Data Model can solve a number of problems in modern hypermedia data modelling. Thus, we give a formal definition of the HC-Data Model. At the end we in short present Structure Editor, an application that supports the HC-Data Model.

1. Introduction

Hypermedia combines the words "hypertext" and "multimedia".

The hypertext technology allows users a non-linear access to information, contained in a collection of textual documents. Hypertext introduces the term of a hyperlink. A hyperlink connects two related documents. Users can follow a hyperlink and in this way jump from the document they currently read to a related document [Maurer et al. 1998].

While hypertext uses only textual documents to present information, multimedia offers a possibility to use other forms of information. One may incorporate graphics, pictures, sounds, animation, video and combine them to a single multimedia document [Maurer et al. 1996].

Hypermedia combines these two technologies into one new. It is based on the hypertext technology, in the sense that it connects documents via associative links, but in the opposite to hypertext, each document is a multimedia document and can have a number of different media objects [Maurer et al. 1998]. Hypermedia imposes a particular structure on the top of a number of multimedia documents. This structure is defined by a particular hypermedia data model that a hypermedia system utilizes.

The most popular hypermedia system today is the World Wide Web a global, distributed hypermedia database. The WWW utilizes the so-called node-link data model. In this model, a particular multimedia document is seen as a node and relations between nodes are denoted as links. Links are always directed, i.e. there is a source document and there is a destination document. Links are embedded into nodes, that is each link is a part of the document definition and is stored in the database as such.

There is a number of problems connected to the use of the node-link data model:

- editing of links is tedious
- logical integrity is not supported
- links are not context-dependent
- the presence of links unrelated to the current context leads to reader disorientation

- the reuse of hypermedia materials is unsatisfactory

WWW is based on a typical client-server architecture. Hypermedia documents are stored as HTML pages on the server side and accessed by clients using a standard Web browser.

HTML (HyperText Mark-up Language) is a mark-up language that gives instruction to the Web browser how to render documents on the users screen. It uses different mark-up tags to embed different types of media objects, such as pictures, video, animation, etc. Further, it allows embedding of pointers to other documents that are used as hyperlinks. Thus, HTML implements the node-link data model and in this way inherits its disadvantages. Therefore, the use of another logical data model, that offers different structuring mechanisms for hundreds of hypermedia documents have been already seriously considered.

The second generation hypermedia data models, such as the Hyperwave data model [Maurer 1996] or the HM-Data model [Maurer et al. 1996] have been introduced and applied on the WWW. These data models utilize so-called hypermedia-composites. A hypermedia composite represents a closed collection of hypermedia documents that has some internal link structure, which may be created automatically and which ensures the integrity of the database. Furthermore, the link consistency as a specific property of hypermedia systems is also guaranteed by the second generation hypermedia data models.

Although the second generation hypermedia data models solve the problems of the node-link data model their usage has also a number of disadvantages, such as:

- there is a need to learn how to use a new logical data model (this might last a long time)
- it is difficult to use a logical data model in a big number of different applications (most of them are adjusted to some specific type of hypermedia applications).

Thus, as we can see, the introduction of new logical data models to the WWW brought a number of new problems [Helic et al. 1999]. Therefore, in his paper we propose a new semantic data model – the HC-Data Model – and we believe that its use can reduce the time for learning the model as well as provide a great flexibility to use the model in a number of different applications. Thus, we believe that the HC-Data model can solve the problems of the second generation hypermedia data models.

2. HC-Data Model

HC-Data Model is a semantic hypermedia data model that operates on HC-Units and HC-Types. The prefix HC here stands for Hypermedia Composite. A semantic hypermedia data model models the hypermedia information as an abstract entity with a number of specific characteristics. For example, the HC-Data model would comprehend a person as an abstract data object *Person* that has hypermedia documents containing a *biography*, a *picture* and a description of *current work* as its properties. An abstract entity *Person* that has a *name*, an *age* and a *profession* can be considered to be an abstract data type, and a *person* with the *name Nick*, the *age 45* and the *profession Scientist* can be seen as an instance of the abstract data type *Person*. In the HC-Data Model an HC-Type is an abstract data type definition and an HC-Unit is an instance of an HC-Type.

The HC-Data Model extends the concept of the hypermedia composite with the possibility to define new types of hypermedia composites. This is done via the concept of an HC-Type which is an abstract data type definition or we can say a meta-definition of a class of hypermedia composites. Instances of an HC-Type are called HC-Units of this type. The HC-Data Model sees a hypermedia composite as an abstract data entity that has a number of characteristics. These characteristics are determined by an abstract data type definition, i.e. by an HC-Type.

An HC-Type defines characteristics of hypermedia composites and their members, i.e. it defines a number of meta-information attributes which will be attached to instances of that HC-Type, i.e. HC-Units and their members. The meta-information attributes appear in the form of key-value pairs. Some of these attributes are fully defined, that is to say both, the key and the value, are specified in an HC-Type. For some of these meta-information attributes only the name of the key is defined whereas the value will be entered when manipulating an HC-Unit of that HC-Type. We can classify those meta-information attributes into two groups:

- meta-information attributes of a hypermedia composite
- meta-information attributes of members of a hypermedia composite

A correct definition of a hypermedia composite type, that is a correct HC-Type has to define the following attributes from the first group:

- *CompositeType* attribute with an assigned value
- *CompositeAccessView* attribute with an assigned value
- *CompositeURL* attribute without a value.

From the second group an HC-Type has to include the definition of at least one member of that HC-

Type (but can and probably will have the definition of a number of different members). This definition includes following meta-information attributes:

- *MemberRole* attribute with an assigned value
- *MemberPosition* attribute without a value
- *MemberURL* attribute without a value.

Additional attributes can also be defined for both hypermedia composites and/or their members with or without assigned values.

For example an abstract data object *Person* that we already mentioned, defined as an HC-Type, would have following attributes:

- *CompositeType* attribute with the value *Person*
- *CompositeAccessView* attribute with the value `file:///c:/composites/person.view`
- *CompositeURL* attribute without a value

The "Person" HC-Type would have three different members with following attributes:

- First Member:
 - *MemberRole* attribute with the value *Biography*
 - *MemberPosition* attribute without a value
 - *MemberURL* attribute without a value
- Second member:
 - *MemberRole* attribute with the value *Picture*
 - *MemberPosition* attribute without a value
 - *MemberURL* attribute without a value
- Third member:
 - *MemberRole* attribute with the value *CurrentWork*
 - *MemberPosition* attribute without a value
 - *MemberURL* attribute without a value.

Furthermore, an HC-Type offers a public interface to manipulate the content of an instance private memory. This public interface includes following methods:

- `public void add(String member_role, URL url);`
- `public void replace(String member_role, URL url);`
- `public void insert(String member_role, int member_position, URL url);`
- `public void delete(String member_role, int member_position);`
- `public CompositeAccessView access();`

The *add()* method adds a member, which might be a hypermedia document or an HC-Unit, to an HC-Unit giving it the specified *MemberRole* attribute.

The *replace()* method is used when a member should get the specified *MemberRole* attribute and replace a member currently having this *MemberRole* attribute.

The *insert()* method is used when a member has to be inserted in a list of members having the specified *MemberRole* attribute exactly on the specified position

The URL argument of these three methods specifies an address of a hypermedia document or an HC-Unit on the Internet or a local file system. It is used by the access method in order to visualise an HC-Unit properly.

The *delete()* method deletes a specified member from an HC-Unit.

The *access()* method is used in order to visualise an HC-Unit following to the definition given in a special file (this file is specified through the "CompositeAccessView" attribute of an HC-Type) by using the existing hypermedia documents and/or existing HC-Units located by the "MemberURL" attributes.

3. Visualisation of an HC-Type

An HC-Type provides the *access()* method in its public interface. The *access()* method is called whenever an HC-Unit of that HC-Type is accessed in the sense of browsing the hypermedia information that the accessed HC-Unit contains. The *CompositeAccessView* attribute of an HC-Type has as its value a URL of a file defining the visualisation mechanism for the particular HC-Type. When the *access()* method of an HC-Unit is called for the first time the definition file is interpreted and a number of visualisation objects is instantiated. These visualisation objects become part of the HC-Unit private memory and are responsible for the proper visualisation of the particular HC-Unit. They also provide a user interface for retrieving the hypermedia

information, i.e. for browsing the content of an HC-Unit.

The most important visualisation object is called *ScreenTemplate*. A *ScreenTemplate* is a rectangular area representing a canvas for visualising an HC-Unit. This canvas is split into a number of rectangles which do not intersect with each other and whose union is equal to the starting rectangular area of the particular screen template. We will call these rectangles screen template cells or just cells. Each screen template cell has a so-called *PlaceHolder* visualisation object as its child. A *PlaceHolder* object is an object that presents a piece of information from a particular HC-Unit as a valid HTML text. In this way a *ScreenTemplate* is composed as a valid HTML document and consequently rendered in a standard Web browser.

An HC-Type defines a number of *ScreenTemplate* objects having one of these *ScreenTemplate* objects is defined as the starting template, i.e. it will be shown whenever the *access()* method of the particular HC-Unit is called. A user will activate computer-navigable links in order to access other *ScreenTemplate* objects. As a result of accessing another *ScreenTemplate* object the starting one will be removed and the content of the accessed one will be rendered.

Let us now classify *PlaceHolder* objects. There are three different groups of *PlaceHolder* objects:

- *PlaceHolder* objects with a fixed content
- *PlaceHolder* objects with a dynamic content
- *PlaceHolder* objects representing computer-navigable links

PlaceHolder objects with a fixed content are the *TextPlaceHolder* object and the *ImagePlaceHolder* object.

The *TextPlaceHolder* object has a piece of plain or HTML text as its information source. This fixed text that a *TextPlaceHolder* object holds is presented in a screen template cell of this object.

Similarly, an *ImagePlaceHolder* object has as its content a fixed picture which is shown in the screen template cell that this object occupies.

PlaceHolder objects with a dynamic content can be the *MemberPlaceHolder* object or the *AttributePlaceHolder* object.

A *MemberPlaceHolder* object has a member of an HC-Unit as the information source. The member is strictly defined through the *MemberRole* meta-information attribute, which means that a *MemberPlaceHolder* object holds the place for a member with the specified value of the *MemberRole* attribute. For instance in the HC-Type *Person* we will have a *MemberPlaceHolder* that holds the place for a member that has *Biography* as the value of the *MemberRole* attribute. Using the *MemberURL* attribute of a member the actual content of this member will be rendered in the screen template cell of the particular *MemberPlaceHolder*. If a number of members has the same *MemberRole* attribute, i.e. if an HC-Unit has a list of members of a particular *MemberRole* attribute then the value of the *MemberPosition* attribute is used to uniquely address a particular member. The value of the *MemberPosition* attribute in a *MemberPlaceHolder* may be altered, i.e. it can be incremented or decremented. In other words an user can navigate through the list of members having the same value of a *MemberRole* attribute. This navigation occurs also as a result of following computer-navigable links defined through a special kind of *PlaceHolder* objects representing hyperlinks.

In the same way as a *MemberPlaceHolder* object an *AttributePlaceHolder* object uses a value of a *MemberRole* and a *MemberPosition* attribute to point out a member of an HC-Unit, but while a *MemberPlaceHolder* object uses the *MemberURL* attribute of the particular member an *AttributePlaceHolder* uses a name of some other attribute of the particular member in order to display the value of this attribute. If the *MemberRole* attribute of an *AttributePlaceHolder* object has a list of members *PlaceHolder* objects representing computer-navigable links can be used in order to navigate through the member list.

PlaceHolder objects representing computer-navigable links are not a special group of *PlaceHolder* objects but a *TextPlaceHolder* object, an *ImagePlaceHolder* object or an *AttributePlaceHolder* object can be defined to be a hyperlink as well. We will call these objects *LinkPlaceHolder* objects. For example the functionality of a *TextPlaceHolder* object can be extended to the functionality of a *LinkPlaceHolder* object of type *TextPlaceHolder*, which means that the text of a *TextPlaceHolder* has been put inside an HREF tag. The destination document of a *LinkPlaceHolder* object can be another *ScreenTemplate* object of that HC-Type or the same *ScreenTemplate* object with altered values of the *MemberPosition* attributes of *MemberPlaceHolder* or *AttributePlaceHolder* objects. In this way browsing of an HC-Unit is carried on.

For instance our HC-Type *Person* can be defined to have two *ScreenTemplate* objects:

- A *ScreenTemplate* object called *access* defined as the starting one
- A *ScreenTemplate* object called *current_work*
The *access* *ScreenTemplate* object has three *PlaceHolders* as follows:
- A *MemberPlaceHolder* object called *biography* that holds a member with the *MemberRole* attribute of the value *Biography*

- A *MemberPlaceHolder* object called *picture* that holds a member with the *MemberRole* attribute of the value *Picture*
- A *TextPlaceHolder* object called *current_work_link* that holds a fixed text (e.g. See my current work) and that is defined as a *LinkPlaceHolder* object which replaces the *access ScreenTemplate* object with the *current_work ScreenTemplate* object.
The *current_work ScreenTemplate* object has two *PlaceHolders* as follows:
 - A *MemberPlaceHolder* object called *current_work_member* that holds a member with the *MemberRole* attribute of the value *CurrentWork*
 - A *TextPlaceHolder* object called *go_back_link* that holds a fixed text (e.g. Go back) and that is defined as a *LinkPlaceHolder* object which replaces the *current_work ScreenTemplate* object with the *access ScreenTemplate* object.

4. Implementation of HC-Data Model

The Structure Editor presented in the following chapter is a system that supports and implements the HC-Data Model. It consists of three components:

- Structure Editor Visual Definition Tool
- Structure Editor Visual Manipulation Tool
- Structure Editor Java Visualisation Interpreter

With the help of the Structure Editor Visual Definition Tool a new HC-Type can be defined. The tool offers a graphical user interface with drag and drop facilities. Authors first define a new abstract entity by specifying its meta-information attributes and finally they define a visualisation mechanism by defining a number of *ScreenTemplate* objects with corresponding *PlaceHolder* objects.

The newly defined type, HC-Type, is then used by the Structure Editor Visual Manipulation Tool in order to create instances of the HC-Type, i.e. HC-Units – collections of existing hypermedia documents and/or other HC-Units. This tool also offers an easy-to-use graphic user interface again with drag and drop facilities. Hypermedia documents are then simply dragged from a tree-like structure, which can be browsed using the Windows Explorer paradigm, to the right place in an HC-Unit. Hypermedia information can be accessed from any kind of information source, such as a Hyperwave information server, an HTTP server, an FTP server or a local file system. This is done through so-called ANT (Active Node Technology) [4] which allows a fully transparent access to any kind of information stored on any type of information server (see fig. 1.).

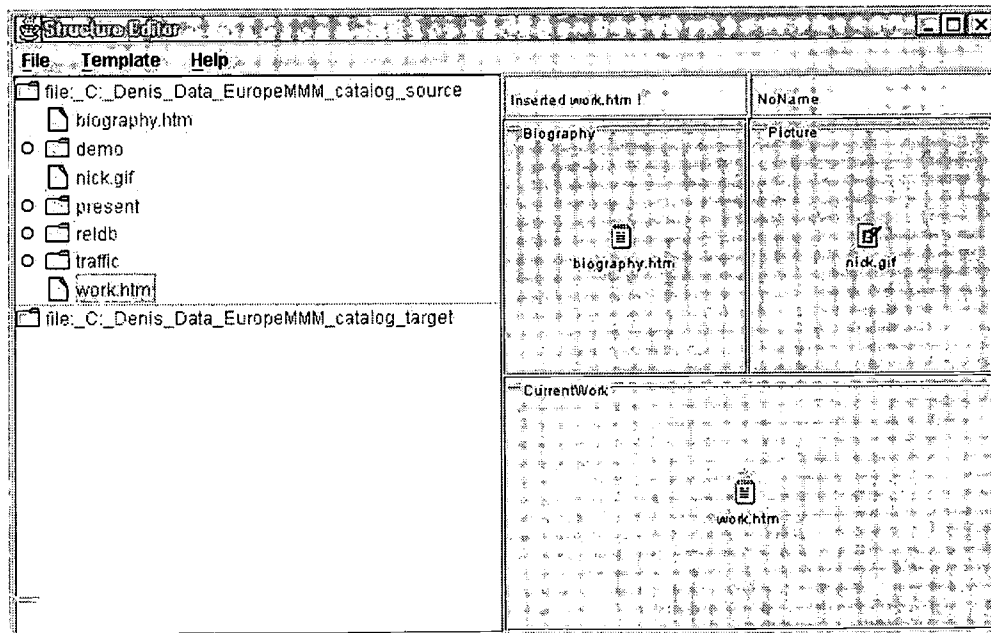

Figure 1: Structure Editor Visual Data Manipulation Tool

Once an HC-Unit has been created it can be published on a Web information server or a local file system. It can then be accessed by any standard Web browser, such as Netscape Navigator or Microsoft Internet Explorer. The visualisation is performed by the definition of the corresponding HC-Type and controlled by the third Structure Editor component, the Structure Editor Java Visualisation Interpreter (see Fig. 2.). This interpreter is implemented as a Java applet and is embedded in the starting page of the HC-Unit created.

5. Conclusion

In conclusion, we would like to notice that the proposed HC-Data Model as a semantic hypermedia model that extends the possibilities of the object-oriented hypermedia data models, such as the Hyperwave data model or the HM-Data Model, can have even bigger possibilities if used in a combination with some of these models. Mapping of the HC-Data Model to the Hyperwave data model is a good example of this combined use and is described in [Helic et al. 1999a]. Even mapping of the HC-Data Model to the node-link data model is possible and needed because of a big number of standard HTTP servers installed world-wide. But the most interesting application of the HC-Data Model would be, as we truly believe, mapping of the HC-Data Model onto XML. Similar to the HC-Data Model XML technology [Microsoft Corp. Homepage 1998][WWW Consortium 1998] allows authors to define new types of hypermedia constructs, i.e. the structure of hypermedia databases, as well as the navigational and visualisation paradigm. Because XML already becomes a standard the combination of the HC-Data Model and XML technology can offer the best possibilities for creating highly structured hypermedia applications.

Linking XML and Databases

K. Hendrikx, E. Duval^[1], H. Olivie

Department of Computer Science

Katholieke Universiteit Leuven

{Koen.Hendrikx, Erik.Duval, olivie}@cs.kuleuven.ac.be}

Abstract: Extensible Markup Language (XML) is becoming a standard format for exchanging documents and data. Various middleware tools that integrate different data sources and make them available over the Web will use XML as a standardized interchange format for data and meta-data. In this paper we describe a XML schema language that describes data sources and allows XML documents to be generated from their data. It allows us to flexibly bind databases and other data sources to XML. The objective is to obtain a flexible, component-based distributed information system architecture that integrates with the World-Wide Web and other XML-aware software tools.

1. Introduction

Extensible Markup language (XML) [W3C 1998] is fast becoming a standard format for exchanging documents and data. XML basically defines and exchanges data structures. This makes it a good format for information integration middleware tools. A typical application is publishing (heterogeneous) databases on the Web. Microsoft alone has at least five tools that allow this, and there must be hundreds of others. These tools all use different languages and formats, making it difficult to change or combine these tools.

A possible solution may come from XML schemas that will allow binding between XML and external data sources to be defined. An *XML schema* is an XML document that formally defines an XML document type [W3C 1999]. In addition a schema may contain additional information about the documents it describes, such as:

- **Data types:** XML defines all values as text, although some values represent numbers, dates or colors. An XML schema should specify specific data types, and a text encoding for each type.
- **Constraints:** XML parsers only check for uniqueness of identifiers and validity of references. An XML schema will allow additional constraints on values and references.
- **Documentation:** In an XML DTD documentation can only be inserted in the form of comments. An XML schema should allow (even require) text to be inserted to document the elements and attributes in it.
- **Binding:** An XML schema may formally describe how the information in XML files is related to a relational database or any other external data source.

The World-Wide Web Consortium will define standard syntax or semantics for XML schemas. The XML-Data schema submitted by Microsoft [Microsoft 1998] is aimed at the integration of XML with relational database and other data sources.

In this paper we will describe a practical system that links XML and heterogeneous external data sources, using an XML schema language.

2. Architectures for Distributed Information Systems

Architectures for distributed information systems have become more and more advanced in order to allow more

flexibility. The main problem is not in creating a working system, but rather in allowing a system to gradually adapt to changing requirements. In this section we describe the currently used architectures and show how these will naturally evolve to a more flexible one that uses XML schemas to separate clients from servers, and servers from the underlying databases.

In a two-tier client-server system, client programs interact directly with the database. The obvious disadvantage of this approach is that clients are very tightly coupled with the database. This makes it difficult to change the system's architecture, the database structure or even change database vendor. With the appearance of Web applets and JDBC, this architecture has become more attractive, because the applet code is downloaded from the server, making it easier to manage change.

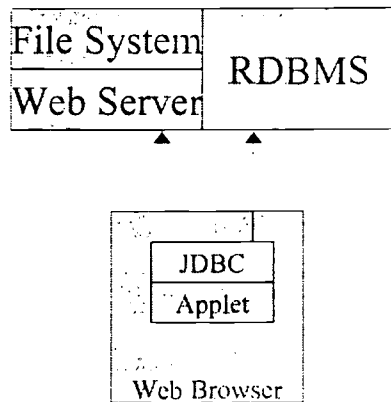

Figure 1: Two-Tier Architecture

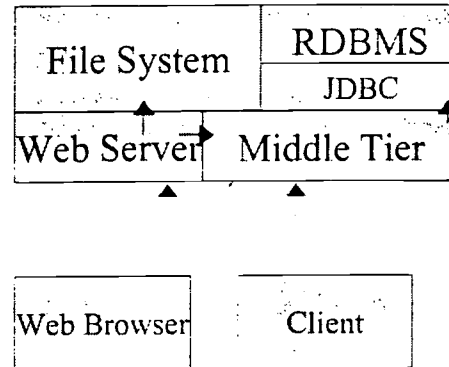

Figure 2: A Common Web-integrated Three-tier Architecture

The two-tier architecture is limited because the client-to-server communication is limited to the database protocol. Also, it is impossible to integrate the application with data sources outside of the database. In a three-tier architecture, a layer is introduced that separates the client from the database. All communication between client and server is routed through this middle tier. When such an application is integrated with a Web server, we get the architecture shown in Figure 2.

3. A Flexible Component-Based Architecture

We want to develop a client-server architecture that allows even more flexibility than the three-tier architecture. We propose to use a component-based architecture that relies solely on XML as an interchange protocol. The components are objects that translate from some data source to XML and back.

The main components are objects called *XML Schemas* that are capable of creating and parsing XML elements. They are adapters that convert the interface of some database to the more general XML Document Object Model (DOM) interface [W3C 1998b].

BEST COPY AVAILABLE

Figure 3: Component-Based Architecture

Figure 3 shows the proposed component-based architecture. At the front is an XML server that operates much like a current Web server. It is given a key that identifies some information resource, and an identifier for an XML schema. From this the server generates a reply, which is an XML file. The XML schema driver is an object that is able to extract information from the underlying data sources and convert it to the appropriate XML DTD. Some schemas are able perform the reverse operation - they can parse an XML file and update the underlying database to reflect the information in that XML file.

The XML document may be delivered with a stylesheet to render it in a Web browser. If the browser does not support XML and stylesheets, an HTML document can be generated.

The schemas can be linked to different data sources such as a relational database, an object oriented database or a file system through a layer of interface drivers. By adding a new driver, a new class of data source can be used. Also, multiple schemas may interact with the same data.

In short, the advantages of the proposed approach are:

- Clients use a standardized and uniform interface (DOM or XML) to different data sources.
- Clients are independent of the data source.
- It allows multiple mappings or views of underlying data.

4. The Schema Language

We have developed a schema language, based on the XML-Data schema specification, to represent the schema objects in XML. We have extended the existing language with constructs that express the binding between XML elements and a database. This binding is based on the relational data model [Codd 1970], which is obviously well-suited to relational data bases, but does not necessarily exclude object oriented databases or flat files.

A schema contains zero or more bindings and one or more `elementTypes`. A binding defines a number of drivers and tables. A driver is identified using a URL such as a JDBC URL. For each table a number of keys and foreign keys is defined. Since a query, as defined in SQL, can be regarded as a virtual table, with a key and foreign keys, it is quite easy to integrate queries as well.

```

<Schema id="company">
<Driver id="oracle" url="jdbc:thin:oracle"/>
<Driver id="fileurl" url="file://pictures/" />
<Table id="employee" driver="oracle">
  <Key id="ssn"><column name="ssn"/></Key>
  <ForeignKey id="superssn" key="ssn">
    <column name="superssn"/>
  </ForeignKey>
<ForeignKey id="picture" key="filename">
  <column name="pict"/>
</ForeignKey>
</Table>
<Table id="department" driver="oracle">
  <Key id="dnumber"><column name="dnumber"/></Key>
  <Key id="dname"><column name="dname"/></Key>
  <ForeignKey id="superssn" key="ssn">
    <column name="superssn"/>
  </ForeignKey>
</Table>
<Table id="pictures" driver="fileurl"/>
  <Key id="filename"><column name="fname"/></Key>
</Table>

```

4.1. Example

The example schema on the left describes a relational database, which stores information about employees and departments. Employees are identified by their social security number (ssn), departments by their number (dnumber) or their name (dname). A department has a foreign key to its manager's social security number. An employee can have a foreign key reference to his supervisor (superssn). We also keep pictures of employees, which are not stored in the database itself. The schema offers a way to integrate both data sources: we define a (virtual) table consisting of the picture files. A special database driver offers access to binary files

stored in a directory of the file system. Employees whose pictures are available have a database field pict which stores the filename. This is, in a way, a foreign key to the (virtual) table holding the files.

The second part defines how the database tuples are represented in XML. Basically a row from the database is represented as one XML element, in which possible related rows are embedded as nested XML elements. Database rows are mapped to XML tag attributes or text, using format specifiers for dates (e.g. date.iso8601) and numbers. The element types in fact represent textual tree-like views of related data in the database.

5. Update Semantics

The views that these element types represent have the following simplified update semantics: there are only two operations: GET and STORE. This first generates an XML file from the database; the second updates the database so that a subsequent GET would generate the provided XML file:

- If a root element (one that has a key) is stored, it is updated or inserted, depending on whether a tuple with the specified value for its keys already exists or not. Related tuples that have no corresponding child element in the XML are removed from the database.
- Values of key attributes are never updated. A new tuple must be inserted.

Because there is no explicit delete operation, it may be necessary to use some kind of garbage collection algorithm to remove superfluous tuples from the database.

```

<elementType id="employee" key="ssn">
  <attribute name="ssn" dt="string"/>
  <attribute name="first-name" column="fname"
    dt="string"/>
  <attribute name="last-name" column="lname"
    dt="string"/>
  <attribute name="birth-date" column="bdate"
    dt="date.iso8601"/>
  <attribute name="salary" dt="float"/>
  <element type="picture"
    occurs="OPTIONAL" foreignKey="picture"/>
  <element type="department-short"
    occurs="REQUIRED" foreignKey="dno"/>
</elementType>
<elementType id="employee-short" key="ssn">
  <string column="lname"/>
</elementType>
<elementType id="picture">
  <string dt="base64"/>
</elementType>
<elementType id="department" key="dno">
  <attribute name="name" column="dname"/>
  <element type="employee-short"
    occurs="ZEROORMORE" foreignKey="dno"/>
</elementType>
<elementType id="department-short" key="dno">
  <string column="dname"/>
</elementType>

```

6. Current Status and Future Work

Our current implementation uses a two step process to generate XML:

- First a simple XML representation of the database tuples is generated. Each column is translated to an attribute of an XML element, using a format specifier. These attributes have the same name as the column, but they can be given an alias to allow a column to be represented twice, but with a different format.
- Then this XML is converted to the desired DTD using a XSL style sheet.

A second XSL style sheet is required to convert posted XML documents into the base DTD that can be mapped to the database so it can be stored. The disadvantage of this approach is that two stylesheets are required that must do inverse tree transforms. But it does avoid the problem of having to guarantee that the transformation implicit in the schema can be inverted. This problem is presumably equivalent to the problem of view updateability in relational databases and is worth further investigation.

Other XML schema languages are being developed, like e.g. DDML [W3C 1999b] that is now accepted as a W3C submission. It uses a simpler model and more extensible model than XML-Data and has a good chance of wide acceptance. DDML will also have a vocabulary for encoding it in RDF, W3C's resource description framework.

This work is inspired by our involvement in the ARIADNE project. For the ARIADNE^[2](<http://ariadne.unil.ch>) (Alliance for Remote Instructional Authoring and Distribution Networks for Europe) project, we have developed a system for distributing information about educational resources on the Internet [Forte 1997]. It uses XML to exchange metadata between the so-called *Knowledge Pools* and client tools. Each knowledge pool stores various resources, some of which are encoded in XML, and makes them available to users. The system uses a relational database to store metadata so it can be queried. Some of the information is replicated among different knowledge pools. The greatest challenge is to design the system so that it remains possible to evolve the metadata structure. Other requirements are:

- Sites must be able to integrate their Knowledge Pool with their own information systems and databases.
- Some sites want to be able to extend the metadata structure but still be able to interoperate with other sites.
- We want to be able to convert to the international standard for educational metadata, which is currently being defined by the IEEE Learning Technology Standards Committee.

7. Conclusion

To better integrate distributed information systems with existing databases, and to better separate the representation of information from the underlying data structures, we have defined a component-based information system architecture. We have defined a meta-schema to bind different information resources to XML files. Such a meta-schema has the potential of being a single unifying view of data. It allows us to create applications without worrying about how this data is stored, by providing a more flexible but standardized interface.

Abstract: This paper describes the conception and prototype implementation of a navigation assistant to be used during browsing sessions in the World Wide Web. A local gateway configured as proxy for the browser logs each browser request in a database. Simultaneously a JAVA Applet shown in an additional window displays the browsed URLs hierarchical in an extended tree-view. The tree-view allows the user to explore the structure of the visited web sites. Therefore, the tool provides fast movement to previously visited URLs. A time series extends the tree-view and allows the user to determine the historical order of the recent requests.

1. Introduction

With the growing importance of the World Wide Web browsing becomes a common activity for most people. The browsing sessions are supported by many tools. The first tool to mention is the personal bookmark file provided by each browser. It enables the user to store links to visited documents in a clear fashion. They can be commented on and ordered by in a hierarchical structure. Another support in the same direction is given to the user by the web portals offered by most search engines. They can be customized in a personal manner and provide easy access to current information. Both, bookmark file and web portal offer great help in remembering document locations and in the later case often offer new links as well [GVU 1996]. But they do not support the current navigation matter during the browsing process. They just offer entry points where to start the browsing session. Although this is a very important aspect, the support of navigation should not be neglected. Navigation is in close contact with movement. Tools that support navigation must provide such entry points on the one hand and allow to control the movement in the space of the World Wide Web on the other hand. Such a control can be given in several different ways. A very simple but helpful feature [Catledge 1995] of this kind is the browser history. Browsers provide a history file that enables the user to navigate in his recent history. By the use of the back and forward button the user can move easily to previously visited documents. The history lists of the browsers show the URLs of the documents as they have been accessed in their historical order. History lists are just flat files equal to a stack that allow the access of recently visited documents. They lack a presentation of the structure of the visited web sites, since they are one dimensional. A two dimensional presentation [Dömel 1995], a kind of site map is sometimes provided by the web sites itself.

There are different methods to build helpful site maps. Many of them [Ayers 1995], [Hirsch 1997] use tree-view like presentations of the hierarchical order of the directories and documents. They provide good support for navigation inside of a web site. Since only a little number of sites provide such functionality, it is a more general approach to implement such a navigation assistant on the client side. Of course, in this case it is not possible to represent the structure of the complete web site. But instead, the combined structure of different web sites can be visualized at the same time.

2. Requirements for a Navigation Assistant
