ABSTRACT -

ERIC

A study was conducted at Milwaukee Area. Technical College to determine if a relationship could be established between $m{arphi}$ improvement in speaking and listening intelligibility and the deliberate structuring of a semiformal atmosphere in communication classes. Students with ACT composite scores below 13 were offered courses specially designed to remedy their linguistic and mathematical problems. In the fall semesters of 1971+72 and 1972-73, students in two of these communication skills sections were tested with a Speech and Listening Intelligibility exam. The two control groups engaged in formal classroom activities, while the experimental groups met in an informal class setting where, there was an opportunity for them to become acquainted with one another. In the posttesting situation, using the same exam, the experimental group students spoke clearly and with confidence. They, seemed to have a rapport with one another that was not evident in the control group. In general, experimental group students exhibited a marked increase in both listening and speaking scores during the semester, while control group students exhibited a decrease in scores. Statistical data, are included. (TO)

Effective Use of Communications Group Sessions on Speech and Listening Intelligibility at Milwaukee Area Technical College

Mariann Maris

BEST: COPY. AVAILABI.E/84

107

Mrs. Maris reports of a study to determine if a relationship can be established between improvement in speaking and listening intelligibility and the deliberate structuring of a semi-formal atmosphere in communications classes. She also discusses the psychological effects of a semi-formal atmosphere on students.

Determining Film Art

Roger Bullis. Mr. Bullis discusses the criteria by which films can and should be analyzed as art. He provides a triangular model of Theme-Form-Content and concludes that if a synthesis of the triangle occurs to any great extent, the film is art.

Film: The Art of Our Century

Toby Goldberg Prof. Goldberg argues that art is a necessary ingredient of human activity, that the art of film has become an increasingly significant feature of our lives, and that film manifests the unity of man with his increasingly technological world.

Second Stage Symbolism

Prohibition, A National Rite of Passage

William G. Kelley', Prof. Kelley examines the propaganda of the prohibition movement of the 1920's and discusses the role of propaganda in periods of social change. His article locates a place for propaganda in a cultural context.

Background

A "Crossover" Communication Skills I program was initiated at Milwaukee Area Technical College for the first time in the first semester of the 1971-72school year. Students are placed in the Grossover courses if their composite score on the ACT is lower-than thirteen. Courses offered to these students are English (Communication Skills), Reading, Speech, Mathematics, or Psychology. All the courses are designed to remedy certain linguigtic and mathematical problems which resulted in a low ACT score.¹ Students who successfully comlete the courses in the Crossover program can enroll in "non-Crossover" or on-remedial programs at M.A.T.C. if they wish to return for another semester. They receive full credit for their Grossover program courses if they pass the course with a "C" or higher.

Scope

In the first semester of the 1971-72 school year and again in the first semester of the 1972-73 school year, two Communication Skills I sections were tested with a Speech and Listening Intelligibility Examination, which are presented in two forms, A and B. Form B was administered in Septembor, 1971 and in September, 1972; Form A in early January, 1972 and 1978. The test, which measures the accuracy of one's speaking and listening abilities, was designed by Terrence Adams, Dean of M.A.T.C. College of the Air. The nonpublished test has been the object of experimentation and the test when conducted by Mr. Adams at M.A.T.C. has proven to be a useful tool to reliably measure a student's ability to exhibit fundamental speaking and listening skills. A student must be able to discriminate between different sounds in order to acquire whatever information an instructor communicates orally in the classroom. This test measures the listener's ability to differentiate "like" sounds. If a person does not speak clearly to his teachers or fellow students, he is not communicating effectively what he knows because of the way he talks. The failure to speak clearly enough to clicit a desired response in the listener could be a source of academic and personal frustration. A total of fifty students in four groups took the preand post- forms of the Speech Intelligibility and Listening Intelligibility test over a two-year period. For the time being, there is no further experimentation with testing and groups in session due to the assignment of the instructor to non-Crossover Communication Skills courses.

The Teste,

A sample test of Form A and Form B appear on the next two pages.

Mariann Maris (M.A. English, Marguette University, 1968) is an instructor of Communication Skills at the Milwaukee Area Technical College. She notes that special credit for this paper are due to the cooperation of Dr. Marvin Ketterling, Counselling Center, M.A.T.C., and Mr. Terrence Adams who authored the Speech and Listening Intelligibility Test and permitted its usage.

Methodology

The Control Groups, I and III, met with Dr. Marvin Ketterling, Counseiling Center Director, in a Communications Group one day a week for eight weeks. The sessions began in the fourth week of the semester and continued through the tweifth week, Groups I and IV did not meet in a Communications Group. Three hours a week were spent in formal classroom activities. Group I did not take Mathematics as their elective. They were enrolled in Psychology. Group II took Mathematics and appeared to be more eager to acquire knowledge in the first weeks of the semester.² Group III could take either Mathematics or Psychology. The same was true for Group IV.

The Speech and Listening Intelligibility test consists of several pages of words listed in a series and divided into 24 categories with a list of four words in each category. The test is 10 pages long and each page has different words. (The samples seen on each of the last two pages constitute a single page, each.) The students in each class are required to read, from a separate sheet, one of the terms in each grouping of words. Each student reads 24 words to the remainder of the class. Those students who are listening are required to circle the word they hear the speaker say. The total number of listeners is multiplied by the total number of correct answers (24) for each group. A speaker would be 100% effective if there were no incorrect words circled by any of the listeners. Each listener writes the name of each speaker at the bottom of each page of the total number of correct answers he circles after listening to all of the speakers. When all of the members of the class have read a list of 24 words, the test is completed.

Each speaker approached the front of the room and faced the listeners in the groups used for this experiment. The pace at which he read the words from the list he was given, the way he enunciated and projected was left to his judgment. The words are "easy," usually single-syllable words so that students were not hampered by any kind of reading problem. Some speakers were immediately aware of the necessity of reading slowly and were able to pace themselves accordingly. Some allowance must be made for poor acoustics. Background noises do affect the speaker's ability to be heard and understood.

Results

The results of the tests are stated in statistical terms on the next two pages The Control Groups Results are shown first; the Experimental Groups Results are shown second.

Discussion *

The results of the pre- and post- tests are interesting, particularly from the first groups, I and II. Generally speaking, speech intelligibility and listening intelligibility improves over the course of a semester in college. Group II, the control group, did not improve; in fact, their speech intelligibility scores in January were lower than the results from Form B of the test which was given in September. The speech intelligibility of the experimental group, Group, I, improved in all cases with the exception of one person. The experimental group was meeting with Dr. Marvin Ketterling in an informal class setting where there was an opportunity for them to become acquainted ' with one another. When they participated in the post-testing situation, they were cognizant of the way their fellow classmates "heard" them. They paced themselves. One of the students was a victim of cerebral palsy, so it took him a longer time to encircle the word the speaker was reading. ' The reader always waited for him to move to the next set of words. In general, they spoke clearly and with confidence. They seemed to have a rapport with one another that was not evident in the control group. The control group seemed in a hurry to complete the test and leave. They hurried through the list and many listeners did not bother to circle words at all.

Because the contrast between scores of students enrolled in Communication Groups for one of the three hours allotted for class time and those who were not in such groups way so marked, the experiment was repeated in the 1972-73 school year. The contrast there was not as great. There may be several reasons. The control group had the highest academic successes among those students assigned to Crossover. They did not take Mathematics unless they wanted to. Most of them were highly motivated. The experimental group had a lower academic high school average and their ACT scores were lower than the scores of the control group. The class met from 8:50 - 9:40 A.M. three days a week and many students in the experimental group found the hours somewhat undesirable. As can be seen from the second set of results, however, Group III's improvement is generally indicative of a greater increase in percentage between Form B and Form A of the test.

89

BEST COPY AVAILABLE

The sharp contrast in scores between Groups I and II and the generally higher scores between Groups III and IV indicate the effectiveness of meeting informally, where many of the regular classroom pressures are not operative. The students who had participated in the Communications Groups with Dr. Kotterling were more sensitive about the way they spoke to their fellow classmates and, in turn, their colleagues were careful about the way the listened and responded to the speaker. They appeared more eager to perform to the best of their ability on the test and made an effort to please. The control groups were not as anxious to please when they were tested. They hurried their speaking at times and failed on occasion to establish eye contact with their audience. Many times they mumbled. The students encircling the words often gave up before a speaker finished. Since their willingness to participate fully was at a tow point, particularly for Group II, the test results were lower.

It is interesting that the control group II was enrolled in a programmed course in mathematics. They were meeting daily frustration. Of the nine students in Control Group II only two passed the course. They expressed disillusionment and dissatisfaction with the course although many of them felt that they worked harder at the course than at any other course they had ever taken, and still they failed. Perhaps the failure in Mathematics affected their performance in Communication Skills I and that frustration was measured in the differences between pre- and post- scores on the Speech and Listening Intelligibility Test.

The differences between test scores are not as great between Groups II and III. For each group changes in the Crossover program at the beginning of the 1972-73 school year prevented students from encountering too many difficulties in their academic programs. Student tutors, for example, were provided to Crossover.students.only. The Mathematics course was limited in its requirements. The result was a more satisfied, optimistic group of students in both the control and experimental groups.

Conclusion

The intent of this paper is to use statistics in a manner which illustrates rather than proves a relationship between improvement in speaking and listening intelligibility and the deliberate structuring of a semi-formal atmosphere in Communications classes. The suggestion can be made that students learn more about listening and speaking clearly when they spend some of their time getting to know one another in a semi-formal Communications Group setting. On the junior college level it is possible for a student to finish a course in Communication Skills I without ever speaking in a public setting to the members of his class; yet the interaction between members of the same classes improved those skills most essential for effective learning — speaking and listening.

FOOTNOTES

1. It must be noted that low high school grade point averages are also used as a determinant for admission to the Crossover programs along with advice from high school guidance counselors.

2. Personal observation of the instructor.
