ABSTRACT
          The WebNet 2001 conference addressed research, new
developments, and experience related to the Internet, intranets, and
extranets. The 452 contributions of WebNet 2001 presented in this volume
consist of the full and short papers accepted for presentation at the
conference. Major topics covered include: commercial, business, professional,
and community applications; e-learning/educational applications; electronic
publishing and digital libraries; ergonomic, interface, and cognitive issues;
general World Wide Web tools and facilities; personal applications and
environments; societal issues, including legal, standards, and international
issues; and Web technical facilities. (MES)

Preface

The first WebNet conference of the new millennium is overshadowed by a human and political tragedy beyond imagination. While writing this preface, many of us are experiencing a horrible uncertainty concerning the fate of colleagues, friends, and members of their families. Globalization helped to develop social, cultural, economic and personal relationships. Therefore, not only the USA but also the entire world, which relies on democratic and human rights, has been hit and deeply hurt by the terrorists' acts of the 11th of September 2001. We are mourning with the victims and their relatives, and we are convinced that justice and freedom will prevail.

The Program Committee and AACE believe that we need more global development and less isolation and marginalization. The WebNet conference as a global conference on the "networked world" can be one small contribution to a sustainable growth that decreases the so-called 'digital divide.' In this spirit, it is our pleasure to present to you the Proceedings of the Sixth WebNet Conference – WebNet 2001. This conference addresses research, new developments, and experience related to the Internet, Intranets, and Extranets.

The 452 contributions of WebNet 2001 presented in this volume were submitted from 51 countries. The volume consists of the Full and Short Papers accepted for presentation at the conference from a collection of 834. All submissions were carefully reviewed by at least three members of the Program Committee and their recommendations used for selection. Borderline cases were reviewed at a special Program Committee meeting where appropriate decisions were made based on re-reviews.

Of the accepted contributions, five were considered outstanding based on the reviewer's scores and comments. The outstanding papers represent the top 1% of accepted papers. These papers are indicated in the conference Final Program. Authors of outstanding papers have been invited to submit extended versions of their papers to the *WebNet Journal* (**www.aace.org/pubs/webnet**).

The coverage of the contributions is wide and gives the attendees of the conference the opportunity to learn more about innovative technological developments and practical experiences in many application areas. This is one of the features that distinguishes the WebNet series of conferences from others that focus on more specific areas. Our intention has been to provide a meeting place of developers, researchers, practitioners, and users as a forum wherein persons from disparate but related fields can meet and learn about new developments that impact their professional lives.

The major areas covered at the conference and presented in this volume include:
- Commercial, Business, Professional, and Community Applications
- E-Learning/Educational Applications
- Electronic Publishing and Digital Libraries

- Ergonomic, Interface, and Cognitive Issues
- General Web Tools and Facilities
- Personal Applications and Environments
- Societal Issues, including Legal, Standards, and International Issues
- Web Technical Facilities.

These general areas have been divided into several more specialized topics.

In addition to the papers included in this volume, participants at the Conference heard leading experts present Keynote and Invited talks; participated in tutorials, workshops, small-group discussions, and poster sessions; and had a chance to see demonstrations of various items of interest. The Conference was preceded by two days of tutorials and workshops, which conveyed the depth and breadth of the conference.

Please plan to attend the next conference in Toronto, Canada, October 14-19. To be present and observe the WebNet series is one of the best ways to stay current with the rapid and intriguing developments of the Web. Periodically check the conference website at **www.aace.org/conf** for information

Last but not least, we would like to thank all authors for submitting their work, and all members of the Program Committee, listed on the following page, for their cooperation and time spent reviewing submissions. Special appreciation is extended to Gary Marks (AACE), who is one of the main driving forces behind this volume as well as the WebNet series of conferences, and the AACE staff who contributed so much to the success of the conference.

The Mentor Project: Designing the next generation of instructional software

Terence Ahern, Texas Tech University, USA; David Dean, Texas Tech University, USA; Roman Taraban, Texas Tech University, USA

The Internet is a wonderful source of information. Information, however, is not instruction. The problem for teachers is not simply access. In order for teachers to weave this content into meaningful lessons.it is necessary for content producers to categorize information into meaningful structures. The solution is multi-faceted. One the one hand content producers need to be able to classify their content in such a way that it makes sense to teachers. One the other hand teachers need a way of structuring lessons in such a way so that they easily used and shared among teachers. The Mentor Project is a follow up to a paper presented at WebNet 2000 which outlined this work in progress. This paper is a report on development of the overall project and the software in particular.

Interactional conflicts among audience, purpose, and content

Jacqui Cyrus, Texas Tech University, USA; Terence Ahern, Texas Tech University, USA

We studied the effect electronic forms of writing, especially collaborative environments such as email and threaded discussions, had on the development of students formal writing skills. Implications for curricular design will be discussed.

A Web-Based Introduction to Programming Course

Leandro Amaral, Federal University of Goiás, Brasil ; Eduardo Albuquerque, Federal University of Goiás, Brazil

Programming is still a myth for many people. Many people think that programming is a very difficult activity and do not want to start learning it just because of rumors they hear. This project aims at the development of a Web-Based course named "IPL – Introduction to Programming Logic", whose objective is to naturally make students familiar with programming logic, by indexing their inherent logic thinking to the one they will be introduced to.

An Assessment Model for Distance Education Courses

Thaisa Barbosa, State University of Campinas, Brazil ; Eduardo Albuquerque, Federal University of
Goiás, Brazil

We present a model for assessment to be used in web based distance courses at UFGVirtual in Brazil. UFGVirtual is a project at Federal University of Goiás - Brazil that aims at developing and distributing non presencial courses based in the web. Although some courses are already being delivered there has been a need to develop more effective ways to assess student's performance, the main goal of this project.

Using User Profiles to Customize Assessment in Distance Education

Thaisa Barbosa Ferreira
Eduardo Simões de Albuquerque
Instituto de Informática, Universidade Federal de Goiás, Goiânia, GO, Brazil
E-mail: {thaisa,eduardo}@inf.ufg.br
Home Page: http://www.inf.ufg.br/~eduardo/

Abstract This work is part of EDUCAR project. We are studying how we can define and use user profiles to offer tailored interface and to customize content according to performance and interest of students. We also plan to provide instructors with information to adapt and define versions of documents suitable to the different profiles.

Introduction

The main objective of EDUCAR project is to create a model for developing and managing Web based courses. The project defines resources for course authoring, keeping track of students progress and assessment. The process of keeping track of the student progress can be made easier if we group students according to common characteristics. E can also use group information to customize assessment tests. We propose the definition of user profiles, that can be obtained automatically.

EDUCAR project is being developed within Federal University of Goiás (Brazil) which is in the beginning of an effort to create a Virtual University. At the moment two courses are already implanted: one for teaching mathematics to high school teachers in public schools and the second is an archeology course. The profiles are going to be tested using these two courses.

Project guidelines

One of the main points in succeeding in any web based project is having an attractive interface. We also think that it should be able to customize the look and feel of the interface (to a certain extent, of course) [SUDARSKY, 1989]

A second point of interest when we make information available to large groups is to control access to the documents. We sometimes have to restrict access to some parts of the content. We should be capable of hiding information without making it obvious for the user that his moves are being restricted. We will be using information gathered from user interaction, his status in the system, defined by his enrolment in the course to dynamically create tailored pages.

Not all information is dynamically obtained. The enrolment process defines the level of access allowed. For example, in our mathematics course, the target population is composed of teachers in public schools. We also plan to make the courses available to all students, including the teacher's own students. In that case, the teachers will have access to some support material, solved exercises that will not be available to the whole group of users.

In the process of creating user profiles, the key point is user identification. The first step is user enrolment in the system. The user is given a password and identification that will be used to keep track of his activities.

The system makes distinction among students, teacher-student and teacher-author. The first is a regular student, the second one is a teacher in a recycling program or needs needs

material to use in his classes and the third one is the teacher responsible for the authoring of the document.

To define the profiles, we keep track of pages visited by each student, time spent in each page, level of details required. The level of details is obtained from the number of available links followed. The information obtained is can also be made available to the students who can then identify his strongest and weakest points.

The use of profiles is still very dependent on the authoring process. The author must rate links according to course objective. Some links, for instance can be rated "must be followed" if it contains basic material. In particular, the authors are being required to define links for students with special needs. Some of those links a hidden from more advanced users, although those defined as teacher-student can choose to have all references available if he is enrolled mainly to gather information to improve his classes.

We are also implementing "grading buttons" that allow users to give grades to certain links. This information is also gathered and used to customize pages to other users identified with similar profiles.

Assessment is another point of interest. Tests can also be defined taking into account user profiles. Slow learner are provided with test more frequently and with rising level of difficulty.

All information gathered by the system is stored in a database [CERQUEIRA, 1999] Statistics on users behavior, links followed, grades given to links, navigation order and pages visited are provided to the author so he can improve his course.

Conclusion

Awareness of user diversity is very important to guaranty effectiveness of instruction material when teacher do not have "eye contact" with students. We must provide an easy o use interface and content in a way that respects students rhythm and time available for studies. A course model must no be a barrier for the student. The main objective of any web based course is not teaching how to use the system but to transmit the intended content. We have found that a large amount of information available can take the focus out of the main object of the course. However, it is very difficult for any author to define how much is too much.

We are still implementing the system so we do not have empirical results to assess the effectiveness of our proposition. However we believe that our project can contribute to the development of better courses, more attractive material, and to make authoring process less empirical than it is today

Technology integration and classroom dynamics

Ahmed Ali
Ohio University, United States
aa172892@ohiou.edu

Abstract: An examination of student attitude towards technology revealed students prefered using technologies that made learning "interesting". Need, access and transferability of technology were major considerations in students' preference for some technology. The Internet is a tool preferred by students to other technologies. The Internet's ability to provide information and make learning "interesting" played a major role in the students' decision. The widespread use of the Internet influenced classroom activities, with students taking more active role, and learning and teaching styles displaying increased student-centered learning approach. For this report, students and an instructor were interviewed, while participant observation was conducted at an instructional lab where undergraduate students were taking a course on technology integration in education.

Introduction

Technology use in educational institutions is a focal issue in learning improvement activities and efforts. Technological advancements and re-evaluation of instructional strategies and curriculum widely contributed to the incorporation of technology. In today's classrooms, technology is perceived to be providing more opportunities to students in their learning. It has changed the teaching and learning strategies. Technology in classrooms provides students with access to materials, overcomes barriers (age, gender and color) in classrooms, and gives learners different styles in classroom learning. Despite these perceived benefits provided by technology in classrooms, it is just a tool (Hyjek, et. al. 1998).

An important technology at the center of this move is the Internet. The use of the Internet as an instructional aid has increased over time in the traditional classroom. Kumani (1999, in Kelch & Karr-kidwell, 2000) asserts the Internet has affected instructional delivery systems in institutions of higher learning. Faculty changed their courses from traditional to web-based while others use the Internet as part of instruction in traditional classrooms. The Internet will have a major impact on learning in this century. However, focusing on the Internet only as an alternative delivery system can create discrepancy in students learning because of costs, experience and attitude towards the Internet. Selection of other alternatives should be based on their ability to generate interactivity as the key is learner-centered learning (Forsyth, 1998, Johnson, 1997).

Despite all the misgivings about technology use in classrooms, it is increasingly incorporated in classrooms, and will undoubtedly become part and parcel of the teaching and learning process. As can be seen from the current trend of integrating information technology in instruction, "the text as the university educator professor knows it might soon cease to exist. It appears unlikely that the pencil and textbook tradition of yesterday's classroom will continue to hold such a dominant position in American education" (Burow-flake, et. al., 2000, p. 72).

If technology is not appropriately used, it can compromise the quality of student education. Technology should be introduced if it is suitable and if users are interested. This study was an investigation of students' perception of various technologies. As a major technology increasingly used for instruction, the influences of the Internet was examined.

Method

The study explored technology integration in instructional activities. An examination of technology use in teaching and learning, notably the Internet, was conducted on a *Technology application in education* course at a university. Attention was paid to the attitude of students towards different technologies, and learning activities and Internet use by students. Comprising students of all majors and undergraduate rank in a mid-western education college, the course was about teaching pre-service teachers how to integrate technology in their disciplines. Participants in the study included all 22 students (14 females and 8 males) and the instructor. The study was conducted in an instructional lab that had the following technologies: 26 PCs, a scanner (image and OCR), two HP networked printers, cobr printer, an LCD projector, and a large projection screen. The computers had Internet connection, speakers and microphones, and various educational application programs such as Word, Access, Excel, PowerPoint, HyperStudio, ClarisWorks, and KidPix.

Data collection techniques included 5 hour-long taped personal interviews with students. Experience in technology and activities in class determined selection of interviewees. Survey questions were distributed to students during the last week of class. The students were requested to place their responses in the instructor's mailbox at the department's office, 16 of which did. The instructor was a key informant. A one-hour in-depth interview with the instructor shed more light on students' attitude towards various technologies, roles of the teacher and the learner, teaching styles, and students learning. Information collected through interviews was triangulated with records of observations made as a participant in classroom activities. Each classroom meeting was observed which was twice a week. As *CourseInfo* web delivery program was used to supplement face-to-face instructional activities, students' online activities were also observed. Data collection and analysis were conducted concurrently (Marshall & Rosmann, 1999) to help draw conclusions from organized data.

Findings, summary and conclusion

There was a general consensus among students and the instructor that technology in general and the Internet in particular had influenced classroom activities. This included teaching and learning styles, students' attitude, instructional roles and classroom management. Students had displayed little enthusiasm for programs that had limited features such as audio, video or animations. Of

the application programs, students spent more time using PowerPoint and HyperStudio than working on their spreadsheet and/or database projects. One student stated that the former were fun to work with and that accounted for many students' preference.

Need, access and transferability of technology was an important consideration in students' choice or preference for some technology. Students displayed interests in learning about technologies they used, or were easily transferable to their immediate or future needs. The teacher corroborated students' views that access to technology outside the classroom influenced students' attitude. For instance, some students were reluctant to use software that was not commonly used elsewhere. Some learned more about printers as they could apply skills gained to work on their printers at home.

The students and the instructor stated that while it is good to use application programs and the Internet together, they gave leverage to the Internet because more could be done with the Internet. Students cited communication, information, and entertainment features that the Internet provides as motivating factors for Internet preference. While not overly favoring the Internet, the instructor added the Internet could be used for instructional activities both within and outside the class. The fun part about software was similar in hardware. When using the various hardware facilities, students were excited about digital cameras and scanners. They used these peripherals to take pictures of themselves and other events for posting on the web. They were more interested in learning about a digital camera than a motherboard. For instance, when teaching about the computer motherboard and other peripherals like printers and zip drives, less than half of the students showed any interest.

Students found in the Internet easy access to multiple sources of current and inaccessible information using multiple means of delivery like text, video and audio. The Internet reduced dependency on the instructor as students found in it supplemental or alternative information to the instructor's. Some students displayed positive attitude towards learning as the Internet combined visual and audio features with the text and the teacher's talk. Meanwhile, the Internet can be detrimental to students' learning if used inappropriately. The study discovered the Internet made classroom management difficult. The teacher became handicapped, with limited roles and responsibilities. Students engaged in different activities, not paying much attention to the lesson or the teacher. The teacher found it difficult to "police students' activities". According to the teacher, students' limited Internet skills diminished efficient use of Internet resources. Students spent considerable time on the Internet that could have been used for other learning activities. Students had developed dependency, preferring to use the Internet to other sources like textbooks. The teacher was concerned students referred to the Internet quite often. On the other hand, the instructor admitted the increasing confidence shown in the Internet had cast doubt on his professional competency even if students did not intentionally do that.

Technology is increasingly used for instruction. Educational institutions implemented use of technology in classrooms. Students and teachers prefer some technologies to others. Of the technologies used, the Internet has become one of the preferred and widely used tools for improving the quality of education. Whether integrated in a web-based or face-to-face learning environment, many people agree the Internet can improve learning. This potential can be tapped if the Internet is incorporated appropriately. The Internet should be used only when it is suitable and even then applied together with other tools. Students should be given training in Internet use while proper and clear guidelines should be established. And the fun part of learning should be reassessed so that learning involves more seriousness and challenges.

Tools for Tracking Employees' Usage of Internet

Samir Al-Khayatt, Richard Neale
School of Computing , Sheffield Hallam University
City-Campus, Howard St., Sheffield, S1 1WB, U.K.
s.alkhayatt@shu.ac.uk

Abstract: The rapid development and deployment of Internet technologies has changed the daily operation of many businesses. Although the Internet is considered a powerful business tool, with its use increasing all the time, you may still find, however, negative aspects linked to its usage in various areas. Reports, so often, maybe found in the computing press of how the Internet is being misused by employees. This paper suggests and puts forward the need for corporate Internet connections to be monitored along with the creation and evaluation of tools to aid the monitoring process.

Introduction

It was stated [1] that more than eight million person-hours of productivity are lost to UK industry each year because of employees surfing the Internet. If an organization is to control its network and computer systems it must put, in place, policies that must be agreed upon by the board of directors and distributed to all staff.

If a policy is not in place in your organization already then the JANET acceptable user policy [2] is arguably the most appropriate. Not only does it cover illegal aspects of Internet use, but also usage that cause annoyance and inconvenience to valid users. It is recommended that there are five points to consider when writing a policy [3].

Proxy logging of Internet usage to a log file may give a small degradation in network performance. This small degradation in performance will be, in most cases, dwarfed by the performance degradation due to policy violation. The proxy server log file lists every web page request made by a users web browser to the Internet, listing the IP (Internet Protocol) address of the requesting computer and the Universal Resource Locator (URL) requested. It should be noted that the proxy log files could grow to unmanageable sizes with in short spaces of time.

It is stated [4] "Procedures for monitoring use of information processing facilities should be established. Such procedures are necessary to ensure that users are only performing activities that have been explicitly authorized". This quote stands to reaffirm the need for monitoring of system usage.

Log files are very important in the monitoring of networks and systems [5]. "On the Internet, however, you have neither a physical description nor fingerprints. Therefore, without logs, making a case is almost impossible".

Commercial Products

Aiding in Proxy log files analysis, many commercially available tools are investigated. These are ranging from freeware products, such as Cache-Stats, to those priced in thousands of pounds. Three products are examined and looked at: Cache-Stats, NetTracker and Cyfin Reporter Pro. Below is a table of various products' features being compared.

	LogLook	Cache-Stats	NetTracker	Cyfin
Cost	N/A	Free	$995	$1,499
Pre-defined reports	Yes	Yes	Yes	Yes
Custom Reports	Yes	No	No	No
Data Analysis	Yes	No	Yes	No
Policy awareness	Yes	No	No	Yes
Data classification	No	No	No	Yes

Table 1 Comparison of Features

System Overview

A list of design criteria and features, based on investigated products, was set out to enable the design and implementation of a customized tool, tailored for corporate use. The desired features are:

- Name lookup (it is more readable if a domain name lookup is performed).
- Schedulable (the ability to run portions of the program, such as name look up and basic summaries at non-peak times).
- The ability to categorize sites into different groups.
- The ability to open any web page reported into a browser.
- Reports per user and per site.
- The ability to analyze any data represented, preferably by clicking on the data with the mouse.
- Highlighting of possible policy violation.

The system, called LogLook, will be constructed of three separate parts; the log file pre-processor, the automatic report generator and an interactive application to aid the System Manager in the examination of log files. Using this three part modular approach will help in the maintenance of the product throughout its life.

The system will be implemented using a database engine to handle the bulk of the processing. The pre-processor will prepare the data from the log file and then load it into the database. Script files that query the database and report the results via email to the System Manager will generate automated reports. The interactilve application will be implemented using a web server. A set of HTML pages will be created to enable the user to query the database. Returning reports will produce HTML pages dynamically to enable the user to view results through their web browser.

Conclusions & Future Development

The analysis tool was put to good use and, within a week, it has been discovered that a large proportion of traffic was non-work related, although it was clear that none of the traffic was illegal or illicit, but mostly made up from soccer news, stock market dealing, looking for new jobs, booking holidays, reading online news papers and many other ordinary sites. Due to commercial senstivity, data cannot be presented in this paper.

Included in the logfile table is data that is not currently used. It is hoped to take advantage of this data in the near future. The data not yet used holds information on the time taken for each download and the number of bytes downloaded. The inclusion of reports that deal with the time spent downloading and the quantity of data downloaded would be useful enhancements to the system.

It was decided to use a database, since large amounts of text data are processed. The decision was to use mSQL [6]. It uses standard SQL for its data manipulation and offers many interfaces to different languages (including C, Perl, Java and Tcl), but the interface to the data , decided upon , was via HTML, using W3-mSQL. mSQL's scripting language, called *lite*, provided utilities to perform DNS name look up.

The next step of this project is to re-design it in PHP [7] and MySQL [8]. This would have several benefits: firstly, PHP and MySQL are free to use for commercial projects, where Hughes Software's miniSQL is only free to education. Secondly, is to enhance performance. MySQL server is now faster than miniSQL on data transactions and data processing.

PHP offers many more features than miniSQL's lite programming language, PHP also has an additional performance increase when it is implemented as an Apache server module. Apache modules are executed much faster than CGI scripts because the server does not have to make an operating system request to spawn a shell to run the CGI program or script in, instead the server just forks a process. PHP also has many features which could be used for the pre-processing of the data ready for uploading. PHP scripts can be run from the command line as well as through a web server.

Another feature of PHP, we hope to use, is its ability to produce simple images (gif or jpeg) which could be used to produce a graphical representation of the data which, in turns, should make it easier to get a quick overview of results.

Virtual Private Network Support in a Corporate Network

Samir Al-Khayatt, Mark Charlesworth, Siraj Al-Shaikh
School of Computing , Sheffield Hallam University
City-Campus, Howard St., Sheffield, S1 1WB, U.K.
s.alkhayatt@shu.ac.uk

Abstract: This paper presents a case study, whereby a large organisation; Sheffield Hallam University (SHU) has considered improving the security of its current corporate network. A model has, already, been built for Sheffield Hallam University's infrastructure network. A scheme is progressing to set up, analyse and test all possible ways of securing information between various end-points of the network.

Introduction

In the process of supporting a proper network security solution, we need to consider and evaluate a number of IPSec-certified products (recent list of IPSec-certified VPN gateways is provided by the ICSA Labs [1] along with a set of criteria for products evaluation [2]) . Other industrial products, which are not mentioned in [1] but are still certified by ISCA include; Cisco's PIX Firewalls (IPSec-support provided) [3], Novell Border Manager [4] and a few others. A number of testing models, to support virtual private network in a corporate network, are being proposed in the following sections.

Novell Border Manager

Novell BorderManager [4] is aimed towards providing users with better security and management on the borders between traditional proprietary networks and the Internet. The suite of integrated components includes; advanced firewall security, authentication and virtual private networking capabilities for the encryption of data and tunneling.

Sheffield Hallam University has a large Novell implementation. It supports a very large Novell NDS network with Novell 5 Servers and NT clients running ZEN, directory-enabled desktop management solution by Novell. That is one reason, perhaps, inclined towards using Novell products. A Cisco 2600 series router [3] will be added on the boundary of the network, effectively forming the border of the network itself.

Proposed Network Setup (1)
Fig. 1 Proposed Network Setup 1

Fig.1 above shows the network setup with a 2621 router placed before the BorderManager, which acts as a VPN Gateway, providing IPSec encryption and user authentication. The Cisco 2621 router, being used, will have a Cisco IOS Firewall. It enhances the existing Cisco IOS security capabilities making it a complete network security solution from an ordinary router. It provides firewall, intrusion detection, authentication and encryption services. It incorporates some advanced security features, such as stateful application-based filtering (context-based access control), defending against network attacks, authentication and authorization of users and real-time alerting.

Windows 2000

An alternative to BorderManager model will be Windows 2000 (see Fig. 2). It is highly recommended as Windows 2000 is understood to be the next major network operating system planned for implementation across the academic communities in general. The enhanced security features, promised by Microsoft, for Windows 2000 need to be investigated. Windows 2000 will act as a VPN Gateway, providing IPSec encryption and user authentication. The network setup below demonstrates the use of Windows 2000

Proposed Network Setup (2)
Fig. 2 Proposed Network Setup 2

Cisco 2621 Router

One of the advantages of using the Cisco 2621 router along with its IOS Firewall features, is that it provides a single box solution not only for the firewall but also for the IPSec VPN encryption and authentication (see Fig. 3). One of the major concerns here is that if all the security services are off-loaded onto one box, then that will create a single-point-of-failure. This situation is not acceptable, however, unless a standby pre-configured router is available, which takes over in case of the router failure. Considering the complexity of the router configuration (security settings and encryption particularities), it is highly unlikely that such an arrangement would be preferred. Such a setup would be still tested, however, in order to check for performance variation from other network set-ups and the ease of management of the network; i.e. managing a single device rather than a firewall and a gateway separately. The network setup shows the router simply positioned between the two networks, promising to provide complete security services.

Proposed Network Setup (3)
Fig. 3 Proposed Network Setup 3

Future Work

Work is underway to set up, analyse and test all possible methods (mentioned in previous sections) for tunneling and securing information between various end-points within the network . Management and distribution of Public Keys (Public Key infrastructure - PKI) is part of the investigation as well .

Conctructivist vs. Objectivist Approaches to Teaching On-Line

By Kay W. Allen

The long-term debate over the most effective way to teach has only been intensified with the introduction of distance education. Whereas the remainder of this paper and beyond could be used to address the many pedagogical/androgogical issues associated with on-line learning, the discussion will be limited to briefly reviewing the constructive approach, also known as discovery learning, and the expository style of teaching. One issue in the whole debate is whether a constructivist or discovery approach, as opposed to an objectivists or expository approach, is the better method to be used to enhance learning, specifically retention and transfer.

For some time, there has been agreement among educators that there are four broad dimensions to be considered when planning instruction. The four dimensions are:
- Student – human development, individual differences, learning styles, motivation, etc.
- Teacher – self knowledge
- Content or subject knowledge
- Pedagogy/Andragogy (See below for further explanations of these terms.)

When one is considering distance education, there is a fifth dimension to be reckoned with. The fifth dimension is the method of delivery, the medium, the whole new environment created by the fact that the instruction will be via some form of technology. The possibility of directly transferring course content and teaching strategies as they exist in a face-to-face class situation into a distance format is not only clumsy but also ineffective.

The scope of this paper will be to review existing concepts related to learning and attempt to construct a bridge from what is believed about face-to-face instruction to learning via a distance education format. The available research on teaching approaches in the distance education environment is rather sparse when it comes to evaluating learning outcomes. By far, the existing body of literature is focused on student reported outcomes, primarily the student's satisfaction with and willingness to repeat an on-line course.

Currently, based on data collected by on-line learners, the belief is that students enroll in distance education courses because of convenience, not because they believe they will actually learn more or even as well as in a face-to-face educational setting. While they are motivated to enroll in an online class, their reasons are usually driven by "I don't have attend class, so I'll have more free time" and "It will be easier" (Personal communication from Charles Dziuban, University of Central Florida).

Pedagogy: The term pedagogy has been associated with teaching children. However, the concept is applicable to any teaching situation. Where content is the "what," pedagogy is the "how" – how the content is taught. One can think of pedagogy as the link between what the teacher wants students to learn and students' actual learning. The specific strategies for teaching a particular subject matter is pedagogy.

Andragogy: The term andragogy is, simplisitically, pedagogy in learning situations where the learner is an adult.

Constructivism:
Theorists writing in the emerging constructivist tradition often contrast their ideas with the epistemological assumptions of the objectivist tradition. Objectivism is the view that knowledge of the world comes about through an individual's experience of it. As this experience grows broader and deeper, knowledge is represented in the individual's mind as an ever-closer approximation of how the world really is. Knowledge is thought to exist independently of learners. Learning consists of transferring that knowledge from outside to within the learner. Constructivist "theory" rests on the assumption that knowledge is constructed by learners as they attempt to make sense of their experiences. Learners, therefore, are not empty vessels waiting to be filled, but rather active organisms seeing meaning. Learners use constructive processes to form, elaborate, and evaluate competing mental structures until a satisfactory one emerges.

The Rhizome, a root like stem, is often used as a metaphor for understanding the constructivists philosophy of learning. This rhizome metaphor likens learning to a mass of roots, a tangle of tubers with no apparent beginning or end. It constantly changes shape and every point in it appears to be connected with every other point. Break the rhizome at any point and the only effect is that new connections will be grown. This metaphor lies at the heart of the semiotic conception of cognition.

Jerome Bruner is one of the learning/instructional theorists who support the philosophy of constructivism as the foundation for understanding how learning occurs and how instruction should be design and delivered. Bruner, who used the term "discovery learning" (1961) defined discovery as learning in which the learner constructs meaning from new situations. Bruner (1971) defined learning as a process in which learners construct new information based on their existing knowledge. In this constructing process, learners fit new material into their personal system of associations and categories already created. He theorized that when learners build knowledge themselves through discovery it aids in retention. Bruner (1961) strongly advocated the discovery method as stated here:

I would urge now in the spirit of an hypothesis that emphasis upon discovery in learning has precisely the effect upon the learner of leading him to be a constructionist, to organize what he is encountering in a manner not only designed to discover regularity and relatedness, but also to avoid the kind of information drift that fails to keep account of the uses to which information might have to be put. Material that is organized in terms of a person's own interests and cognitive structures is material that has the best chance of being accessible in memory. That is to say, it is more likely to be placed along routes that are connected to one's own ways of intellectual travel (pp. 26-32).

Bruner (1971) advocated that learners become good problem solvers in order to give some assurance that they will be able to apply the material they have learned in an educational arena to a variety of situations. He believed that an important part of teaching should be to arrange educational environments that will "optimize learning according to various criteria - to optimize transfer or retrievability of information" (Bruner, 1966, p. 165). He insisted that the goal of education is to give students enough tools to function in the world and therefore students need to be able to make sense of the world in their own fashion. He said, "Our aim as teachers is to give our students as firm a grasp of a subject as we can, and to make as autonomous and self-propelled a thinker as we can - one who will go along on his own after formal schooling has ended" (Bruner, 1961, p. 23).

Objectivism:
The more traditional expository teaching approach is based in the objectivists paradigm. The expository approach is the traditional method used in schools and can be defined as an approach to instruction wherein learners receive, in final form, the content of what is to be learned so that it can be readily assimilated.

From the perspective of the objectivist, the world is structured and that structure can be modeled and mapped onto the learner. The goal of the learner is to "mirror" reality as interpreted by the instructor. Knowledge is external to the knower and so can be transferred from one person to another. The learner's role is to remember and reproduce the knowledge that is transmitted by the teacher or professor. This may be manifested by the "sponge method" of instruction.

Not all researchers feel that a constructivist or discovery approach is the best approach and argue for the more traditional expository approach to instruction. Ausubel and Robinson (1969) argue that although transfer and problem solving are indeed admirable educational objectives, that they should not be the major function of the school. Acquiring subject matter content should be the major goal of education with problem solving supporting this goal.

Immediate Recall.
There is evidence to advocate the use of the expository method of instruction for the purpose of immediate recall. Rowell, Simon, and Wiseman (1969), compared the expository method of learning with that of discovery. They first created a learning task that was equally unfamiliar to the subjects. Their subjects were post-graduate, full-time students at the Department of Education of the University of Adelaide. Both methods of learning were employed for

the same duration. The participants were given unfamiliar symbols akin to hieroglyphics to learn. These symbols could be combined together to form other meaningful symbols.

All participants were given a test immediately after the learning period. The researchers found significant differences in favor of the expository method. They concluded from their study that the expository method of instruction has greater pedagogic merit. According to the interpretation of the researchers, within the framework of Bruner's view of knowledge construction subjects in the expository group "acquired a better organized and more comprehensive schema than did discovery subjects" (Rowell et al., 1969, p. 242). However, they hypothesized that the results from their study may have been biased either by the fact that their participants were well versed in the method of expository learning from having learned by this method throughout their lives or that the time limit imposed on the discovery learners impeded them from adequately creating ways to assimilate new information. These factors, they conclude, may have given the expository learners an edge in immediate recall.

Haselrud and Meyers (1958) found similar results in their study with codes. Their subjects had better results on immediate recall when the expository method was used as compared against a discovery method. Teacher directed methods were shown to produce increased short-term retention in many studies (Ray, 1961; Wittrock, 1963; Hines, Cruickshank, and Kennedy, 1985).

Bruner (1961), however, had different results in his study of word-pairs. He divided twelve-year old children into groups that received either expository or discovery teaching methods. The subjects were instructed to remember word-pairs and were told that they would have to repeat them later. He found that those subjects who were explicitly given a rule associating the pairs (using the expository method) had worse results on his test of immediate recall than the discovery group who came up with their own associations between word-pairs.

Scott (1970) conducted a study on the effects of immediate recall, retention, and transfer using the methods of expository and discovery instruction when presenting geometry concepts. His subjects, sixth graders, were divided into two groups: expository and discovery groups. The subjects in the expository group were taught geometric concepts followed by examples in which relevant attributes were pointed out. The subjects in the discovery group were given examples of geometric concepts and had to create their own meaning. He concluded that neither group, expository nor discovery, seemed to have an advantage when a test of immediate recall was given.

A partial replication of Scott's (1970) study was conducted by Nelson & Frayer (1972). They studied the effects of instructional method on immediate recall and retention only, and had very different outcomes. Their study found that the expository group had significantly higher scores on tests of immediate recall than the discovery group.

Retention.
Research shows that the discovery method is overwhelmingly better than the expository method in terms of retention of knowledge. Another result from the study done by Rowell et al. (1969) showed that the discovery group faired better on the hieroglyphic-like symbols test ten weeks after the initial learning period. The researchers concluded that the discovery group's improvement was due to the participants' long-term arrangement of new knowledge into their existing knowledge constructs. Bruner (1961) he also found excellent retention with the discovery group in his word-pairs study of 12-year-olds.

Kersch (1958) conducted a study with 60 college volunteers. After separating the volunteers into an expository group and a discovery group, he taught them two rules of addition: the odd numbers rule and the constant difference rule. Consistent with the research presented so far, he found that although the expository group did better with immediate recall, the discovery group retained the material longer when tested one month later. He found that students in the discovery group continued to practice their new knowledge on their own after the initial learning.

In Scott's (1970) study of geometry concepts he found evidence to support his hypothesis that the discovery group would perform better on tests of retention. He discovered that the test scores of the students in the expository group declined over time while the discovery group's test scores increased over time thereby showing greater retention. Nelson and Freyer's (1972) replication of

Scott's (1970) study showed different findings, however. Although Scott found an advantage to the discovery method in terms of retention, Nelson and Freyer (1972) found no significant advantage for either group in terms of retention.

Logo is a list-processing computer language developed by Bolt, Beranek, and Newman at the Massachusetts Institute of Technology in the 1960's (Kenney, 1987). Logo uses turtle graphics (which is in effect an electronic sketchpad) that is used to create figures and other geometric constructs. Logo has been used in schools to promote the learning of geometric concepts through discovery and problem solving. Cook (1988) conducted a study in which high school mathematics classes were divided into two groups: Logo learning (discovery) and traditional (expository). Experienced teachers taught both groups. The Logo learning group met in the computer laboratory for a forty-five minute period every other day for fifteen weeks. The results of her study indicated that there were no significant differences between groups on retention.

Transfer.
Discovery learning, according to the research, does well with regard to transfer immediately after learning and over a longer period of time (Ray, 1961; Good, Forley, & Fenton, 1969; Rowell, et al., 1969). In their three-year study at Carnegie Mellon, Good et al. (1969) showed that discovery methods used in a social studies curriculum made individuals better learners. They concluded that the participants in the discovery groups were able to apply the concepts learned to other similar social science concepts.

Gagné and Brown (1961), in their study with 33 male ninth and tenth grade students, found that those that learned the principles of a number series through expository teaching did the worst on transferring their new knowledge to other similar situations. The discovery group had better results at transfer. Their results, therefore, indicate a discovery approach to teaching the derivation of new rules is best. They also concluded that learners that are given direction towards the discovery of new rules fair best on transfer than learners that are either explicitly given the rules or are left to their own devices to derive the rules (Kittle, 1957; Wittrock, 1963).

Scott (1970), in his geometry concepts study, did not show better results for the discovery group in regard to transfer. In fact, he concluded that neither approach had advantages over the other method of learning.

Expository teaching, however, seems better suited when transfer is necessary for standardized tests. Expository teaching gives learners precise and controlled bits of information that is amenable to these traditionally multiple-choice tests. Discovery instruction, where learners pursue more personal lines of reasoning, cannot be standardized (Keegan, 1995). Exam performance has been shown to be better when teaching techniques closely resemble testing methods (Godden & Baddely, 1975).

Conclusion
The research shows that each method of instruction, expository (objectivism) and discovery (constructivism), has its advantages. In non-specific subject area studies, discovery learning seems to be better for both retention and transfer while the expository method seems to be better for immediate recall. The implications, therefore to educational instruction seem to be enormous. If retention and transfer are primary goals of education then the available research indicates that the discovery method may be better than the expository method. Further research is necessary in order to shed more light on these conflicting research results.

On-Line Teaching
Until enough research is conducted to determine how on-line learning is best facilitated, we should at least be aware of what has been learned from the research conducted in the more traditional face-to-face learning format. As is the case in any learning situation, the teacher must be aware of what the desired outcome of the learning is to be. Planning to teach on-line courses does not mean the consideration of fewer of the dimensions of learning, but rather adds the dimension of the technology. The person or people who design, develop, and deliver on-line learning must still consider the teacher, the student, the content, and the pedagogy/andragogy in addition to the technology.

The 2BeOn System
A Multimedia Workbench for Telework and Interactive Television Research

Abreu, Jorge T. Ferraz de
Almeida, Pedro Alexandre F. S.
Branco, Vasco Afonso da Silva
Mealha, Óscar Emanuel Chaves
Department of Communication and Art
University of Aveiro, Portugal
[jfa, almeida, vab, oem]@ca.ua.pt

Abstract: This paper refers to the implementation of the 2BeOn system, a multimedia workbench designed to test and evaluate the integration of communication and management services supporting work, leisure and information activities. The association of synchronous and asynchronous communication services is planned to provide a more complete answer to user needs in what concerns their interpersonal communication. The system results from a transdisciplinary effort and is being applied to support research in Telework and Interactive Television areas. Regarding Telework, the focus relies in building an integrated environment of communication, collaborative and management services to support remote work. From the perspective of Interactive Television the system aims to understand how the users may exploit online communication services, when engaged in leisure or information TV programs.

Introduction

Among the variety of Internet applications, interpersonal communication services are getting a substantial importance. The mass adoption of services like Instant Messaging (IM), mainly supporting informal communication (Nardi et al. 2000), and their availability in different devices reflects this trend. The 2BeOn workbench emerges from this context, enabling to test and evaluate practices of integration of communication and management services in two fields of application: Interactive Television and Telework. The general purpose of the system is to enable users "To Be Online", communicating or collaborating through the use of synchronous and asynchronous services.

System description

Being based on a server-client platform with all personal information (profiles) stored in the central database, any user connecting to any 2BeOn terminal, either on PC, TV or mobile devices, will get his customized environment and specifications. The system comprises the following main components:
Figure 1 – 2BeOn's structure

User tracking - the core module of the system, that allows to verify the status of users (who is on/offline or in a break) and other traceable information;

Interface Engine - continuously applies the user's profile information to dynamically adapt the visualization and interaction interface based on a network of interrelated adaptable interface agents;

Communication services - synchronous (voice and video communication, chat, IM) and asynchronous (email, clip-email) services. The system applications lead to the development of specific collaborative features, such as: recommendation of TV program (TVPR), through text or voice messages assigned to video trailers automatically recorded during a TV session, and remote task assignment to work colleagues (on a team work scenario).

Content/interaction tracing - designed to improve users collaboration by allowing to search and contact other users based on their topics of interest or work competencies. For this the system performs a constant analysis of the users' patterns of interaction: peers contacted, TV channels viewed or intensity of use of communication services.

The system uses customized and customizable software agents that, dealing with information from different services and from the online database, can, e.g., select the online communication device that can reach the addressee in a more efficient and direct way.

Application areas

The workbench is applied to different research areas, with adaptations on the interface interaction and the development of specific features oriented to each research area: Telework and Interactive Television (ITV).

The application of the 2BeOn system for remote work scenarios focuses on the following research concerns: i) What are the major guidelines for the development of a telework oriented multimedia communication environment; ii) In what manner the integration of communication and management services, complemented with automatic support mechanisms, is able to improve communication between co-workers. It is believed that this environment act to increase the effectiveness not only of individual teleworkers but of their fellow members as well (Niles 1997); iii) How the dynamic creation of work groups may improve the work performance and contribute for the promotion of work communities; iv) How can the system assist the work progress by synchronizing processes and helping the user in finding information, tracking competencies or controlling his or other tasks?

In the context of ITV, the system aims to promote interpersonal communication by using communication services to discuss common themes or by using TVPR. This type of application differs from the emerging forms of ITV, which are basically oriented to on-demand gathering of information and access to dedicated services (Stewart 1999), but not to the promotion of interpersonal communication. In addition to study how TV users can exploit the 2BeOn features, the research also comprises the following topics: i) How to cope with the technical limitations of the TV as an output terminal; ii) What is the relation between TV content and the establishment of conversations; iii) What is the relation between the use of communication services and TV consumption, in the users perspective; iv) How can the system help to reinforce the socialization between communities of interest?

Evaluation procedures

The evaluation adopted until this moment, based on interviews, has shown that the integration of communication services satisfies the users. The data mining provided by the internal register mechanisms enables to evaluate and detect necessary changes to the inner structure of the system. The formal evaluation procedures will be addressed by means of: i) online questionnaires/interviews, supported by multimedia demonstrations of the system's features (for details see http://www.ca.ua.pt/2beon); ii) qualitative and quantitative testing of the working prototype.

Conclusions and future work

The developed workbench has proven to be capable to support research in interactive television and telework areas in the field of interpersonal communication, collaboration and management activities. The experience has also shown the potential interrelation between both areas. For example, Interactive television may act as an additional terminal to stay alert to work and perform some basic tasks.

The Effects Of College Students' Educational Level And Gender On Their Use Of The Internet As: (A) An Instructional Tool, (B) A Research Tool, (C) A Communication Tool, And (D) An Entertainment Tool

Abdulrahman Al-Motrif, King Saud Univ., Saudi Arabia

The main purpose of the present study is to investigate the pattern of the Internet use by Ohio University students in educational activities in four domains: (a) as an instructional tool, (b) as a research tool, (c) as a communication tool, and (d) as an entertainment tool. It focuses on the gender and educational level as potential factors influencing the use of the Internet among college students in the four domains. Using quantitative research methodology, the data were collected through a survey completed by 800 students from Ohio University. Two-way ANOVA was conducted to investigate whether or not the statistical differences revealed in the descriptive statistic results were significant. Chi-Square statistical procedure (crosstabulation) was used to examine the relationship between the independent variables (gender and educational level) with other variables such as computer ownership, hours of use of the Internet per week, and the correlations between students' GPAs and their use of the Internet. Findings from the study reveal that gender evidently plays a significant role in the overall use of the Internet in daily activities. Males still generally dominate the use of the Internet in the four mentioned domains. More graduate students use the Internet for instructional, research, and communication purposes than undergraduate students. At the undergraduate level, this study interestingly reveals that more female students use the Internet for research and communication purposes. It is also revealed that more male undergraduate students use the Internet for entertainment purposes. The descriptive statistical results show that fewer female graduate and undergraduate students, as well as male graduate students, use the Internet for entertainment purposes. The study indicates that students' GPAs have significant, positive correlation with the use of the Internet as an instructional tool, a research tool, and as a communication tool. However, it is indicated that the correlation between students' GPAs and the use of the Internet as an entertainment tool is negative and not significant. It is concluded that gender and educational level are relatively effective predictors in looking at the pattern of college students' use of the Internet the previously mentioned domains.

Attitudes of King Saud University Faculty Toward Development and Implication of a Telecommunications-Based Distance Education Program as an Alternative to Conventional Teaching

Sara ALOraini, King Saud Univ., Saudi Arabia

Today, institutions of higher education in Saudi Arabia are faced with the problems of overcrowded enrollment and lack of sufficient facilities to provide appropriate educational services to the country's qualified students. Many students do not have access to higher education because they live in remote areas and do not have any means of transportation to attend on-campus programs. Many others would like to participate in college or university programs, but are not able to do so due to a number of personal problems such as commitment to their families, their jobs, and lack of necessary programs suitable to their future needs. During the past few years, Saudi higher education institutions have been debating the feasibility of implementing distance education programs as an alternative to regular class-room instruction. King Saud University has recently taken the issue more seriously and is seeking an immediate solution to the problem. For such reason, this research study was conducted to investigate faculty attitudes toward development and implementation of a telecommunications-based distance education program suitable to the needs of Saudi students. The resulting analyses of the collected data led to the following conclusions and implications. 1. Although a vast majority of the participating faculty members had little knowledge of using a computer, most of them demonstrated positive attitudes toward the feasibility of facilitating students with distance education programs as an alternative to traditional on-campus classroom instruction. 2. A majority of the faculty members believe that the success of a distance education program is ultimately dependent on a number of institutional strategies, including sound policies and procedures, compatibility, quality assurance, adequate course offering, appropriate faculty training, necessary staff and administrative support, reasonable faculty workload, and satisfactory faculty rewards. 3. Certain personal and professional characteristics of the faculty members were found to be influential in their attitudes toward the use of computers and communication networking facilities for distance education. Finally, the study concludes with several recommendations to Saudi institutions of higher education and other interested groups as well as a number of suggestions for future research on the issue of distance education.

Traditional Classroom Evolving: E-Learning on the Horizon

Shahram Amiri
Vice President for Information Technology and CIO
Stetson University
421 N. Woodland Boulevard
DeLand, Florida 32720
USA
samiri@stetson.edu

Abstract: The traditional classroom and traditional teaching are not mutually exclusive from the new and exciting innovations that e-learning is bringing to the teaching and learning processes. In actuality, the traditional classroom is embracing these new paradigms of pedagogy that are dramatically changing the content of curricula and course delivery methods, and the pace at which these new methods are being adopted by academia is increasing significantly. This presentation brings to the forefront how these emerging technologies are opening an exciting new chapter in the rich history of the traditional classroom.

As time progresses, so too does technology within the field of higher education. Nearly 40 percent of all college classes used Internet resources as part of the syllabus in 1999, compared with 15 percent in 1996 (Web-Based Education Commission, 2000). In general, Internet usage has increased dramatically. In 1996, Amazon.com, the largest Internet bookstore, recorded sales of less than $16 million. In 1997, revenues increased to $148 million (Applegate, McFarlan, & McKenney, 1999). In the educational system, 64 percent of schools in the United States have Internet access today, a figure up from 35 percent in 1994 and 50 percent in 1995 (Coley, Cradler, & Engel, 1999). Web technology represents one of the most rapidly expanding fields, taking only three years to reach 50 million users, while radio technology took 50 years to reach the same amount of users and television took 15 years. The incorporation of technology into the higher educational system seems vital because technology will supplement education to work for the advantage of all those it touches. So far technology has already penetrated the education of higher institutions and proved successful by giving the forum a new perspective. The introduction of technology has created many complications because much of the population has a difficult time adjusting. Solutions exist, though, and when activated, the growth of technology will prove successful in transforming the learning environment.

Many goals have existed in the educational system since the beginning of education. These goals have included: to center learning around the student instead of the classroom; to focus on the strengths and needs of individual learners; and to make lifelong learning a reality. With extra enhancement from technology, these goals become attainable. "The process for bringing new content into the curriculum in higher education is often slow by corporate standards," (Harris, 2001). Therefore, technology becomes fundamental to keep the educational system current. "E-learning is getting a faster start as a supplement to classroom teaching than as a pure delivery channel," (Zastrocky & Yanosky, 2001). This insinuates e-learning does not try to replace the traditional higher education institution, but rather attempts to complement the conventional approach to teaching and learning. Technology does not aim to exchange teachers for computers, but endeavors to do more with what we already have and use. "Investing in the development and support of skilled teachers...offers great promise," (Web-Based Education Commission, 2000). By itself, e-learning will not increase test scores or ensure educational equity for all learners, but it will help aid the journey to attain these goals. Technology offers "Opportunities to expand individualized learning, provide access to a much broader and richer set of educational materials and human resources and promote learning-to-learn skills (Web-Based Education Commission, 2000).

Recently, corporate universities have emerged to compete with traditional learning institutions. These corporate universities base themselves solely on technology. Traditional colleges and universities must do a better job reminding their "customers" why they operate the way they do and must reclaim the high ground in the competition to attract traditional and non-traditional students. Higher education must refine its "marketing message" to incorporate corporate university ideas. Without integrating technology into schooling, the corporate universities will surpass traditional universities in contemporary education.

Traditional universities do have an advantage of objectivity over corporate universities, thus protecting the interests of their students while promoting the principles of liberal arts education and lifelong learning. Many corporate universities do not realize, "The focus must not be on learning objects, but must be on the object of learning." In addition, " 'real' universities have an advantage over corporate universities because the traditional university's breadth of disciplines, its role in research, and the relationships it fosters between faculty and students," (Zastrocky & Yanosky, 2001).

Overall, a traditional university is better positioned to pay closer attention to the student's developmental needs by creating a learning environment conducive to critical thinking and lifelong learning. "Institutions of higher education have several strengths that are not found in other instructional environments, [including] dedication to independent research, academic freedom, and the ideal of student enlightenment leading to wisdom," (Harris, 2001). Most importantly, "The excitement and stimulation of a comprehensive intellectual life probably remains the university's greatest competitive differentiator," (Zastrocky & Yanosky, 2001).

However, when technology combines with the conventional higher education environment, the best circumstances under which to learn becomes reality. "Technology gives us the power to provide access to information and guidance in every dormitory room, after all, and we need to think how to use that power in conjunction with the physical presence of faculty members and facilities," (Katz, 2001). With technology in use, even more outlets become available for students to turn to. "Technology has affected more traditional student relationships by making possible a wider variety of online administrative services, emphasizing the 'customer service' aspect of student relations – simply browsing the Web exposes students to an immense variety of resources, including multimedia material, that in sheer size dwarfs the collections of the largest university libraries," (Zastrocky & Yanosky, 2001).

The traditional university atmosphere must not dramatically be altered to make way for the corporate learning philosophy because the interaction between faculty and students proves necessary to maximize learning. "Many new online degree programs take a hybrid approach to achieve both community and convenience for a student cohort, interspersing brief periods of face-to-face interaction with longer periods of remote distributed instruction," (Harris & Yanosky, 2000). The face-to-face relations provide a student with an experience for objectivity. In addition, a faculty member can provide concepts and views that the student may have not yet explored. "Even when students stay within disciplinary boundaries, they benefit from the faculty's participation in a larger community of ideas and approaches," (Zastrocky & Yanosky, 2001). With the implementation of technology within the higher education setting, teachers and students work together to accomplish a goal, unlike corporate universities, which force the students to conquer goals independently. "While technology can help a student overcome learning problems, the student and teacher must still put forth a great deal of effort and hard work...Faculty still must prepare hard and long and be part of creating "new knowledge," and students still must study to prepare for the world ahead of them," (Zastrocky, Harris, & Yanosky, 2000). With these ideas in mind, "The higher education faculty/student relationship is one in which a professor with deep expertise and a strong commitment to nurturing and advising inspires his or her student to higher levels of achievement, and provides a role model for humane, dedicated professionalism...[this serves the] 'students' personal development and intellectual growth," (Zastrocky & Yanosky, 2001). This "personal development and intellectual growth" cannot be attained at a college level sans the professor interaction and technology. Studies have shown "...Higher student graduation and completion rates in distributed learning courses when online instruction was conducted by traditional departments rather than separate specialized distributed learning units." This suggests direct faculty contact remains a key component of student success, a facet not attainable through a purely corporate university atmosphere (Zastrocky & Yanosky, 2001).

E-learning in the conventional university atmosphere has many advantages. Content portals and online resources provide an excellent improvement for textbooks and reading lists. Multimedia and interactive content can supplement the traditional chalk and talk method of teaching. Most importantly, parents can be updated on their children's progress constantly with real-time student information systems rather than just report cards every quarter or semester. "Institutions with rich, Web-enabled applications for communications, collaboration and e-commerce will have the strongest competitive advantage if these innovations move the institution toward its educational mission," (Harris & Yanosky, 2001). Traditional universities can add technology without changing the status of the university, but corporate universities cannot add faculty without defying the university's original intention of solely technology. The corporate university cannot be modified into a primary outlet of education, but it remains possible to rework the traditional university to attain this goal.

Steps that traditional higher education institutions must take in order to ensure competition for corporate universities include: web access to students' enrollment and advising; PC access for every student and faculty member; full suite of knowledge applications, including messaging, calendaring, and collaboration; 24/7 technical

support; faculty and student access to a learning management system; library with growing digital collections and search capabilities; and enterprise portal including e-commerce capability. In addition, traditional universities must have a strong Website presence and Internet access in teaching environments (Harris & Yanosky, 2001).

The first step to transforming a conventional institution of higher education into an e-learning environment consists of "…mapping out the relationship between the learning environments [the universities] wish to foster and the bandwidth access needed to reach desired student population (Harris & Yanosky, 2000)." The Web-Based Education Commission's counts regulatory change, e-learning research, and e-learning training and professional development among the other vital characteristics of an environment attempting the incorporation of e-learning. Regulatory change consists of relaxing some of the education rules, for instance, the rule stating at least 50 percent of instruction is to be done in the classroom. If this rule was more lax, teachers could assign more Internet assignments, requiring the use of the Internet within the home. E-learning research calls for increased funding, which the Web-Based Education Commission deems necessary for the progression to e-learning. The nation's universities should make the development of highly skilled educators their most important priority, which falls under the e-learning training and professional development category (Yanosky, 2001). The Multimedia Educational Resource for Learning and Online Teaching (MERLOT) is a "collection of online learning materials and support resources to help faculty enhance instruction," (Web-Based Education Commission, 2000). With devices such as MERLOT, universities are well on their way to accomplishing the traditional university atmosphere while at the same time intertwining e-learning. It is impossible to create this type of environment, however, without taking the necessary steps for accomplishment. "…Technology is not something that happens to us. It is something we create. We must not confuse a tool with a goal," (Katz, 2001).

"The Internet is bringing us closer than we ever thought possible to make learning of all kinds, at all levels, any time, any place, any pace – a practical reality for every man, woman, and child," (Web-Based Education Commission, 2000). Already the Internet has shown its glory in corporate universities. Growth in corporate universities can be attributed to: traditional business schools seeming too far removed from the pulse of the business world, enterprises realizing that developing people is key to future survival, and advances in technology allowing companies to economically and effectively deliver distributed learning causing the learning to become continuous and immediate (Harris, 2001). An example of e-learning at work evidenced at Hundred High in Wetzel County, West Virginia. Hundred High received infrared ports in every classroom, allowing students to connect all over campus. Not only did this increase test scores above the national mean in every subject on the Stanford Achievement Test, but it also allowed students to discover themselves through the Internet. Scott McGlumphy, a mediocre student at Hundred High before the infrared ports, accumulated an interest in anthropology in addition to top grades. Web-based learning environments prove so successful because they provide support and challenge through representation, expression and engagement. Web-based testing may ask students "…to place works of art along a timeline, to design a building to meet a set of constraints or to troubleshoot a faulty system." Students then become part of their assignment, rather than just a spectator (Web-Based Education Commission, 2000).

In general, technology allows a lot more interaction and individualism students can learn at their own pace. For example, New Jersey's Hunterdon Central Regional High School created an online magazine, *Electric Soup*, with the help of English teacher Florence McGinn. McGinn wanted to use technology to "…open up opportunities for individualized learning and challenging her students to take on fresh, empowering roles" (Web-Based Education Commission, 2000).

Other positive aspects of the Internet include: offers education in places where there is none and extends resources where few exist, connects people, communities, and resources to support learning, extends learning day and place, adds graphics, sounds, videos and interaction to give teaches and learners multiple paths for understanding. (Web-Based Education Commission, 2000). With technology, a student in even the most remote settlement can have access to the same references as a student located in the most cosmopolitan city. This use of technology creates the perfect circumstance for distance education. Even elite universities are hungry to get into distance education. "Collaboration for distance learning will help bring together larger institutions and colleges and smaller universities," (Katz, 2001). Technology demonstrated its usefulness in the medical profession when six patients were given heart procedures in Israel, Italy, and New York City with three to eight cameras present in each locale to broadcast the operation to 7,000 cardiologists. This allows cardiologists not present for the operation to receive the same experience as if they were in attendance (Web-Based Education Commission, 2000).

Technology acts as the "equalizer" of education, allowing students access to libraries and research centers everywhere. Even students in the most poorly funded districts will have the same access to materials as wealthy students. This becomes beneficial because, for instance, only 60 percent of high schools offer Advanced Placement courses, but a private sector provider, APEX Learning, provides courses in 10 AP subjects online, as well as AP

preparatory materials (Web-Based Education Commission, 2000). This increases the use of distance learning that so many universities yearn for.

Time signifies another element that loses relevance in the learning environment when technology becomes involved. With technology, a student can download a copy of a book long after the library closes. This extricates some of the boundaries currently placed on learning and allows the "extension of the learning day and place."

E-learning can provide the solution for minor problems that have long lingered in the educational system such as overcrowding, inadequate textbooks, and lack of parental interaction. "Zurich, Switzerland's top universities are working [to solve] a surplus of students and limited budgets...The Swiss Virtual Campus will relieve crowded university classrooms while improving teaching practices and keeping a lid on costs," (Studer, 2001). In addition to ceasing the problem of overcrowding, technology allows easier transportation of books as well as consist revisions and updates because corrections can be made to the sources immediately. Instant attention will also be given by the facilitation of parental interaction by increasing the communications between the classroom and home. With the Internet, parents can be kept up to date by e-mail use, web castings of daily classes and grade postings on the web.

Information technology helps in the conventional institution of higher education by bringing visualization of difficult concepts through graphical displays or video presentations, performing tedious calculations to test theories and build bridges to understanding, using virtual reality and simulations, enabling Web-based "virtual field trips" that allow students to interact with museum collections and scientific experiments, and creating extra institutional learning communities that bring together students and instructor who share common interests in a subject (Zastrocky, Harris, & Yanosky, 2000).

For e-learning to be advantageous, it must become the standard in American higher education, not the exception. "The biggest barriers to learning [technology] are money, time, and fear," (Web-Based Education Commission, 2000). In 1999, the barriers to e-learning included: not enough computers (78%); lack of release time for teachers to learn computers (82%); and lack of time in schedule for students to use computers in class (80%) (National Center for Education Statistics, 2000). The fact that not enough computers exist in the school system can be attributed to the federal government providing only 6.1 percent of all elementary and secondary education funds (Web-Based Education Commission, 2000). Currently only $3 billion is spent on technology, averaging to $70 per pupil. For all students to reap the benefits of technology, $15 billion must be spent, or $300 per student (Coley, Cradler, & Engel, 1999).

Other issues that stymie e-learning include high costs of equipment and instructor training, increased demands on instructors time, limited computer access in less affluent areas and lack of information in the necessary format. The Web-Based Education Commission's Report recounted the costs for technology as including payments to utility and Internet service providers, technical support, instructional content, trained educators and administrators, and upgrades as newer equipment become available (Web-Based Education Commission, 2000).

Trained educators and administrators represent the most essential element to an effective e-learning system. As maintained by the National Center for Education Statistics, "...teachers who perceived that lacking computers and time for students to use computers as great barriers were less likely than their colleagues to assign students to use computers or the Internet for some instructional activities." Teachers were more likely to use technology and the Internet when the technology was available to them, available in their classroom, and available in greater numbers (National Center for Education Statistics, 2000).

Even when technology becomes more readily available in higher education, there must be more enthusiasm on the part of faculty to gain the necessary skills to utilize these new technology tools in the classroom. "Only 15 percent of U.S. teachers reported having at least nine hours of training in education technology in 1994" (Coley, Cradler, & Engel 1999). The National Center for Education Statistics said, "...Teachers who reported feeling better prepared were more lkely to use these technologies than their less prepared colleagues." Furthermore, educators must be willing to dedicate some of their own time to learning about technology as "Teachers cited independent learning most frequently as preparing them for technology use (93 percent)." (National Center for Education Statistics, 2000).

Activities signify an appropriate preparation for computer-based learning as "Teachers who spent more time in professional development activities were generally more likely than teachers who spent less time in such activities to indicate they felt well prepared to use computers an the Internet for instruction" (National Center for Education Statistics, 2000).

The goals for technology must be met in order for the system to utilize its effectiveness. There must exist greater access to broadband connectivity, guidance in the best uses of the Web for learning, understanding of how people learn differently with the Internet, and content that leverages the powerful capabilities of the web (Web-Based Education Commission, 2000). Steps for the universities to push towards e-learning consist of: organizing lobbying strategies for what is likely a busy season in educational legislation; designing more flexible e-learning

programs to reach non-traditional learners; and developing action plans for a quick institutional response to new opportunities in education research and teacher training (Yanosky, 2001). "Institutions that put the right technologies together with the right strategies, tactics, and processes, and have the right skills in place," will attain an effective staff (Nelson & Zastrocky, 2000). An effective staff will be made though, not born.

The most important ingredient is the presence of a local hero with the vision, courage, and stamina to challenge status quo. Growth with technology can be attained through partnerships that bring together the federal government, state and local agencies, the private sector, and educational institutions. The Congress and Administration must create an e-learning agenda aimed at assisting local communities, state education agencies, institutions of higher education, and the private sector to maximize the power of the Internet for learning. A call to action to help implement the e-learning agenda should incorporate policymakers and politicians, college presidents and parents, teachers and teacher educators, and students and business leaders (Web-Based Education Commission, 2000).

Already steps have been taken within the government to help implement e-learning within institutes of higher learning. Education is the Bush administration's top domestic priority and e-learning is one of the most politically attractive components of the education agenda. Even partial implementation will be beneficial. "President Bush's first communication to Congress was a K-12 agenda which, though primarily focused on the accountability and school choice, called for 'increased funds to schools for technology' through a consolidation of federal technology programs," (Yanosky, 2001).

Testimonies from the community showed the Web-Based Education Commission there was a need for powerful new Internet resources, such as broadband access, continuous, relevant training for educators, new research on how people learn in the Internet age, high quality online educational content, relief from outdated regulations that impede instructional innovations in any time, any where, any pace learning, safeguards to protect privacy, and sustained funding. A research program to set up the framework for this e-learning agenda can be attained by establishing a benchmark goal for federal investment in web-based learning; focusing on high payback targets of educational opportunity where present links between learning theory and technological innovation appear particularly promising; supporting the creation of learning communities and tools for collaborative knowledge building and dissemination among researchers, teachers, and developers; and supporting a sustained effort to track the use of the Internet in education and how the web is transforming learning (Web-Based Education Commission, 2000).

To increase technology, the education community also must continue the current voluntary system of accrediting higher education institutions and programs, create mechanisms for users to share their commercial and noncommercial resources and experiences regarding online courses and programs, articulate frameworks for what constitutes good online courses and encouraging private sector education providers to develop their courseware in concert with these frameworks (Web-Based Education Commission, 2000).

"Banks and retailers, food and beverage companies, and clothing manufacturers all need employees with greater technical capabilities than our schools are currently providing to fill the high-skilled jobs necessary in today's economy," states the Web-Based Education Commission's Report. Thus e-learning is deemed essential within the educational system of higher learning for cultivation of a workforce prepared to meet the challenges of lifelong learning. The merging of innovative applications of technology with the traditional classroom creates an atmosphere conducive to the changing pace of today's global citizenship and global economy. The technological advancements created and utilized through e-learning in institutions of higher education will most surely supplement the quest for a "new breed of literate citizens" capable of dealing with the modernization of today.

The Vision of an Interplanetary Individualized Virtual University in the Age of Globalization.

Panayiotes S. Anastasiades
Visiting Lecturer, University Of Cyprus, Department of Computer Science
e-mail: panas@ucy.ac.cy   URL: www.cs.ucy.ac.cy/~panas/
Department of Computer Engineering and Information Systems,
Polytechnic School, University of Patras.
Chairman of the Permanent Scientific Committee on Social Issues of the Greek Computer Society

Abstract: The new technologies of communications and information, together with the Internet boom, help create a totally different environment in the sensitive area of education. The process of globalization pushes towards the creation of a uniform economic, social and cultural environment, which veils the national peculiarities of the state entities. Sooner or later, the educational systems will be called upon to converge with the choices and needs of the new global financial model. The new educational technologies of the Internet lay the foundation for a new interplanetary educational system, especially in the area of universities. The delineation of the basic traits that will govern the new worldwide virtual individualized university is the main objective of this work.

Introduction

The rapid development of the new technologies of communications and information (Dutton, William,1996), in conjunction with the massive use of computers and the Internet boom (Morneau Jill & Anderson Kim, 2000), create new data at an international level. The transfer of capitals in the new technological environment released a gigantic power on the part of international capital market. The very rapid and secure flow of vast amounts of funds towards every direction created the conditions for the consolidation of the phenomenon of globalized economy (Eichengreen, 1996). The advent of globalization has a catalytic effect on almost the entirety of economic, social and cultural life of the developed – and not just the developed – world (Melas, 1999).

The educational systems are called upon to serve the new dogma, the new vision, the new reality. This is the dogma of the free, according to many (Friedman, 2000), or wild, according to others (Deppe, 1995), market. The vision of free, according to the powerful ones, or the nightmare of unbalanced, according to the weak of our modern world, access at a planetary level. It is the reality, according to the financially developed states, or the imposition of worldwide financial suzerainty upon the social edifice, according to the developing world. Conventional educational systems are unable to keep pace with the demands of a world where the universal spiritual values show signs of weariness compared to the respective material ones (Anastasiades, 2000). Based on the above approach, the materials that will build the new model of interplanetary individualized university have already started to take form.

Thus, in this work, the author is giving, from his viewpoint, a detailed outline and expounds the basic features of the interplanetary virtual individualized university. The structure of the work is as follows: In the second part there will be a brief mention to the basic concepts that constitute the new educational environment. In the third part, there will be an analysis of the concept of the individualized virtual university, through the use of a theoretical example. Finally, the conclusions of the work will be presented in the fifth part.

The Virtual – Potential University

The new technologies of communications and information change radically the area of education. Open and Distance Learning is defined as all the knowledge and skills gotten through indirect information and guidance, which includes all the technologies and other forms of distance learning. (U.S. Distance Learning Association, 1998)

The educational material is getting innovated with the aid of advanced multimedia applications (Collis, & Smith, 1997), which help create an interactive cooperative distance environment for the students.

The global internet is the unified technological and information platform (Washington DC, 2000) where technologies, educational materials and methodologies converge.

The European Union and its member states are taking careful steps towards the new directions coming into sight at a worldwide level. The priorities and objectives relating to the use of the new multimedia technologies, and especially the Internet, in the area of education are clearly defined as part of the action plan of the European Union e-learning (EU COM(2001)172 Final).

At this point, it is quite important to demarcate the concept of virtual university as distinct from the term of "open university".

According to (Peraya, 1994), there are two different classes of adults, corresponding to two different models of distance learning.

The model of Open University satisfies the educational needs of adults who wish to improve their knowledge and skills, with the main objective of upgrading their professional qualifications.

The model of virtual university is addressed to groups of adults who wish to attend a complete course of study and get a certificate.

The meaning and content of the individualized interplanetary virtual university

The conventional educational environment (Kaye, Rumble, 1977) or, in other words, the first category of teaching activities (Moore, 1977), served quite successfully the social and financial needs of an era which seems to fade away with time. The new technologies of communications and information make possible the development of a totally different educational environment, by means of the "educational technologies", as they are called (Hawkridge, 1976).

One of the characteristics of the new technological age in the area of education will be the transition from a student-centered education (Delling, 1994) to the concept of independent studies (Wedemeyer, 1973). This encourages the development of a flexible educational system, which will be able to adjust itself to the needs and demands of small groups or even individual trainees.

The individualized environment of education would be defined, as part of this study, as that model which encourages the student to freely and independently select the courses, teachers and university departments, in order to become qualified in the faculty or subject of his preference.

The materialization of an open and pluralistic learning environment cannot be restricted within the finite limits of a country or university, as they are today. It requires the constitution of supranational educational entities, as part of which unified criteria for the evaluation of university departments will be established, and at the same time students will be encouraged to take part. Typical endeavors in this direction, in the European area, are the proclamations of Prague and Bologna .

The United States of America will be able to move more easily in that direction, utilizing their multiyear federal experience.

The next step in the development of the new virtual model will be the effort to homogenize the curricula of the university departments. This could be achieved through the development of a flexible structure, which will include branches, sections, subjects and studies leading to specialties, faculties etc.

BEST COPY AVAILABLE

In the area of information technology, for example, the respective departments tend to align their curricula to internationally accepted standards (Computing Curricula, ACM- 2001).

Thus, the development of a uniform system of evaluation, the homogenization of curricula and the establishment of open and clear systems, will encourage students' mobility in the virtual university spaces which are being formed. From the students of a single university, we go rapidly to the students of the interplanetary virtual university. Further analysis of the suggested model will be attempted through the use of a theoretical example, which will try to give the routine of a student and a teacher in the new reality.

The student

The entering of students to the unified virtual university area will be unrestricted, meaning that the trainees will not necessarily choose to study in a certain university. They will choose subjects, faculties and studies that will be established through the selection of a certain number of courses – mandatory and optional – which might be offered by different university departments, probably in different countries around the world. This means that the students of the new educational model will select their teacher and course and not necessarily a certain university or faculty, as they did up to now, creating a pluralistic teaching package that will correspond to their own needs and desires.

Through a homogenized supranational system of evaluation (a combination of the leaving certificate degree with examination results as needed), the students will secure the right to study with certain teachers, depending on the courses they choose.The difficulty encountered by the students in securing certain teachers and, therefore, certain courses, will be dependent on the supply and demand that will be established in the unified virtual university area.Thus, it is highly probable that in the future we will no longer have university or department graduates, but graduates of faculties and subjects who will have selected courses, major and optional, delivered by teachers of their own choice in different universities, maybe even in different countries. The individualized educational environment for the new type of students of a unified virtual university starts becoming a reality.

The teacher

The teacher will be called upon to operate in a totally different environment, where the students will have selected him because they trust his work and not just based on the reputation and influence of the university he is working in.

On the other hand, the teacher will be constantly evaluated based on the level of students he was selected by, reversing the reality of today, which many times forces him to engage in research at the expense of teaching.

Most probably the teachers will continue to belong in university departments, which will provide them with authority and all the necessary equipment, as well as the administrative structure they need in order to deal successfully with the high demands of such a model.

The University

The university and the respective departments will be called upon to adjust their operation to the new data, without however being themselves in danger. They will continue to be the authentic authorized regulatory structures that will see to the development of the proper educational environment.

The difference is that they should now be able to support, at a technological, pedagogical and administrative level, that environment where the new individualized model of virtual teaching services will be able to thrive.

At the same time, the degree of acceptance of the teaching personnel of each university by the new type of students will greatly affect both the evaluation of the departments and the universities in whole, expanding the procedure and the content of evaluation.

Conclusions and future research

The new educational technologies, and particularly the technologies of communications and information, provide the necessary multimedia and internet tools in order to realize the vision of open horizons education. The development and estab lishment of a supranational homogenized teaching and administrative environment in the area of higher education creates the conditions for the formation of a new individualized virtual learning model at a planetary level. The new university model will be called upon to answer the challenge of globalization and the ever-increasing demands of the labor market. At this point, a serious question arises in relation to the driving force behind the developments in the area of higher education, and this is economy and the needs of the enterprises. If this turns out to be true, then all of us need to deliberate on the future and outlook of higher education. We need to deliberate on the pedagogic and cultural consequences, the factor of language diversity, and the ris k of eliminating all those peculiarities, which ensured global variety, as part of the conventional educational system. We need to consider the appearing social dimension of an interplanetary learning model in the area of higher education. These are issues, challenges and questions that will be the target of future research endeavors.

Abstract

This paper presents a framework for modelling distance learning environments. These learning environments may be either supported by informations and communication technology or in a computimg system. In this paper, the process of constructing a learning environment is seen as a modelling process, similar to the software development process in software engineering, where every phase must be accomplished in order to provide an adequate adaptation of the student to the environment. This framework is being used by the research team at the Distance Learning Education group - PUCRS Virtual - to create and monitor extension, undergraduate and "latu-sensus" graduate courses.

1 Introduction

Developing learning environment is much more than to translate ordinary classes to a communication and information technologies based environment . This process begins with the design of educational elements (or pedagogic architecture) and a software engineering study.

This paper sketches the main phases of the development process of such learning environments. These phases do not follow a strict order, as to allow the designer to better adapt the environment to its intended use, and to provide some freedom to the development team.

2 Learning Environment Modelling

The framework proposed for the construction of learning environments is divided in six phases. The first phase refers to educative design, phase 2 to computational modelling, and phase 3 to implementation of the environment. Phases 4, 5 and 6 describe environment evaluation from a pedagogical perspective, taking into account issues as ergonomy and usability.

2.1 Educational design

The first phase in the learning environment construction refers to the educational design, basically the definition of the pedagogic architecture of the environment. This phase should be performed by a team constituted by professionals with large experience in teachers' education and preparation, with a critical vision of the use of technology in education, experts on the course contents and with wide knowledge about computation, especially computer networks and hypermedia. In this phase is important to check the following information:

Public's identification
Definition of the goals
Definition of the subject area
Definition of the specialisation-area
Content definition
Definition of the teaching and learning strategy
Definition of the types of tasks (learning of concepts, problems solution, project development, knowledge construction, forum of discussions etc)
Definition of the interaction styles (synchronous / asynchronous)
Definition of the interaction degree (high, low) of the activity (example: problem solution -high)
Definition of the group activities: (co-ordination of activities, decision making, brainstorming etc)
Definition of work schedule
Definition of roles: the student's role, the teacher's role.

Table 1: Pedagogic requirements

In the context of learning environments the pedagogical proposal should promote autonomy and critical thought. Besides, the pedagogical goals should be linked with a list of methods associated to traditional activities and a list of the possible methods associated to distance activities.

Traditional class	Distance class
Printed class notes are distributed in the first class.	Class notes are available at the Web some time prior to the first class.
Questions are asked and answered in classes.	In order to reduce the time that the lecturer uses with explanations, questions and their respective answers are organised in FAQ's. Questions are asked through electronic mail, for instance.
The students' list is supplied to the teacher in the first class.	The students' list and their respective e-mails are available for everybody at the beginning of the course.
The dates of exams are defined by the lecturer, accomplished in the defined days and checked by him.	Exams are checked automatically and offered in regular opportunities.
Application of evaluations at the end of each unit to verify the student's performance. The students follow the normal rhythm of the group.	From the exams the lecturer can verify the performance of the student step-by-step and to identify those students with difficulties. Then, the lecturer can organise small tutorials or discussion teams for such students. They can also follow the exams in your own rhythm.
In the traditional classes the lecturer works with large groups and it stimulates the collaboration through exercises and activities in the lab.	In the distance approach is important to plan meets by chat in order to provide the direct interaction between lecturer and students. Also communication tools will be welcome to announce general subjects or discussions for the team. A Webpage to obtain a feedback of the students.

Table 2: Traditional *versus* distance activities

2.2 Computational Modelling

A learning environment can be supported by communication and information technologies (C&IT) or by a computing system. These two forms present pros and cons. A computing system is a "closed package" where

very often it is very difficult or impossible to modify parts of system. Besides, an environment based C&IT is an user system interface supported by hypertext and elaborated through a language for formatting of information in the Web. So, the primary goal of a Web page is to propagate information and not to constitute an learning environment.

The second phase refers the computational modelling of the environment that will be implemented through a Web page. This phase follows similar structure to the technical requirements of a traditional software.

The project of the learning environment has as starting point the pedagogical proposal and as product a computational environment designed as integration of media, services and Internet tools as well as by computing systems. The requirements of this phase are the following:

Storage way: web, CD-Rom
Definition of the computational environment or programming language
Definition of the tools and services of the Internet
Definition of the computing systems
Definition of the modules related with other research areas: artificial intelligence, virtual reality, database etc
Definition of the requisites necessary to the development: software to graphic support, CD-Rom recorder etc

Table 3: Computing requisites

The project of the environment graphical design should consider the following aspects:

Definition of the electronic and printed media (hypertext, text, sound, image, animation etc)
Elaboration of materials (edition of texts, sounds, images etc)
Selection of images and sounds
Creation of a virtual library
Definition of colours patterns
Elaboration of the graphical design
Elaboration of the conceptual maps and of the contents modelling
Final check of the project

Table 4: Requirements of the learning environment project

In order to provide a learning environment by Web page, the elements need to be linked in such a way that is possible to introduce or to illustrate concepts, accomplish experiments, activate tasks and motivate the social interaction. The next table presents a parallel between and Web page and learning space:

Web Page	learning space
Class notes are available in order to facilitate the access to the material used in the classes.	Class notes are available with the objective of student can read the material before the beginning of the course.
The FAQ is available with the goal of informing on technical aspects in the use of computing systems.	The FAQ is available with the goal of socialise the information classes, it means to inform on technical aspects about the use of computing systems and on theoretical aspects of the course.
The students' list is available with the goal of make easier the verification the inscription in the course and	The students' list besides make easier the verification the inscription in the course and the access of the

the access of the exams result.

The list of exercises is available with the goal of facilitating the access to the exercises and verify the knowledge about the contents presented in the course.

The exams preparation is made by a list of solved exercises offered to make possible the auto-check by student, identify their difficulties and clarify its together the lecturer.

Computing systems are available with the goal of tasks manager and to illustrate concepts.

Internet Tools are available with the goal of increase the interaction between student and lecturer.

exams result is made available with the goal of facilitating the contact between students and lecturers.
List of exercises:

The same that the Web page

The exams preparation is made trough of tests with automatic correction. These tests are offered to make possible the teacher to accompany the acting of the student step-by-step. From these tests is possible to identify the students with difficulties.

Computing systems are available with the goal of introduce or illustrate concepts, to verify hypotheses and to tasks manager.

The same that the Web page

Table 5: Page Web versus adapts of learning

2.3   Environment Implementation

The third phase describes the construction of the environment. For the implementation of the environment some specific programming language can be used (html, java, asp, etc) or some course manager platform, like WebCT [7], AulaNet [6], Learning Space [8] etc.

This phase must be accomplished by professionals of the computer science. For the implantation of the environment issues like physical space, the kind of network, connection of the personal computers, Internet access should be considered.

2.4   Ergonomic evaluation

The fourth phase refers to ergonomic evaluation. In this phase some issues should be observed for a better integration of media: links; visualisation form and the freedom for environment navigation. During this evaluation phase will be observed:

Referred to the navigation:
Is there some facility in the navigation?
Do they have a navigation map?
Are the buttons well defined and easily identified?
Is there some freedom degree in input/output of the pages?
Does it possess menu of commands?
Referred to the Legibility:
Are the colours appropriated ?
Is the size of the illustrations and of the sources are appropriated?
Is the interface design well done?
Referred to the media use:
Does has in the user interface multimedia resources, animation, graphs and illustrations?
Is there integration among the media?
Is there speed of system answers fast?

Referred to the user help:
Is there access for the helps? (for instance, contextual, index or hypertexts type)
Referred to the printing:
Can the illustrations be printed?
Can the content be printed?

Table 6: Ergonomic criterions

2.5 Pedagogic evaluation

The fifth phase refers to pedagogic evaluation, which should be compatible with the pedagogic proposal defined in phase 1. This phase should be made preferentially by professionals of the education sciences and of the cognitive psychology, qualified to evaluate the pedagogical functions that the software can reach. Given the learning channels that can be wakened up, finally a series of elements should be questioned carefully. The evaluation should take into account the following elements:

Content
is it coherent with the target audience?
is the sequence coherent?
Does it stimulate several learning forms?
Interdisciplinary (software allows research)
Goal
Coherent with the target public?
Coherent with the curriculum ?
Is the Language adapted the public?
How are mistakes treated?
Research
Reflection
Direct Answer
Construction of the answer by the student
Is the software motivating for the student?
The software is self-didactic or does it need the the teacher's intervention?
The program can be used in several situations in class (individual, small or big groups)?

Table 7: Requirements for Pedagogic Evaluation

2.6 Usability evaluation

Sixth and last phase refers to evaluation of the environment with the students. In this phase validation activities and pilot tests with the students (preferably with students that are not of the regular in the course). The goal is to detect the satisfaction degree, motivation and difficulties in the use of the environment as well as the offer of support mediations. This phase is of extreme importance to give feedback to the pedagogical and technical team that designed the environment and to suggest modifications and updating for future versions.

3 Final considerations

In the study of the requirements for the creation of learning environments that use integrated multimedia can be noticed the need of organisation previous structuring of the activities, otherwise the learning process can be harmed.

As final consideration, the importance of the teacher's paper is stood out as mediator of this teaching-learning process, seeking to create attitudes of collaboration, to stimulate the student's reasoning, to intermediate the learning process, regulating the interaction and investigating the cognitive conflicts that take the student to question your own thought.

A Web-Based Learning Quiz Server

Hiroyuki Anzai, Kyushu Kyoritsu University, Japan ; Takayuki Hirahàra, Kyushu Kyoritsu University, Japan

A kind of web-based CAI server system called WebQS is reported. WebQS has been developed in order to support teachers to make students interested in reviewing materials they were taught. WebQS stores quiz materials sent from teachers and then sends to students quiz pages constructed from the quiz materials. Teachers help students learn by means of not only answering quiz questions but the WebQP also corrects the answers followed by a written explanation for the students to read.

A dynamic menu delivery system and distribution system for user content

Arito Asai, FujiPhotoFilm, JAPAN ; Yoshiaki Watanabe, FujiPhtoFilm, JAPAN ; Masahito Terada, FujiPhotoFilm, JAPAN ; Hiroshi Suganuma, FujiPhotoFilm, JAPAN ; Norihisa Haneda, FujiPhotoFilm, Japan

We announce the following two technologies to create a system capable of providing services tailored to each customer, as well as a system for simplifying the image upload process. First is our Dynamic menu delivery system. Our image viewer software called FinePixViewer displays various service menus related to images. Through the online user registration, the menu server collects the user profiles, manages the menu information for each service, and sends menus appropriate for each user to FinePixViewer. As the result, service providers can control to send their own menus to their desirable customers. Next is our AUP (Application Upload Protocol) technology as the core of the distribution system for user images. AUP is the protocol for seamless uploading of images stored on user computers to web services. By incorporating the AUP module into their web services, service providers can create web sites that readily accept images uploaded from FinePixViewer.

Importance Of Sociopersonal Variables In Computer Studies

Tom Assan, University of North west, South Africa

Nearly all human behaviour is influenced by both cognitive and the non-cognitive aspects of a person. In line with this idea, a computer literacy course is expected to exploit both cognitive and non-cognitive domains. The Faculty of Education made computer studies compulsory for all first year students in 2000. As the course progressed many students wanted to drop out of the course, the main excuse being that there was too much work involved in the course. Considering the deprived academic background of most of the students who took the course, the researcher felt that factors other than the one mostly cited could also contribute to the violent apprehension for the computer literacy course. Meece (1981) identified six possible dimensions of anxiety: dislike, lack of confidence, discomfort, worry, fear and dread, and confusion/frustration. Wigfield & Meece (1988) further on reduced the six possible dimensions of anxiety to two main factors: negative affective reactions (fear, dread, nervousness) and worry (cognitive concerns). The Wigfield & Meece (1988) Anxiety Scale was administered to a sample of first year Faculty of Education Computer studies students (n=130) and correlated its measures with their performance on the achievement test in computer studies constructed by the course tutor. The result of the research study suggested that attitude towards the computer studies course, anxiety, self-confidence in learning computer course, attribution patterns, task oriented motivation, experiential background and personality types were the variables which influence learning of the computer studies course. The first year computer studies tutor should be aware of these variables and the characters of their relationships to performance in basic computer course, and he should make effort to create lectures conducive to learning.

The blended e-learning imperative: Strategy and technology that enables collaboration and interaction in distributed e-learning.

Abstract:
Learners, more aware than ever of the importance of acquiring new knowledge, are demanding robust delivery solutions that are more effective and time-efficient. Given this situation institutions must take a closer look at e-learning as a <u>blend</u> of educational experiences, new technologies, and delivery via the Internet or private intranets.

Problem:

The phenomenal growth of e-learning we are experiencing today is fueled by several factors, among them: (1) increasingly reliable, scalable, and affordable telecom networks, (2) a growing movement in business, industry, government, healthcare, and education to unify global corporate cultures and standardize employee education using an on-demand, anytime/anywhere model, and (3) a growing industry trend to attract and retrain consumers with value-added services like eKnowledge databanks for sharing information and e-learning degrees supported by an extended point-of-delivery.

The e-learning capacity and the e-learning offerings available from institutions and consortia will be even more critical as the war for talent drives more learners to upgrade skills and migrate to new job markets. More specifically, institutions will need to change and revisit their learning vision because distributed e-learning will be required for future success.

Additionally, networks are maturing and capable of carrying new mission critical applications that maximize existing equipment and bandwidth and provide the proper infrastructure for the desired learning outcome. One key to success is delivering rich media over existing networks via satellite or fiber optics, videoconferencing (ISDN), 128K Intranet connections and Uni-cast or Multi-cast solutions.

Optimizing the investment in an e-learning environment is critical for successful integration with existing programs. Institutions and organizations that implement a blended e-learning solution must consider how people, processes, and technologies are affected.

Innovative solutions demand speed and agility. -- Institutions will need to substantially increase the distance and pace at which their delivery capabilities grow; people must be learning/sharing knowledge all the time. Historically, institutions delivered a variety of content through instructor-led, self-study, and sometimes computer-based methods. However, learning is a continuous process resulting in increased capability, for both the individual and organization. When learning takes place, a person can do something they were not able to *do* before, *think* in a new way, *act* differently. Nevertheless, providing instruction, no matter how good, does not guarantee that learning will happen. To enhance capabilities, institutions must think beyond classes, events and activities, and broaden their focus to include the whole context of learning - training, coaching/mentoring, performance support tools, knowledge sharing, hands-on learning experiences, etc. Ultimately, people want to gain new knowledge and feel empowered to apply and share what they've learned.

Implications:

● **Connectivity.** Learning delivery involves key strategic actions to increase ways to connect people to each other and to learning, make a denser web/network, facilitate learning through technology and non-technology-based methods. Connectivity refers to a variety of linkages, relationships, channels that result in easier access to knowledge and others' learning; more interactive, learner-focused development opportunities; and enhanced knowledge sharing and coaching. All can enable learning any time, any place, anyway. Institutions need to significantly enhance e-learning capabilities with these connectivity variables. This means using web-delivered content, multimedia courses, real time video and audio collaboration, and virtual-reality/simulations to offer much more varied learning experience, in a more timely manner - on demand, with less time and place restraints. In the New Economy, accessing the right information at the right time (without hassle), and understanding what needs to be accessed/learned, are two necessary requirements for success. Imagine an integrated system which allows learners to assess their developmental needs, identify learning options to meet those needs, and gain immediate access to learning opportunities (through online course registration and distance learning, collaboration, knowledge sharing forums - internal and external, etc.). These integrated systems should also build in feedback loops to keep information flowing and maximize learning transfer.

● **Resources.** Providing resources involves key strategic actions focused on people, tools and processes that support learning. Making the right resources – people, tools and processes - available is critical to creating an environment that fosters growth and motivates talented people to excel. To enhance resources in an e-learning environment, institutions must champion and stimulate coaching and mentoring. Today, helping learners acquire and develop the specific competencies required for success is necessary, but not sufficient. e-Learners need mentors who help guide their personal and professional development. This means expanding curriculum to facilitate learning in areas such as career management, health/fitness, personal and financial planning, and technology.

Alliances. Forming alliances involves key strategic actions focused on building relationships and partnerships that increase an organization's ability to facilitate e-learning. Institutions must form and strengthen strategic partnerships, rather than attempting to do it all alone.

Broker leading edge e-learning solutions. Given the diversity of learning needs in our global society, and the pace of change, it is impossible to develop and deliver all the right learning options internally. Instead, institutions must also broker leading edge learning solutions. Strategic alliances with learning product vendors and external faculty, for example, can complement existing learning design/delivery capability.

Convene global e-learning forums. This means bringing together the best and brightest minds (internal and external) to tackle e-learning issues, forming strong links with other organizations to document/share best practices, and establish strong leadership in e-learning through sponsorship of e-learning forums.

Expand the e-learning community to cross the entire value chain. Making some e-learning opportunities available to suppliers, employers, business partners, and learner families will allow institutions to further demonstrate their commitment to being partners in success - on a professional and personal level.

Lead the development of e-learning in the New Economy. Institutions must set the direction for the field of e-learning by forming alliances necessary to support leading edge research and development efforts.

● Relevance:

Our experience has taught us that it is important to consider the following integration requirements when defining e-learning objectives:

- *Sufficient financial resources:* A business case must provide leadership with the arguments they need to obtain a substantial budget.
- *Access to a computer for all people involved*
- *An e-learning environment* that is compatible with the needs of the participants and the subject matter
- *A culture* that encourages the implementation of an e-learning solution
- *A realistic timeframe.* Not all e-learning fits a semester schedule and not all e-learning requires simultaneous start and stop dates.
- *Interactivity and accessibility* that are compatible with technical requirements and new technologies.
- *Enough resources* to provide the necessary support through help functions, coaching, and mentoring.
- *A balance* between e-learning and conventional instruction methods.

A Characterization Study of World Wide Web References in Korea: Analysis and Caching Implications

Hyokyung Bahn, Yong H. Shin, and Kern Koh
School of Computer Science and Engineering, Seoul National University
Seoul, 151-742, South Korea
{hyokyung, yhshin, kernkoh}@oslab.snu.ac.kr

Abstract: In this paper, we present a characterization study of World Wide Web references in Korea. Our study focuses on the contents analysis of Web references to exploit the analysis results in the contents caching. The analysis consists of three parts: Web document based analysis, Web server based analysis, and international link based analysis. In each part of the analysis, we present the distribution and top ranking subjects of references, and show the areas of interests that are frequently referenced by the Web users in Korea. Finally, we present how the analysis results can be applied to the contents caching.

Introduction

Due to the recent popularity of the World Wide Web over the world, the Web has become one of the most important communication channels for human societies in Korea. In this paper, we present a comprehensive analysis of the Web reference behaviors in the Korean Education Network (KREN), which is one of the main Internet service networks in Korea. There have already been a number of workload characterization studies for Web references. Most of these studies have focused on the formal analysis of workload characteristics. This paper, however, presents a characterization study focused on the contents analysis of Web references rather than the external analysis of workload characteristics. We use the proxy server logs at KREN to characterize the Web reference behaviors in Korea. We first present the ranking and distribution of Web documents and show the characteristics of popular Web documents. Then, the same analysis is done for Web server ranking and distribution to show the characteristics of popular Web sites. Finally, we present the usage of international links of KREN and analyze the characteristics of international Web accesses. The purpose of this paper is to present a workload characterization study of the Web references in Korea and show the areas of interests that are frequently referenced through the Web. This can eventually be applied to the contents caching of popular Web information, which plays an important role in relieving the problem of network congestion and access latency on the Web.

Analysis of Web References at KREN

KREN is the Internet service network for universities, schools, and educational organizations in Korea. The root of KREN is located at Seoul National University and downlinks are connected with other universities (45Mbps) and 140 regional centers in Korea. The root of KREN is connected with other top links in Korea: the National Computerization Agency (155Mbps), DACOM (155Mbps), Korea Telecom (90Mbps), ThruNet (100Mbps), Nowcom (45Mbps), etc. International links of KREN are connected with Sprint in the US (45Mbps) and TeleGlobe in Canada (45Mbps).

We use the proxy server logs of KREN to analyze the Web reference behaviors. Proxy servers act as agents on behalf of clients to send HTTP requests to Web servers and are often used to manage the local copies of Web

Table 1: Characteristics of the KREN proxy log used.

Total Period	6 days
Total Requests	5,704,851
Total distinct Web documents	1,308,730
Total distinct Web servers	988,036

Web Document Based Analysis

Our first analysis focuses on the frequency of reference for different Web documents. Clearly, not all Web documents are equally popular. (Fig. 1a) shows the number of times that a Web document has been referenced versus the ranking of the document, where ranking 1 is the most frequently referenced document. Note that both axes in the figure are in log scale. The curve in the figure shows that references are excessively biased to some hot documents. The curve is almost a straight line, which means that the reference frequency of the i-th popular document (i.e., ranking i) is proportional to $1/i^b$, where b is the slope of the line. This type of distribution is called a Zipf-like distribution. In (Fig. 1b), we illustrate the cumulative frequency of references versus the fraction of the total Web documents referenced. Note that the Web documents shown in the x-axis are sorted into a decreasing order based on the reference counts. The figure shows that 10% of the distinct documents are responsible for about 70% of all references and 30% of documents are responsible for 80% of all references. This also shows the evidence for the skewed popularity of Web documents.

The next step in our analysis is to classify Web documents by URL type. Classification is based on the suffix used in the URL (for example, GIF, HTML, CGI, MPG, etc). (Tab. 2) shows the distribution of URL types. As shown in the table, 75.2% of the total Web references are made to image files such as GIF and JPG. This is because Web pages often contain many image files such as banners, logos, icons, and buttons. Since these images are often small, the total sizes of the images are only 48.4% of the total object sizes. HTML documents are responsible for 13.6% of the total references and 8.3% of the total sizes. Multimedia data such as audio and video are responsible for only 0.3% of the total reference counts, but for 11.3% of the total sizes. This implies that even though multimedia data are not frequently referenced via the Web when compared with other data types, the size of the multimedia data accounts for quite a large portion in Internet traffic.
(a) Reference frequency vs. document ranking.   (b) Cumulative distribution of Web documents.

Figure 1: Distribution of Web documents.

Table 2: Distribution of URL types.

Data type	Total count	Total Mbyte
Image	2627982 (75.2%)	14134.1 (48.4%)
HTML	475182 (13.6%)	2404.4 (8.3%)
Application	24925 (0.7%)	1942.2 (6.6%)
Multimedia	8700 (0.3%)	3290.2 (11.3%)
Others	357659 (10.2%)	7433.3 (25.4%)

We examine the top 50 URLs in KREN proxy logs. There are many URLs which belong to the same Web server. This is because the distribution of Web servers is also heavily skewed. (Detailed discussion on Web server distributions will be provided in the next subsection.) The most parts of the top 50 URLs are GIF files (38 out of the top 50 URLs). There are three CGIs, three ASPs, and only two HTMLs. The two HTMLs are the homepage of Netscape, and the Simmany site, which is one of the most popular search engine sites in Korea. The Netscape site is frequently referenced because the Netscape Web browser sets the default Web page as the Netscape site.

Web Server Based Analysis

From the Web documents based analysis, we showed that references for Web documents are excessively biased to some hot documents, which can be characterized as a Zipf-like distribution. In this subsection, we present the same analysis on Web servers. Since Web documents are formatted with hyperlink structures, the origins of skewed popularity may be not only human-originated preferences, but also structure-based effects. For example, the main page of a Web server can be frequently referenced while the leaf page of the same server may rarely be referenced due to the different arrangement of hyperlink structures. However, this factor is less influential in the case of Web servers, and hence we can see the human-originated reference behaviors more accurately by server-based analysis. (Fig. 2a) shows the number of times that a Web server has been referenced versus the ranking of the server. Like the Web document case, references are excessively biased to some hot servers. The distribution is again characterized as a Zipf-like distribution. This implies that most of the skewed references are originated from the human preferences and not from the structural effect of Web formats. In (Fig. 2b), we illustrate the cumulative frequency of references versus the fraction of the total Web servers referenced. The figure shows that 10% of the Web servers are responsible for 80% of all references and 30% of servers for 90% of all references. This again shows the evidence for human preferences for some popular Web sites.
(a) Reference frequency vs. server ranking.   (b) Cumulative distribution of Web servers.

Figure 2: Distribution of Web servers.
Figure 3: Percentage of references made to each group of sites.

We visited the top 100 popular sites and classified into nine groups based on the contents provided by the sites; *news, portal, ISP, business, organization, entertainment, Web hosting, program*, and *others*. Each group is defined as follows:

- *news*: daily news sites, newspaper homepages, and homepages of broadcasting company,
- *portal*: portal sites and search engine sites,
- *ISP*: Internet Service Providers and online service sites,
- *business*: servers of companies, e-businesses, and advertisements,
- *organization*: nonprofit corporation and universities,
- *entertainment*: sites for entertainment such as sports, game, and adult,
- *Web hosting*: Web hosting sites,
- *program*: homepages for computer program and program download sites, and
- *others*: unknown or vanished sites.

(Fig. 3) shows the percentage of references made to each group of sites. The figure shows that *news* sites are responsible for the majority of references (44% of the total references), and all of the other categories are responsible for less than 10% of the total references except for the *ISP* (12.5%). There are six *news* sites out of the top 10 sites, including Joongang (ranking 1), Chosun (ranking 2), and Donga (ranking 5) which are three major newspaper publishing companies in Korea. From this result, we can conclude that *news* is the most frequently referenced information through the Internet by KREN users.

International Link Based Analysis

In this subsection, we analyze the usage of international links of KREN. The purpose of this study is to extract some peculiarities of international references. As explained previously, the international link of KREN is connected with Sprint in the United States (45Mbps).
Figure 4: Usage of international links.
Figure 5: Percentage of international references made to each group of sites.

(Fig. 4) shows the usage of the link for a week. The curve in the upper position represents the usage of the incoming link (from Sprint to KREN) and the curve in the lower position represents the usage of the outgoing link (from KREN to Sprint). As shown in the figure, the usage of the incoming link is larger than that of the outgoing link. Note that the incoming part of the international link has often been the bottleneck point of KREN and has recently been extended several times to relieve network congestion. The usage of the incoming link increases and decreases periodically and the cycle is one day. This is due to the human life cycle of the 24-hour pattern. The peak time is during the office hours (12:00-15:00) and the idle time is the midnight or dawn (3:00-6:00).

To see the reference behaviors in the international lnk, we gathered all the HTTP data passing the international link using a transparent proxy server. We examine the top 100 international sites that are most frequently referenced through the international link by KREN users. We classified these sites into categories as done in the previous subsection. (Fig. 5) shows the percentage of references made to each group of sites. The figure is obviously different from the case when domestic references are included. *Entertainment* sites are responsible for almost 30% of the total international references. Specifically, *adult* sites occupy 90% of the total entertainment sites and 38 out of the top 100 international sites are adult sites. Note that no domestic adult site was found in the top 100 servers in the previous subsection. We think that this is because adult sites in Korea are controlled and regulated by Korean domestic laws. *Program* sites are responsible for more than 20% of the total international references. These sites include the homepages of Microsoft, Netscape, Realplayer, etc. One major reason for this phenomenon is that most Web browsers and PC softwares often set the program to connect their download sites automatically. Note that the rankings of the Microsoft and Netscape in the top 100 international sites are 1 and 6, respectively. Another interesting result is that *news* sites occupy only 0.5% of international references (only one site, CNN exists in the top 100 international sites). This implies that most of the ˎ *news* sites visited by KREN users are domestic sites, that are written in Korean.

Caching Implications

In this section, we present how the analysis results can be applied to the contents caching. Web users can benefit from this contents caching in terms of latency reduction because a more narrow Internet access is possible. Moreover, contents caching could save network bandwidth and reduce the load of Web servers.

Since the majority of references are made to domestic *news* sites, this news information should be prefetched or pushed into the cache server to be efficiently accessed. International Web documents can be prefetched at midnight when the international link is free. *Program* sites can be mirrored to domestic local sites to save the network bandwidth. *Adult* sites can also be mirrored since they are the majority of international references. It may be helpful to prioritize the contents to be cached based on their relative importance. For example, we can give *news* sites higher priorities than *adult* sites.

Related Works

To date, there have been a number of efforts that attempt to characterize the workload of Web references. The characterization can be done from various viewpoints such as from the Web client side and the Web server side.

In the case of Web server side studies, Arlitt and Williamson present a workload characterization study for Internet Web servers (Arlitt 96). They show some invariants from their workload characterization, such as the successive connection rate, file type distributions, file size distribution, etc. Almeida et al. propose models for temporal locality and spatial locality of reference in streams of requests arriving at Web servers (Almeida 96). They show that temporal locality can be characterized by the marginal distribution of the stack distance model and spatial locality in a reference stream can be characterized using the notion of self-similarity. Some studies present the workload characteristics of specific Web servers. (Arlitt 00) show a workload characterization study of the 1998 world cup Web site. (Menasce 99) characterize the workload of E-commerce sites.

In the case of Web client side studies, Nagarajan and Raghavan characterize the behavior of Web clients and design a prefetching engine that exploits the characterization (Nagarajan 00). Web proxy server side analysis shows more generalized characteristics of the client side behaviors. Breslau et al. present the distributions of Web request streams seen at proxy servers (Breslau 99). They show that the Web document request distribution seen by Web proxy caches follows a Zipf-like distribution. Jin and Bestavros show that temporal locality of Web reference streams seen at proxy servers emerges from two sources, i.e., the long-term popularity of Web documents and the short-term temporal correlations of references (Jin 00). Pitkow summarizes the Web workload characterizations from three points of view; the client side, the Web server side, and the proxy server side (Pitkow 98).

Conclusion

In this paper, we presented a characterization study of Web reference behaviors in the Korean Education Network, specifically focused on the contents analysis. From this analysis, we showed the areas of interests that are frequently referenced by Web users in Korea. We also presented how the analysis results can be applied to the contents caching of Web objects. We believe that the characterization and analysis study presented in this paper can also be helpful to government policy makers and e-business people, as well as researchers related to caching technologies.

Abstract: The first goal of this study was to examine the impact of nine Web-based learning modules on learning as measured on both online module quizzes and in-class exams. The modules were designed to support fundamental concepts in entry-level college mathematics courses. The second and third goals of this study were to determine the (a) learner characteristics and (b) strategies that affect student performance on the nine web-based learning modules. Findings indicated that students who scored above 80% on the module quizzes also did better on in-class exams. Those who were self-motivated, focused and self-disciplined had greater success in the online module environment than students who participated haphazardly or erratically in the modules. We conclude that Web-based modules support learning when used systematically by learners and that such modules extend the reach of the classroom teacher and reinforce classroom instruction.

Objectives

Although web-based computer-assisted instruction is becoming openly accepted and used, there is little quantifiable data as to its effectiveness in helping students become successful learners. Given the money being allocated and commitments being made to the use of technology in homes and schools, it is incumbent upon educators to demonstrate that student use of technology can result in adequate or above average student success. In addition, researchers need to identify those learner characteristics and behaviors that foster quality learning and development in technologically-based environments so that educators can provide differential instruction to their students.

This study examined the impact of nine web-based learning modules, designed to support fundamental concepts in entry-level college mathematics courses, on learning as measured on both online module quizzes and in-class exams in two university level mathematics courses. Concepts were presented in class and then students were expected to interact with the online modules to expand and clarify their in-class learning. The second and third goals of this study were to determine the learner characteristics and strategies that affected student performance on the

nine web-based learning modules as well as course test scores. Specifically, answers to the following questions were sought.

1. How does the use of the nine web-based learning modules designed to support fundamental concepts in entry-level college mathematics courses impact student success on in-class tests and quizzes?
2. What are some of the characteristics of learners who exhibit satisfactory performance on both the nine web-based learning modules and in-class tests and quizzes?
3. What are some of the learning strategies of learners who exhibit satisfactory performance on both the nine web-based learning modules and in-class tests and quizzes?
4. What are some of the characteristics of learners who exhibit unsatisfactory performance on both the nine web-based learning modules and in-class tests and quizzes?
5. What are some of the learning strategies of learners who exhibit unsatisfactory performance on both the nine web-based learning modules and in-class tests and quizzes?

Theoretical Framework

The explosion of available online educational materials and increased access to technology and the Internet in classrooms across the country has shifted educators' attentions to areas such as computer-assisted and online learning (Anglin & Morrison, 2000; Brown, 2000a; Brown, 2000b; Francek, 2000; Kessler, Rosenblad, & Shepard, 1999; Liaw & Huang, 2000; Levinson & Surratt, 2000; Lyall & McNamara, 2000; Mioduser, Nachmias & Lahav, 2000; Norman, 2000; Owston, 1997; Reiber, 1992; Spodick, 1995; Starr, 1996; Wagschal, 1998). With the ability to easily access online and interactive learning materials from any location via an Internet connection, parents, educators, and legislators are seeing the Internet as a cost effective way of leveling the learning environment for students across the country (Francek, 2000; Kessler, Rosenblad, & Shepard, 1999), as well as tailoring the learning environment for each learner (Haury, 1999; Keup 1998; MacKnight, 1998; Roth, 1999; Svetcov, 2000).

Researchers and practitioners alike have expressed concern about whether students can learn as well in a web-based environment as they do in a face-to-face environment (Bonk & Dennen, 1999; Diaz & Cartnal, 1999; Leasure, Davis & Thievon, 2000; Sankaran, Sankaran & Bui, 2000; Zielinski, 2000). Studies have shown that learning can actually be enhanced using the World Wide Web. Ross and Schultz (1999) and Sankaran, Sankaran and Bui (2000) found that the use of innovative Web applications could address a wide range of diverse learning styles. Online conferencing gives students who might be too shy to speak up in a face-to-face setting a chance to voice their opinions and participate in discussions they might not normally participate in (Bonk & Dennen, 1999). Instead of being tied to a traditional classroom schedule, students are able to participate in Webb courses at a time and in a place that works best for them (Leasure, Davis & Thievon, 2000).

Methodology

This study examines the impact of nine JAVA-based computer modules in mathematics on learning as measured by quizzes and in-class exams in core curriculum, university level, finite mathematics courses. The study also looks at learner characteristics, (e.g., background, course goals, etc.) and at strategies employed by students while working on the modules. This is a mixed methods study in that it features both qualitative and quantitative methods for data collection and analysis.

Participants

Subjects. The participants in this study included 147 students enrolled in two fall semester sections of MATH 141(Business Mathematics I) and 191 students in two fall semester sections of MATH 166 (Topics in Contemporary Mathematics II). The total sample size for the study was 338.

Courses. One of the selected MATH 141 classes will have access to the nine web-based instructional modules although participation will be optional for these students. The second Math 141 class will not have access to the

modules and will be used as a control group. For the MATH 166 courses, students will be required to complete the nine web-based instructional modules over the course of the semester, (approximately one per week). The four classes will create a continuum of module use going from nonuse to partial use to complete use and interaction. These classes were chosen for the study because of the close alignment of curriculum goals and coursework with the scope and content of the modules. Although the two courses are designed for different populations, the content of both courses is virtually identical. Concepts, order in which material is presented, and amount of class time spent on each topic are the same. In addition, the instructors for each of the classes using the modules is a developer of the system, hence, they should be able to seamlessly incorporate the modules into the class curriculum.

Procedures

Access. Students gained access to the modules over the Internet. All students were required, as a part of their coursework in mathematics, to obtain a TAMU student computer access account. Modules were accessed through a secure password protected account. This means that only students enrolled in the specified sections were able to login to the modules through the campus open access computer labs or through personnel PCs. The math modules run on any operating system platform using a JAVA enabled browser (e.g. Netscape or Internet Explorer).

Data Sources. Data Sources included (a) a demographic survey, (b) nine web-based instructional module quizzes, (c) three in-class quizzes, (d) three in-class, paper based quiz surveys, (e) an in-class final exam, (f) an exit survey, and (g) face-to-face interviews.

At the beginning of the semester, students completed an online demographic survey ascertaining the gender, age, course expectations, and study habits of each participant. By being in a proctored room, the researcher assured that each student was completing the tests themselves without the help of study aids, calculators, or outside assistance or help. The demographic survey information was used to make sure that the four classes being studied were similar in makeup and overall ability.

During the course of the semester, individual module login data, and quiz performance data on the nine web-based instructional modules were gathered and recorded into a secure database. Data related to the use of the modules— (a) number of attempts to take each quiz, (b) first score on each module quiz, (c) last score on each module quiz, and (d) highest score on each module quiz for each student, were gathered and sent to a secure database.

As a normal part of expected course work, students completed three in-class quizzes. The quizzes took place approximately once a month, were created by each individual instructor and consisted of both multiple choice and workout problems.

Students also were asked to complete a survey each time they took an in-class quiz, establishing study habits and student expectations. The survey specifically looked at how students used the modules as a part of their study and preparation for each major exam as well as their judgement of module effectiveness for facilitating their primary learning goals.

At the end of the semester students took an in-class final exam. While all instructors' exams were unique, they all contained a sampling of 4 or 5 identical questions aligned with the concepts covered both in text and in the online applets.

All participating students will also be asked to complete an exit survey at the end of the semester, which will be given at the end of their final exam or during the study session just prior to their final exam. In addition to the eleven questions that they have been ranking on a Likert scale following each of the three in-class quizzes, this survey will also include fourteen additional open-ended questions. These additional questions will be optional for the students and will focus on the strategies students used during the course of the semester to complete the online modules.

During the final exam, participants will be asked to complete one last survey. This survey well again ask students to identify their gender and class ranking as well their current and expected grades for the course. Students will then be asked to rank their feelings about the modules on a 1 to 100 point Likert Scale.

Interviews at the end of the semester will be used to add description and validity to the information gathered through the quiz surveys. Following the third in-class quiz, students' grades on module quizzes one through eight and grades on in-class quizzes one through three will be analyzed in order to place students within a 4

by 4 matrix. Three students from each matrix category will be randomly chosen for an interview. This should provide a list of twelve randomly selected students. Interviews will be conducted between the third exam and the end of the semester.

Data Analyses

By creating a mixed methods study, an attempt was made to not only to verify that there was some learning effect but also to identify some learner characteristics and strategies, which could interact with the modules to effect learning. The quantitative data, which included the scores on the nine web-based instructional module quizzes, scores three in-class quizzes, and the score on the in-class final exam, was the most effect way to look for a relationship between student achievement and the modules and to answer question one. By correlating scores on the quizzes included as a part of each of the nine-based modules and scores on the in-class exams and the final exam, as well as the final course grade a re lationship should become evident.

Module quiz scores, in-class exam scores, and final course grades were used to answer question one, how did the use of the nine web-based learning modules designed to support fundamental concepts in entry-level college mathematics courses impact student success on in-class tests and quizzes. Module quiz scores, in-class exam scores and final course grades were analyzed to determine if modules had had an effect on learning in mathematics. Highest module quiz grades for each module quiz were averaged and then compared to average exam scores and the final course grade across groups: Module Use Group, Optional Module Use Group and the Control Group. The correlation coefficient is a direct measure of the relationship between variables. To measure the association between the modules, exam scores and final course grades, a Pearson product-moment correlation was run. To further compare the modules, exam scores and final course grades a Multivariate Analysis of Variance (MANOVA) was run. Scores on exams and the final course grade are the two dependent variables, and our hypotheses are that each will be positively affected by module use. When a statistical significance was found then Tukey's Post Hoc Test was run. A Tukey's Post Hoc Test will show which comparisons are significant when all possible pair wise comparisons are carried out.

The qualitative date which included the demographic survey results, the three in-class, paper based quiz survey results, the exit survey results, and the twelve face-to-face interviews, most effectively looked for learner characteristics and strategies of students who use the web-based modules. By using the survey information and interviewing students face-to-face, there is a chance to identify some of those learner characteristics and strategies that most effect learning with the web-based modules. The interviews and observations made during class visits and discussions with each professor should provide thick description about what is actually happening with the students during actual module use.

To answer questions two and three, what were some of the characteristics of learners who exhibited satisfactory performance on both the nine web-based learning modules and in-class tests and quizzes and what were some of the learning strategies of learners who exhibited satisfactory performance on both the nine web-based learning modules and in-class tests and quizzes, module quiz scores and learner characteristics as identified through the demographic survey were analyzed to determine if they could have had a confounding effect on learning attributed to module use. A statistical frequency was run on the demographic data and analyzed to determine differences between the groups that could have confounded effect results. While the demographic survey looked at multiple learner characteristics, variance was only found in gender, major, grade in high school algebra class, high school geometry class, student's comfort with computers and average reported web browser use. Highest module quiz grades for each module quiz were averaged and then compared across learner characteristics. To further compare the module quiz scores and the demographic variables a Multivariate Analysis of Variance (MANOVA) was run comparing highest mo dule quiz scores, final course grades and learner characteristics. If a statistical significance was found then Tukey's Post Hoc Test was run in order to determine which comparisons were significant.

Interviews, the three in-class exam surveys, the final exam survey, the post final exam survey, and average module quiz scores and the average number of module quiz attempts for each of the nine modules were analyzed in an attempt to answer questions four and five, what were some of the characteristics of learners who exhibited unsatisfactory performance on both the nine web-based learning modules and in-class tests and quizzes and what were some of the learning strategies of learners who exhibited unsatisfactory performance on both the nine web-

based learning modules and in-class tests and quizzes. Module data was analyzed to determine what learner strategies for completing the modules, in regards to the number of attempts made to complete each module quiz and the scores received on each attempted module quiz developed over the course of the semester. How much time students spent in each module, how students performed on module quizzes and how students approached module quizzes was of particular interest in establishing learner strategies in using the modules.

An analysis of the three in-class exam surveys was done to look for emerging learner strategies. Specifically, a statistical frequency was run comparing in-class survey one, two, three, and the final exam survey results. The frequencies were analyzed to determine changing trends in study habits, allotted study times, and perceived effectiveness of these activities.

A content analysis was used to identify emerging topics and themes regarding students' learning strategies described by students during interviews and on the post final exam surveys. Participants were assigned a pseudonym and a number, which corresponded their placement within the interview selection matrix. Transcripts and survey questions were analyzed and separated into meaningful units. Cards were created for each unit of meaning and each card was assigned a string of numbers. Cards were coded for card number, type of data (interview or survey), interviewee, date of interview, and interview matrix location if applicable. For example: 12.I.SS.12/02/01.1/1 would indicate that card 12, was part of an interview with Sam Spade conducted on December 2, 2001 and he was a part of the low number attempts and high module quiz grade group. This form of coding was used to create an audit trail.

Interviews and surveys provided invaluable sources of data. Themes and topics as well as supporting statements were determined by multiple sources including these interviews and post final surveys, as well as the in-class surveys and observations made throughout the duration of the study.

Results

Findings indicated that the web-based modules contributed positively to students performance in the course. Average module quiz scores, adjusted exam scores, and final course average were highly correlated. Students who scored above 80% on the module quizzes also did better on in-class exams and final course average. Based upon qualitative data, including ongoing in-class surveys and follow-up interviews we found that those who were self-motivated, focused and self-disciplined had greater success in the online module environment than students who participated haphazardly or erratically in the modules. Students who had a plan for completing the module activities and quizzes scored higher on the quizzes and in-class exams. Many students who skipped through the module activities as quickly as possible, without reading the information presented or working through the interactive activities, eventually did well on the module quizzes. These learners often made ten or more attempts at the quizzes before achieving a score of 80% or better, but they did not do as well on the in-class exams. Planning, applying the modules repetitively and thoughtfully, and consciously making connections between course activities and module activities were strategies that positively impacted module effectiveness. Based on these findings, we conclude that Web-based modules supported learning when used systematically by learners. Conversely, students who did not plan, repetitively engage in the modules, or make connections did not successfully use the modules for learning.

Significance of the Study

The Internet can be a powerful and useful tool. Education can no longer ignore the Internet's potential for the classroom and learning but neither can education abandon its need for standards and accountability. This study focuses on the connection between web-based learning modules and their impact on student success as well as identifying some of the characteristics of learners who succeed or do not succeed in this environment. The insights gained here can help to provide a basis for designing additional web-based, modular environments in which students can find learning success can be used to identify students who may require preliminary training in how to learn online. In addition, effective strategies identified in this research can be the basis of such preliminary training.

Distance courses based on the integration between andragogic and constructivist principles using web, for permanent formation on health human resources: the proposal of Oswaldo Cruz Foundation, Brazil.

Elomar Castilho Barilli, Oswaldo Cruz Foundation, Brazil; Antonio Ivo Carvalho, Oswaldo Cruz Foundation, Brazil; Gerson Cunha, Federal University of Rio de Janeiro, Brazil; Luiz Antonio Braga, Federal University of Rio de Janeiro, Brazil; Pedro Cesar Silva, Oswaldo Cruz Foundation, Brazil

The main proposal of this work is to present the dynamic construction and application in the Distance Courses offered by FIOCRUZ that use the web as an strategic element of contribution to form professionals related to health sectors, its fundaments, methodology of construction, assuming a transformer role, to estimulate an education that forms and reconstruct, through a didatic experience, aiming a personnel growth for the development of individual habilities to understand and feel the world, allowing the complete practice of the real citizenship.

Embedded self-assessments in Executive Education courses: Improving participant learning and perceptions of course quality

Background: We have been building online Executive Education courses for Cardean University as employees of UNext. At UNext, these courses are referred to as "Quantum" courses, to distinguish them from traditional academic courses in Cardean's online MBA program. Quantum courses provide a six to ten hour learning experience that provides information about a relevant business topic (e.g. change management, brand management, and financial statements) as well as an opportunity for learners to apply what they are learning in a relevant task. Quantum courses use many interactive techniques and "widgets" to engage and motivate students. Widgets are javascript-based XML objects that course development teams use to build common interactive instructional segments. One class of widget is the self-assessment. Self-assessments are used in some courses to provide a quick way for learners to ascertain whether they are learning anything or not. How effective are these self-assessment techniques? To date, no research (that we are aware of) has attempted to evaluate the effectiveness of any of these instructional devices in online executive education. We have been relying primarily on "good design principles" and preliminary user experience testing to guide our designs and implementations. While we do not consider this reliance on principle invalid, we have undertaken a research project designed to establish the effectiveness of embedded self-assessments.

Researching the effectiveness of using embedded self-assessments on student learning and perceptions of learning is beneficial to UNext in several aspects. First, it will help to determine if these assessments are indeed helping the students to learn and retain the content of a course. Second, as developing quantum courses is a resource intensive process, learning whether embedded self-assessments are useful to students would help in not only improving the courses, but also streamlining production to focus on course design that effectively helps students learn. Additionally, learning about how the student perceives the self-assessments is also beneficial. Even if there is no difference in learning (measured by post-assessment) between students who take courses that have self-assessments and course that do not have self-assessments, if the student perceives that they are learning more, this may be valuable in itself. Even the perception of increased learning may lead to greater learner satisfaction. In the business of e-learning, satisfied learners generally leads to satisfied customers.

Study questions: In order to learn more about the use of self-assessment questions in Quantum courses, this study answers two major questions.
1. Do embedded self-assessments affect student attitudes or perceptions about learning in a Quantum course, as measured by a survey administered after course completion?
2. Do embedded self-assessments affect student learning in a Quantum course, as measured by a multiple choice post-assessment?

Participants: Thirty participants who fit the target profile for Quantum course students will complete the study. Participants should be degreed business professionals, interested in the course topic, and familiar with using the Internet (browsing the world wide web, using email, etc.) but should not be familiar with the specific course content. Participants are asked to volunteer three to four hours of their time (in one sitting) for the study. Participants are offered small compensation for their participation, in the form of light refreshments and gift certificates to local restaurants. It is not expected that this compensation will affect the results of the study.

Context: Participants complete two courses from one Quantum course suite, "Get the Net." This Quantum suite is designed to help professionals understand, recognize, and analyze working Internet business models using information gathered on the Internet. It explains key economic principles that underlie the Internet's rapid transformation of business strategy and culture. The research team observes participants as they complete the study under one of two conditions. One condition is "Quantum course without embedded self-assessments." The other condition is "Quantum course with embedded self-assessments." Participants in both conditions are given a final attitude survey and a comprehensive (approximately twenty question) post-assessment. Quantitative analysis of the survey responses and post-assessment results, and qualitative analysis of participant debriefing transcripts is used to generate findings and recommendations.

Method: The courses chosen for the study are the first two courses in the "Get the Net" Quantum suite. The course titles are "Evolution of the Firm" and "Age of Human Capital." These courses were chosen because of an expected high level of participant interest in the topic, content that is new to the participants, and the minimal existing use of self-assessments in each course.

The research team created a set of embedded self-assessments for four of the five sections in each course. The fifth course section already includes an assessment component, and self-assessments do not "fit" the instructional purpose of the section. The team also removed the minimal amount of embedded self-assessments that existed already in the courses, taking care not to change course content or activities which demonstrate content mastery.

Participants complete the study during a single three to four hour time block in the User Experience Lab at UNext's Bloomington Development Center in Bloomington, Indiana. This lab is equipped with multiple testing stations, at which the participants will complete the study and access the online courses. Participants are briefed on the use of the testing station computers, how to access the course, and the overall topic of the study, but will not be informed of the particular study group they are in. Participants are instructed to complete each of the courses thoroughly and that their learning will be assessed after they complete the courses. One study group completes the courses without the self-assessments and the other group completes the courses with the embedded self-assessment condition applied.

All participants complete one attitude survey and one comprehensive post-assessment after completing both courses. The attitudinal survey asks the participants questions about how they feel in regards to the assessment techniques used in the course; whether or not they found them useful. They are also asked questions concerning their thoughts on the course content itself and their perceived mastery of it. The survey uses a Lickert scale for participant responses. The post-assessment serves to assess the participants' mastery of the course content for comparison between the two study groups. This assessment uses a mix of multiple choice and short essay questions.

Analysis: A comparison will be made between the survey responses between the groups of participants in each condition. Specifically, we will look for evidence of correlation between the existence of embedded self-assessments and student perception of learning and attitude toward the overall course experience. Additionally, we will look for evidence of correlation between the existence of embedded self-assessments and student achievement on the post-assessment. The post-assessments will also be analyzed to determine if one group performed better or worse than the other. A rating scale will be used to rate the essay responses and three raters will be used, the average of their ratings being calculated to determine scores.

Expected findings: We expect that the existence of embedded self-assessments will increase the student's perception of learning, and will also increase the student's learning of course content. If this expectation is upheld by the study data, this may lead to a recommendation that more embedded self-assessments be included in Quantum course suite designs. If the study finds that self-assessments do not positively influence student perception of learning or actual student learning as measured by the attitude survey and post-assessment, respectively, a recommendation will be made to reconsider the current use of self-assessments. This may lead to removal of self-assessments or the re-design of self-assessments in order to increase their effectiveness.

At the time of this proposal submission, the study design has been finalized and we are beginning to gather data. At the time of the Webnet 2001 conference, all data will be gathered, analysis will be complete, and preliminary findings will be reported.

Navigation Objects and Facilities for Exploring Hyperworlds

Jutta Becker
Know-Center
Inffeldgasse 16c
A-8010 Graz, Austria
jbecker@know-center.at

Abstract: The integration of virtual worlds is going to play an increasing role within existing web information systems and environments. Although a virtual world is a 3D information space itself, other hyperlinked 3D worlds are parts of the complete information network. In many cases the entry (view) point within one hyperlinked world has no connection with the exit location of the previous 3D world. Furthermore the navigation within the world at issue is very often bound to predefined browser features. To improve the navigation within and between web-based 3D worlds we present 3D Web elements for interactive or autonomous transportation within one world as well as traveling between hyperworlds.

Introduction

In contrast to existing 2D web information systems the third dimension provides the user with a variety of additional information in combination with extended exploration facilities. Although it is well known that the work with a 3D environment seems to be more natural and users can profit from their knowledge about the real world they could easily be lost in space. Users are familiar with desktop interfaces and the handling of hyperlinked multimedia information being aware of the difference between this kind of information network and a printed work. Concerning 3D worlds the similarity to the real world, especially the visual appearance, as well as missing details will be recognized at once, but the differences and new facilities in most cases not. It is important to realize that a virtual world might be flat, have any other form with or without boundaries or be an empty space. Moreover hyperlinked virtual worlds (hyperworlds) could form a higher logical world. Although interaction tasks like selection and transformation of objects play an important role for exploring hyperworlds [Hand, 1997; Mind, 1996] the focus of this work is on navigation task: the user is moving and looking around to get any possible information from different points of view. Without appropriate navigation possibilities, the exploration of the 3D information space will be bound to predefined browser features. Furthermore traveling between hyperworlds will be reduced to the "beam me up" from one puzzle of a higher world to another without having any connection. We present Web elements to extend exploration facilities within a single virtual world as well as to support a smooth traveling from one sub-world to another without the need of jumping. Some of these Web elements do not only realize an easy to use transportation but the change of roles. Using the markup language XML for the definition of these new Web elements and meta-structures, the integration within different kinds of web-based visualization environments based on VRML/X3D and/or Java3D will be supported.

Web Elements for Navigation

Walking or flying are the most familiar types of navigation within virtual worlds. The user is performing the navigation transporting her through the surrounding environment. In general she is presented by only using her viewpoint. A look around will not show any feet or hands or other parts of her body. Within multi-user environments a virtual role will be chosen using a 3D object, the avatar, to visually embody the user for the other participants in the joined virtual world [Martin, 1999]. If appropriate input devices are available one could not only transfer the virtual position into the virtual environment but also the real body movements [Macedonia; Rosenblum,

1998]. Although using an avatar additionally allows the user to visually perceive herself, in general this feature is not used. The concept of our new Web elements is the integration of the user's viewpoint with any 3D object to present the current user, if needed. For user transportation within a single virtual world the position and orientation of these Web elements, the navigation objects, will be manipulated. To realize the traveling between virtual worlds they are extended to a combination of several viewpoints, hyperlinks of the shared worlds and the connecting 3D object.

Navigation within one virtual world

Beside the possibility to take a role (humanoid, animal, a camera etc.) with the aim of exploring the surrounding world from different points of view, a 3D object could as well present transportation objects like vehicles, ships or perhaps an animal (Figure 1).
Figure 1: different 3D objects for user presentation or transportation
a) only viewpoint, b)+c) humanoids, d)+e) take animal roles, f) drive with a vehicle

Important is to split up each navigation object into appearance, position of the users viewpoint relative to the objects position and an interactive or autonomous transformation of the chosen 3D object. The complete element will be handled like any other group element (e.g. a group or transform node, having its own coordinate system).

```
<!element Navigation (Appearance, PointofView, Rules)>
```

Appearance: According to the fact, that a transportation object might represent different roles or vehicles, the desired 3D object are integrated using an *inline structure* (optional hyperlink reference). If no extra 3D object is needed only the *origin coordinate system* of this transportation object will be positioned within the higher world. Inlined objects should have the right size in contrast to the user and other objects in the virtual environment. If every 3D model is correctly specified in "meter" no further definition is needed. Otherwise the optional definition of a *bounding box* provides the overlaying application with scaling information.

```
<!element Appearance (Origin, Inline?, BoundingBox?)>
```

Viewpoint Position (point of view): For the first persons view [Barrilleaux, 2000] the viewpoint will be embodied in the chosen object near a place where eyes would be found in reality (A) Figure 2) using the *initial position* transformation. This initial position is the offset for further transformations and might be used as camera position to get the visual perception of a chosen role or the highest priority point of view within a vehicle (e.g. the driver). Other points of view (second person view [Barrilleaux, 2000]) will be reached using the *additional position* transformation, e.g. to realize a ride with the presented creature (B) Figure 2) in addition a take the role.

```
<!element PointofView (InitialVP, AdditionalVP*)>
```

Navigation Rules (transformation): The navigation facilities of the new Web elements are described independent of predefined browser features. Nevertheless existing exploration facilities could be combined with the additional navigation rules or be filtered to use only a subset of the produced input information. *Autonomous* movements of any 3D object offer a lift to explore the surrounding environment without any further interaction. This *type of*

navigation will ignore any other interaction information from browser features or the higher application besides switching viewpoints. The *semi-interactive* mode allows start and stop interactions or e.g. speed variation but no free movements. The complete *interactive* controlling (virtual driver license) manipulates the transportation object according to all available *Degrees of Freedom*. To simplify the definition of vehicle and role characteristics *predefined navigation types* provide a set of *DoF* definitions, to describe allowed movements and rotations e.g. for walking or flying. These predefined sets could be overwritten using the separate *DoF* description. Beside the possibility of controlling the movement of the chosen navigation object it might be useful to allow movements relative to the navigation object (e.g. changing the place in a bus or slide forward or backward sitting on a pelican like (B) Figure 2). The additional *boundary type* classifies this relative movement into *rigid* (no movement allowed), *limited* (e.g. external boundary like inside a room) or *free* (any relative position possible).

```
<!element Rules NavType?,PredefNavType?, DoF?, FurtherNav?, BoundaryType?)>
```

Figure 2: different viewpoints for different points of view
A) explore with the point of view of the 3D object (be a pelican),
B) explore the world, riding on the 3D object (swim with the pelican)

Every defined viewpoint within the navigation object could be handled as a camera position. We decided to take the initial viewpoint as rigid camera position, presenting the first person's point of view. All other points of view could be manipulated according to the desired application domain and exploration demands. During traveling through the current virtual world boundaries will be reached and the demand comes into being to travel to the next world.

Traveling between hyperworlds

The existing facility "beam me up" allows traveling between two worlds without any predefined pair of locations. In general an object with a hyperlink will be selected to activate the "beam me up". According to existing predefined viewpoint positions the first available will be taken as entry point. The presented Web elements for hyperworld traveling are combining viewpoints and objects/worlds with the aim to realize a connection between the entry and exit viewpoints of the participated hyperlinked worlds.

Hyper (door) link: Walking through a door is the simplest solution for hyperworld traveling. Any object with nearly no depth will be placed in both participated worlds. This door is linked with one viewpoint serving as entry and exit viewpoint according to the direction of traveling (a) Figure 3).

Hyper (tunnel) link: Three-dimensional objects with an existing boundary like a tunnel, a lift or any other form of a room will be passed through, to reach the new world. A set of viewpoints is presenting the possible entry and exit points of this object. An object entry point is equivalent to the exit point of the previous world. Leaving the object at a specified exit point will result in being transformed to the entry viewpoint of the next world (b)+c) Figure 3).
Figure 3: a) hyper (door) link – using an object with nearly no depth and one viewpoint, b) hyper (tunnel) link – simple version combines a room with entry and exit viewpoint, c) complex room objects with several entry/exit viewpoints and transformations between them, d) a complete world with specified entry and exit viewpoints

Hyper (world) link: If complex room objects will be defined as separate worlds, they need an entry and exit viewpoint being connected with suitable viewpoints in the shared worlds (d) Figure 3). Leaving the $world_i$ at the exit viewpoint means an entry into the in between (hyper)$world_j$. The user could explore this world or is transformed automatically to the exit viewpoint being transferred directly to the entry point of the destination ($world_k$).

Every exit viewpoint will be the entry viewpoint if the user is going to travel in the reverse direction. According to the predefined viewpoint orientation a reverse movement is needed. Going backward may be uncomfortable and unnatural. The problem will be solved taking only the entry and exit position and combine it with the last navigation direction and/ or speed. If the exit viewpoint had been reached using a navigation Web element being combined with a 3D object, this element has to be transferred to the other world too, to maintain a chosen role or transportation vehicle.

New Facilities using Navigation Objects

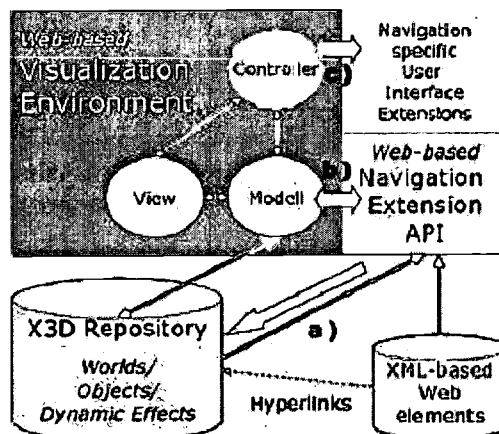
Predefined browser features could be used, but will be filtered according to the allowed navigation rules. Every 3D world could be extended with hyperworld linking or with additional transportation facilities. The existing web-based visualization environment is still using its X3D repository. Without any extensions, the new navigation API could import any 3D object with dynamic effects, transform it according to the new navigation description and export existing 3D formats (X3D or VRML97) for indirect usage (Figure 4 a)).


Figure 4: new navigation API with X3D export (a), methods for updating the visualization model (b) and user interface extensions (c)

The new API allows the direct manipulation of the visualization model for the integration of the new Web elements with the complete functionality (Figure 4 b)). Using new user interface components (further input devices or virtual handles) the navigation possibilities will be improved (Figure 4 c)).

Within the following example a dynamic object is taken as transportation object. It is not important, whether the dynamic effect is integrated using the possibility of sensors, routing and interpolation lists [www.web3D.org, 2000] or whether the transformation information is updated using Java or JavaScript [java.sun.com, 2001]. This description is used for the navigation extension combining the object with a viewpoint.

```
//Original                              //Extension
<X3D>...                                <X3D-nav-extension>
   <Transform                             <Navigation
     DEF= 'desired-transportation          DEF='object x transportation'>
           -object'                          <Transform
     translation='x y z'...>                   DEF='position-relative-to
        <Inline URL='"object x.wrl"'.../>          object'...> //Origin
   </Transform>...                             <Viewpoint
//any dynamic effect description updating      DEF='navigation viewpoint'
the transform node...                          description='transportation
</X3D>                                                        with object x'.../>
                                            </Transform>
                                            <Inline url='"object x.wrl"'.../>
                                          </Navigation>
                                        </X3D-nav-extensions>
```

The Web element usage is split up into three phases:
1. Entering transportation / take role
2. Drive with transportation / navigate dependent of role and degrees of freedom (fly, swim, walk etc.)
3. Exit transportation / switch back to default role or use a new one

Concerning hyperworld traveling the visual perception problem of empty space behind a world with no visual boundaries had to be solved (e.g. open door in Figure 5). According to existing or not existing boundaries of the involved hyperlinked worlds (closed rooms or open environments) inside or outside views are needed. The arising textures of each world will be mapped to a cylindrical or room-based background object.

```
<!element hyperdoor (Viewpoint, Inline,World1,World2,Background1?,Background2?>
```

Figure 5: Using a hyper (door) link and a background object, presenting the next world until it is really entered.

To enter the new world any selection had be performed (e.g. select a hyperlink, collide with an object, touch a touch-sensor). After this selection the new world will be uploaded. The solutions for long loading times is the integration of long tunnels or other room-based objects, because the pass through time could be used for loading the next world.
Figure 6: Walking/Driving through the hypertunnel takes time, could be used to load the next world

To simplify the first prototype implementation we had chosen only the usage of simple viewpoints for hyperlinking virtual worlds and no complex roles and transportation objects

Final Remarks and Future Work

Designer and user of virtual worlds have to decide whether it is useful to jump between to locations with the "beam me up" facility or to travel smoothly within or between virtual worlds according to the actual application domain. The change of roles and the usage of any autonomous element as transportation element will open new "points of view", use boats, cars, spaceships or switch roles from human, to fish to pelican. Switching between interactive and autonomous navigation extends virtual environment interfaces with new interactive features as well as guidance.
Using intelligent loading schemes could improve view and storage saving and support intelligent divis ion of complex virtual worlds into several sub-worlds without problems of entry and loading. Within future implementations hyperworld traveling will be improved using complex transportation objects or virtual roles for the definition of the exit- and entry-point. The interactive definitions of new transportation objects or hyperworld linking as part of a browser interface are as important as the integration of extended perception features. The integration of stereo viewing or the definition of a set of more than two viewpoints e.g. to perceive the impression of viewing like an insect, as well as the combination of visual and haptic feedback [Becker, 2001] will provide users with complete new experiences within virtual 3D information spaces.

The Internet as a Foreign Language Learning Resource

Gunnar Bergh
Göteborg University/Mid-Sweden University
P.O. Box 200
SE-405 30 Göteborg, Sweden
bergh@eng.gu.se

Abstract: The purpose of the present paper is to give a brief survey of linguistically useful databases and tools available on the Internet. Drawing on the experience from a recent learning project at Göteborg university, the exposition is mainly confined to such ICT resources which involve the learning/usage of English.

1. Introduction

As a result of the rapid development of information and communication technology (ICT) in recent years, there are a host of interesting language learning resources on the Internet which are freely available to the enterprising student. Stored on various servers throughout the world, these resources consist of different types of (meta)language collections and specialized software applications: the former category includes database resources such as electronic handbooks (dictionaries and grammars), free text packages and language corpora, while the latter refers to sophisticated tools for language analysis and transformation, e.g. taggers, parsers, translators and summarizers.

Yet, while this smorgasbord of linguistic facilities has a wide range of educational application, the problem is usually that rather few language students are aware of what is on offer and how such resources could be applied to the everyday learning situation. The purpose of the present paper, therefore, is to give a brief survey of some relevant linguistic databases and tools, and to refer to some aspects of their usefulness in an educational context. Drawing on the experience from a recent learning project at Göteborg university, the exposition will in substance be confined to such ICT resources which involve the learning/usage of English.

2. Databases

As generally recognized, the mainstay of language learning is to be found in the fields of lexical, grammatical and pragmatic knowledge. On the Internet, there are a variety of databases which can assist the learner of English in these matters, focusing in particular on the study of fundamental lexis and grammar.

2.1 Handbooks

2.1.1 *Lexical resources*

One of the major database resources is the electronic dictionary. It comes in several different forms and sizes, all in order to satisfy the lexical needs of a variety of different learners. Thus, there are dictionaries which are monolingual (e.g. *The Cambridge International Dictionary of English*: http://dictionary.cambridge.org), bilingual (e.g. *The Lexin Lexikon*: http://www-lexikon.nada.kth.se/skolverket/sve-eng.html) or even multilingual (e.g. http://www.traducation.com/electronicdictionary.htm). Whereas these resources typically deal with a single (international) standard of English, there are other dictionaries which feature comparisons between two standard (or even non-standard) forms, so-called bidialectal dictionaries (e.g. *The American-British/British-American Dictionary*: http://www.peak.org/~jeremy/dictionary/dict.html). Diachronically speaking, there are etymological dictionaries (e.g. *Merriam-Webster Collegiate Dictionary/Thesaurus*: http://www.m-w.com/dictionary), providing lexical data with information about their historical origin and development, and also (collections of) historical dictionaries (e.g. *Early Modern English Dictionaries* (16): http://www.chass.utoronto.ca/english/emed/patterweb.html), i.e. dictionaries published in earlier periods of the language. A recent addition, thanks to the development of multimedia facilities, is also the so-called talking dictionary (e.g. *Encarta World English Dictionary*: http://dictionary.msn.com/Default.asp) where the pronunciation of lexical items is given in both graphic and auditive form. In general, the credit of these electronic dictionaries is that they are interactive, up-to-date and convenient to use, and that they cover, collectively speaking, a substantial part of a vast multilingual lexical field which it would otherwise be difficult to find swift access to.

2.1.2 *Grammatical resources*

On the grammatical side, we find a good selection of electronic handbooks dealing with syntactic as well as inflectional and derivational aspects of language. Representative examples include *The Internet Grammar of English* (http://www.ucl.ac.uk/internet-grammar) and *An On-Line English Grammar* (http://www.edunet.com/english/grammar/toc.cfm). Through resources of this type, the learner can access information on a variety of grammatical facts, view (often authentic) examples of target constructions, and even test their comprehension of the contents by means of selected exercises (with immediate feedback provided by a server). Indeed, in that respect, some of these sites come close to offering full-fledged grammar courses. Another versatile type of grammar database is represented by *The Leicester English Grammar Project* (http://www.le.ac.uk/ee/jmc21/legp/), providing information and quizzes not only on present-day English grammar but also on earlier varieties of the language, such as Old English. Given their easy-to-use hypertext interface, often with built-in search applications, these electronic handbooks seem to increase the motivation of many language learners in their grammar studies and to facilitate their understanding of the subject. On the down side, however, we must note that there is a great deal of variation in the grammatical terminology used, a situation which detracts somewhat from the general pedagogical value of these databases.

2.2 Text collections

2.2.1 *Free text collections*

Free text resources on the Internet consist basically of collections of literary or journalistic publications. On the literary side, there are a host of electronic writings available, including not only fiction but also drama and poetry: one good starting-point, for example, is a site called *English Literature Sources on the World Wide Web* (http://www.rice.edu/Fondren/Netguides/eng.html), which features an A-W list of literary works, from African American women writers of the 19ᵗʰ century to the William Blake archives. On the journalistic side, there are a wide selection of newspapers and magazines on offer, e.g. the *Guardian*, the *Independent, USA Today* and the *Hindu,* as well as *Time, Planet Science* and *BBC Top Gear Motoring*, all of them made available under the heading *English newspaper collection* (http://www.geo.ed.ac.uk/home/news.html). For both types of text, it turns out that they can be used profitably for the systematic study of language and/or content, with particular reference to the structural mapping of specific text types.

2.2.2 *Corpora*

Language corpora are probably among the most useful web resources available for language learners. Made up of samples of texts or utterances which are designed to be more or less representative of a language or language variety, and which are made accessible through a search interface, they are represented in particular by so-called standard corpora, e.g. *The Cobuild Corpus* (http://titania.cobuild.collins.co.uk/form.html and *The British National Corpus* (http://thetis.bl.uk/lookup.html). These corpora contain written (90 per cent) as well as spoken (10 per cent) language produced during the 1990s: the former consists of a 56-million-word selection from the Bank of English, including both British and American English, while the latter is comprised of 100 million words of British English only. The main virtue of these databases is that they can be employed to look up the usage of all sorts of (reasonably frequent) present-day English language patterns, be it syntactic constructions, lexical collocations, idiom applications or spelling conventions, providing frequency figures for different alternatives.

2.2.3 *Search engines*

Also, as a helper in the use of web-based textual databases, the language learner is equipped with a set of search applications which are able to scan the Internet for specific types of (language) information. Most of them are of the general search engine type which is designed to find web pages containing a predefined search string and present addresses to these pages in the form of a list of hyperlinks, e.g. *All the Web* (http://www.alltheweb.com) and *Google* (http://www.google.com). However, there are also more sophisticated versions of such engines, e.g. *WebCorp* (http://www.webcorp.org.uk). This application does not only find relevant web pages but also present their contents in the form of a KWIC concordance, i.e. a list of matches where the sought-for item is highlighted and accompanied by its own linguistic context. In this capacity, WebCorp makes it possible to use the huge amounts of text published on the Internet as a unified language corpus, in principle functionally equivalent to the Cobuild and BNC corpora, since it produces the same kind of output.

3. Tools

The linguistic tools available on the Internet relate to more sophisticated aspects of language study. On the one hand, they provide learners with an opportunity of performing different types of grammatical analysis, either in terms of word class tagging or constituent parsing; on the other, they offer a means of transforming texts, either in terms of translation from one language to another or condensing a full text into a short summary. However, it should be noted that most of these applications tend to suffer from accuracy problems, in particular the transformation software.

3.1 Analysis applications

3.1.1 *Taggers*

Web-based taggers typically deal with categorial identification. Focusing on the lexical level, the application analyses the word class patterns of a text and adds interpretive labels (or tags) to the words involved, e.g. *noun (NN), verb (VB), article (AT), conjunction (CT)*, etc. (often with further subclassification). Representative examples of this type of tool include the *UCREL tagger* (http://www.comp.lancs.ac.uk/computing/research/ucrel/claws/trial.html), the *ENGTWOL* tagger http://www.lingsoft.fi/cgi-bin/engtwol) and the *MBT* tagger (http://ilk.kub.nl/~zavrel/tagtest.html). To take an example, if the UCREL tagger is given the task of analysing the sentence *A language is a dialect that has an army and navy*, the following tags are returned:

A_AT0 language_NN1 is_VBZ a_AT0 dialect_NN1 that_CJT has_VHZ an_AT0 army_NN1 and_CJC navy_NN1

Having a rather detailed appearance, these automatically assigned tags seem to correspond quite well with the general consensus of word class identification in English (with the possible exception of *that*, which is here classed as a conjunction rather than as a pronoun). In other words, this is a potentially useful tool for students trying to break into the charmed circle of English grammar.

3.1.2 *Parsers*

Parsers are similar to taggers in the sense that they add interpretive labels to a text. The difference is, however, that they deal with functional rather than categorial identification, i.e. the output of the parser is typically a set of constituent labels, e.g. *subject, predicator, direct object*, etc. Accordingly, the analysis aims at the phrasal rather than the lexical level. The *Functional Dependency Grammar (FDG) parser* (http://www.conexor.fi/analysers.html#testing) and the *ENGCG parser* (http://www.lingsoft.fi/cgi-bin/engcg) are good examples of such applications, the former building functionally labelled dependency links between constituents and the latter providing shallow syntactic analysis of constituents on the basis of morphosyntactic tagging. By this description, it is also made clear that parsers and taggers tend to work together, and that it is sometimes hard to draw a sharp line between them, functionally speaking.

3.2 Transformation applications

3.2.1 *Translators*

Among the tools for textual transformation, the electronic translator is clearly a resource which carries an interesting learning potential. Using this type of application, it is in principle possible to key in a text in one language and have it immediately translated into another. Such translators include *Babelfish* (http://babelfish.altavista.com/translate.dyn) and *Promt's Online Translator* (http://www.translate.ru/eng/), both of which offer a choice of translation from/into a set of major Western languages, e.g. English, German, French and Spanish. Unfortunately, the accuracy of these applications varies considerably: in some cases, the translation of a simple monotransitive sentence can go completely wrong, as when Babelfish translates *She kicked the bucket* into German *Sie trat die Wanne* and then back into English *It stepped the tub*; in other cases, the performance is much better, as in the suggestion of Promt's Online Translator to translate a complex sentence such as *England expects every man to do his duty* into Spanish *Inglaterra espera que cada hombre haga su deber(impuesto)* and then back into English *England hopes that every man does his(its) (well versed) duty*. Given such accuracy fluctuations, it goes without saying that these translators are potentially hazardous to language users and should therefore be employed only with great precaution.

3.2.2 Summarizers

Finally, there is also a recent addition to the category of language transformation tools, viz. the summarizer application. Represented here by the *Multilingual Interactive Document Summarizer* (http://messene.nmsu.edu/~mcm/minds/MindsDemo/mindsDemo.html), this tool is designed to give users an opportunity to condense a text into a relevant summary in the range of 5-30 per cent of the original. Again, however, functionality problems arise when the tool is put into practice. When given the task of summarizing (at the 5-10 per cent level) the first section of the present paper (1. Introduction), the application returned the following "summary":

> Yet, while this smorgasbord of linguistic facilities has a wide range of educational application, the problem is usually that rather
> few language students are aware of what is on offer and how such resources could be applied to the everyday learning situation.

As this output is identical with the first sentence of the second paragraph, it is clearly far from being a proper summary of the original text. In other words, caution must again be recommended.

The Protection of Youth from Victimization in Cyberspace: Implications of Online Research for Practice and Policy

Abstract: This baseline study of online activity among adolescent girls in the United States and New Zealand focuses on identifying the prevalence of participation in at-risk behavior in cyberspace that may result in abuse and exploitation. The information is important for the design of prevention and safety programs for adolescents engaged in online activity. Survey results confirm that a significant number of adolescent girls are engaging in risky activities when online, including disclosing personal information, sending personal photos to online acquaintances, and arranging face-to-face meetings. Many respondents continue potentially problematic offline practices as a result of these online interactions. The data also suggest that there is a lapse in preventative intervention to create and maintain awareness and safety for young people.

As a new phenomenon there is a paucity of research or models to predict the likelihood to engage in at-risk activities online which may be associated with subsequent exploitation. Whether social interactions in cyberspace are beneficial or problematic may depend on the influence of parents, teachers, and peers whose guidance may assist students in making informed decisions and allow them to demonstrate an ability to apply online critical thinking skills and productive social participation.

In a web-based study conducted in conjunction with Seventeen Magazine Online, CyberAngels, the College of Education at the University of South Florida, and the Department of Child and Family Studies at the Louis de la Parte Florida Mental Health Institute, an online survey was developed and placed on the Seventeen Online site to assess level of Internet use, involvement in varied at-risk behavior online, incidents involving negative interactions in Cyberspace, and perceived mechanisms to promote safety and well being. The differences in girls' use of technology (AAUW, 2000) combined with data confirming adolescent girls as the group most likely to be targeted for assault (National Center for Missing and Exploited Children, www.missingkids.org), established the need to devote the study to investigation of girls' experiences in cyberspace. Subsequent to release of the U.S. study results, the online survey was replicated by a child advocacy group in New Zealand, a country that has implemented a national Internet safety initiative.

Among both study groups, 14-16 year old girls comprised the largest pool of respondents. Among the U.S. survey participants approximately 50% spent less than six hours online weekly compared to 44% for the New Zealand group. The percent of users online six to nine hours per week was nearly identical for both groups; however, New Zealand girls exceeded their U.S. counterparts in the percent online for over ten hours per week (33% vs. 27%). Both groups primarily accessed the Internet at home, and instant messaging was universally identified as the most popular activity. In both countries the percentage of adults monitoring the use of the Internet was quite small (<4%)and is a likely contributor to at-risk behavior in impressionable teens. Among all respondents in the Berson, Berson and Aftab study (1999), less than 4% indicated that a parent, caretaker, or teacher always discussed their online activities with them. 26% occasionally were engaged in a discussion about their online activities. 38% rarely were asked to discuss their online experiences, and 31% indicated that adults never discussed their online activities with them. Yet this dialogue with significant adults seemed to make a difference for many young people.

Patterns of Interaction Online
In the study, many of the reported online interactions focused on a culture of deception in which some

respondents primary activities involve the exchange of verbally harassing or sexually suggestive chat. In contrast other young women are using online dialogue as a way to empower themselves and find a voice. In face-to-face interactions they may perceive that superficial characteristics (body size, facial features) are judged as more important than personality. These visual cues are not available during online exchanges. In AAUW's study of teenage girls (1999) many girls admitted repressing their authentic self in order to fit in with peers. However, in cyberspace, the pressures to fit in and act a certain way are moderated by the perceived anonymity and false security of being protected behind the computer screen, often in the comfort and safety of one's home. Cyberspace provides girls a context where they can shed their traditional expectations and explore alternative aspects of themselves. After all, "the computer can't see you blush" when you enter this fantasyland where the innocent can be sexy, the obedient can be naughty, and even the meek can swear with the best of them (Berson, 2000).

The at-risk activity of disclosing personal information was more prevalent among the U.S. respondents (59% compared to 34%), but actually meeting or agreeing to meet someone as a result of an online interaction was nearly twice as common among New Zealand girls compared to U.S. participants (24% compared to 12%). Both groups were equally prone to send pictures of themselves to someone they met on the Internet (approximately 25% of the respondents).

Development of a Victimology Profile

Using the results from the Seventeen online survey of adolescent girls, our ongoing analyses are focusing on development of a victimology profile based on probability of online risk. We have used logistical analysis to isolate variables that predict at-risk activity. The participants reported online experiences which challenged them to confront choices conflicting with the development of attitudes, values, and social functioning. These dependent variables include giving out personal information online, agreeing to meet with someone, receiving or sending photos, receiving and sending suggestive or threatening email, and participating in chatrooms where the content resulted in discomfort. They also identified factors which may moderate risk (independent variables), and these variables have been used to develop odds ratios and subsequent log of the odds through a logistic regression model. These include preventative activities (supervision, education, discussion) by significant adults (parents and teachers). Initially the log odds are being modeled as a linear function of the predictors, and then more advanced measurement analysis will result in consideration of multiple predictors simultaneously.

We have considered a logistic regression where the log odds of agreeing to meet with a stranger are modeled as a function of discussing Internet safety with a teacher, discussing Internet safety with a parent, and the interaction of these two predictors. The interaction is statistically significant, leading us to conclude that the effect of teacher discussion on the predicted log odds depends on whether or not there was a parent discussion. If there was no parent discussion, the odds ratio for the teacher discussion variable is .580. If there was parent discussion, the odds ratio for the teacher discussion variable is .822 (.580*1.418). In both cases having discussed Internet safety with a teacher reduces the predicted odds of agreeing to meet with a stranger. The effect of teacher discussion, however, is greater when there has been no discussion with a parent.

In the New Zealand sample of 344 girls, 81 indicated that they agreed to meet a stranger in person. The odds of this behavior occurring are .308, but these odds are unequal across groups. Agreeing to meet a stranger may be a function of age. Based on the study results, as adolescent girls get older, the odds of agreeing to risky behavior increases with 17-18 year olds almost four times more likely to meet a stranger than 12-13 year olds.

Similarly, the advice or counseling that the individual received may also influence agreeing to meet a stranger. An odds ratio calculation with the New Zealand sample indicated that girls who have not read or head about Internet safety from parents or caregivers were certain to agree to meet with strangers. On the other hand, adolescent girls who had a discussion with parents reduced their odds of engaging in this potentially dangerous behavior. More specifically, girls who had not discussed Internet safety with a parent or guardian were almost four times as likely to agree to meet with a net acquaintance.

The resulting model of risk and intervention will be used to inform knowledge of the experience of a large sample of adolescents and will contribute to more intensive projects to understand mental health issues associated with online victimization of youth. This information is being applied to the development of cybersafety interventions and public policy through cross-national collaborative efforts.

The dangers of IT enthusiasm.

One of the dangers that lurk in the path of new technologies is to be undermined by the very use they have been chosen to deliver by us enthusiasts of IT. Uses that are innappropiate for them, or even when they may be worthwhile, they do not take full advange of that certain technology's potential may end up making it seen rather banal.

This is specially so when the saying "there is no second chance for the first impression" applies. Non technical people who witness for the first time a demonstration of a new technology that fails, or proves unsatisfactory, do not necessarilly distinguish content from container, do not always differ the technology with the specific use it has been given. The tendency to be prejudiced against the technology developes, when the responsibily of that failure is in the mismatch of use versus the technology chosen.

To dimish this "danger from within" the very IT members, I have given a few of the available technologies some thought, and have come up with some hopefully useful and simple checklists, based on 10 years in charge of academic computing, and before that as academic software developer/faculty. Self deprecatory humor is included.

The idea is to take a quick, practical look at a couple of checklists to see if an adequate number of points are met to insure the appropiateness of the technology to the occasion or content.

What should be taken into account when putting teaching material on the Computer?.
What adds value to teaching material on the Web?
What adds value to the use of videoconferencing?
What adds value to the use of video on demand?

These checklist are not complete here as I am translating them at the moment, but I can speed up the process if you need this information to decide admittance of this paper...

What should be taken into account when putting teaching material on the Computer?.
Short History
At our university we had the usual Computer Center in the sixties with an IBM 1620, later with a Burroughs 3500, etc., and the use of computers done mainly by engineering and math students. The change of paradigm came in 1985 with the Macintosh's graphic interfase and the approval of a campus wide proyect to insert computer labs in all other areas, such as art, literature, social sciences, languages, etc.

In the late 80's we designed a plan to introduce teachers to the use of computer aids in their work, and devised a yearly contest of ideas where financing was won to be able to carry out those more promising ideas. Some interesting products came of these efforts.

We produced a software developed for history students called "Tierra" (Land on sight!) regarding Columbus´ discovery, and the following year were able to win the "Wheels for the Mind Contest" as best university in Latin America.

We produced the best Hypercard application for LA with "HyperEstática", to teach structures to architecture students.

MacWorld considered as Best International Entries in a Superstacks contest (a Canadian SW being the third entry) a couple of teaching software we produced: another history teaching aid (Revolution!) and a second SW for architects (Earthquake!)

Why these programs were succesfull as compared to the multiple other ones (about 200) we produced is a source of practical knowledge.

Some of the software we have produced can be seen on
http://www.puc.cl/html/frameswacad.html

A usefull aid in designing teaching tools is the acronym IRAAA, that stands for Intensity, Repetition, Attention, Association and Affective links.

1 Intensity
The earthquake SW had a brief introduction where some buidings moved and toppled and the cry Terremoto! was heard and read. Similar ocasions presented themselves within the SW for some key concepts, as when showing the effects of rigid buildings founded on rigid soils, etc.

The more senses involved in delivering the message makes it more intense, and gives it a better chance of being remembered by the different types of memories individuals have: drawings (better than a thousand words) for those with visual retentiveness, sound for those those with audio retentivenes, movement for those with kinestesik memory.

2 Repetition
Repetition fixes knowledge to the neurones as we know from kindergarten and up. The trick is of course to have some repetition and some variability interwined, so as to avoid the dullness of plain repetition. One of the great advantages is that with hyperlinks you can use different roads to get to the same conclusion and reinforce it. The other possibility is to repeat the concepts but with variations in the depth in which the subject matter is covered.

In the Earthquake SW you could move through the whole SW at a simple introductory level to get a first overall view, go through it at an intermediate level for normal study content, or inmerse and analyze matters in depth by clicking on icons that contained more detail in some themes (similar to boxes in books or magazines). But in software you don´t have the distraction of on view boxes as you have in books, you don´t see them unless you choose to do so by clicking on an icon and making the boxes appear).

3 Attention.

Capturing the users attention and retaining it is no minor chore, starting with the need to give it a remembrable name. Give it a short simple name that catches the attention of those interested and that manages to conveys its contents.

If you fall into the temptation of naming your software with a long name in sake of accuracy name/content such as ..."Genetics of the degradation of lignite mediated by fungi" or..."Mecanisms of transcriptional activation of defense genes to stress in plants" (yes, they are the real names) and no one will be able to repeat it.

We had The use of Computer Aided Design as exemplified by its Applications on Classical Architecture of Palladio, and left that as a subtitle with simply "MacPalladio" as remembrable one, which brought the Macintosh Computer to mind, and Apple's funding to the institutional pocket.

4 Association.

Whenever possible, images that had the possibility to be known by the students were used, as when depicting buildings with different static loads according to their use: a photo of the actual classroom, a photo of the campus library for 600 kgs/sq.meter, etc This also favours the idea of establishing association with things in real life.

5 Affective links.

In both software programs to teach structures we had a character that explained some concepts (such as twisting a rod to show flexion in beams). A trio of characters was designed, and students were requested to choose the one they felt most identified with, which turned out to be a lanky, bearded, woolscarfed representation of a local architecture student.

Here comes the WEB.
Short History
Communication in the 80's was slow and dull compared with todays possibilities of multimedia material, such as comparing the telex machines to faxes.

At the time data communication networks came through another university, older and owned by the state. We decided to band together with other universities and become independent, creating the first ISP as there were no commercial providers of internet in the country at the time. When Internet service was taken up by the commercial sector later on, we sold out in order to concentrate on our specific mission in <u>teaching</u> and research and hired the service for ourselves.

We were the first university to provide e-mail and free internet access to all our students. We designed our university site and put information on the web for our students to see, and discovered to our surprise we were amongst the country's top ten sites as far as number of hits go.

A reduced number of teachers were enthusiastic about the Web, a large number stepped back and shrunk from HTML, FTP, ISP and such. And many of the enthusiatic ones wanted someone – not themselves- to paste the books they had written on the web.

So we produced a typical course website and easy to use tools to enable faculty to interact with the web, and here we are now, convincing faculty that a new teaching approach is needed – not just pasting the stuff they have.

We have designed a WebSite that has three areas:
Teaching Materials
Administrative Information
Communication aids.
I do not plan to go into detail of the typical website for a course at the Universidad Catolica since it can be easily appreciated at:
http://www.puc.cl/html/framecur.html

The issue I plan to analyze is the appropiateness of the material that can be put on the Web.
The possibitities of putting material on the web are varied. You can of course put reading material. Some consider that more of a way to distribute said material that a way to have people read it, since a number of users still prefer studying material in hardcopy than reading it on the screen. You can put presentation slides, which can be used for class and the students can review the same material later. You can put video clips to be seen on demand. And you can produce a variety of didactical games students have to go through.

What adds value to teaching material on the Web?

1 When simultaneity is not possible in real life or is very difficult.
We all know the advantages of an animated model to explain how an internal combustion engine works, but there are instances when a moving model is more valuable still.
The vision of a cross section of a human heart in movement and the sound a certain cardiopathy makes on the stethoscope is only made possible by superimposing an animation and the recording of the sound., since the cross sectioned real heart will certainly not be moving!

2 When size scale is different to normal: microscopic or macroscopic
The difficulty in giving access to an electronic microscope to a large number of students makes it desirable to make the most of such occasions. A round of previous practice on the computer makes the use of limited access equipment highly effective. This is also valid for telescopes and such, especially since the university's astronomical observatory is located rather far from the main city campuses.
etc

The use of Videoconferencing and Video on Demand.

Short History

As the university has four campuses in the city of Santiago and one 600 miles to the south in Villarica, videoconferencing was thought of and approved as a technological investment.

A selection of courses was made to apply the technology, and feedback was collected to move things onto the right path.

Our idea was to select the best teacher for a course amongst the many who had responsibility of teaching different sections of the same couse, thus giving all the students the advantage of having the best teacher available. However, students declared in their polls that they were not very pleased to watch the teacher on a TV screen.

Interaction was diminished rather than increased, because most students were camera shy, and would rather avoid making a comment or asking a question when they realized they would be the main character on the screen while doing so.

As the class went on tape, we tried putting those tapes to be seen by the students by themselves when they had been unable to go to class. The most sought after remedy was to borrow the classmate's notes rather that review the tape, especially if it hadn't been edited. It seems that hesitation, repetition, umhs and ahs are well tolerated in presential classes, but not at all well received when taped.

Videoconferencing was on the other hand quite succesful when used in other instances.

We used it for the revision and correction of some master's theses at the engineering school, enabling some of the reviewers to participate from far away (Carnegie Mellon in Pittsburg). The small group and the interactivity made it a worthwhile event.

Some use of video conferencing was set up for architecture studio reviews, where it was also considered most valuable. The plans, elevations and illustrations were shown, and the cross cultural comments were interesting to faculty and students in Chile and in Holland.

Videoconferencing was used as one of the aids for a course that had half its students in Chile and the other half in Monterrey, Mexico. The course, called doing bussiness between Chile and Mexico, simulated the establishment of import and export trade, and went through the exercise of creating joint ventures and doing the import and export procedures of goods.

What adds value to the use of videoconferencing?

From these experiences we aks ourselves a couple of questions before diving headlong with enthousiam and just doing it.

1. The source is far away.

V/Cis more valuable when someone is geographically very far (a Nobel prize winner delivering a conference in Sweden) or the elements analized belong to other latitudes (Fauna in Tierra del Fuego/Patagonia)

2. Abundant interactivity.

The typical lecture class where the teacher speaks and the students listens and nods
may not be a sign of approval but of a lossing battle with sleep. Video conferencing seems to bloom with equivalent participation of those involved, and become rather boring in the instances of one sided patronizing of communication.
etc

Video on demand

As properly used visual aids in motion are very valuable in quite a few instances, we evaluated and bought video on demand servers from Real and Apple. Similar to what happened with static graphic material to be put on the web, most faculty at first want to do the old things with the new resources.

What adds value to the use of video on demand?

1. Video of a scarce occasion.

When a certain event is very unfrequent its register in video makes it more valuable.
Por example, video takes during an earthquake, a flood, the mating of an animal of one a year fertile period, an operation to separate siamese twins...

2. Time scale is different to normal.

A process can take much longer than the lapse of a semester, such as the growth of trees for the forest/lumber industry, or a process can be so quick as to be difficult to behold by the normal eye (MIT's high speed photography lab). In these instances the use of animation brings the process into the adequate time frame by accelerating it or freezing it, and permitting its repetition.

3. Editing

Video on demand clips simply have to be short and interesting. Students expect something different than running across a video on loan from the video library when they click on a clip.The limited success of video from libraries seems to come from the fact that few people have the time to seat through the lengh of a whole didactical video.
Frequently there is the need to review only a part contained within that video tape. This ease of selection difference can be optimized with short, well indexed video clips on demand.
etc

The dangers of IT enthusiasm.

One of the dangers that lurk in the path of new technologies is to be undermined by the very use they have been chosen to deliver by us enthusiasts of IT. Uses that are innappropiate for them, or even when they may be worthwhile, they do not take full advange of that certain technology´s potential may end up making it seen rather banal.
This is specially so when the saying "there is no second chance for the first impression" applies. One of the great advantages is that with hyperlinks you can use different roads to get to the same conclusion and reinforce it. The other possibility is to repeat the concepts but with variations in the depth in which the subject matter is covered.
In the Earthquake SW you could move through the whole SW at a simple introductory level to get a first overall view, go through it at an intermediate level for normal study content, or inmerse and analyze matters in depth by clicking on icons that contained more detail in some themes (similar to boxes in books or magazines). But in software you don´t have the distraction of on view boxes as you have in books, you don´t see them unless you choose to do so by clicking on an icon and making the boxes appear).

3 Attention.

Capturing the users attention and retaining it is no minor chore, starting with the need to give it a remembrable name. Give it a short simple name that catches the attention of those interested and that manages to conveys its contents.

If you fall into the temptation of naming your software with a long name in sake of accuracy name/content such as ..."Genetics of the degradation of lignite mediated by fungi" or..."Mecanisms of transcriptional activation of defense genes to stress in plants" (yes, they are the real names) and no one will be able to repeat it.

We had The use of Computer Aided Design as exemplified by its Applications on Classical Architecture of Palladio, and left that as a subtitle with simply "MacPalladio" as remembrable one, which brought the Macintosh Computer to mind, and Apple's funding to the institutional pocket.

4 Association.

Whenever possible, images that had the possibility to be known by the students were used, as when depicting buildings with different static loads according to their use: a photo of the actual classroom, a photo of the campus library for 600 kgs/sq.meter, etc This also favours the idea of establishing association with things in real life.

5 Affective links.

In both software programs to teach structures we had a character that explained some concepts (such as twisting a rod to show flexion in beams). A trio of characters was designed, and students were requested to choose the one they felt most identified with, which turned out to be a lanky, bearded, woolscarfed representation of a local architecture student.

Here comes the WEB.
Short History

Communication in the 80's was slow and dull compared with todays possibilities of multimedia material, such as comparing the telex machines to faxes.

At the time data communication networks came through another university, older and owned by the state. We decided to band together with other universities and become independent, creating the first ISP as there were no commercial providers of internet in the country at the time. When Internet service was taken up by the commercial sector later on, we sold out in order to concentrate on our specific mission in teaching and research and hired the service for ourselves.

We were the first university to provide e-mail and free internet access to all our students. We designed our university site and put information on the web for our students to see, and discovered to our surprise we were amongst the country's top ten sites as far as number of hits go.

A reduced number of teachers were enthusiastic about the Web, a large number stepped back and shrunk from HTML, FTP, ISP and such. And many of the enthusiatic ones wanted someone – not themselves- to paste the books they had written on the web.

So we produced a typical course website and easy to use tools to enable faculty to interact with the web, and here we are now, convincing faculty that a new teaching approach is needed – not just pasting the stuff they have.

We have designed a WebSite that has three areas:
  Teaching Materials
  Administrative Information
  Communication aids.
I do not plan to go into detail of the typical website for a course at the Universidad Catolica since it can be easily appreciated at: http://www.puc.cl/html/framecur.html

The issue I plan to analyze is the appropiateness of the material that can be put on the Web.

The possibitities of putting material on the web are varied. You can of course put reading material. Some consider that more of a way to distribute said material that a way to have people read it, since a number of users still prefer studying material in hardcopy than reading it on the screen. You can put presentation slides, which can be used for class and the students can review the same material later. You can put video clips to be seen on demand. And you can produce a variety of didactical games students have to go through.

What adds value to teaching material on the Web?

1 When simultaneity is not possible in real life or is very difficult.

We all know the advantages of an animated model to explain how an internal combustion engine works, but there are instances when a moving model is more valuable still.

The vision of a cross section of a human heart in movement and the sound a certain cardiopathy makes on the stethoscope is only made possible by superimposing an animation and the recording of the sound., since the cross sectioned real heart will certainly not be moving!

2 When size scale is different to normal: microscopic or macroscopic

The difficulty in giving access to an electronic microscope to a large number of students makes it desirable to make the most of such occassions. A round of previous practice on the computer makes the use of limited access equipment highly effective. This is also valid for telescopes and such, especially since the university's astronomical observatory is located rather far from the main city campuses.

etc

The use of Videoconferencing and Video on Demand.

Short History
As the university has four campuses in the city of Santiago and one 600 miles to the south in Villarica, videoconferencing was thought of and approved as a technological investment.
A selection of courses was made to apply the technology, and feedback was collected to move things onto the right path.
Our idea was to select the best teacher for a course amongst the many who had responsibility of teaching different sections of the same couse, thus giving all the students the advantage of having the best teacher available. However, students declared in their polls that they were not very pleased to watch the teacher on a TV screen.
Interaction was diminished rather than increased, because most students were camera shy, and would rather avoid making a comment or asking a question when they realized they would be the main character on the screen while doing so.
As the class went on tape, we tried putting those tapes to be seen by the students by themselves when they had been unable to go to class. The most sought after remedy was to borrow the classmate's notes rather that review the tape, especially if it hadn't been edited. It seems that hesitation, repetition, umhs and ahs are well tolerated in presential classes, but not at all well received when taped.
Videoconferencing was on the other hand quite succesful when used in other instances.
We used it for the revision and correction of some master's theses at the engineering school, enabling some of the reviewers to participate from far away (Carnegie Mellon in Pittsburg). The small group and the interactivity made it a worthwhile event.
Some use of video conferencing was set up for architecture studio reviews, where it was also considered most valuable. The plans, elevations and illustrations were shown, and the cross cultural comments were interesting to faculty and students in Chile and in Holland.
Videoconferencing was used as one of the aids for a course that had half its students in Chile and the other half in Monterrey, Mexico. The course, called doing bussiness between Chile and Mexico, simulated the establishment of import and export trade, and went through the exercise of creating joint ventures and doing the import and export procedures of goods.

What adds value to the use of videoconferencing?
From these experiences we aks ourselves a couple of questions before diving headlong with enthousiam and just doing it.

1. The source is far away.
V/Cis more valuable when someone is geographically very far (a Nobel prize winner delivering a conference in Sweden) or the elements analized belong to other latitudes (Fauna in Tierra del Fuego/Patagonia)

2. Abundant interactivity.
The typical lecture class where the teacher speaks and the students listens and nods
may not be a sign of approval but of a lossing battle with sleep. Video conferencing seems to bloom with equivalent participation of those involved, and become rather boring in the instances of one sided patronizing of communication.
etc

Video on demand
As properly used visual aids in motion are very valuable in quite a few instances, we evaluated and bought video on demand servers from Real and Apple. Similar to what happened with static graphic material to be put on the web, most faculty at first want to do the old things with the new resources.

What adds value to the use of video on demand?

1. Video of a scarce occasion.
When a certain event is very unfrequent its register in video makes it more valuable.
Por example, video takes during an earthquake, a flood, the mating of an animal of one a year fertile period, an operation to separate siamese twins...

2. Time scale is different to normal.
A process can take much longer than the lapse of a semester, such as the growth of trees for the forest/lumber industry, or a process can be so quick as to be difficult to behold by the normal eye (MIT's high speed photography lab). In these instances the use of animation brings the process into the adequate time frame by accelerating it or freezing it, and permitting its repetition.

3. Editing
Video on demand clips simply have to be short and interesting. Students expect something different than running across a video on loan from the video library when they click on a clip.The limited success of video from libraries seems to come from the fact that few people have the time to seat through the lengh of a whole didactical video.
Frequently there is the need to review only a part contained within that video tape. This ease of selection difference can be optimized with short, well indexed video clips on demand.
etc

Student Perceptions of Team-Taught Site-Based Mathematics Course

Sally Blake, UTEP, USA ; Mourat Tchoshanov, UTEP, USA; Art Duval, UTEP, USA ; Connie Della-Piana, UTEP, USA; Sandra Hurley, UTEP, USA

University professors move classes to a local middle school in an attempt to increase mathematical conceptual knowledge through a teacher assessment model.

Title: Collaborative Learning – Tools from The Education Network of Ontario

Mr. Val Blokowski, Executive Director, The Education Network of Ontario

Summary
In this paper I will discuss how the Education Network of Ontario was established, the service it provides to the education community in Canada and overseas, and explain our approach to online learning through specific student projects, their relevance to the curriculum, and how we have created online simulations that are based on topical events that have greater meaning for students.

Introduction/Context

The Education Network of Ontario (ENO) was founded in 1993 as a collaborative project between the Ontario Ministry of Education and Training and the Ontario Teachers' Federation. We incorporated in 1997 and are a private Canadian not-for-profit corporation.

The Education Network of Ontario provides a wide range of telecommunication services for the Junior Kindergarten to Grade 12 education community in Ontario, including Internet access, member email accounts, student and teacher education projects and over 185 online education conferences and newsgroups.

Internet access for members is provided by us as one of Ontario's largest Internet Service Providers (ISP) serving members through 25 local dial-up servers and 1-800 access for members outside of the local dial-up server areas.

We use a web-based conferencing system to provide users with over one hundred and eighty moderated conferences and discussion groups, in English and French. A wide range of topics such as educational reform, curriculum development and equity give educators from all parts of the province an opportunity to discuss issues related to education. ENO users have unlimited access to international electronic mail.

The initial stage of the Education Network of Ontario was a UNIX-based, cross-platform, TCP/IP protocol distributed network application which provided bilingual (English and French) electronic mail, moderated conferencing (facilitated newsgroups), and database and Internet access across Ontario. It started with just eighteen members in 1993 and has grown to register more than ninety thousand teachers, administrators, trustees and education faculty, well over half of the K-12 education personnel of the province. The organization, a public sector Internet and Intranet Applications Service Provider has moved from project funding from the government to an independent not-for-profit corporation with an active and informed Board of Directors selling services to various levels of government and public sector organizations.

The project has retained dial Internet access from any home, school or cottage location in Ontario and mail and conferencing services. However, ENO is fully retooled to enable browser-based moderated Intranet newsgroups, model classroom projects with interactive web creation scaled to suit 100,000 teachers as they develop creative, industry-standard content. A bilingual call centre supports all of the members and a web site supplies automated tools for registration and access and service 'fixes'.

Statistical Notes

Quantitative analysis tell us that our membership of 90,000 educators use the dial access an average of 18,000 times a day. Statistics show total online time of nearly 20,000,000 minutes a month. Our servers handle as many as 100,000 messages a day. Some of our classroom activities sites register as many as 30,000 hits a day during peak activity times. Analysis indicates a tremendous interest in and usage of the Internet and our resources with 90% of the connect time after school and all through the night.

Teachers' Practices

Our anecdotal analysis and day-to-day experiences tell us a great deal about how educators use this suite of services. One focus of the teachers continues to be moderated conferences/newsgroups that they open to solve such endemic concerns as 'local' versus 'standardized' evaluation, reporting to parents, community work/learn programs, and general subject-based or level-based curriculum issues. Whenever a new provincial license for software is purchased, a conference is opened in which the technical support team from the vendor can discuss issues of use and technical implementation. This 'mode' has expanded to include professionals from the Addiction Research Foundation who help teachers work positively with addicted students and the addiction resources regularly circulated to schools as a part of this agency's mandate. A large school district's school custodians are working on practical identification and warnings about workplace issues and hazards.

Smaller groups of teachers voluntarily initiate a series of professional activities such as writing primary school curriculum units themed on ideas such as two-dimensions – measurement, journaling, drawing, electronic and snail mail. This arose from a typical and very successful example, the web-based project devoted to showing young students how to conceptualize two dimensions with a central fictional character called 'Flat Stanley'. After the provincial collaboration, teachers mount and maintain the curriculum units on an ENO web site. The project is now international with hundreds of schools participating.

Model Classroom Projects - Overview

We have developed several curriculum activities to encourage appropriate use of the Internet by students. These activities have been developed using a basic framework that can be applied to other curriculum projects. All projects focus on problem-solving activities that encourage students to develop enquiry and research skills. These online simulations are based on topical events that have greater meaning for students.

Communication

Communication is a key aspect to all student projects. Participants are provided with an account on the Education Network of Ontario system. We do this in a secure environment. Student access to the ENO system includes the ability to use email, work in moderated conference areas and create web pages specific to their project. This provides for effective on-line communication for all partners in the program. All projects have a unique web site that serves as a place where teachers and students can obtain up-to-date information about the project and activities. These interactive web sites allow for student-to-student conferencing, online mentorship and the sharing of information. Students use a series of web pages to showcase their work.

Access to specific sections of the projects or online simulations is open to the public and other parts of the programs are closed to registered participants. A series of conference areas promote dialogue among elementary students, secondary students and professional mentors. Students are expected to have a basic level of computer and Internet technology skills at the start of the project. Additional skills are gained throughout the project.

Team Web Pages

A unique model for developing team web pages has been created. Basic templates are used in all projects that are simple to use yet effective in their application. Student teams can upload text, graphics and files to their team web sites. These pages are live on the Internet as soon as the work is submitted. There is the ability to have project participants make comments on the team pages and therefore students receive authentic feedback on their work. This allows students to work collaboratively on their project.

Curriculum Connections

All Student Projects are tied closely to provincial curricula. Teachers are provided with a series of matrices that demonstrate the skills and knowledge acquired through the different programs. Evaluation strategies are included in each project to assist teachers as they work with this new approach to learning.

Expert Mentors

One of the most rewarding aspects of our Student Projects is the involvement of expert mentors. These volunteers work in the classroom and online with teachers and students and offer real life experiences for the participants. Mentors participate actively in newsgroups and answer questions from students across the country. University students from many Canadian institutions work in the online environment providing feedback to the younger students as they make their plans. The involvement of experts in the field of science, technology and engineering provide authenticity to the programs. Several projects use secondary level students as mentors for elementary students. This cooperation between schools enhances the understanding of the concepts being covered by both groups of students.

Examples of ENO Student Projects

I will describe three ENO Student Projects to illustrate our successful approach to online learning.

Community Project

This online simulation activity is aimed at students at the middle school level. Students are presented with the challenge of designing and constructing a model Community and Cultural Centre in the community of Enoville. In order to have their construction companies considered for the project, student teams (an engineer, architect, land developer, and town planner) must complete a community profile of their local area. This is submitted online to the virtual "municipality" for approval. Once approval has been gained, students must complete a series of tasks throughout the project including a Public Meeting utilizing videoconference technology.

The Planning Process for the students is as follows:
- Create a Design Company
- Develop a Local Community Profile
- Examine the Enoville Profile
- Determine the Location of the Community Centre
- Submit a Formal Proposal
- Present their Materials at a Public Meeting
- Complete the Master Planning Process
- Present their Materials at a Second Public Meeting
- Construct the Community Centre
- Open the Community Centre through a Virtual Ceremony

Student construction companies use their web pages to showcase their work. As students work through the planning process, they are able to show their work through the Internet and get advice from the online community as their plans for the local centre are developed.

Throughout the 8-week project, secondary school students and professionals in the community mentor elementary school students. These roles include engineers, land use planners, members of the local municipality and staff at various government agencies. They provide feedback and advice to the construction companies at all stages the program. This is a vital component of the program and serves as a model for online collaboration and partnership. It provides teachers at the elementary school level with a way of working with experts in the community. They can also benefit from the expertise of the High School students who are experts in urban planning and geography. This mentoring is done by email, by answering questions in the newsgroups and by making comments directly on the students' web pages. This interaction provides authenticity to the project. All groups benefit in this arrangement and the younger students gain valuable feedback on their work.

Canadian National Marsville Program

One of our largest projects involving 4,000 students and teachers across the country is a complete online and face-to-face environment, the Canadian National Marsville Program. It is a content, activities and teacher professional development project based on the concept of intermediate-level students creating a living environment for themselves as pioneer astronauts and settlers of Mars. Students work through four months of content and activities about their survival. They upload team mission patches and then their air, water and food supply system drawings to their team's web pages. They access mentors' comments from Spar Aerospace and the Canadian Space Agency. They communicate with one another as they improve their devices and prepare for the final 'link-up' day. Using this on-line environment prior to the face-to-face event enhances classroom learning. It is not an add-on or a distracter for offline activities.

The Canadian National Marsville program is an Internet-based simulation of the first colonization of the planet Mars. Student teams from Grades 5 to 9 are assigned the task of creating a self-contained settlement on the planet that will allow them to conduct scientific and engineering activities while on the planet. The program runs simultaneously in several centres across the country. It runs from late January until the final Link-Up day event on April 28, 2001.

As part of the cross-Canada Marsville program, students work in teams in their classes and communicate through Internet connections with their counterparts in other regions of the country. Scientists and engineers serve as mentors and work directly with teachers and students in the classroom and on-line as they design their version of the settlement on the red planet. The success in the completion of the program depends on cooperation and teamwork. Throughout the activities, students are provided with opportunities to share their experiences and knowledge with their peers as well as with a wider audience.

I'll describe each of the two phases of the program.

Phase One - Preparation for Mars

Marsville encompasses educational activities inside and outside the classroom. Students are assigned roles within the context of the larger Martian settlement. Mission teams solve simulation-based problems using the Marsville materials. Each team of 6-8 students must design and construct a working model of one of the nine life-support systems required for the settlement.

In order to live on Mars, students must find out more about the planet. They learn about the atmosphere, terrain, climate and the complexities of living in this environment. Once they are familiar with the harsh conditions of the planet, they are able to start to plan their life-support system for the settlement. Student teams must discover how their life-support system operates here on Earth. They conduct research in their own local area and contact local community members for assistance. Student then gather information from other Canadian sites in order to discover the diversity of the country and the need to take many issues into account while designing their system. They use Internet to share ideas with students across the country.

Each mission team is partnered with two teams from nearby schools. These three teams comprise a Habitat Crew, communicating with each other through written and electronic means only. The Habitat Crew is responsible for cooperatively designing and constructing their section of the settlement that will house them on Mars. They will be responsible for building a large dome for their crew when they arrive at the Marsville settlement. These teams do not meet until the final Link-Up day event at the conclusion of the research stage. Their planning has taken place over the Internet! This stage lasts approximately 10-12 weeks.

Phase Two - Link-Up Day

On April 28, 2001 all the mission teams in each of the Canadian sites gathered to construct their own Marsville settlement. Crews set up their physical solutions to the specific Martian biological or social system previously assigned to them. Students shared their problem-solving strategies, successes and challenges, and worked on their final project - the governance of Marsville. On Link-up Day (LUD), the Canadian sites were connected through videoconferencing systems allowing the explorers to "meet", on-screen, their fellow space travelers across Canada and to compare solutions.

Throughout the Link-Up day, each site was able to use the Internet Cafes set up at their location to communicate with other Marsville explorers. Students used digital cameras during the day to take pictures of their habitats and system designs to show others what is happening in their part of the settlement. These digital images were posted on the CNM web site as they were taken and broadcast to all the Canadian sites. This live interactivity means that students can work in real-time to compare their Marsville activities. In addition, parents and community members who were not able to attend the actual event were able to watch the progression of the Marsville colonies. The event now has a global audience with the inclusion of these Internet activities.

Robotics Challenge

The Robotics Challenge is a unique multi-year educational project aimed at students in grades four to twelve. It provides opportunities for students to learn about science, technology, math and design through the development, programming and testing of autonomous robotic devices using the LEGO ROBOLAB materials. Funding has been provided through the Ontario Ministry of Energy, Science and Technology's Youth Science and Technology (YS'nT) project. The Challenge is a joint initiative with Ontario School Boards, Spectrum Educational Products and the Education Network of Ontario. Over forty School Communities will be involved by the end of 2003

A large professional development component is included as an integral part of this program. In the first year of the project, twenty-two lead teachers from across Ontario will use the ENO web site to discover how to use the ROBOLAB materials in their classrooms. An online tutorial, conference areas and team challenges will ensure that teachers are successful. Videoconferencing cameras will be used to enhance this online training. The following year, these lead teachers will mentor additional teachers from other school communities.

A variety of regional events are planned to provide opportunities for students to demonstrate their skills with ROBOLAB. Online events will include team challenges, data collection and sharing of programming knowledge.

Research

In all of this activity, ENO is in varying degrees enabling personal, small group and province- and nation-wide professional development. One of our projects involved developing on an on-line course about telecommunications and writing for the technical environment for senior secondary students in English or Business Studies. We found that there were two distinct types of professionals at this time. The creation of modules of a course requires a tremendous amount of design, content knowledge and technical skill. Many teachers could create small modules of engaging material. However, the ability to knit together usable modules for online and fact-to-face which would withstand scrutiny was not a part of every interested teacher's agenda. Those who had deep skills and interest were interested in operational structures for courseware, markup standards such as SGML and XML that would produce a stable course framework, testing procedures that involved feedback from students, and Intranet applications such as newsgroups and chat to support 'classroom routines'.

A second research project involved working with and training aboriginal moderators for newsgroup systems since their population is widely distributed in far northern rural and urban areas and much of their education and community practice depends on online access and newsgroups. The adoption of our multi-display and access newsgroup system is evidence of our success. We are also technical partners developing dynamic and managed caching systems for groups like them with limited resources and digital access in our far north.

Research such as this has led The Education Network of Ontario to be a member of the client community for the TeleLearning Network of Centres of Excellence program and corporation. We are now represented on the Board of Directors and are serving as Chair of the Board. We are working on an agent-based portal and professional portfolio project for individual and small group educational professional development. The research reports and 'lessons learned' from this virtual network of researchers inform our practice and development at every turn.

Partnerships and Sustainability

Because our budget is overwhelmingly involved in the accomplishment of our core activities, we use technical research partnerships with organizations such as Group Telecom, Cisco, Virtual Talker, and Telus to work toward our objectives of seamless and intuitive access to industry-standard and integrated applications such as Voice over IP and interactive video.

Our work with the Ontario education community has burgeoned to other Ontario and Canadian government ministries and jurisdictions. This gives us economy of scale and allows us to move services through a developing spectrum not dependent on individual contracts.

We are called upon to export our expertise to work with education in Jamaica and China. We are using our experience as the model for integrating technology into the new secondary curriculum in Brazil. This will involve four projects in all of the provinces and with nearly one hundred schools and hundreds of teachers over the next three years.

All of this creates a healthy and knowledgeable corporation able to develop and offer vertically integrated services to communities, professional groups and government ministries and agencies.

XML-Based Content Object Reference Builder

Paul Bohman, Utah State University, USA; Shane Anderson, Utah State University, USA; Jeff Isom, Utah State University, USA

The challenge is to create a truly useful Web-based reference resource that can house massive amounts of content (both informational and instructional) in various formats, and serve it out in ways that are appropriate for audiences of various levels of expertise in the subject matter. It isn't enough to store information. The trick is to organize it in such a way that it can be found quickly and easily. The purpose of Reference Builder is to create just such a system. The end-user is able to get in, obtain the necessary knowledge, and get out. The user could also choose to linger a while and participate fully in the instructional modules. At any time the user can contribute to the community by posting messages on the site. Finally, when the user returns, all of that user's highlighted sections, bookmarks and notes will be intact, thus truly becoming a personalized resource that will be used again and again.

Experiencing the Unseen, the Unheard, the Blurry and the Confusing: Simulating the Experience of People with Disabilities on the Web

paulb@cpd2.usu.edu

Abstract: In an effort to provide a method of inspiring greater conceptual understanding and affective response in learners who are being instructed how to design disability-accessible Web content, the authors created Web-based simulations to provide an environment in which learners can experience some of the same difficulties and frustrations experienced by people with disabilities on the Internet. Built-in instructional augmentations increase the instructional value of the simulations and allow the learners to focus on the most salient aspects of the experience, e.g. the unique challenges experienced by individuals with disabilities on the Internet.

Purpose of the project

The task of learning how to design Web pages that are accessible to people with disabilities is one that requires the acquisition of an appropriate skill set, knowledge base, conceptual understanding of why the task is necessary, and proper motivation. Obtaining the skills (e.g. using a computer, creating Web content) and the knowledge base (i.e. the background information about Web design and disability access guidelines) are requisite to the task, but these elements alone are insufficient to stimulate the conceptual and affective involvement of the learner. Without such involvement, the learner may be able to produce accessible Web content to s ome degree, but may still not understand why it is important to do so, or may make faulty assumptions based upon rote knowledge, rather than on a true understanding of the principles that make Web content either accessible or inaccessible to individuals with disabilities. The end result is that the learner may commit errors while attempting to produce disability-accessible Web content. In addition, the learner may question whether the task is necessary at all.

While all aspects of the learning process are important to the end goal of training learners to produce disability-accessible Web content, the focus of this project is on the design of instructional materials that facilitate the acquisition of cognitive understanding and affective motivation.

The reason for choosing simulations

There are many methods that could have been used to accomplish the instructional goal. However, when the end result is one of conceptual and affective response,

> [t]he most effective and efficient and instruction takes place through experiencing realia or models in the presence of a variety of instructional augmentations designed to facilitate learning from the experience (Gibbons 2000).

In this case, simulations are used to model disability types and specific adaptive technologies used by those who have these disabilities. The targeted, somewhat denatured experience offered by these simulations allows learners to momentarily experience the Internet as if they had the specific disability. The simulations can provide insight and a sense of perspective that is otherwise difficult to achieve. Mere explanations do not often carry the same weight as actual experience, even if that experience is only simulated and temporary.

Instructional features of the simulations

The simulations provide exploratory opportunities, to one degree or another, allowing the learner to interact with the environment in a non-linear fashion. Still, because the goal is instructional, some tasks have been given to the learner, and an introduction has been provided, so that the learner has some sense of purpose upon entering into the simulation environment.

In each case, the learner is given a task, or a set of tasks to accomplish. During the course of these tasks, the learner is likely to experience some of the same difficulties and frustrations that people with disabilities often experience. The completion of the assigned tasks is not the true instructional goal. The true goal is to feel, recognize and understand from first-hand experience the obstacles that people with disabilities face on the Internet. In order to ensure that the learner understands the simulation's true goal, an interactive debriefing is conducted at the end of the simulation.

Overview of the individual simulations

Blindness. People who are blind often use software that reads the text on the screen to them. This simulation provides a typical experience of what a user with blindness could encounter when trying to find information on a Web site. The learner is given the task to find three pieces of information. Keyboard commands are used to navigate through the site.

Low Vision. Individuals with low vision use screen magnification tools to enlarge portions of the screen. This simulation demonstrates what the screen would look like to someone who has partial vision. It also allows the learner to zoom-in on certain parts of the Web page to see the effects. Text stored as bitmapped images can become unreadable when magnified.

Color-Blindness. Someone who is color-blind can experience problems finding information on a website if the only indicator for the content is its color. This simulation provides a variety of real-life tasks for the learner to perform, such as choosing the correct route on a color-coded subway map. This task can be virtually impossible for someone who is color-blind. The learner is shown a Web page, as someone with color-blindness would see it. The learner is then asked to select the correct information on the page. Because color is the only indicator for differentiating between the items, the learner is forced to guess.

Cognitive Impairments. Users who are cognitively-impaired may have a difficult time finding information on a Web site. This simulation provides the learner with an opportunity to experience one type of cognitive disability by placing the learner in an over-stimulating environment. The learner is required to find specified information on a confusing site by navigating using the mouse. In addition to navigating, the learner is required to catch dropping bombs by moving a man back and forth across the screen using the keyboard. The simulation also contains distracting background noises. The combined effect of these stimuli creates an environment that makes it difficult for the learner to concentrate on the task of finding the specified information.

Hearing Impairments. The increased use of multimedia on the Web has created challenges for users who are hearing-impaired. This simulation allows the learner to experience some of the problems that a deaf or hearing-impaired learner might encounter. The learner is presented with the task of finding information on the site. The learner navigates through the site using the mouse, however much of the essential navigation content is in audio format only. While this can create an entertaining effect for most users, it makes the sight unusable to users who cannot hear. To create this effect, the audio portion of the site is turned off and the learner is forced to make a guess about what the links are for. The simulation also includes a task to find information from a news story that has no audio.

Motor Impairments. Motor impairments can make it difficult for individuals to use a mouse. In addition, users with motor impairments often use specially designed keyboards to input information. This simulation provides the learner with an opportunity to experience what an individual with motor impairments might deal with when filling out an on-line form. The learner is provided with a simulated alternative keyboard to use while entering all the data. In addition, there is a simulated trackball mouse. The use of these simulated adaptive technologies causes the learner's mouse pointer to move in a haphazard fashion, similar to the labored muscular movements of individuals with some kinds of motor disabilities. This causes the learner to miss keys they were intending to hit. In

BEST COPY AVAILABLE

addition, a time limit is set for filling out the form. If the learner does not complete the form in the specified time period, the form will reset itself.

Conclusion

Because the idea of designing Web content with the needs of the disability community in mind is somewhat removed from the everyday experience of most Web developers, it is sometimes difficult to motivate them to design accessible Web content. It can also be difficult to explain to them the logic behind certain accessibility guidelines. By focusing in on certain challenges faced by individuals with disabilities, the simulations provide environments in which conceptual understanding and affective responses can occur.

Abstract: When browsing through an intranet, the browser presents information which is often distributed over a set of many files. These files are then connected via hyperlinks or definitions of frame sets. For an information retrieval system it is very helpful to look at such a set of files as one unit - as a logical document.

Since the introduction of HTML 4.0, it is possible to add logical relations to hyperlinks, but this feature is used very rarely so far. So most HTML files do not contain any explicit information about logical units except the hyperlinks. On the other hand, many HTML files also contain hyperlinks to files outside their logical document. So the problem is to decide whether a set of files is linked strong enough to be looked at as one logical document, where the boundaries of such a logical document are and how to enter it.

In this paper we describe a method to detect logical documents within a collection of files. This method only uses knowledge about hyperlinks within the files and some features of the files like size and the position in a file system (i.e. the full path).

Introduction

The method described in this paper is part of a system called "WIR - Weaving Intranet Relations". The WIR system integrates algorithms and procedures of statistics, corpus linguistics, information retrieval and statistical pattern recognition in order to compute the similarities between all documents of a given collection or between an external document provided by the user and the documents of the collection. (Bohnacker, 1999 and 2000)

Currently the WIR system runs on an intranet with about 46000 HTML files. Knowing all the similarities between these HTML files, the system may be used as a kind of search engine where the user specifies his interests through the document currently displayed in his browser.

The main characteristic of the WIR system is that no external knowledge (lexicon, terminology, etc.), but only knowledge computed from the texts of the collection is used. Working with an early version of the system treating each single HTML file as a document we found that many documents were too small to gain any statistical relevance within the WIR system or to provide any value for the user. They are only useful when embedded in their environment (e.g. a frame set). This environment we call logical document.

Therefore we developed a method to detect logical documents within a collection of HTML files based on the links and frame set definition in these files. A collection of linked HTML files can be regarded as a graph with the files being the nodes and the links being directed edges between the nodes.

The Link Graph

A collection of somehow linked files can be looked at as a graph with nodes representing the files and directed edges representing the links between the files. In HTML a link is coded as hyperlink within a source file and points to a destination file. Since there are different types of links, we have to handle different types of edges. The first task is to transform a set of files into a computable representation of the link graph.

From Hyperlinks to Typed Graph Edges

We create a node for every file in the collection. Then we parse all files. For each node we determine the outgoing links, i.e. HTML links pointing to other files in the collection. We don't handle links pointing out of the collection. For each outgoing link we determine the node associated with the file the link points to (the destination node). The link information is stored twice: For the node where the link is defined (the source node) we store an identifier of the destination node and the link type (see Table 2). For the destination node we store an identifier for the source node and also the link type.

Adding Implicit Edges

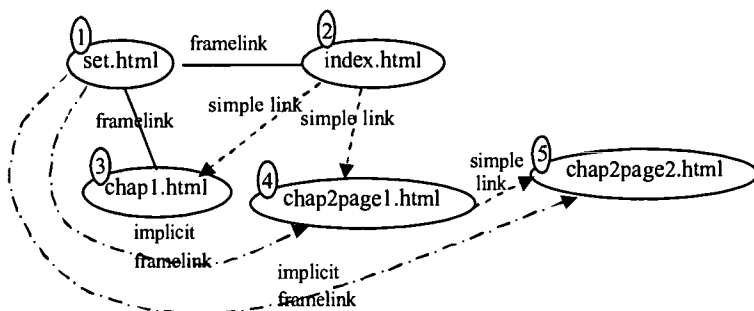
A special problem with links to or inside HTML frames is shown in figures 1 and 2: File 1 defines a frame set, file 2 contains a table of content and appears in the browser window together with one of the files 3, 4 or 5. The frame links define a strong connection between 1, 2 and 3. But although 2 and 4 or 2 and 5 may appear together in the browser window in the same way as 2 and 3 do, there is no strong connection between these nodes, only simple hyperlinks. So a clustering algorithm would perhaps group 1, 2 and 3 together, but not 4 and 5 although 4 and 5 appear in the same context as 3. Therefore we add implicit frame links as shown in figure 3. This approach works for simple frame sets as well as for nested frame sets and for frames referred to from multiple files defining frame sets.
Figure 1: A typical frame set as displayed in the browser window
Figure 2: Links in the frame set


Figure 3: Links in the frame set with implicit frame links

From Typed Graph Edges to Weighted Graph Edges

When examining how HTML files are organized, we found the following statements to be true in most cases:

1. Files in the same frame set have a strong relationship, because a user can see them at the same time in the same browser window.
2. Files in an iframe (=internal frame) also have a strong relationship to their surrounding documents, but not as strong as frame sets, because usually an iframe is more an independent region.
3. Files linked with a simple hyperlink are not related as strong as files in a frame set.
4. Files with bidirectional hyperlinks - file A has a link to file B and file B has a link to file A - are related stronger than files with a simple unidirectional hyperlink.
5. If two linked files are on the same server in the same directory, they are related stronger than files in different directories. The larger the path distance between two files the weaker is their relationship. Two linked files on

different servers only have the weakest relationship at all. The path distance is the number of directory changes necessary to get from the directory of file A to the directory of file B. Examples are shown in table 1.

6. If the logical links as defined in HTML 4.0 are used, the files have the strongest relationship at all.

file_A	File_B	path distance
/dir1/file_A	/dir1/file_B	0
/dir1/file_A	/dir1/dir2/file_B	1
/dir1/file_A	/dir2/file_B	2
http://server1/file_A	http://server2/file_B	9 (=max.)

Table 1: Examples for path distances

Once the graph is built with typed edges, the edge types are transferred to edge weights using table 2 as lookup table. This table shows the weight of an edge depending on its link type and the path distance. The weights in the table consider the six rules stated above.

typed edges \ path distance	≥3	2	1	0
unidirectional hyperlink	1	2	3	4
bidirectional hyperlink	2	4	6	8
iframe link	3	6	9	12
frame link, indirect frame link	4	8	12	16
logical link (HTML 4.0)	5	10	15	20

Table 2: Look-up table to transform path distance and link type to a weight

Detecting Subgraphs

A subgraph is a set of linked nodes in the link graph that have stronger links between each other than with their neighboring nodes not in the subgraph. Such a subgraph is considered to represent a logical document. So the task is to divide the link graph into subgraphs (top down approach) or to cluster the nodes of the whole link graph together to subgraphs (bottom up approach). When detecting subgraphs we have to consider the following aspects:

1. We have to define criteria to value how good a hypothesis for a subgraph is. These criteria are modeled as a combination of fuzzy functions (see Valuation Functions). Some of these criteria are application dependent.
2. We have to find an algorithm that finds a division of the graph into good subgraphs according to the valuation function mentioned above. From the view of graph theory one would prefer an algorithm that finds the optimal solution. However, due to the possible size of the graph - currently more than 46000 files - this is not possible. So we use a heuristic straight forward algorithm looking only one step ahead to find a good solution without running into combinatorial problems.
3. Obviously there are many files already representing a logical unit, even if they contain some links to other files. Therefore we prefer a bottom up approach starting with each file being a logical document.

Best Edges First

The idea of the *best edges first algorithm* is that in general the nodes connected with the highest weighted edges are the best candidates to merge to a logical document. Therefore if we process the edges in the order of decreasing weights, we have a good chance to avoid ambiguities at an early state of the algorithm and later these ambiguities will either have disappeared or − if solved in the wrong way − will not lead to further errors because they are processed near the end of the algorithm. In the following we summarize the algorithm in seven steps:

n is the number of nodes $\qquad$ i and j are nodes
(i,j) is the edge from node i to node j $\qquad$ $D_1 \ldots D_m$ are hypotheses for logical documents, i.e. sets of nodes

1. From the link graph create a *list of edges* sorted for descending weights
2. Create n logical documents, each containing one node in the link graph.
3. For each node set a *reach_all* flag. This flag means that from this node all other nodes in the logical document can be reached via links. This is true so far because all logical documents contain only one node.

4. Take the next edge *(i,j)* with *(i ∈ D_k) ∧ (j ∈ D_l) ∧ (k≠l)* from the list of edges that fulfills the condition that the *reach_all* flag is set for node *j*. This condition ensures that there will be at least one node in the union of D_k and D_l from where all other nodes can be reached. The algorithm terminates if there is no more edge left satisfying this condition.

5. Value the union of the two sets D_k and D_l using the valuation function f_{VAL}, see below.

6. If the valuation exceeds a threshold *minval*, merge the logical documents D_k and D_l to logical document D_{kl} and update the *reach_all* flags of all nodes in D_{kl}.

7. Continue with step 4.

Valuation Functions

As described in the algorithm in step 5, we have to provide a valuation function f_{VAL} that values the merging of two sets of nodes – i.e. candidates for logical documents – D_k and D_l to a union set D_{kl}. f_{VAL} is modeled as a combination of the fuzzy functions described below.

Weights of all Edges: f_1

An important criterion are the weights of the edges between nodes inside the merged set D_{kl}. The valuation function uses the sum of the weights in relation to the number of nodes. This is not the same as the average weight, because there may be much more edges than nodes, what makes a logical document more likely.
$$s = \sum_{inner\_edges} edgeweight$$

n = number of nodes in D_{kl}

maxweight = highest possible weight of a link as defined in table 2

Figure 4: Fuzzy function for the weights of all edges

Number of nodes: f_2

A logical document may consist of 1 up to ~100 files. Logical documents with several hundreds of files are not very useful. Of course this criterion depends very much on the application.
n = number of nodes in merged logical document D_{kl}

$x1$ = threshold where it becomes unlikely that a logical document consists of so many nodes

$x2$ = threshold where the certainty for a logical document does not decrease any more

Figure 5: Fuzzy function for the number of nodes

Amount of Text: f_3

Another criterion is the amount of text collected in a logical document. This again depends very much on the application and is correlated to the previous criterion:
a = overall amount of text of merged logical document D_{kl}

$x3$ = minimum amount of text in a logical document

[x4,x5] defines the optimal range for the amount of text

$x6$ = threshold where the certainty for a logical document does not decrease any more

Figure 6: Fuzzy function for the amount of text

Weights of Connecting Edges: f_4

The weights of the edges connecting D_k and D_l is another important criterion: The rating function uses the sum of the weights of the edges connecting D_k and D_l in relation to maximum weight of a single edge as defined in Table 2.
$$c = \sum_{connecting\_edges} edgeweight$$

n_k = number of nodes in D_k
n_l = number of nodes in D_l
maxweight = highest possible weight of a link as
defined in table 2

Figure 7: Function for the weight of the edges connecting D_k, D_l

Nodes with Incoming Edges: f_5

Typically only one or a few files of a logical document are refered to from outside the logical document. Therefore if many nodes in set $D_{k,l}$ have incoming edges, this set is probably not a valid logical document. Anyhow, it may be a valid part of a logical document that can later merge with the other parts. So we have to take into account later – when combining the fuzzy function (see subsection 3.2.6) – that this criterion is only valuable when it is obvious that the set should not grow much more through future merges.
i = number of nodes with incoming edges in $D_{k,l}$
$x7$ = threshold where it is absolutely unlikely that
$D_{k,l}$ is a valid logical document

Figure 8: Fuzzy function for the number of nodes with incoming edges

Combining the Fuzzy Functions $f_1 ... f_5$

To value the merging of D_k and D_l to $D_{k,l}$ we combine $f_1 ... f_5$ as shown in the formula given below. We take the mean of f_2 (the number of nodes) and f_3 (the overall amount of text) because these two functions are correlated and should not become too dominant. We take into account that f_5 is valuable only with large sets by multiplying it with $n/x1$ and compensating this loss by adding $(1-n/x1)$. As defined in subsection 3.2.2, n is the number of nodes in $D_{k,l}$ and $x1$ is the number of nodes where a logical documents becomes unlikely.

$$f_{rate} = f_1 * \frac{f_2 + f_3}{2} * f_4 * \left(\frac{n}{x1} * f_5 + \left(1 - \frac{n}{x1} \right) \right)$$

Parameter Settings

The free parameters of the method are ...
* ...the weights of the links as defined in table 2
* ...the variables $x1 ... x7$ defining the fuzzy functions. The following settings lead to good results within WIR
    - number of nodes: $x1 = 25$, $x2 = 75$
    - amount of text in logical document (number of characters): $x3 = 20$, $x4 = 100$, $x5 = 10000$, $x6 = 200000$
    - maximum number of nodes with incoming edges: $x7 = 5$
* ...the threshold *minval* for the minimum valuation allowed for a logical document (see Best Edges First, step 6). Within the WIR system, *minval* = 0.5 leads to good results.

Finding the Core Node

In HTML it is necessary that each logical document has one node - the core node - that defines an entry page for the user to browse the document. A core node should fulfill the following criteria:

- All other nodes of the logical document must be reachable from the core node via links inside the logical document. So a user can browse the whole document without leaving it, starting with the core node.
- A core node should be reachable from outside the logical document. The more links point to a node from outside the logical document, the more likely it is the core node.
- Another criterion for a core node is the position of the corresponding file (the core file) in the directory tree: Typically the core file is in the same or higher directory as the other files, i.e. the more often the path of a candidate for a core file is part of the path of other files in the logical document, the more likely is it the core file.

These criteria are again modeled as fuzzy functions and then combined using methods of fuzzy logic. All nodes of a logical document are valued with this combination of functions and the best node is considered to be the core node.

Implementation, Test and Evaluation

The method described above is implemented in ANSI C, integrated into the WIR system and runs on Windows NT and Linux. We used two independent sets of HTML files to adapt and test the method:
- Set 1 is an intranet consisting of 46750 HTML files. We adapted the parameters manually for this system to get best possible results. This is also the intranet the WIR System is currently running on.
- Set 2 is an extract of 17248 HTML files of another intranet we used to test the system without adapting.

So far we don't have any objective measure to evaluate the results. For each set we manually evaluated the 50 largest logical documents and 50 logical documents randomly chosen from the remaining documents consisting of at least 2 files. We divided the results into three subjective categories good, still ok and bad. Table 3 shows the results of the evaluation described above: Row 3 and 4 show that with set 2 (no adaptation of parameters) the method has trouble with large logical documents while small logical documents are almost good. These large documents are mostly frame sets grouping articles in archives. Many of these articles don't have any relation as regards content.

On a 900 MHz PC the generation of the link graph for Set1 and Set 2 took 12:49 min resp. 3:38 min. Detecting subgraphs and core nodes took 4:44 min resp. 0:11 min.

		Good	still ok	bad
set 1 (46750 files)	Largest 50	40	8	2
	Random 50	39	6	5
set 2 (17248 files)	Largest 50	25	16	9
	Random 50	46	2	2

Table 3: Evaluation of the results

Conclusion and Future Work

This paper describes a method for grouping linked files to units we called logical documents. The method currently works for HTML files and may be adapted to other kinds of linked files. The method is quite fast and the results are good, if the parameters are adapted to the domain it runs in. Otherwise the results are still acceptable.

The method can be used within search engines or other information retrieval systems. Such a system can either handle a logical document as one document and just present the core file to the user. This works fine for small logical documents. For large logical documents the system can present an overview about the logical document and highlight or rank relevant parts. Future enhancements may include automatic adaptation of parameters based on statistical knowledge about the domain the system runs in and a better way to evaluate the results.

Abstract: The paper presents different possibilities for implementing a virtual guide, able to assist visitors of a web site. While the user would browse the site, the virtual guide would present him/her small videos presenting the current web page, speaking abo ut the content, the different links or the way to use the different web applications. Another possible use is to guide the visitor along a personalized guided tour, where the guide will lead him/her on one of a certain number of generated paths, presenting for example the different steps for obtaining certain results.

The paper presents two possible implementations for such an application, as well as their respective advantages and disadvantages. The complete application is currently in the final phase of development and is based upon a combination of the two different implementations identified.

1.Introduction

One of the main trends for our present day society is to generalize automatic information processing, by using new technologies, and to globalize information and communication processes, mainly by using information networks. This is known as the information or cognitive society. Within the educational process this process created new needs, offering at the same time new means to face those needs. One can notice the rise and evolution of new methods, based on various information technologies, which aim at offering an alternative instructional support, or even at replacing classical educational methods.

New educational systems should aim at preparing people to integrate themselves in a continually evolving society and a dynamic workforce (see Garito 1996). Those systems must provide people with the capacity to retrain in different other fields when the necessity for this arises. This leads to a change in the educational model, from a tcacher-centered instruction to student-centered instruction. This new student-centered model encourages students to become responsible for their education and to follow individual learning paths, changing the role of teachers (instructors), who are supposed to emphasize cooperative learning and project-based activities (see Microsoft 1999). The teachers become coaches who assist students in using multimedia databases and in navigating through the knowledge available in the Internet. One person should be able to use new technological tools in order to obtain new information, to acquire useful knowledge during a re-training, that he can take whenever he/she deems suitable.

We assist lately at an expansion of the use of Intern et, with more and more servers appearing each day, each of them containing complex content. This makes difficult to find information on the Internet, and quite often inexperienced users "get lost" on the web. Big websites offer a large quantity of informat ion, containing numerous links and often not even an experienced visitor can find the desired information. It seems clear that in some cases it is necessary some sort of a virtual interactive coach, able to replace a real teacher in guiding the

visitor around a website. One cannot expect to have the assistance of a real teacher each time when he is using the Internet, but it seems reasonable to think that he might use a program that will offer similar functionality.

Most websites offering a guided tour today do that using pictures containing screen captures of the site, with different explanations. There are available tools for creating a guided visit of a site, using Real Player or Windows Media technology. Both of them offer synchronization between a video stream and web content, allowing to change the content when the video stream reaches specific points (see Bota 2001 and Real Networks 2000). However none of those techniques offer any kind of user interactivity: the first one is practically a form of a hypertext manual, while the second one can lead the user only on a specific path, without much user interaction.

The authors researched different possibilities for implementing such a virtual guide, able to assist the user. The user should be able to navigate around, while the virtual guide will present him/her small videos of a person presenting the current web page, speaking about the content, the different links or the way to use the different web applications. Another possible use of the application should allow the user to take a guided tour, where the guide will lead the user on one of a certain number of predefined paths, presenting for example the different steps for obtaining certain results. The paths do not have to be defined in advance; the application should be able to generate one specifically for the user, tailored for his/her needs. While the first approach allows a better interaction between the user and the virtual guide, the second one can be used for implementing certain learning tours on using web applications – e-commerce, e-banking, internet search and so on – or for guiding the user around a website, along a recommended path – virtual museum, virtual art gallery, e-learning sites–. One of the requisites of the application was to offer the possibility of use for persons using a low speed connection to the Internet.

The paper presents two possible implementations for such an application, as well as their respective advantages and disadvantages. The application is currently in the final phase of development and is based upon a combination of the two different implementations identified, in order to maintain the main advantages and surpass the possible weaknesses of the different possible approaches.

2. Framework of the application

Since most of the actual web pages are designed to be viewed optimally at a resolution of 800x600, the application was supposed to offer this space for the visualization of the web pages. Considering that beside the web page there has to be shown the video stream and some control buttons, the application uses a window of 1024x600 pixels. This allows dividing the window in three different frames, two on the left – the upper one, *video frame*, containing the video stream and the one below, *control frame*, with the control buttons – and a bigger one, *content frame*, having 800x600 pixels at the right that would contain the web pages and permit the user to normally browse the web pages.
Figure 1: General structure of the interactive visit of a web site

The video streams used for the explanations are maintained in Windows Media format and are visualized with the help of the Windows Media Player. In order to offer the possibility to users connecting at lower speed to use the application a special approach on maintaining the video streams was used. Some website CDs are distributed to the users, each of them containing video files. The same video files are maintained on a video-streaming server, in order to send the video to users that do not have the CD or a specific video on their CD. The video files maintained on the server contains a multiple bit rate encoded format, in order to offer a good quality even on lower speed connections.

In order to present the user with a short video sequence specific to each web page and to allow the user to navigate around, changing the video content when the current web page is changing – usually when the user is following a link – it is necessary a way to detect the current web page and select the appropriate video sequence. For using the application the user is accessing a web page on the CD that is automatically redirecting the user to a web application, passing as well as a parameter the version of the CD. This allows the existence of different versions for the CD containing the video files. The web application connects to a database that maintains information on the locations of the video files – both on the video streaming server and on the CDs – and allows changing the video content whenever is necessary. For each change the application looks up into the database the information for the URL of the current web page and, based on the version of the CD used by the user, is indicating either a video file on the CD or a URL for video streaming (Fig. 1). This technique allows deploying the video content to the supposed users on CD, lowering the necessary bandwidth for the video-streaming server and for the clients. The implemented version check ensure that users having an older version of the video content CD will still be able to use correctly the application.

3. Changing the video stream

In order to correctly change the video stream is necessary to know the URL of the web page currently visualized into the content frame. For detecting the current web page were identified two basic different approaches: client-side (active) and server-side (passive). The first one uses client-side scripting to actively look for a change of the visualized web page, detect and execute different actions when this event is encountered. The second one uses a server-side parser in order to modify the web pages, changing each link to point towards the parser and passing as a parameter the original link.
Figure 2: Passive identification of web page change

In the first case a short JavaScript code checks periodically (each two seconds) for a change into the web address of the content frame and when the page changed connect to a small web program passing the URL of the new page and the version of the used CD. It gets from the program a link to the video content that should be shown into the video frame and changes the video stream of the Windows Media Player object, in order to start playing back the desired video. The main disadvantage of this approach is due to security restrictions of JavaScript: it prevents scripts on one server to access properties of documents on a different server. This restriction is

BEST COPY AVAILABLE

implemented in order to prevent scripts from fetching private data such as directory structures or user session history. In case both the script and the web page are situated on the same server this is not a problem, but if it is necessary to present video content for web pages not situated on the same server this security restriction raises a few problems: in case the pages are situated on servers of the same domain it is possible to modify the origin domain used by JavaScript for security checks to a suffix of the real domain and solve the problem. In case the domains of the web pages are completely different it is necessary to use signing techniques on both pages in order to surpass the problem. While it seems reasonable to consider that in some specific cases this could be a suitable solution – for example the pages are situated on the different national web servers of the same company –, in some other cases this is almost impossible.

The second solution is a passive one, in the sense that each time the page changes automatically a request is sent to the application, that takes appropriate actions. It uses a server-side program that modifies the web pages before sending them to the client. This means that each page shown in the content frame is obtained from the server of the application, and each link is modified in order to point to the application on the server and pass as a parameter the original link. Each time the user chooses to follow a link, the browser will send a request to the server and the application will obtain the original page, parse it in order to identify the links and modify it appropriately (Fig. 2). Below is presented an example of a small web page in the original form and respectively in the form the browser of the user gets it (Tab. 1).

Table 1: A simple web page before and after parsing

The program realizing the parsing (*parse.php*) maintains into the session of the client the necessary information in order to construct a complete URL (protocol, server name, port, path). This way in case the author of the web page used a relative link is possible to create a corresponding URL. The program connects to the web server that hosts the original web page, gets the web page and parses it in order to make the necessary modifications of the HTML code. At the end it sends the modified page back to the client and save the information for constructing a complete URL. The technique works fine for simple web pages, but some specific problems arise with web pages using client-side scripting to change the current web page.

In case the web page uses JavaScript or VBScript to change the current web page it becomes quite difficult to locate the links and change them adequately, since not always the links can be recognized inside the code. Although it is possible to dynamically construct a URL and change to that one the current page, most web pages do not use such techniques. This means that this kind of pages could be parsed correctly. There is a different case when the change of the current page is requested through a plug-in: Macromedia Flash, Real Player, Apple QuickTime, Microsoft Windows Media Player and others are able to generate different actions either as a response to user interaction, or at predefined times during a video playback or a animation. Since the URL for

the new page is contained into the content requested by the plug-in, and the format is usually proprietary, it is practically impossible to change the URL on the fly in order to detect the change of the web page.

Since both approaches have specific disadvantages, probably the best solution would be to use a form based on both approaches. It would be possible this case to use the active approach to detect the changes done by problematic client-side scripting or plug-ins, if the web page is situated on the same server with the application and the passive approach for content situated on other servers or other domains.

4. Pre-defined paths

Beside the possibility to guide the used while he/she is browsing, the application can provide the user a guided visit on the Internet – of a specific site or a group of sites –. The paths can be constructed on the fly, choosing which page to present next after a specific one based on the initial user preferences, interests and so on. For example different visits can be obtained for the same virtual museum: chronological order, based on topics or other motivations.

Before starting the guided visit the application can request the user to specify certain parameters that are used to generate a personalized path for the user. In order to implement different paths is necessary to automatically change the page shown into the content frame when the video stream presenting it reaches the end. An event can be implemented into the video streams, forcing the execution of a piece of JavaScript code each time the video stream reaches a specific point – this case the end of the stream –. The code connects to the application, requesting the URLs for the next video stream and web page on the current path. The application maintains a session with information on the path followed by the user, so that it can choose the correct URLs and send them to the client. Practically the code changes the current page of the content frame to a URL pointing to the application; the browser request the page; the application generates a small web page that contains the code to change the video stream of the Windows Media Player object and to change the visualized page into the content frame.

5. Conclusions

In a simple form the presented application can be successfully used for realizing a multimedia presentation of a web site, distributing most of the band consuming content (video content) on CDs to the end users. It fits well for different companies in order to present their site to potential customers, to familiarize them with the interface and with the facilities offered through the web. It can be used by e-commerce companies to realize a description of the products, so that each time a potential buyer is visiting the page of a specific product, a video presentation of the product can be shown. Since the application supports different versions, it is possible to show a newer video for specific products, offering i n this way the possibility to have a special video in case of promotions.

In a more complete form the application can be used successfully for e-learning, with a professor creating video descriptions of different sites on the Internet, and the students either browsing around and seeing the video descriptions, or taking one guided tour, personalized for their specific needs.

The authors implemented a simple form of the application and a more complete one is currently in the final stage of developing. As soon it will be finished it will be tested on a limited number of topics connected to a course of Computer Programming.

Abstract

Is the current fascination with technology at all levels of education warranted? Are the right questions being asked before technology is implemented into the instructional process? What is the inherent danger in asking the wrong questions? If one wrongly answers the aforementioned questions, the instructional process that technology is intended to enhance will be undermined.

Robert Wauzzinski, drawing on the work of Ian Barbour (1993), describes four viewpoints towards technology – Optimist, Pessimist, Realist, and Structuralist – in *Discerning Prometheus* (2001). One's viewpoint will shape not only one's attitude towards technology but also the types of questions asked concerning the role of technology in the educational process. Drawing on the four viewpoints described by Wauzzinski, the authors will employ a Structuralist perspective in order to (1) suggest the types of questions that should be asked; (2) explore how the use of technology at the elementary level undermines students' professional and higher education experience; (3) recommend means for employing technology in the instructional process.

Introduction

Is the current fascination with technology at all levels of education warranted? Are the right questions being asked before technology is implemented in the instructional process? What is the inherent danger in asking the wrong questions? If one wrongly answers the aforementioned questions, the instructional process that technology is intended to enhance will be undermined.
(It should be noted at that out set that the authors are not Luddites. Each of them uses and employs technology as well as teaching others on its use in the instructional process.)

It is intuitively obvious that very little critical thought has taken place about the role of technology in the instructional process. Professional rags such as *Syllabus* continually hail the virtues of technology with little, if any, regard to its liability. The current rage is to "pilot" online courses. Even pilot programs, as helpful as they may be, still fail to ask the right questions. Robert Wauzzinski, drawing on the work of Ian Barbour (1993), describes four viewpoints towards technology – Optimist, Pessimist, Realist, and Structuralist – in *Discerning Prometheus* (2001). One's viewpoint will shape not only one's attitude towards technology but also the types of questions asked concerning the role of technology in the educational process. Drawing on the four viewpoints described by Wauzzinski, the authors will employ a Structuralist perspective in order to (1) suggest the types of questions that should be asked; (2) explore how the use of technology at the elementary level undermines students' professional and higher education experience; (3) recommend means for employing technology in the instructional process.

In order to put the intent of this paper into perspective it is necessary to provide an overview of Wauzzinski's four viewpoints. We would encourage you to reflect on these categories as they relate to your understanding of the role and place of technology in the educational process. In addition it should be noted that even though one perspective may best describe your attitude towards technology that there is no guarantee it will be employed in the decision making process.

The first viewpoint is the technological **optimist**. The technological **optimist** believes that technology is neutral or value-free. This viewpoint is rooted in a thorough commitment to the autonomy of human reason and an unwavering commitment to the inevitability of progress. The future is always a projection of the good of the present. Human beings are seen as technological innovators; technology should be developed for the betterment of all. (Wauzzinski, 2001) From this vantage point it is only through the employment of technology that all our educational woes will be eventually solved. The **optimists** believe that all schools must be networked and comprehensively employ computers throughout the curriculum. The "benefits" are hailed; questions regarding the liability are not adequately considered or ignored.

The technological **pessimist** believes that technology is inherently evil because it compromises human freedom and that the problems created by technology are insurmountable. The technological **pessimist** would argue that employing technology in the instructional process would ultimately destroy it. One of the ways this has taken place is by emphasizing its "entertainment" value.

The technological **realist** using Reason attempts to view technology from a cost-benefit perspective. The **Realist**, lousing risk assessment, attempts to maximize the benefits and limits the consequences of employing technology. The **Realist** acknowledges that there is always a "trade-off" involved. This perspective will often seek a technological solution to problems encountered and thus is often in danger slipping into the **optimistic** viewpoint.

The technological **structuralist** attempts to view life holistically and believes that technology should complement the whole of life. Technology is considered good by the **structuralist** but often distorted. The **structuralist** attempts to wrestle with the role and place of technology as it relates to all of life. They also believe that technology will play a different role depending on its context. In other words, families are not businesses and thus technology's role will be different in a family than in a business. The Structuralist would ask, "What is education?"; "What does it mean to educate?" The **structuralist** acknowledges that technology shapes those who employ it.

The **structuralist** perspective offers the greatest promise for those willing to wrestle with both the potential benefits and liabilities of employing instructional technology. Please note, the liabilities have not generally been wrestled with until after the technology has been implemented. Sherry Turkle (1997), the MIT sociologist of technology, notes that we have "made a mistake in not discussing ethical and moral issues of technologies before the technology is upon us." Two observations are in order (1) Asking hard

questions about the role and place of instructional technology is hard work; (2) Not asking the questions explicitly is not an option, too much is at stake.

Asking the Right Type of Questions

There are five fundamental questions that must be posed before one even begins to consider the use of instructional technology. They are:

These questions are complex and difficult to answer. Adrian Dupuis in *Philosophy of Education In Historical Perspective* notes that the lack of an agreed upon definition of education makes educational reform impossible because no one knows what they are actually reforming because for "the most part they repeat, sometimes in different words, the clichés of decades ago." (1985) In spite of the challenge the above-mentioned questions cannot be ignored.

For example, I [DG] find PowerPoint to be a helpful tool in organizing and preparing lecture notes. I also find it helpful, sometimes, as a visual aid when lecturing. In general, I find it to be a straightjacket when used in the classroom. PowerPoint enslaves one to a particular order; it robs one of flexibility and sucks the dynamism out of the student-teacher relationship. It focuses student attention on "getting the data" rather than tracking with larger themes and questions posed by the material. And though the handouts produced are helpful, students become enslaved – more concerned with what slide one is on rather than the larger themes and questions posed by the material.

Instructional technology is not the guilty party. It is the educators who see it a panacea for addressing the current educational crisis – whether real or perceived. The hard questions are only beginning to be asked, and the real issues addressed. The virtual world is not the same as the real world. Virtual relationships are not the same as real relationships. Painting on the screen is not the same as finger-painting on butcher paper. It is not an inadequate substitute.

The hard questions must be asked. If technology is not properly employed, the results will be disastrous and the educational process and establishment will be further undermined. Raising the hard questions does not make one a naysayer; it stimulates one's thinking about instructional technology and how it might complement the educational process rather than undermine it.

Now that we have suggested the types of questions that should be asked our attention will turn to how the use of instructional technology at the elementary level serves to undermine the students' professional and higher education experience.

Technology in the Elementary Context

What is the definition of education and what are the effects of the computer on the developmental, behavioral, and physical needs of children? Experts (Kelly, 2000) are beginning to speak out against early computer use. They say that too much use, too early, "may actually undermine the development of the critical skills that kids need to become successful, diminishing creativity and imagination, motivation, attention spans, and the desire to persevere" (Kelly, 2000).

What is the definition of education and what are the effects of the computer on the developmental, behavioral, and physical needs of children? Experts (Kelly, 2000) are beginning to speak out against early computer use. They say that too much use, too early, "may actually undermine the development of the critical skills that kids need to become successful, diminishing creativity and imagination, motivation, attention spans, and the desire to persevere". (Kelly, 2000). states that it is his belief that knowledge is the development of children's capacities in ways that enable them to become active and constructive participants in the life of society. Anne Alpert, principal, says that she can tell from afar which of the younger students are home-computer users and which are computer-free. The computer users are less inclined to take the small risks that build competence and creativity and more likely to have trouble negotiating the politics of the playground. The computer-free students, who spend hours doing old-fashioned activities like playing dress-up and reading books, are social and outgoing, curious, and work well in groups.

What is knowledge and how does the computer fit into the development of skills children will carry with them through the rest of their lives i.e. language and socialization, the ability to organize thoughts, the concept of cause and effect, problem-solving, creativity, imagination, self-motivation, and self-confidence? There are many theories/philosophies concerning knowledge, but if we consider how knowledge relates to conduct, Dewey (1916) contends that knowledge that does not affect conduct is of little or no value. In his essay "My Pedagogic Creed," published in 1897, he How do people learn and how does the computer fit into the essential learning, which requires experience, experimentation, reflection, and hands-on observation?

What is the nature of the teaching-learning process and how does the two-dimensional format of computers fit into the child's "real world"?

What is the role of the teacher/instructor in the process? Sherry Turkle states, "Too much of the time we think the computer is supposed to do it all, and we don't really appreciate how important the people are…It's the computer plus the human environment around the computer that matters."

Conclusion:

There is scant evidence that computers teach basic skills any better than traditional methods, or that children who don't have computers are somehow "left behind." Conversely, there is abundant evidence that an uncritical infatuation with computers as an educational panacea is replacing skill building and learning with formless play while forcing art and music lessons, and in some cases math textbooks, off many school budgets. (Healy, 1999)

Longtime educator and administrator, Healy is actually a fan of computers. But she is dismayed that so many people in and out of education hold the almost religious conviction that computers in classrooms equal better learning experiences. Making children computer literate, she argues, in no way guarantees they will develop the cognitive skills they need. In fact, she presents much evidence that computers can help children disconnect intellectually, emotionally, and socially. When examining Childs Growing Mind, 1990., who contends that, in our fervor to embrace computers, we have overlooked their potential to harm youth, particularly young children. Drawing on extensive interviews with school administrators, teachers, parents, and children themselves, Healy concludes that the problems caused by excessive computer use are staggering: Among regular users, for example, visual impairment is now the norm, and hard-core cyberchildren, lacking sufficient physical exercise, as a result also grow up less fit mentally than their parents. Even more disturbing is the potential impact on brain development, since the processes of thinking aloud, questioning, creative problem-solving, and communicating will be inevitably downplayed by those who rely on computers to process data. Despite the shrill alarm she sounds, Healy doesn't dismiss computers outright, and she maintains that, used moderately and guardedly, they can enrich young people's lives:

When 125 ``at-risk" students in New York City were given home computers with online hookups, for example, Internet-research began to substitute for television viewing and severely withdrawn pupils began to communicate with one another online. For in-school use, the perfect model, in Healy's view, is the Gold River Discovery School outside Sacramento, Calif. Here, students who use computers are ``continually coached on how to take responsibility and reflect on their learning." Hands-on learning always precedes computer use, and virtual reality is never allowed to take the place of genuine experience. Throughout, Healy intersperses her assessment with p ractical advice: She urges parents and educators to be wary of software that is overly stimulating to the senses alone, to avoid programs that give ``rewards" for completing tasks, and to be on guard that children don't avoid playing with friends in favor of spending more time interacting with their computers. A timely and sensible challenge to the prevalent notion that computers necessarily enhance mental development and learning.

SOME FINAL QUESTIONS:
* When should children start using computers?
* How should schools incorporate computer use into their curriculum?
* Which types of computer software programs should be avoided?
* Are children who don't have computers in class and at home doomed to fall behind their peers?

Designing a Collaboration Environment for Teleworkers

Dipl.-Inform. Iris Braun, Dipl.-Wirtsch.-Inf. Ulf Zschuckelt
Dresden University of Technology
Chair for Computer Networks
D-01062 Dresden
braun|zschucke@rn.inf.tu-dresden.de

Abstract: Teleworking enables a more flexible scheduling of working time and places of work on the way to the modern information society. The rapid development of cooperative application software and electronic networking systems such as Internet and the penetration of web-based applications have demonstrated the enormous potential of technical facilities for new employment models. This paper defines requirements for an effective and flexible collaborative environment supporting coupled work scenarios for teleworking. An important feature of such an environment is to support synchronous collaboration with audio/videoconferencing and data and application sharing between distributed teleworkers. New communicative and collaborative software solutions are preconditions for such scenarios. The article points out the deficits of existing applications and suggest a solution for a meeting point for teleworkers based on our experiences with teleworking in the context of the intermobil project.

Introduction

A number of factors are driving the growth in teleworking. Teleworking is an industry trend that addresses not only business issues but also provides tangible "quality of life" gains for the workforce at large. Teleworking offers a company access to a broader base of qualified employees and reduces corporate overhead in real estate and related expenses. So a "real time" work environment with immediate access anytime, anywhere to corporate information sources can be created. Teleworking may also offer the opportunity for workers to have more choice in terms of where they work and live. As the teleworking trend emerges and evolves, it will ultimately change the current definition of "the workplace". The flexibility of teleworking can offer wide-ranging, powerful business solutions. In our project work we focus at a special kind of teleworking - Telecommuting, where the teleworker variable commute between office and home workplace. Also called alternating teleworking is surely the mostly used form of teleworking because it combines the advantages of teamwork in an office with the flexibility of homework.

Problem Description

To tide over the local distribution teleworkers can interact with others by text based communication like instant messaging or chat and finally by an audio/video conference with application and data sharing. At the different working locations they can be connected with the internet via Ethernet, ADSL, ISDN or analog modem. If their work requires cooperation with other team members the following problems can be detected:
- it is often unknown, on which place the teleworker operates at the moment and which communication tools he could use (depending on the available equipment of the working place like video cameras etc.)
- simultaneous communication with several teleworkers requires a very high co-ordination effort using different other telecommunication channels like email or telephone before the properly collaboration can start

Requirements to a collaboration environment for teleworkers

If all teleworkers are equiped with the necessary infrastructure (Internet binding) and required hard and software, theoretically each teleworker can initiate a video conference with each other teleworker. But the teleworker has to know:
- whether the communication partner is linked over the network at all
- which communication tools he could use (video camera, microphone, etc.)
- the IP address of the computer of the communication partner

So it is necessary to communicate over other telecommunication channels like email or telephone to get this information before the real collaboration can start. The communication partners notify their current position over this channel by transmitting their IP addresses and the tools they want to use. The main requirement for a

collaboration environment is to provide this necessary information for all teleworkers. For this purpose the following requests exist:
- the collaboration environment can be used from any workstation which is connected to the internet
- each Teleworker can detect immediately who is reachable at the moment
- he can choose a communication tool to collaborate immediately with any team member without the assistance of other communication channels

Initial stage for solution

For managing the communication relations between the distributed partners a meeting point for working groups is needed. Such an application can use the mechanism of a directory service on a central system which is always reachable under the same network address. Such directory services already exist at the market but they provide countless functionalities which are not necessary for an effective application. For effective collaboration systems are required, which provide only the absolutely necessary functions and are fast and simply controllable by the user. For this reason an server system is needed, which takes over the functions of a communication head office. This server application has to provide the following functions:
- receive and store the communication parameters (IP addresses, status etc..) of each teleworker
- publish the current communication parameters of all Teleworker
- administration, release and blocking of the provided collaboration services like multipoint video conference system (MCU) or document sharing

The Client of the collaboration system at the teleworkers side should support the following functions:
- cyclic transfer of the communication parameters to the head office
- starting a collaboration session e.g. a video conference to one or more team members using the communication parameters provides by the meeting point

Implementation

An solution for this problem can be a web-based client-server-system which integrates several collaboration tools. The client logs on at the server and send frequently his parameters over a special TCP-Port to the server. The server application use a central database to store and manage the communication parameters of all teleworkers. If the server won't receive any data from the client, he will send an request of acknowledgement and then mark the teleworker as logged out from the system. This type of session management facilities might be enough to control the participated teleworkers. Using a html-form the teleworker can request the communication parameters and status of any other team member logged on at the system. For easier handling the solution should integrate several collaboration tools e.g. as COM+-applications like NetMeeting. At the client-side ActiveX controls can be used for starting the communication applications directly from an WWW browser site. At the moment we are developing and testing several implementations based on the explained concept.

Conclusion and future work

Related work shows that the new dimension of coupled work in teleworking scenarios becomes more and more important and that tools already exist to support synchronous communication. But the requirement of a general-purpose environment supporting effective and flexible collaboration between mobile and location independent teleworkers is not fulfilled by these systems. Therefor we defined the requirements to an collaborative environment for teleworkers and developed an universal solution for a meeting point. Implementation and testing of the applications under practical conditions are now in progress. We are planning to improve the interface between these services and others and to integrate more various collaboration applications.

Using The Balanced Inventory of Desirable Responding to Determine Accuracy of Self-Reporting Instruments: Web-Based Vs. Paper and Pencil

Dawson Hancock, University of North Carolina at Charlotte, USA ; Claudia Flowers, University fo North Carolina at Charlotte, USA ; Marty Bray, University of North Carolina at Charlotte, USA

Along with the World Wide Web's growth as a means of disseminating information it has also become a poplar and economical means of gathering information. This ongoing study attempts to determine the efficacy of the World Wide Web as a data gathering instrument by comparing students' responses to similar Web-Based and Paper-Based survey instruments. This paper describes in detail an ongoing study in which graduate students at a major southeastern university were given a combination of paper-based and web-based survey instruments that measured the likelihood that they would provide accurate responses to a number of questions. At the end of the study a repeated measures statistical analysis will be conducted to determine the efficacy of the web-based versus the paper-based instrument.

Effects of Direct Vs. Non-direct Instruction
In a Teacher Preparation Technology Class

Abstract: This paper describes a study that is currently under way to determine the efficacy of direct versus non-direct instruction in a teacher preparation technology class. The study will examine five sections of the target class. During the first week all students will receive a pre-test and a motivation assessment. Both classes will be conducted using the same instructional techniques until the last third of the course when one module will be modified. Three of the sections will receive indirect instruction while the other two will receive direct instruction. A posttest will be administered to all of the sections. Once all data are collected, researchers will produce descriptive statistics to show the means and standard deviations of students' scores on the PCM instrument, MSLQ, and achievement test. Two 2x2 ANOVAs will be calculated to evaluate the hypothesized interactions. Follow-up analyses will be performed as needed to evaluate differences between cell means.

Introduction

This paper describes a study that is currently under way to determine the efficacy of direct versus non-direct instruction in a teacher preparation technology class. Given the number of technology related teacher preparation classes currently being offered in colleges of education across the country the need to determine and describe effective instructional strategies is of the utmost importance. This study will examine the effects of students' conceptual levels and teachers' instructional strategies on students' motivation and achievement in a computer technology course. In this paper the conduct of the study will be described.

Participants

UNC Charlotte undergraduate, post-baccalaureate, and graduate students enrolled in EIST 4100/5100, an introductory computer technology course, will participate in this study.

Procedures

Five sections (3 sections during spring 2001 and 2 sections during first summer session 2001) of relatively equal size will be taught by either direct instruction or non-direct instruction

During the first class, students will be given approximately twenty minutes to complete the Paragraph Completion Method (PCM) instrument (Hunt, Butler, Noy, & Rosser, 1978) for assessing conceptual level. This instrument instructs students to write at least three sentences in response to a series of items that indicate how a person handles conflict and uncertainty and how that person thinks about role structure and authority. The manner in which a person completes the sentences indicates that person's level of conceptual complexity. Scores may range from "0" (i.e., no conceptual complexity) to "3" (i.e., maximum conceptual complexity). Individuals with high scores tend to show fewer tendencies to engage in bifurcated thinking, greater independence of judgment, greater tolerance of ambiguity, and greater ability to integrate different perspectives than individuals having low scores.

During the second class of week #1, all students will be pretested using the "Basic Technology Competency for Educators" instrument (Flowers, Antonak, & Algozzine, 1997) -- a self-report of basic technology skills -- to assess the equivalence of the sections on technology skills. We anticipate no statistically significant differences ($p > .05$) between the direct and nondirect instruction sections on perceived technology competencies.

The first two-thirds of all classes will be taught in a similar manner using published study guides. However, during the last third of the class, while teaching their students to synthesize and apply the material learned previously during the course, one instructor will use direct instruction in his section and the second instructor will use nondirect instruction in his sections.

Direct and non-direct instruction will be implemented using Cicchelli's (1983) Instruction Pattern Observation Instrument. The instrument describes instruction as direct if the professor: (a) is the dominant leader who establishes and enforces rules in the classroom; (b) structures learning tasks and establishes the time and method for task completion; (c) states, explains, and models the lesson objectives and actively maintains student on-task involvement; (d) responds to students through direct, right/wrong feedback, uses prompts and cues, and if necessary, provides correct answers; (e) asks primarily direct, recall-recognition questions and few inferential questions; (f) summarizes frequently during and at the conclusion of a lesson; and (g) signals transitions between lesson points and topic areas.

The instrument describes instruction as non-direct if: (a) professors are a catalyst or helper to students who establish and enforce their own rules; (b) students are allowed to select the learning task and the manner and order in which it is completed; (c) students are presented with examples of the content to be learned and are encouraged to identify the rule of behavior embedded in the content; (d) professors respond to student work through neutral feedback and encourage students to provide alternative/additional responses; (e) professors ask mostly divergent questions and few recall questions; (f) students are encouraged to summarize and review important lesson objectives throughout the lesson and at the conclusion of the activity; (g) students are encouraged to choose new activities in the session and select different topics for study; and (h) students signal their readiness for transition to the next learning set.

Applying the principles of direct instruction, the first instructor will use prepared scripts to teach during the final third of the class. These scripts will establish all the class rules, all the learning tasks and objectives, and the final product to be created. The instructor will remain the focal point of all instruction. Applying the principles of nondirect instruction, the second instructor will introduce the material to the students and establish broad parameters in which the students may work during the final third of the course. Students will determine the lessons' objectives and goals, identify the important procedures of the course, and take primary responsibility for their own final products.

At the end of the course, students' motivation to learn in the course will be assessed using the Motivated Strategies for Learning Questionnaire (MSLQ) (Pintrich, Smith, Garcia, & McKeachie, 1991). The MSLQ is a 31-item, self-report instrument that may be used to assess college students' motivation to learn in the classroom. Students usually take approximately fifteen minutes to complete the MSLQ.

Following administration of MSLQ at the end of the first class of week #16, students' achievement during weeks #14 to #16 will be measured using a professor-made, performance-based test. The test will require students to produce an electronic product that incorporates many of the tasks taught during the previous weeks. A total of about 20 features will be expected in each student's product. Points will be assigned when the features were present. Students will be given approximately fifteen minutes to complete this test.

BEST COPY AVAILABLE

Once all data are collected, researchers will produce descriptive statistics to show the means and standard deviations of students' scores on the PCM instrument, MSLQ, and achievement test. Two 2x2 ANOVAs will be calculated to evaluate the hypothesized interactions. Follow-up analyses will be performed as needed to evaluate differences between cell means.

Abstract: The Carl D. Perkins Vocational and Technical Education Act of 1998 made the community colleges the point of access for training and education for special populations. Physical barriers are obvious problems that limit access for individuals with disabilities, and community colleges have made reasonable accommodations for individuals with disabilities. However, there are on-line barriers that limit Web-based content that have often been overlooked. This study examined the content accessibility of community college home pages. A total of 253 community college home pages were evaluated for content accessibility. Only 22.1% of the community college home pages were accessible to individuals with disabilities.

Introduction

Access and opportunity have become the hallmarks of post-secondary education. The community college extends far beyond the traditional, limited freshmen-sophomore experience and provides a setting where almost anyone can learn (Parlinchak, 1998). Community colleges serve all citizens and provide a range of services that support special populations. As the number of students continues to increase, especially among special populations, so does the need for support programs and services.

The Americans with Disabilities Act (ADA) of 1990 provides the same civil rights protection to individuals with disabilities that apply as a result of race, gender, national origin, and religion (Button & Wobschall, 1994). Title III of the ADA directs that public facilities make reasonable modifications to control discrimination and support accessibility in policies, practices, and procedures (Council for Exceptional Children, 1994). As a result of this landmark legislation, accessibility alterations such as providing ramps to elevated areas and providing accessible signage through height adjustments and raised lettering have become commonplace across the United States.

The Perkins Vocational Act of 1984 called attention to America's need to support individuals who were less fortunate by birth or economic circumstances. The Act underscored the need for improving vocational programs and serving special populations of students. The Act created an awareness of the population of people that had gone unnoticed with little or no training. This Act made community colleges the point of access for training and education for special populations.

The World Wide Web (WWW) has become an invaluable resource for many people with disabilities. Accessibility across platforms and geographic distance makes the WWW an ideal universal tool for gathering and disseminating information (Heflich & Edyburn, 1998). In fact, it is estimated that 34.4% of community colleges use the Internet to disseminate training and educational programs to special populations (Gibson, 2000). Wong (1997) discussed using the Internet for increased self-advocacy by individuals with physical impairments. It is ironic, however, that while technological developments have enhanced and provided new exciting opportunities for the WWW, they have, at the same time, complicated and limited the accessibility of the content and resources for individuals with disabilities.

Physical barriers are obvious accessibility concerns. Web page developers need to be just as aware that on-line barriers can create significant problems for some users. The Americans with Disabilities Act requires that all organizations make reasonable accommodations for individuals with disabilities. Even though there has not been a judicial ruling on WWW accommodations for individuals with disabilities, home page developers should work towards designing and building Web sites that are accessible to all individuals. It is important that Web page developers use and follow standards that allow accessibility to all WWW users.

A variety of disabilities can reduce accessibility to the WWW. Visual, hearing, movement, cognitive, speech, and other impairments can limit availability of information. Assisted technologies or accessibility aids, such as Braille output systems, keyboard modification, screen enlargement utilities, voice output utilities, and other technologies allow individuals with disabilities to access information on the WWW. However, because of the complexity of many Internet resources, some information cannot be accessed with these aids. Developers of accessibility aids continue to identify and develop features that can overcome some of these barriers, but there are many simple strategies that Web page developers can use with very little effort that would make their services more accessible.

The Trace Research and Development Center at the University of Wisconsin at Madison produced the *Unified Web Site Accessibility Guidelines* (Trace Research and Development Center, 1998). This information was transferred to the Web Accessibility Initiative (WAI) of the World Wide Web Consortium (W3C) and used to produce the *Web Content Accessibility Guidelines 1.0* (Chisholm & Vanderheiden, 1999a). The primary goal of the guidelines is to promote content accessibility. The guidelines do not discourage content developers from using images, video, and other multimedia tools; rather, they explain how to make multimedia content more accessible to a wide audience.

The *Web Content Accessibility Guidelines 1.0* (Chisholm & Vanderheiden, 1999a) is organized around two general themes and 14 guidelines or general principles of accessible design. The themes are (a) ensuring graceful transformation and (b) making content understandable and navigable. The document provides the rationale behind the guidelines and includes some groups of users who benefit when they are applied to Web pages. In addition, a list of checkpoints is provided that explains how the guidelines apply to typical content development scenarios. Each checkpoint is specific enough to be verified, while general enough to allow Web developers freedom to use appropriate strategies.

The guidelines that primarily address the theme of ensuring graceful transformation, Guidelines 1 through 11, assist Web page developers in producing sites that remain accessible despite constraints confronted by people with disabilities. For example, Guideline 1 states that Web developers should provide equivalent alternatives to auditory and visual content. Text can be rendered in ways that are available to almost all browsing devices and accessible to all users, but auditory and visual content are not. Guidelines 12 through 14 primarily address the theme of making content understandable and navigable. This includes providing navigation tools and orientation information in pages with maximize accessibility and usability. Not all users can make use of visual clues such as image maps or graphical information, but with orientation information, users can understand many of these graphical images. The *Web Content Accessibility Guidelines 1.0* document provides much more detail in developing content accessible Web pages (Chisholm & Vanderheiden, 1999a).

Building Web sites that comply with standards for accessibility should be a high priority for Web page developers. To date, little research has documented the extent to which accessibility goals have been reached. The purpose of this study is to examine the accessibility of community college home pages and provide information on making them accessible (if they are not) to individuals with disabilities.

Method

To examine the accessibility of community college home pages a descriptive study was conducted. The sampling technique used to select community college Web sites and the evaluation procedures are discussed in the following section.

Sampling

The population Web sites for this study was community colleges located in the United States. A list of 720 community college Web sites was generated using the search engine *go.com* (2000). A random sample of 260 community college home pages was selected for content accessibility evaluation in this study.

Procedures

Each home page was analyzed using the software package *Bobby 3.2* (Center for Applied Special Technology, 2000), which allows researchers and other professionals to evaluate Web pages in accordance with the W3C Web Accessibility Initiative's guidelines. *Bobby 3.2* produces a summary report that consists of (a) the number of Priority 1, Priority 2, and Priority 3 access errors, (b) user check data, (c) the types of accessibility errors, and (d) the ease in correcting the accessibility error. Priority 1 access errors are problems that seriously affect the page's usability by people with disabilities and the Center for Applied Special Technology (CAST) strongly suggest that Web developer correct these errors. For a page to obtain Bobby Approved rating, the home page cannot contain any Priority 1 errors. Priority 2 access errors are considered important for access but are not as vital as Priority 1. Priority 3 access errors are third-tier access problems that a Web developer should consider correcting.

Some accessibility errors cannot be confirmed using *Bobby 3.2*, but *Bobby 3.2* provides user check data that informs the user that manual examination and human judgment are required for examining a specific area of the home page. For example, when different font colors are detected, *Bobby 3.2* identifies multiple color fonts and reports this as a user check, meaning that it may potentially be an accessibility problem. In this study the user check data was not manually examined but will be reported as potential accessibility problems.

For a full description of the types of access errors see the *Techniques for Web Content Accessibility Guidelines 1.0* (Chisholm & Vanderheiden, 1999b). In this study only the initial home page was evaluated; that is, no links from the home page within the domain were evaluated. Scores for each home page were tabulated and further analyzed.

Results

Of the 260 community college home pages randomly selected for this study, only 253 pages were available for evaluation. Approximately three-fourths (77.1%) of the home pages (n=195) were not approved by *Bobby 3.2* (2000) as content accessible. This indicates that at least one Priority 1 error (seriously affects accessibility) was detected on these pages. There was an average of 1.01 Priority 1 accessibility errors on the community college home pages. In addition, the average number of potential Priority 1 accessibility errors was 8.48.

There were three types of Priority 1 accessibility errors detected on the home pages. Most of the community college home pages (64.2%) did not provide alternative text for all images. A few of the home pages did not provide alternative text for image map hot-spots (17.3%) and did not provide alternative text for each applet (5.5%). All the Priority 1 accessibility errors were rated as easy to correct.

Almost all the home pages (99.2%) did not identify the language of the text. Approximately 90% of all community colleges home pages (a) did not specify a logical tab order among form controls, links, and object, (b) did not provide keyboard shortcuts to links, (c) did not provide a descriptive title to links, and (d) used deprecated (i.e., included elements that have been replaced by newer elements) language features. Using tables in home pages create additional types of accessibility problems. Community college home pages used tables to format text documents in columns (77.2%), did not provide a linear text alternative for tables (81.9%), and did not provide a summary and caption for tables (77.6%). Many of the home pages used movement in their images (78.7%).

Using color on home pages can create problems in differentiating items on the page. Most of the pages needed examining for foreground and background colors contrast (92.1%) and used color fonts to convey information (87.4%). The majority of sites did not use an extended description to convey information beyond what was in the alternative text (84.2%). Again, the inclusion of tables on home pages could create potential accessibility problems. Most of the home pages needed to be examined for the use of structural markup to identify their hierarchy and relationship (80.7%) and examined for the presence of headers for the table rows and columns (72.4%). When scripts are used to convey information or functionality, alternative content needs to be provided (54.3%).

Discussion

Community colleges have played an important role in the training and education of individuals with disabilities. This study provides empirical evidence that most community college home pages are not accessible to individuals with disabilities. With very little effort all the home pages could easily be corrected to eliminate the more severe Priority 1 accessibility errors.

Web developers at community colleges need to examine their Web sites for accessibility problems. It is strongly recommended that validation methods be used in the early stages of Web development, which will help make problems easier to correct and assist developers in avoiding many accessibility problems. There are two suggested methods of validating a Web page for accessibility (Chisholm & Vanderheiden, 1999a). First, automatic tools are available for scanning the site and providing data. Bobby and other validation services should be used to provide information concerning accessibility problems. Automatic tools are convenient but do not identify all accessibility issues, therefore it is recommended that each site be examined by a knowledgeable individual and individuals with disabilities to ensure clarity of language and ease of navigation. The processes of rapid prototyping and formative evaluation have been used for many years to help develop educational software and have recently proven to be useful in the process of Web site development (Corry, Frick, & Hansen, 1997). Expert and novice users with disabilities should be invited to view home pages and provide feedback about accessibility or usability problems and their severity.

Community colleges are leaders in educating special populations. The WWW has become an invaluable resource for notifying special population students of services available at their institution. Creating home pages that are accessible to a diverse group of users would insure the universality of the WWW.

Improving the Performance of CBIR Systems through global Application of User Feedback

Lars Bröcker

Fraunhofer Institut für Medienkommunikation
Schloss Birlinghoven
D-53754 Sankt Augustin
Email: Lars.Broecker@imk.fraunhofer.de

Abstract: This paper introduces a framework that aims at resolving some of the problems CBIR-systems are facing, especially the problem of lacking semantical information from visual primitives. The goal is an improvement of the quality of result sets. This is achieved by making use of user feedback to cluster images into different thematic groups and the global use of feedback (instead of just session-based use of feedback). The framework is designed to be usable with any CBIR system, since it is implemented as an interface between user and system. Evaluation results of a prototypical implementation are given.

Introduction

Content-based image retrieval is receiving much attention because of the ever growing amount of images available in digital formats. Many of these images are not supplied with metadata so that there is no possibility to query the collection using customary techniques. The cost needed to provide a document with descriptive metadata is on average 3.63 $ US according to [Roderick 1999]. This average holds for images too, since an adequate and encompassing description of an image needs at least as much time as writing a summary for a text document.

CBIR is an alternative to the expensive creation of textual metadata. CBIR systems usually compute a *signature* comprising of the values for a varying set of *automatically* extractable features for each image. These features typically include color histogram and texture data or shapes easily recognizable in the images. Because these features make no assumptions about semantics they are often called *visual primitives*. Only the signatures are compared in the course of a query to the system.

The biggest problem of today's CBIR systems is the *semantic gap*. This name outlines the fundamental problem inherent in the use of visual primitives. Depending on the actual weights and features used in a query, images with differing semantics can appear to be very similar when compared according solely to their signatures. See (Fig.) for an example.

In order to improve the quality of responses to queries, many schemes have been proposed, ranging from classical techniques from text retrieval like relevance feedback or term re-weighting schemes [Squire et al. 1999] to the application of special forms of neural networks [Woods et al. 1998]. An extensive overview of CBIR systems in existence can be found in a technical report of the university of Utrecht [Veltkamp et al. 2000]. Many of these approaches depend on user feedback on the quality of the results, since human perception is far superior to computers at the task of identification of image contents. But nearly all of these systems discard of the information given by the users after their respective queries have been processed instead of using it in order to improve on the overall quality of the responses of the CBIR system.

The approach presented in this paper utilizes user feedback to its full extent in order to improve the results for future queries as well.
Figure 1: Example for different results using different features when comparing the same two images

The Approach

The approach has to satisfy several requirements: The main requirement is independence from any specific CBIR system, since the approach is supposed to be used as an addition to an already existing information system. In order to provide a stable service it needs to be independent of features that could become deprecated in a new release of the CBIR system used. Since the composition of the signatures is often a trade secret of the vendor, the approach has to build its own data structures that keep score of modifications to the data.

These requirements suggested the best way to implement the approach, namely as an interface between user and CBIR system through which all communications are conducted. This additionally allowed for a better encapsulation of the underlying system so that changes in the information system do not influence use of the system.

Since automatic clustering using the CBIR system is out of the question (because of the high error margin) the approach introduces the concept of thematical groups. A group is built around a common distinguishing feature. Users may be allowed to create their own groups or alternatively the groups can be pre-created by the maintainers of the system. The creation of a group is a straightforward process: They are created through a simple CBIR query complete with an example image and the results and especially the parameters of the query are saved. Additionally, these groups contain two membership lists, the *hotlist* and the *coldlist*. The *hotlist* contains all images that are relevant results, while the *coldlist* consists of the mismatches.

To which of these lists an image of the group belongs depends on the value of one parameter, λ, with $\lambda \in [0,1]$. Values of $\lambda \leq 0.5$ gain the image inclusion in the *hotlist*, while images with $\lambda > 0.5$ are considered part of the *coldlist*. New members of the group start with an initial value of $\lambda = 0.5$, so that in new groups initially all images belong to the *hotlist*, because of lacking information to the contrary. Since this process depends solely on the CBIR system, mismatches may very well occur. But that is not a problem, mismatches will be taken care of during the life cycle of the group.

A query using groups is processed as follows:
The parameters of the query are given to the underlying CBIR system, which performs a normal query on the database. The results from this query are then analyzed by the interfaced. The ratings for images belonging to the group in question are modified according to these rules:

1. Let **r** be the rating the image received from the CBIR system.

2. Let **m**= $min(r, 100 - r)$

3. Let **r'**= $r - m + 2 * m * \lambda$

136

Step 2. is necessary since the approach uses its own scale on which similarity is measured. This is done to ensure independence from vendors. A rating of 0 means complete congruence to the example, whereas a rating of 100 stands for complete dissimilarity. the variable **m** denotes the radius of the biggest interval having **r** as midpoint and being entirely inside the interval [0,100]. Step 3. then computes the new rating for the image by multiplying the size of the interval (2 times m) by λ and adding that value to the value of the left edge of the interval. This step gives images from the *hotlist* a better rating while images from the *coldlist* are punished.

After all of the results have been processed, the threshold is applied to the modified result set. Only the images satisfying the threshold are then presented to the user.

The presentation of the results includes the possibility to give feedback on the images. Positive feedback indicates that the image is a relevant image for the group that was selected at the start of the query (and vice versa for negative feedback). The feedback is used to modify the value of λ. If an image is rated and is not a member of the group in question, this image is added to the *hotlist* of the group with $\lambda = 0.5$ regardless of the type of feedback it received. If an image is already part of the group, λ is actualized differently depending on the type of feedback:

positive feedback $f^+(\lambda) = 1 - \sqrt[s]{1 - \lambda^s}, \lambda \in [0,1], s > 1$

negative feedback $\lambda' = f^-(\lambda) = \sqrt[s]{1 - (1 - \lambda)^s}, \lambda \in [0,1], s > 1$

These two functions effect the necessary modifications on the parameter λ. Negative feedback causes the parameter to grow whereas positive feedback lessens it. The additional parameter **s** that is introduced in these functions allows scaling of the impact of one piece of feedback in relation to the size of the expected user basis. In a system with named users or a highly specialized environment the possibility of wantonly false feedback is relatively small. Thus greater trust can be placed in the users. Considering a bigger audience, e.g. a search-engine on the WWW, the possibility of abuse is much higher, so less trust is put into individual ratings. This makes **s** effectively a gauge for the trustworthiness of the users. The smaller the value for **s**, the bigger the impact of individual ratings on the new value of λ.

These are the parts that build the framework. As can be seen, no assumptions are made about special features of specific CBIR systems. The approach only uses the ratings that are generated by the underlying image retrieval engine. These ratings need to be converted into the internally used scale. The scale transformations and the user interface are the only parts that need to be changed in order to adapt to a new CBIR system, allowing for rapid development of the application and full reusability of data collected with the previous system.

Results of an Evaluation

In order to evaluate the approach outlined in section a prototype (called GIVBAC) has been implemented and tested against an image database consisting of about 1500 images. GIVBAC is designed to be an interface to Virage Search Engine included in the InterMedia-cartridge of Oracle 8i. This engine uses four different features, namely global color, local color, texture and shape, which may be accompanied with weights defining their importance and a threshold that defines the maximally allowed difference to the example, measured on a scale from 0 to 100. The evaluation consisted of five performance tests, each one measuring the changes in performance for one particular thematic group of images. The members of these groups were determined before the tests in order to enable application of *recall* and *precision* measures (for a definition of these measures, see [Baeza-Yates 1999]). The groups covered the following topics: cards, people, planets, pyramids and rhinos.

The tests consisted of 25 queries to GIVBAC each. Every query used an example from the group chosen at random. The weights for the features were freely selected by the test persons, just as in a real scenario. User feedback was collected on each of these queries. The queries which generated the groups were used as references against which the changes in performance could be measured. Every fifth query was followed by a query using the reference image and parameters. The actual results at these points
Figure 2: Evaluation results: Diagram for the group depicting cards

were then plotted in a recall-precision diagram alongside the reference query. The user group for the tests consisted of five users, so s was set to a relatively small value, namely 1.01. Larger values for this parameter would lead to the same conclusions but would need more iterations.

(Fig.2) shows the results for a group with rather homogenous contents: playing cards. Every image has the same structure and background, the only differences lie in the value of the cards. This group performs very well even in the reference system. GIVBAC is outperforming the reference after five iterations but the increases are mainly in precision and not that significant due to the high quality of the reference query. At the 25th query an increase in recall occurs, a welcome side effect of the voting process. In this context it has to be noted, that traditionally precision-recall diagrams use the full extent of the x-axis but since CBIR deals with thresholds, the full 100% of recall is almost never reached.

(Fig. 3) shows a group that shows the performance of GIVBAC in an environment that is especially bad for CBIR engines. The group in question has rhinos as a theme. The images hugely differ in composition, virtually the only common theme is indeed, that on the images somewhere a rhinoceros can be seen. Even some of the test persons could only solve their task through the list of relevant images. The diagram clearly shows the significant increases in precision as well as recall during the course of the experiment. These two diagrams represent the opposite sides of the spectrum encountered during the experiments. GIVBAC outperformed the reference query in every test, with varying levels of success. The greatest gain was achieved for the group depicting rhinos. The result set size for this group was reduced by 48% in the course of only 25 queries while simultaneously raising the maximum recall to 90%. This raise is achieved because images which were initially rated worse than the threshold have been promoted to a better ranking through positive user feedback. Even the group depicting cards (which has very good retrieval properties) has profited from the use of user feedback. The gain is lower – only 18% – but under the circumstances of this group this still means, that the first 80% of the relevant images for this group are shown, before the first mismatch is encountered. The same query for an unmodified system only manages this feat for the first 50% of the group.

The results of the performance tests show the feasibility of the approach. The improvement covers

Rhinos

Legend: Reference — After 5 — After 10 — After 15 — After 20 — After 25
Figure 3: Evaluation results: Diagram for the group depicting rhinos

precision as well as recall, so that the result sets are at least as good as in an unmodified system. The tests also showed, that the approach works even under difficult suppositions, although this may necessitate a greater number of iterations until satisfactory results are reached.

1 Conclusion

This paper describes the outlines of an approach that aims at improving the performance of CBIR systems by using results from user feedback outside of the scope of the queries the feedback was given to. The approach presented is used as an interface to an already existing CBIR system and its database, but is independent of a specific CBIR system. That allows for easy adaptation to changes in the underlying system or an exchange for a new one.

The approach uses thematic groups that can be generated by the owners or users of the system. Feedback is given on the relevance of results according to one of these groups. An additional feature of the approach is its scalability with regard to the expected size of the user base.

Evaluation results are given and they show the possible gains if the approach is used. Both precision and recall can be improved, with the gains in precision being larger than for recall.

Further work will include inclusion of a client using this approach into a digital library developed at our department so that it may be used by a wider audience. This will allow collection of long-time data on the performance of and user feedback on the client itself.

While being most suited for the image parts of digital libraries in which some degree of control over the use of the system can be exerted, application of the approach is possible in search engines on the WWW, due to the scaling factor. Usage in such an environment would however necessitate additional work in the areas of right management (such as: Who is allowed to create new groups? Should feedback of named users count for more than that of anonymous users? etc), which is outside the scope of this work.

Integrating Internet-based Mathematical Manipulatives Within a Learning Environment

Evelyn Brown
University of Houston - Downtown
Houston, Texas, USA
browne@.dt.uh.edu

Caroline M. Crawford
University of Houston – Clear Lake
Houston, Texas, USA
Crawford@cl.uh.edu

Abstract: The use of manipulatives within a mathematical classroom environment has traditionally been offered through the use of manufactured or teacher-created concrete objects. Manufactured manipulatives are ones such as cuisenaire rods, color tiles, colored craft sticks and pattern blocks. Teacher-created concrete objects consist of cardstock, foam or other paper templates. These are used to provide tactile-kinesthetic learning activities to enhance mathematics conceptualization. The Information Age offers mathematics educators the opportunity to integrate the use of digital manipulatives similar to manufactured and teacher-created ones using the World Wide Web as an innovative medium to expand the learner's conceptual framework of understanding. The availability of such Web-based mathematical manipulatives is an ever-expanding possibility that can be integrated into student-centered learning environments.

Introduction

The integration of manipulatives within the mathematical learning environment is not an original concept. Manipulatives have been integrated into the learning environment for numerous years. Pre-information age counting activities involved the use of fingers which maybe looked upon as one of the earliest manipulatives. The primary purpose of the manipulative was to offer a concrete visualization of mathematical concepts that lead towards an understanding of the mathematical concepts as defined by learning objectives.

> All students should be able to reason and communicate proficiently in mathematics. They should
> have knowledge of and skill in the use of the vocabulary, forms of representation, materials, tools,
> techniques, and intellectual methods of the discipline of mathematics, including the ability to
> define and solve problems with reason, insight, inventiveness, and technical proficiency.
> (Connected Mathematics Project, 2001, paragraph 2)

Within this framework of proficiency, manipulatives create familiar, concrete and understandable representations of information that are often "unfamiliar, abstract, and confusing to students" (Burns, 2001a, paragraph3). The appropriate integration of manipulatives within the learning environment ensures the learner's conceptualization of mathematical theories and tasks at a level appropriate to the learner by providing stimulating visual and concrete representations.

Manipulatives

Manipulatives have been integrated into learning opportunities for years. "One of the first advocates of 'hands-on learning' was the Swiss educator Johann Heinrich Pestalozzi (1746-1827). Pestalozzi asserted that students need to learn through their senses and through physical activity" (Resnick, Martin, Berg, Borovoy, Colella, Kramer and Silverman, 1998, paragraph5) and rebelliously struggling for "things before words, concrete before abstract"

(Pestalozzi, 1803). However, the introduction of manipulatives within a mathematical environment has exponentially expanded the conceptualization of the theories related to the task by the learner. Numerous positive attributes can be associated with manipulatives, as manipulatives can offer the following aids within the learning environment:

1. Manipulatives help make abstract ideas concrete.
2. Manipulatives lift math off textbook pages.
3. Manipulatives build students' confidence by giving them a way to test and confirm their reasoning.
4. Manipulatives are useful tools for solving problems.
5. Manipulatives make learning math interesting and enjoyable.
   (Burns, 2001a, paragraph 3)

However, the use of manipulatives within the learning environment comes with specific procedural tasks. Burns (2001b, paragraph 1) describes several specific "musts" that need to occur to facilitate positive correlations when manipulatives are used. Concurrently, our classroom experiences with manipulatives reinforce these "musts" as follows.

1. The instructor conducts on-going dialogue with students about why manipulatives help them learn math.
2. Ground rules are set and consistently communicated as students work with manipulatives.
3. Students are encouraged to develop a system for using and storing materials in the classroom under the teacher's direction. Materials managers are appointed to help with these tasks.
4. Time given to students for free exploration provides for more "on-time" behavioral applications as necessary.
5. Manipulatives are a natural for writing assignments, giving students' a writing focus. That is, to describe, to illustrate, to outline what happened, etc.
6. Parents are given opportunities to gain hands-on experiences using the manipulatives.

All the aspects discussed above refer to the concrete manipulatives that are available within learning environments. Mathematical manipulatives have been integrated into the learning environments to expand the learner's conceptual framework of understanding and to develop a link between theory and concrete explanations of mathematical concepts. But we are at the beginning of a new age, the Information Age that begins the shift from mere concrete manipulatives that can only aid the learner in conceptualizing the more simplistic mathematical theories towards digital manipulatives that offer the learner a conceptualization of more advanced, difficult mathematical theories in a digital arena. Digital manipulatives can be appropriately and successfully integrated into a mathematical learning environment through the use of World Wide Web-based materials. The use of digital manipulatives provides an interactive environment with immediate feedback to explore in-depth mathematical theories that would be difficult to simulate with concrete models. Additionally, younger students are able to "see" (conceptualize) concepts that would normally be regulated to in-depth abstract mathematical principles.

Manipulatives Available on the World Wide Web

World Wide Web-based manipulatives offer a creative, useful variety to the learning environment. These interactive materials enhance the knowledge and understanding of learners, while creating a conceptual understanding of mathematical theories beyond the mere formulaic models of traditional mathematical coursework. "These new manipulatives – with computational power embedded inside – are designed to expand the range of concepts that children can explore through direct manipulation, enabling children to learn concepts that were previously considered 'too advanced' for children" (Resnick et al, 1998, paragraph 4).

As examples of digital mathematical manipulatives available on the World Wide Web, GeoComputer (Riverdeep Interactive Learning Limited, 2001) offers the ability to create, flip, and rotate shapes to make colorful designs while simulating the concepts of reflections, translations and rotations. Students are also able to have interactive experiences with basic principles of geometry and measurements. Number sense concepts including fractional computations are enhanced by using pattern blocks and other virtual manipulatives embedded in Web-based applets developed specifically for use within a mathematical learning environment. The use of such manipulatives within a mathematically appropriate learning environment enhances the learner's conceptual understanding of material that would previously be considered too advanced or inappropriate.

Through the appropriate and successful integration of the mathematical manipulatives within a Web-enhanced learning environment, "children, by playing and building with these new manipulatives, can gain a deeper understanding of how dynamic systems behave" (Resnick et al, 1998, paragraph 12). Further,

> Such explorations would not be possible with traditional (non-computational) manipulative materials. Computation and communication capabilities play a critical role: they enable physical objects to move, sense and interact with one another – and, as a result, make systems -related concepts more salient to (and manipulable by) children. (Resnick et al, 1998, paragraph 12).

Numerous Web-based mathematical manipulatives are available for appropriate and successful integration within a mathematical learning environment. However, the engagement of the learner in innovative ways of thinking and learning about mathematical concepts is the focus of the exercise.

Conclusion

Web-based mathematical manipulatives are available for integration into the learning environment. However, thoughtful consideration must be given to the instructional design of the course and the specific learning objectives for each module of instruction. The focus of Web-based manipulatives is to enhance the learner's understanding of advanced theories and levels of understanding; "Our primary goal is not to help users accomplish some task faster or more effectively, but rather to engage them in new ways of thinking. In short, we are interested in Things That Think only if they also serve as Things To Think With" (Resnick et al, 1998, paragraph14). The Web-based manipulatives offer the computational abilities that aid in the communication of advanced concepts and theories to the learner. The focus is on the learner and the conceptual framework of understanding that is created due to the appropriate use of digital, Web-based mathematical manipulatives.

Designing and Developing WebQuests for the Mathematical Learning Environments: Focusing Upon Higher Order Thinking Skills Within the Learner-Centered Learning Environments

Evelyn Brown
University of Houston - Downtown
Houston, Texas, USA
browne@.dt.uh.edu

Caroline M. Crawford
University of Houston – Clear Lake
Houston, Texas, USA
Crawford@cl.uh.edu

Abstract: Mathematical learning environments emphasize the importance of higher order thinking skills within the learning environment. One aspect that offers the integration of mathematical subject matter, higher order thinking skills and a learner-centered emphasis of instruction is the design and development of WebQuests for the mathematical classroom environment.

Introduction

Mathematics is a subject matter that has been traditionally taught as a drill-and-practice in a formulaic environment that emphasized a "correct" or "incorrect" response by the learner. Yet times have shifted towards a more constructivist learner-centered and group work emphasis. After all, "Effective teachers intuitively know that student attitudes and academic achievement are improved when learning experiences revolve around the interests, talents, and needs of students" (Texas Metronet Incorporated, 2001, paragraph 1). With the rise of the World Wide Web and the availability of a bounty of useful Web sites, the integration of the Web within the mathematical learning environment has found that its time has come.

Bloom's Taxonomy of the Cognitive Domain and Higher Order Thinking Skills

Higher order thinking skills provide opportunities to further examine and broaden the focus upon Bloom's Taxonomy. Thomas, Thorne and Small (2001) offer a brief description of what higher order thinking skills emphasize.

> Higher Order Thinking, or HOT for short, takes thinking to higher levels than just restating the
> facts. HOT requires that we do something with the facts. We must understand them, connect them
> to each other, categorize them, manipulate them, put them together in new or novel ways, and
> apply them as we seek new solutions to new problems. (Thomas, Thorne & Small, 2001,
> paragraph 7)

Basically, higher order thinking skills (HOTS) can be broken into three categories: content thinking; critical thinking; and, creative thinking. Each aspect of HOTS emphasizes a different level within Bloom's Taxonomy. The complex levels of thinking processes associated with HOTS parallels the synthesis and evaluation levels of Bloom's Taxonomy. As patterns of higher order thinking are emphasized in learners within all levels of the educational system, each subject area emphasizes the creation of innovative aspects that aid the learner towards the creation and reconceptualization of thought patterns; in other words, viewing the information from numerous perspectives and within real-world environments. The introduction of the World Wide Web into the mathematical learning environment will emphasize the synthesis and evaluation levels of Bloom's Taxonomy while also focusing efforts upon higher order thinking skills.

Learning Activities for the World Wide Web

The World Wide Web (Web) is an enormous storehouse of information that is freely available to anyone in the world. However, so much information can cause confusion and despair on the part of both the professional educator and the learner. Therefore, careful consideration must be given to appropriate learning activities that integrate and emphasize the strengths of the Web. The task of the educator is to design and develop appropriate learning environments for the learner, whether this is in an instructor-centered or a learner-centered manner. Over the previous ten years a growing interest in constructivism, and an appropriate inquiry-oriented, problem-solving learner-centered learning environment has matured. The focus upon the learner's needs and the opportunity for the professional educator to take on the role of the facilitator, also annoyingly referred to the "guide on the side" rather than the all-knowing "sage on the stage". As group work has also developed a following, these aspects were melded into an innovative formula referred to by Dodge (1998, 2001a, 2001b) as a WebQuest.

WebQuest

One Web-based design that offers higher order thinking skills is the WebQuest. A WebQuest can be integrated within numerous subject matter areas; however, mathematical learning environments offer special emphases towards the use of the World Wide Web in a real-world problem-solving situation. The emphasis is placed upon creating a mathematically appropriate focus for an environment that develops an active, creative problem-solving community. Dodge's definition of "A WebQuest is an inquiry-oriented activity in which some or all of the information that learners interact with comes from resources on the Internet, optionally supplemented with videoconferencing" (Dodge, 2001a). Designing and developing a successful WebQuest must integrate the following elements within the WebQuest environment: An Engaging Opening; The Question / Task; Background for Everyone; Roles / Expertise; Use of the Web; Transformative Thinking; Real World Feedback; and, Conclusion (Dodge, 2001b, paragraph 1).

Through the careful review of WebQuests available on the Web and a creativity that is found in all mathematical subject matter experts, numerous interesting, subject-specific, inquiry-oriented group products can be created and integrated into a mathematical learning environment for learners to emphasize the real-world application of mathematical concepts and theories. Further, uploading the WebQuests to a Web server will allow other educators around the world the opportunities to integrate these WebQuests into their own appropriate learning environment, through which other learning environments can ensure that active learning occurs.

Conclusion

Mathematical learning environments naturally, due to the nature of the subject matter, focus upon higher order thinking skills. However, the introduction of WebQuests within the mathematical learning environment offers problem-based, real world applications with a learner-centered focus. The information available on the World Wide Web further defines and develops the perfect match of real-world information and subject matter expertise. The movement towards a realization of the strength when pairing two such powerful areas, the mathematics subject area and the World Wide Web, can only lead towards an innovative learning environment that emphasizes the learner's complex thinking processes and metacognitive processes.

The Network for English Acquisition and Reading Star Schools Program (NEARStar): Teaching Elementary Students to Read English via the Web

Zoe Ann Brown, Pacific Resources for Education and Learning, USA; David Brauer, Pacific Resources for Education and Learning, USA

· NEARStar is a 5-year grant from the U.S. Department of Education's Office of Educational Research and Improvement to Pacific Resources for Education and Learning (PREL), a non-profit educational training, research, development and technical assistance organization in Honolulu, Hawaii. The purpose of this grant is to develop research-based student instruction to teach beginning English reading and language to early elementary non-English speaking students, gather progress data through embedded assessments, and provide professional development to teachers, all delivered over the World Wide Web. Students learn to read English while engaging in interactive, game-like environments filled with animations, music, songs, and stories. Their teachers are a mouse-click away from just-in-time professional development resources that help them continue to build students' English skills.

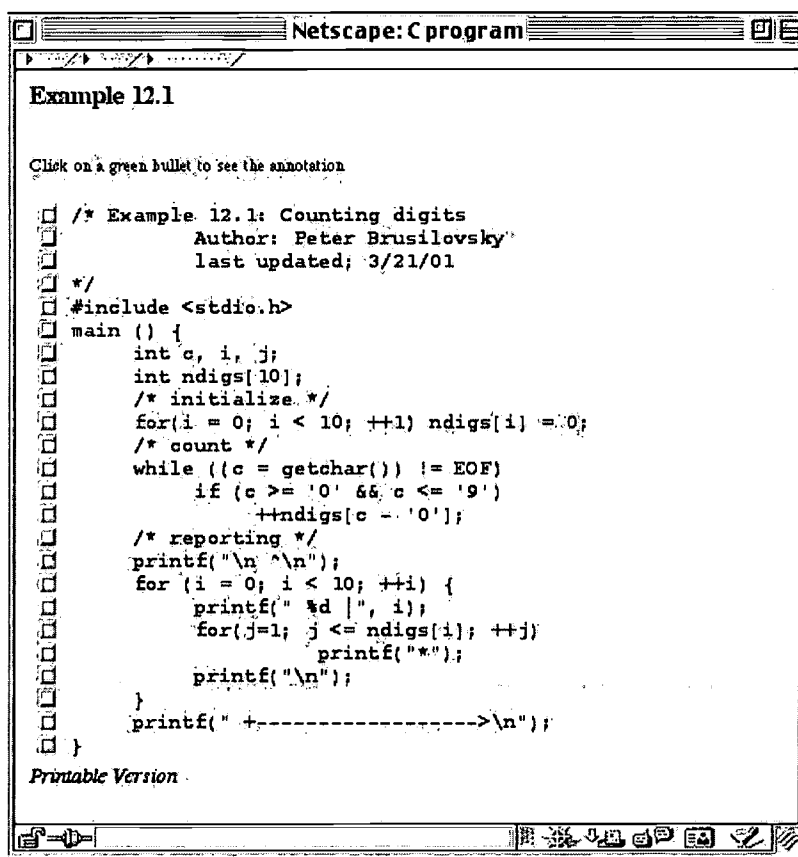
WebEx: Learning from Examples in a Programming Course

Peter Brusilovsky
School of Information Sciences
University of Pittsburgh
Pittsburgh PA 15260
peterb@mail.sis.pitt.edu

Abstract: Experienced and novice programmers often use program examples they have created or learned in the past to solve new programming tasks. Experienced teachers of programming-related courses know and use the power of example in their teaching. This paper presents WebEx - a Web-based tool for exploring programming examples that enables teachers to use example-based programming approach with heterogeneous classes. WebEx maximizes learning opportunity for every student, gives every student a second chance in understanding key programming examples, and encourages every student to explore example programs.

Introduction

It has often been claimed that humans use solutions to previous problems to solve new problems or planning tasks. Especially in the domain of programming, both experienced and novice programmers often use program examples they have created or learned in the past to solve new programming tasks. Experienced teachers of programming-related courses know and use the power of example in their teaching. The traditional approach to using examples in programming courses is the following. For each lecture the teacher prepare some number of carefully chosen problem-solving examples in the form of small programs. The teacher during the lecture analyzes these examples. To let the students further explore the examples and use them for solving assigned problems, the teacher provides the code of all analyzed examples as a part of printed or online lecture notes. Authors of good programming textbooks (who are good teachers themselves) also follow this approach and provide a lot of explained program examples in their books. To encourage the students to run and explore the provided examples many authors nowadays choose to place the code of all examples either on a CD supplied with the book, or on the book's Web site.

The problem with the traditional approach to using programming examples in the classroom is that it works well only for small homogeneous groups of students. Students in a homogeneous group have about the same level of programming knowledge and the same speed of material acquisition. Working with a small homogeneous group a teacher can usually predict the number and the complexity of examples for each lecture and choose the proper pace and level of detail for the presentation. In large heterogeneous classes where students have very different starting level of knowledge of the subject and acquisition capabilities the effectiveness of the traditional example-based approach decreases dramatically. Different students need essentially different speed and level of details in example explanations. Moreover, weaker students usually need more examples to understand the same concept. A teacher facing a heterogeneous classroom is destined to "lose" both strongest and weakest parts of the class during the lecture. Unfortunately for the students who have failed to understand examples presented in the class, there is no easy second chance. Even in a situation when the code of all examples is available online, it has little use for these students because the code itself lacks the explanation part.


We have designed WebEx, a Web-based tool for exploring programming examples to enable teachers to use example-based programming approach with heterogeneous classes. Our goal was to maximize learning opportunity for every student, to give every student a second chance in understanding key programming examples, to encourage every student to explore example programs and re-use it for problem solving. The core of WebEx is a database of explained programming examples prepared by teachers in a special "dissection" format. The environment lets each student to explore program examples in his or her own pace and order. In particular, weaker students will be able to work with more examples and explore each example in more detail. Currently we are using WebEx in the context of a course on Data Structures and Programming Principles at the University of Pittsburgh. However, WebEx is language and course-independent and can be used with any programming-related course. This paper presents the first version of

WebEx, compares it with earlier approaches to use technology in the context of example-based teaching of programming courses, and summarizes its benefits.

A Web-based environment to support learning from examples

The idea and the tool

The key innovative idea of the suggested project is to replace bare code of programming examples offered on the course Web site with *self-explaining examples*. To provide self-explaining examples we intend to use a popular approach to example explanations used in a number of programming textbooks and sometimes referred as "dissections" (Kelley & Pohl, 1995). With this approach, an author of an example (a teacher) supplies textual explanations for each line in the example program. The explanations serve at least two different purposes. First, it explains the student the meaning of each program line and its role of in the overall solution of a programming problem. Second, it comments on a particular way of using language constructs in every line of code thus bridging the gap between student general knowledge about programming language constructs and practical skills of their use for solving programming problems.

Figure 1. The code of a programming example is left intact in WebEx.
Green and white buttons to the left indicates availability of a comment for the given line.

In a typical programming textbook a dissected example is provided in a special format where each line of code is followed by explanations that can vary from a line or two to several paragraphs of text. This format has a clear problem: even in textbooks that use a special font and color for the lines of code, the code is hard to comprehend since the lines of code are spread among the explanations. The explanations are not easy to comprehend either.

Usually, a student has a problem with just a few lines of code in a program and need explanations for just these lines. Presenting all explanations at once distracts the student from concentrating on most needed explanations. Finally, reading through a large "dissection" is a rather passive kind of learning.

WebEx, a Web-based tool for interactive exploration of programming examples, was designed to overcome the problems listed above. Our key idea is to leave the example code intact as much as possible (Figure 1). The program example looks in WebEx just the same way it looks in a program editor. The only visible difference is a presence of green or white bullets to the left of each line. Green bullet indicates an availability of explanations for this line of code. While bullet tells that there are no explanations for the line. Naturally, clicking on a green bullet opens an explanations note for the selected line (Figure 2). In a spirit if a good hypertext, this interface let the user to use his or her preferred browsing strategy. Some users may want browse the example line by line. Other students may concentrate on the most hard-to-understand lines and selectively read explanations for these lines. In the example on Figure 3 the role of the line being explored is not obvious even for good students who may have no troubles with understanding all other lines. When exploring this example such students can go straight to this troublesome line ignoring other unnecessary explanations.

│       printf(" +------------------->\n");                           │
│  }                                                                  │
│  Printable Version                                                  │
└────────────────────────────────────────────────────────────────────┘
```

Figure 2: In WebEx example explanations are shown one at a time next to the line being explained (the bullet and the font for this line is changed to provide the context)

WebEx approach offers several benefits over the traditional book format. First, the code of the example is shown as an easy-to-grasp single chunk, instead of being distributed among the comments. Second, explanations are shown one by one helping the student to concentrate on one thing. Third, from being a passive reading activity the work with every example become an interactive exploration. As an extra benefit, every action of the student in this environment can be recorded thus providing a teacher with a possibility to monitor the student activity and giving an educational researcher a powerful tool to explore how student work with examples in a programming course.

While the first version of WebEx is already in use by students, we need some time to evaluate the effectiveness of WebEx as a teaching and learning tool. It is out hope that a database of interactive explained examples will give every

student a second chance to understand key programming examples. Each student will be able to work with the examples in his or her own pace requesting only necessary explanations.

Here the value of c is a code of a digit. The value of the array elements corresponding to this digit is incremented by one. Every time a digit is found, the value in that array position increases by one, thus counting each digit that it reads in. To get from a code of a digit to an index in the array The ASCII code for the character '0' is subtracted from c. That is for '0' the expression c - '0' will have the value 0, for '1' it will have the value 1 and so for.

Figure 3: With WebEx a student can selectively choose explanations of the most hard to understand lines of code that are usually different for different students

Implementation

The database of examples is implemented using Microsoft Access. The interactive part of the environment (example exploration and navigation between examples and concepts) is implemented using Microsoft Internet Server and Active Server Pages technology. The choice of Microsoft tools is determined by their free availability for faculty and students or our university. Besides, Microsoft Access system is relatively easy to use and has a simple interface. We have found that teachers and teaching assistants have no problems with copying, commenting, and contributing their examples in Access tables. Currently, we use WebEx in the context of a Blackboard CourseInfo (Blackboard, 1999) course management system (CMS), however, it is independent from CourseInfo and can be used as a standalone application or in conjunction with any CMS.

Related works

While the idea of interactive self-explaining examples on the Web is innovative, the idea of a shared database of examples is not entirely new. We know (and will use an experience of) several example-based programming environments that let the students use a database of examples in the process of problem solving (Brusilovsky & Weber, 1996; Brusilovsky, 1992; Burow & Weber, 1996; Faries & Reiser, 1988; Guzdial, 1995; Hohmann, Guzdial & Soloway, 1992; Linn, 1992a; Linn, 1992b; Redmiles, 1993). With two exclusions, the only function of example-based programming systems was to help the student find a relevant example. In most of the cases the systems simply let the student pick a static program example from a large list or search for an example using keywords. Two systems went further and provided some interface to the student to explore an example. In a system designed by Redmiles (1993) explanations for an example were "hardwired" into the system's code by the author himself. ELM-PE (Burow &

151

Weber, 1996) applied an Artificial Intelligence approach. Using its knowledge about programming goals and an ability to "understand" the program, it can interactively generate a goal-based explanation of every function of any program example represented in the system. Our approach is integration of these two. WebEx can provide an explanation for every line of a program in any language with a very little authoring overhead. WebEx is a practical tool that can be used in any programming course. Still, like the tools mentioned above it has an important research agenda - to explore how the students ue examples in programming courses.

Current development

Student side

The experience of the previous works on databases of examples lets us anticipate a problem of navigation. As we noted, known databases typically let the student pick an example from a large list or search for an example using keywords. However, an experiment with ELM-PE environment (Weber, 1996) shows that only in two thirds of all cases were the users able to find the most relevant example using these simple example-selection tools. For our case the navigation problem may be even more serious since the estimated number of examples in our environment will be several time larger than in the known databases.

To help the students navigate in our database of examples we plan to organize all examples into a hyperspace. This idea was originally explored by Linn (1992b) who also has shown that this hyperspace has to be structured following expert-level understanding of the subject. We intend to apply a concept-based approach to structure the hyperspace of examples. The concept-based approach was originally suggested by the author to structure the hyperspace of pages in the InterBook system (Brusilovsky, Eklund & Schwarz, 1998). The core of the concept-based navigation is a glossary of concepts used in the course - from C programming constructs (assignment operator) to higher level concepts (loop). The users are able to observe a description of each concept in on a separate glossary page. The system maintains two-way links between an example and each concept used in this example. That means that from each concept page students are able to move to all examples that demonstrate the use of this concept. Vice versa, from each example page the student will be able to move to description of each involved concept. This approach supports rich navigation. In particular, starting from an example of interest, the student will be able to move to an explanation of a troublesome concept used in this example and from that to another simpler example that uses this concept. Our experience with InterBook shows that this organization can successfully support navigation in a hyperspace with several hundred of content pages (i.e., examples) and more than a hundred of concepts. In addition to the new concept-based access to examples we intend to keep currently implemented syllabus-based access where the student can get a list of links to all examples relevant to a given lecture.

Teacher side

One of the key assumption behind WebEx is that examples in a database are contributed by several instructors who teach different sections of the same course. Thus, from being a secondary support for teaching a particular section of the course, the database of examples will become a shared resource for the whole course, a place to accumulate the "instructional wisdom" of several teachers. Once initiated, this database can be used by several generations of instructors who can also contribute their favorite examples. As it often happens are taught by different instructors in different years. In this situation the shared database of examples will offer a significant reduction of work for a new instructor of the course. Instead of preparing and testing a large amount of examples to analyze at every lecture, a teacher can simply pick and re-use a subset of examples from the database that he or she founds most relevant. The students themselves may have an access to the whole wealth of explained examples that will allow weaker students to work with more examples than were presented in the classroom.

We are now working currently on improving teacher's side of WebEx. In the original version of WebEx the teachers have to create and annotate examples using Microsoft Access directly. This approach worked well for one or two teachers. To support a larger community of teachers working on the same course we are developing a Web-based interface for teachers to create, update, and re-use examples. The goal is to make the system a tool in teacher's hands; to support all major activities of a teacher working with examples. Our experience shows that it is one of the main keys to the success of any educational system in the classroom.

Summary

Instead of providing a summary of the paper we have chosen to provide a summary of WebEx benefits.

- WebEx maximizes an educational opportunity for each student in an example-based programming course by providing a possibility to explore and reuse self-explaining programming examples. It provides a "second chance" for the students who miss the lecture or students who do not understand it completely. It also provides support for possible distance students.

- The teacher is able to spend less time on a routine analysis of examples during the lecture and devote more time to interactive and creative work with students. There is no need to ensure that most of the students "got" the examples since all of them will have a second chance. We expect some release of instructor's time that is currently spent on example analysis during recitations and office hours.

- The database of examples will serve as a "community" resource for all instructors of the target course. The amount of time required for a faculty to prepare a quality lecture for this course is significantly reduced.

- The database of examples developed and structured by experienced teacher can help less experienced instructors to teach the course better

- Due to the problem-independent nature of the tool, the WebEx can be applied in the context of teaching different programming related courses.

Distance Learning Using a WWW Lesson Composer, Presenter, & Organizer[*]

John Budenske, Jason Judt, and Jim Newhouse

Architecture Technology Corporation

Abstract for Short Paper

An approach for a software tool, the Science and Technology Literacy Desktop (STLD), that can organize disparate online educational content into coherent lesson plans, automatically generate links to related reference material, and provide assessment of student comprehension is presented. Based on an enhanced web browser concept, it allows access to a wide variety of material and formats, yet provides the controls necessary for an instructor to administer effective lessons. This software takes a significant step beyond current educational software offerings that lack extensibility to a range of information as broad as that found on the Internet.

Short Paper

(max 1875 words)

Introduction

The introduction of the internet has brought a whole new perspective in how to provide learners with educational materials. Of greatest potential is the use of materials already resident on the WWW. A student can go to a number of WWW sites and access an abundance of material on many topics. With many institutions such as zoos, museums, and libraries hosting WWW portals into their treasured contents, taking students on virtual tours can be accomplished from a simple desktop computer equipped with a standard WWW browser.

Unfortunately, allowing the student to "surf the Web" will not work as a lesson. The student will encounter a vast array of uncontrolled information. Currently instructors do not have the tools to identify, filter, and index the desirable materials. Nor are there tools to support the student's endeavors in understanding the material. There is too much information available and instead of being a time-saving device for producing quality lessons, the WWW ends up being another sink-hole of instructor time. Thus, we have concentrated on providing a tool, called (for historical reasons) the Science Technology Literacy Desktop (STLD), to aid instructors in identifying, filtering and organizing information as well as support the student in understanding the presented material.

The STLD appears as a Web browser, providing a familiar interface along with additional functionality brought together to provide an enhanced learning environment. By virtue of being a Web-based tool, it allows instructors to incorporate their own material, as well as incorporating existing Web-based material into a lesson. Projects can now be designed to allow the student to browse on-line through lesson material that is resident on the WWW. Instead of developing material from scratch, the instructor can organize a lesson that is composed of "pointers" to already existing WWW material along with auxiliary instructions and background information. Activities and check-point quizzes can also be integrated. A complete lesson can be composed and stored within the STLD, and then later browsed by a group of instructor-identified students. As students interact with a lesson, the STLD tracks their activity, providing the instructor with student status and progression.

In order to support the student's learning of the lesson material, the STLD also provides the capability to have the student "click" on a word or term and have options presented to them for performing further research (e.g., from a simple dictionary

---

look-up, to accessing an encyclopedia, or even another WWW site dedicated to that topic). This capability is supported by having the instructor identify on-line reference materials, CD-ROM materials, WWW sites, and other on-line sources (e.g., picture databases) that contain information pertinent to the curriculum they are teaching. These references are contained within the indexing scheme of the *STLD*, and are automatically hyper-linked (with no instructor burden) into the lesson document being browsed. For example, a student reading an article on giraffes may encounter the word 'herbivore' and wish to know its definition or antonym, see pictures of various herbivores, or be interested in seeing exotic herbivores found in mythology. The student only needs to select the word and then identify the type of information desired.

It is the instructor who selects the education material so as to tune the lesson to the student, constantly challenge the student's skill level, and maintain their interest. The tools that the instructor uses must allow for the flexibility of selectable material

Unfortunately, pulling such pieces together into an actual lesson is very challenging and time consuming for the teacher due to the up-to-the-minute aspect of the information. The pieces can be from varied sources, in varied formats, and not at all close to a presentable state in terms of a classroom lesson. This is where our approach differs from other pedagogical tools. We are concentrating on methods of presentation and comprehension that would allow the addition of new on-line material (especially Internet) by the instructor with minor effort. Thus, the lesson can be tuned to the students and to current events, constantly challenging their skill-level and maintaining their interest, while reducing human instructor load.

Approach

Our approach is to quickly develop a series of *STLD* prototypes, incorporating latest advances in technology, and testing new concepts for viability. This allows a quick determination of which technologies are feasible in the short-term and which are not yet mature for insertion, but deem to require monitoring of new advances. We have been investigating technologies from Java-based browser development, speech understanding, pattern recognition and manipulation, ontologies, readability, machine understanding of text and concepts, and artificial intelligence-based text generation. We are not attempting to replace or duplicate existing web browser products, only to provide tools that will aid in organizing and presenting on-line material into a defined lesson after it has already been discovered. This also includes a tool for retaining

develop extensions that can be added to current versions of such applications, and that focus on aids for science and technology literacy. We believe that many of the capabilities being developed by this effort are also applicable to general literacy and education.

Usage of the *STLD*

The envisioned usage of the tool is that of the instructor identifying on-line reference materials, CD-ROM based materials, Internet sites, and other on-line information sources (e.g., picture databases) that contain information pertinent to the curriculum they are teaching. The instructor interacts with the "Lesson Generator" and the "Add-Reference Wizard" components of the *STLD* in identifying these sources. Using these components, the teacher is walked through a series of simplified questions and options pertaining to the Internet pages that compose the lesson, instructions associated with the lesson and with each page, identified resources and reference; and activities or quiz questions automatically generated in association with each web page. At this point the lesson is defined and registered into the teacher's lessons area. Students can access the lessons through the *STLD* Internet browser. The resources/references identified by the teacher are contained within the indexing scheme of the *STLD*. Whenever a student desires additional definition or background on a specific topic or word, such information from the identified references has already been automatically hyper-linked into the document being browsed and thus the student can access the information with a mouse-click and a menu selection. For example, a student reading an article on giraffes may encounter the word 'herbivore' and wish to know its definition, antonym, or examples of other herbivores. Other example uses include loading up a picture of a giraffe from a picture database, or searching a mythology encyclopedia for myths about giraffes. Such information would be found in the on-line dictionaries, encyclopedias, and other references in abundance across the WWW and identified by the teacher during the lesson generation. The student only needs to select the word and then identify the type of information desired. The automatic hyper-link generation has already cross-referenced the word with the reference material, and the desired information can be accessed across the web and displayed for the student. The benefit is that auxiliary web-based reference information is easily accessed,

and thus utilized, enhancing the learning experience. The wealth of the WWW can be quickly organized into a focused lesson with linkage out into more WWW wealth. This approach can also work for general browsing where there is no defined lesson plan. Instead, references have been identified and thus can be quickly hyper-linked into a web document as it is loaded into the browser.

The *STLD* can be used by students – either with or without instructor customization – to browse the Internet by downloading any document and having the full science and technology literacy reference aids available to them. The hyper-linking does not alter the original document, nor interfere with any other hypertext already residing in the document. Essentially, this browser functions as any other Internet browser, yet with added functionality to support science and technology literacy.

When multiple references are identified, they are listed as possible options for selection based on what type of reference source each is (dictionary, encyclopedia, thesaurus, or specific Web pages on the selected term/concept). The options may be filtered or ordered based on the age appropriateness and the reading level of the student. The student's reading level can be estimated through initial solicitation of age/grade from the student augmented by the use of intelligent tutoring techniques that observe the student's usage of the tool, and based on their actions and the documents they are reading, infer their current reading level. Similar readability metrics can be applied to the reference material to provide a gross-level matching. Essentially, we desire to avoid mismatches such as a second grader using a college level dictionary or a college level reader using a children's picture dictionary. As the student progresses, records of their estimated reading level can be kept along with information on topic interests. This information can be used to provide suggested documents for the student to read based on age, reading level, and interest.

As each new Internet document is downloaded, readability metrics similar to those used to assess the student's level, can be calculated and provide reading difficulty statistics on the document and anticipate the fit of the document to the student. From this the *STLD* can provide guidance to the student towards a better fit to their abilities, and thus reduce the frustrations associated with searching and filtering for articles that match the student.

Finally, the student would have the option to generate and participate in activities or to take a quiz upon the material. Both activities and quizzes would be automatically generated from the browsed document's content, presented to the teacher for review (during lesson generation) and then during the lesson given to the student for on-line interactions. Since the activities (i.e, word bingo, crossword puzzles, etc.) and quiz questions are generated from the browsed material, it provides a vehicle for the student to self-check comprehension. The automatic generation is based on the artificial intelligence techniques in lexical databases, large-knowledge-base designs, and pattern matching and manipulation.

Conclusions

We presented the concept of the *Science and Technology Literacy Desktop* that provides both student and teacher with the capabilities to find, organize, and understand science and technology related material on the WWW. This ongoing research and development effort is attempting to apply new technology to the problem of science and technology literacy in our classrooms. The results of this effort should be applicable beyond science and technology literacy, finding use within other focus areas of education and training, as well as general literacy, English as a second language (ESL), and even as a general WWW browsing aid.

Ask Smartypants! A Web-Based Tool to Help Busy Educators Keep Up With Research About New and Emerging Technologies

coralloc@ael.org

Abstract: The Institute for the Advancement of Emerging Technologies in Education (IAETE) and Knowledge Management Software, Inc. have partnered to create a Web-based solution that provides access to summaries and syntheses of literature related to new and emerging technologies. Panels of experts drawn from various industries are identifying resources that provide valuable information about potentially useful emerging technologies. Content experts will summarize articles from a variety of sources. Education experts will meet quarterly to glean the implications for education from the summaries, develop applications for consideration, and identify possible challenges. Results will be posted to the *Ask Smartypants!* Web site where educators may search the database of summaries through a simple interface using natural language queries. Users will receive syntheses of possibly relevant research and will rate the usefulness of the returned syntheses. The software will "learn" which reviews best answer particular questions. Subsequent searches will be modified to reflect these evaluations.

In this day of information overload, how can professionals keep abreast of useful information about new and emerging technologies? Amid literally thousands of journals and trade magazines, articles are published at astounding rates. It would be difficult for a single professional to skim every publication and nearly impossible to read every article. This is not a problem exclusive to education. Similarly, busy physicians likely do not have time to read every medical research journal, but it is important for them to be aware of best practices and promising treatments. The Evidence-Based Medicine model was developed by The Centre for Evidence-Based Medicine (Oxford) and helps busy doctors make use of medical research in their daily practice by providing two resources: *Best Evidence CD-ROM* and the *EBM Journal*. The CD-ROM reviews research on relevant conditions, symptoms, treatments, and diagnostic tests. The journal presents abstracts collected from approximately 70 journals that were screened by a panel of expert clinicians and deemed valid, as well as clinically important. The journal drastically reduces the amount of reading time needed to cull the significant studies from hundreds of journals (Willinsky, 2000).

Like the physicians mentioned above, busy educators struggle to find time to read research and informative articles on promising technology practices and potentially valuable emerging technologies. To make things more difficult, information about new and emerging technologies is not always found in education journals, because cutting-edge devices and practices are often developed with other industries in mind and appear in popular media first. Thus, even after reading about potentially significant ideas in education or other industries, educators and administrators are often left without a clear understanding of how they can adapt such ideas for use in classrooms, schools, and districts.

The Institute for the Advancement of Emerging Technologies in Education (IAETE) and Knowledge Management Software, Inc. have partnered to create a tool that will assist practitioners in finding research and other information relevant to their needs. Modeled after the Evidence-Based Medicine paradigm, *Ask Smartypants!* is designed to assist practitioners in the identification, evaluation, interpretation, and application of the most relevant research related to new and emerging technologies.

More han 1,000 journal titles have been collected to represent ten content areas: Aeronautics & Space Science, Biological Sciences, Business, Computer Science & Automation, Education, Engineering & Technology, Medicine & Health, Military, Physics, and World Wide Web & Internet. The titles were identified using recommendation lists from prominent associations and organizations, in addition to *Magazines for Libraries* (Katz & Katz, 2000), a publication used by academic and public libraries in collection development.

Using a modified Delphi technique, IAETE is assembling the publications that provide reliable, valid, and useful research, as well as valuable information from trade journals and popular titles about potentially useful emerging technologies. The modified Delphi group is comprised of panels of experts representing each of the ten content areas. Each member of every panel is asked to identify from the list of journals those that provide useful information about new and emerging technologies relative to his identified content group. The questionnaire requires members to indicate recommended retentions and deletions from the original list of journal titles. Additionally, the members are asked to suggest additional titles that should be included.

After the questionnaires are returned to IAETE, they will be analyzed, and titles will be divided into categories: 100% consensus, 75-99% consensus, 50-74% consensus, and under 50% consensus. A second questionnaire will be dispatched to the panels, including the titles receiving 50-100% consensus and recommended additions. The process will be repeated. Once consensus is reached on the resource list, IAETE staff will begin to arrange for subscriptions to the selected titles and a Tier-1 Review Group will be identified.

The number of journals selected during this modified Delphi process will determine the number of members in the Tier-1 Review Group. (For example, there may be 15 members representing Education and only 5 members representing Aeronautics & Space Science.) Each member of the Tier-1 Review Group will be responsible for monitoring assigned titles, selecting useful articles from the publications, and composing summaries based on a template provided by IAETE. Guidelines for selection and composition are under development by IAETE and will be distributed to Tier-1 group members.

Once the Tier-1 Review Group has been launched, a Tier-2 Review Group will be assembled. The members of the Tier-2 Review Group will be experts in education who have hands-on school and/or classroom experience and are thereby able to glean the implications for education from the summaries completed by the Tier-1 Review Group and evaluate its potential for impact. The Tier-2 Review Group will meet quarterly to develop school and/or classroom applications for consideration and to identify possible challenges that may arise as a result of implementing the applications.

Following the Tier-2 Review Group's quarterly meeting, the knowledgebase will be populated and the Web site (www.asksmartypants.org) will be fully operational. Educators will be able to type a natural language question on the Web site to receive a list of possibly relevant research reviews. The user will be asked to evaluate the usefulness of the returned reviews. Through the user's response, the software "learns" which reviews best answer each question. Using confidence ratings, future output is modified to reflect user satisfaction on previous searches.

Furthermore, questions that are not answered to the user's satisfaction are forwarded via email to the site administrator, resulting in a list of questions that are not being answered by current research. As a result, IAETE plans to draw on users' unanswered questions to shape future research agendas. As gaps are identified, research can be planned to address that need. In essence, practitioners will begin to influence the research conducted by IAETE, as well as the entire R&D community.

Abstract: This paper will present a case study analyzing the design process and interactive web product developed by instructional technology graduate students at Virginai Tech to support the NASA CONNECT distance education program. The NASA CONNECT program will be described and the various ways to interact with this dynamic program will also be enumerated. NASA CONNECT is an award winning distance education program that incorporates multiple modes of delivery and student engagement and is managed out of the NASA Langley Research Center, located in Hampton, Virginia. Serving thousands of students each year, NASA CONNECT is but one of a myriad of educational programs sponsored by NASA. But some might question "Why NASA is involved with education at all?"

Why is NASA Interested in Education?

The National Aeronautics and Space Administration has as one of its cross cutting strategic enterprise goals the charge of sharing NASA's content knowledge with k-12 education and enlightening inquisitive minds through supporting the nations education goals and standards in science, mathematics, technology and geography. NASA's top administrator, Dan Goldin, in his April 1999 address to the United States Congress, House of Representatives Committee on Science stated:

Education is the single most important issue our generation faces today that will influence our Nation's course for the future...NASA's success depends on the educational system to produce the highly skilled and knowledgeable workforce that is necessary to perform this cutting edge work. Likewise, the Nation's educational system looks to NASA for inspiration and to exemplify doing things that once were only imaginable -- feats that motivate and encourage our students to study science, mathematics, technology, and engineering. Future leaders of America, even if not astronauts, scientists, or engineers, must have a fundamental understanding of science, mathematics, and technology to reap the rewards of NASA's discoveries.

NASA CONNECT Program Overview

As stated previously, The NASA Langley Research Center produces the NASA CONNECT program, which is targeted toward middle schools students in grades 5-8. The overarching goal of NASA CONNECT is to establish the "connection" between the mathematics, science, and technology concepts taught in the classroom and NASA research as tied to appropriate national standards. NASA CONNECT capitalizes on multiple modes of dissemination (web, print, and video) and utilizes several methods of student engagement (interactive virtual labs, hands-on classroom inquiries, critical student discourse using complimentary video questionnaire guides). A series of live video broadcasts provide the foundation for the NASA CONNECT program and are broadcast nationally over NASA TV, Satellite and PSB TV stations. An in-depth teacher guide is also available to download after registering to participate in the free NASA CONNECT learning program. Samples of the titles for the 2000-2001 season include: (a) MEASUREMENT, RATIOS, AND GRAPHING: 3, 2, 1...Crash; (b) GEOMETRY AND ALGEBRA: Glow with the Flow; (c) DATA ANALYSIS AND MEASUREMENT: Ahead, Above the Clouds; and (d) FUNCTIONS AND STATISTICS: International Space Station (ISS)-Up to Us.

NASA CONNECT: Asynchronous Interaction

The video component of NASA CONNECT may also be viewed asynchronously by dubbing the copyright free content during a live broadcast or by ordering a high fidelity copy from NASA CORE (Central Operations of Resources for Educators) for a nominal fee.

CORE is a worldwide distribution center for NASA-produced multimedia materials and can be found on the web at: http://www.core.nasa.gov. Interested parties may request via phone, fax or print mail other multimedia productions in addition to previous NASA CONNECT videos. The NASA CONNECT video series may also be dubbed free of charge by bringing a blank VHS tape to the nearest NASA Educator Resource Center (ERC) in your state. To locate the nearest ERC available to you visit the ERC Network on the web at: http://spacelink.nasa.gov/ercn/.

The interactive web-based virtual labs, hands-on classroom inquiries and student video questionnaires from previous and future NASA CONNECT topics are available on the web at the NASA Langley Research Center and may be located at: http://connect.larc.nasa.gov/. To locate current and future topics click the "2000-2001 Season" link found at the URL above. Previous components of prior shows may be found by clicking on the "Educators" link on the home page and then the link titled "Library of Shows" that appears atop the new page that loads for educators.

Our "Virtual Lab" Web Component

Our design project developed an interactive prototype web-based instructional unit to support the video program titled: *Algebra: Mirror, Mirror on the Universe*, which originally aired in April of 2000. In this multi-modal program students were encouraged to discover how algebra and telescopes are used in space exploration and why optics (the study of light) is important in astronomy. Students are guided to discern for themselves through the virtual web lab component the value of placing orbital observatories in space. Students move from backyard astronomy to mountain observatories and the Hubble Space Telescope to discern what we can learn about the origin of our universe and galaxies. Ultimately, a discussion of the Next Generation Space Telescope is presented. Topics like the electromagnetic spectrum, red shift, right ascension, and declination are discussed in detail with vivid multimedia animation and strong user control, feedback and interactivity.

A Look Back: Designing the "Virtual Lab"

We first met with the NASA CONNECT team members to discuss possible directions for our instructional program. The folks at NASA did not have a concrete vision as to what they wanted for the instructional program. They provided us with a list of science and math standards for students in grades 6 through 8 that they were interested in addressing, as well as an extensive list of information about telescopes. From that list we chose as many key concepts as we thought would be appropriate for the length of the instructional program, the development time, and

the age group involved. With this information at hand, we set out to develop an interactive program that would help students learn about telescopes and celestial observation while at the same time covering certain required science and mathematics standards.

We started by creating a context in which students would help NASA scientists search back in time for the origins of the universe. Astronomers are constantly attempting to see farther back in time in an effort to discover the origins of the universe. The way they do this is through the use of telescopes to observe celestial objects that lie at great distances from the Earth. Due to certain scientific occurrences, the more distant the objects that we are able to view, the further back in time we are looking. The way we implemented this context was by developing an interactive simulation in which students can view the night sky from different locations on Earth and in space using increasingly more powerful viewing instruments. Each student takes on the role of an observer on the Earth who is using various viewing instruments to view the night sky. As the program progresses they learn more about telescopes, including their advantages, limitations, and the factors that influence their operation.

From the start we also wanted to incorporate many of the stunning images that have been provided by the Hubble telescope. This includes images from the farthest reaches of space that have never before been seen – images that have captivated people all over the world since they were made public. This fit in perfectly with our simulation because the final scene of the simulation would allow students to use the Hubble to view celestial objects.

Our design project may currently be found at: http://www.albyers.com/CONNECT/index.htm. The NASA Langley Learning Technology Program Manager is now overseeing the formative review and revision of our content and design. In hindsight, the design process may have been simplified if: (a) the graduate student instructional designers could have coaxed more salient program objectives from the NASA subject matter experts, and (b) more time could have been allowed to conduct early formative revision of the product, such as expert reviews, one-on-one student reviews, small group and pilot testing.

Student Progression and Interaction through our "Virtual Lab"

The virtual lab begins with a Web-based introductory section that introduces students to the idea of looking back in time. Inquiry questions are used to gain attention and provide an advance organizer to help direct students' attention. The types of questions include, "Where did the human race come from?", "How did the Earth come into being?", and "When did the universe begin?" these types of questions help lead students into taking on the role of a curious astronomer. It is also a way of gaining the students' attention through the use of decorative images produced by the Hubble telescope.

The completed instructional program/virtual lab contains three separate simulation scenes of increasing depth and interactivity, surrounded by a variety of supporting instructional materials. The simulation portions of the virtual lab were developed in Macromedia Director and then exported as a series of Shockwave movies, while the supporting material was developed as Web pages. Director was chosen for its ability to easily combine different graphical elements with sound effects, as well as for its animation capabilities. Director's Lingo programming language was utilized extensively to control the switching of graphics as well as the movements of the various telescopes across the viewing window.

The simulation part of the virtual lab comprises three different interactive "scenes". In the first scene students begin on Earth using only their naked eyes to view the night sky. In addition, they have a choice of three different viewing locations: mountain, desert, or city. Each location provides a different level of viewing depending on several factors. At the end of this scene students have learned the optimal Earth-based location for viewing the night sky, as well as the various obstacles that can make viewing more difficult.

Once the student has determined the optimal viewing location, this leads into the next scene of the simulation. In this second scene students are limited to one Earth-based location, but they are now given the option of using several different viewing instruments with which to observe the sky, including a telescope and a larger mountaintop observatory. It is at this point that they are introduced to the concepts of right ascension and declination. This is the coordinate system that is used by astronomers to locate objects in the sky using telescopes. Since students now have the use of two different telescopes we programmed the simulation so that students must first choose which telescope

they wish to use, and then decide which part of the sky they wish to view using their selected telescope. After determining where they wish to point their scope, they must enter the appropriate coordinates (in the form of right-ascension and declination) for that location in an entry window in order to move the telescope to that location. The telescope viewer then moves to that location in the sky. If there is an object to see at that location it appears within the scope. If a student clicks on the scope at that point he or she will then see an enlarged picture of the object. These pictures are actual NASA photographs that approximate what the object would look like using that particular telescope.

By focusing the scopes on different sections of the sky students are able to view various celestial objects, some of which are not viewable with the naked eye. Those that *are* viewable with the naked eye are seen in much greater detail when using one of the telescopes. By the end of this scene students will have learned that telescopes allow us to view celestial objects in much greater detail than we can using just our eyes, and that even more powerful telescopes allow us to view new objects that are farther away from the Earth, and thus farther back in time. At end of this scene, however, students realize that there are limitations even with mountaintop observatories, and that astronomers have still not been able to see all the way back to the origin of the universe.

This leads to the third scene of the lab, in which students blast off into space to view celestial objects without the impediment of the Earth's atmosphere. At this point they have advanced to using the Hubble telescope, and can view the same objects as before in the greatest detail available to us. In addition, the use of the Hubble opens up the sky to allow them to view even more distant objects, including objects that have never been seen before: start clusters, great spiral galaxies, and brilliant nebulae. In programming this scene we were able to make use of many of the breathtaking images captured by the Hubble telescope.

Supporting Sub-lessons within the "Virtual Lab"

In addition to discussing the operation of telescopes, we chose to include other concepts that were deemed important to the overall context of the program. They were chosen based on how well they could be incorporated into the concepts covered in the simulation scenes. We did not want to give the impression that the simulation was "stopping" while we fed the students needed verbal information. The goal was to make it seem as though students were interacting with a continuous instructional program.

These concepts are introduced during Web-based "sublessons" that fall between the three different simulation scenes. At the end of each simulation scene students enter one of these sublessons, where they are first presented with a review of the concepts covered in the previous scene. After that, new concepts are introduced that will enable students to progress to the next scene of the simulation. For example, before moving on to the scene that features the Hubble telescope, students first go through a sublesson that discusses what the Hubble telescope is and why it is important to astronomers. In doing so students understand that when astronomers reach the limits of what they can observe in the sky, they must turn to new technologies to enable them to see further and thus continue their cosmic quest to discover the origins of the universe. Colorful graphics, Shockwave animations, and JavaScript quizzes are employed in the sublessons to help keep students interested throughout these non-simulation segments of the program. In addition, these sublessons are where we chose to integrate the various math concepts that were deemed important by the NASA team.

Keeping Track of Cosmological Time in the "Virtual Lab"

During the development process it was important for us to keep in mind the ultimate goal of students' celestial observations, which is to search back in time for the origins of the universe, and galaxies in particular. To that end we integrated a way for students to keep track of how far they have progressed in this quest. Throughout the program they keep track of their progress through the use of a chronometer. The chronometer is a graphical representation of how far back toward the origin of the universe students have been able to view at that point in the simulation. The chronometer is updated throughout the program as a student progresses to using more advanced telescopes, and thus is able to see more distant objects. At the end of each part of the simulation students see that there is still farther to go, and that we need to use more advanced techniques in order to keep traveling back in time. This progressively leads to the subsequent sections.

No Answer in Sight: The Need for the Next Generation Space Telescope

At the end of the program students can see from the Chronometer that there is still farther to travel in order to see back to the origins of the galaxies, and that new advanced telescopes must continually be developed to help astronomers in their quest. Students realize that we are continually limited in our knowledge of certain scientific questions, and that our knowledge and understanding is limited by the power of our observations. The program then finishes up with a discussion of several advanced telescopes that are currently being developed and/or deployed. These next generation telescopes are necessary to help us answer the complex questions posed to us by the universe around us, and to provide greater explanatory insight into the cosmological origins of the universe.

Will any of today's students become tomorrow's astronomers? It is hoped that programs such as this, and the many others provided by NASA CONNECT, will help to stimulate student interest in science, mathematics and technology, and by doing so help shepherd in a new generation of space explorers, scientists, and engineers who will attempt to solve these challenging endeavors.

In Closing:

This paper analyzed the instructional design process employed to develop a "Virtual Lab" in support of the NASA Langley CONNECT distance education program. NASA CONNECT is a series of educational programs developed by the NASA Langley Research Center that employ multiple ways to engage middle school students in learning standards-based mathematics, science and technology using NASA content. The CONNECT programs employs multiple modes of delivery and student interaction via web-based virtual labs, classroom inquiries and video-facilitated student discourse.

Our interactive shockwave-based project in support of a NASA CONNECT "Virtual Lab" is described in detail and the design decisions that transpired are reflected upon. Internet URL's are also provided throughout our document for readers to access not only the NASA CONNECT program, but also our existing version of the project, as well as how to obtain prior NASA CONNECT programs via NASA's Central Operations of Resources for Educators.

Digital Storytelling: Creating Multimedia Narratives as School Projects Using Desktop Movies

Kate Kemker
Brendan Calandra

Today, teachers in traditional classrooms are inspiring their students through the discovery of desktop movie making. Desktop movie projects are a powerful way to teach across curricula as students create their own videos. Producing desktop movies engages critical and creative thinking in order to plan and produce programs (Jonassen, Peck, & Wilson, 1999). Digital storytelling projects, for example, demand a project synopsis, storyboards, a shooting script, and a production log (as well as development of the actual media) (Apple, 2000). Students need only a camera, a computer, Final Cut Pro and their imagination to create their own digital story.

A Scenario

A schoolteacher somewhere in the U.S. began one of her classes with an opening lesson on the Holocaust. Her application of multimedia tools and content, however, made this year's exploration of the historical event a memorable one for her students. Through the utilization of the Web site *A Teachers' Guide to the Holocaust*, students embarked on virtual field trips to concentration camps, and to far away museums and other historical sites. The students were also able to view video clips of Holocaust survivors and listen to traditional Jewish music of the time period. After touring virtual exhibits on the Web, students then broke into groups to begin discussing different aspects of the Holocaust.

Group A decided to focus on the music that came out of the Holocaust using MIDI (digital music) and text files of lyrics from traditional Jewish and partisan resistance songs. Group B chose to focus on the Treblinka extermination camp. They collected images from Web galleries, examined interactive maps, took virtual reality tours of the camp, and researched original documents created by victims, perpetrators and others. Group C wanted to look at the Holocaust from a child's perspective. Group C decided to use a collection of children's drawings, poems, and diary entries from the Terezín concentration camp to create a multimedia collaborative project through which they would try and better understand the sad stories of children caught in the horrors of the Holocaust.

The group elected to create a digital video to be presented to their class. The subject once taught through traditional textbooks had been transformed. The project integrated technology, connectivity, content and human resources in the production of a digital story describing events during the Holocaust as seen through children's eyes. Motivation was high throughout due to the pride students took in the development process and the final product.

Desktop Movie Making

Advances in desktop computer technology make it possible to capture and manipulate sounds, video, and special effects to create a single presentation (Alessi & Trollip, 2001). This innovative technique is called desktop movie making. The use of desktop movies as a medium for student collaborative projects engages them in planning, writing, visualizing, organizing, creating, and a host of other meaningful learning activities (Jonassen, Peck, & Wilson, 1999).

In television journalism, the video essay serves as an alternative to traditional narrative or voice-over modes of presentation. A video essay follows an underlying theme or storyline and presents information entirely through video. This type of story format is similar to digital storytelling. One difference is that the desktop movie editing process is simple enough that almost anyone can do it.

Traditional linear video editing involves viewing the video from the beginning and then cutting the tape as you go along. This process involves a variety of equipment and is very time consuming. With the creation of non-linear editing systems, such as Final Cut Pro, video editing can now be done on the computer. The term "non-linear" refers to the random access capabilities for searching, recording, and playing back digital video sequences stored on the computer's hard drive. With a nonlinear editing system, you can begin editing at any point in a video. The information stored on a hard drive may be accessed, nearly instantaneously, at any point from any point on the hard drive. When students are engaged as producers of media, there is more learning taking place than when students are receivers of media (Alessi, S. & Trollip, S., 2001).

Conclusion

Today, teachers in traditional classrooms are inspiring their students through the discovery of desktop movie making. Desktop movie projects are a powerful way to teach across curricula as students create their own videos. Producing desktop movies engages critical and creative thinking in order to plan and produce programs (Jonassen, Peck, & Wilson, 1999). Digital storytelling projects, for example, demand a project synopsis, storyboards, a shooting script, and a production log (as well as development of the actual media) (Apple, 2000). Students need only a camera, a computer, Final Cut Pro and their imagination to create their own digital story. Like the invention of written language, the potential of using desktop movies in the classroom, in which the students are able to create their own movies, seems to represent a major landmark in human history (Forman, & Pufall, 1988).

Developing Web -based Multimedia for an Educational Web -site: The Use of Quicktime Audio, Video, VR technology and JavaScript-based Interactivity

Brendan Calandra
Kate Kemker
Ann Barron
Christine Harmes

Abstract

The *Teacher's Guide to the Holocaust* is an instructional Web site comprised of over 7,000 HTML pages using a wide range of digital media from text to video and virtual reality. It was designed and developed by graduate students in the Instructional Technology program and the staff of the Florida Center for Instructional Technology, at the University of South Florida. The program was designed to provide a one-stop resource for teachers of the Holocaust.

A variety of media was used in developing the *Teacher's Guide*. The media ranges from text files to video and JavaScript based interactivity. This paper briefly describes the design and development of the following multimedia elements of *A Teachers' Guide to the Holocaust*: Interactive Quizzes, Digital Audio and Video, Java Script-Based Glossary Widows, and Virtual Reality Panoramic Pictures.

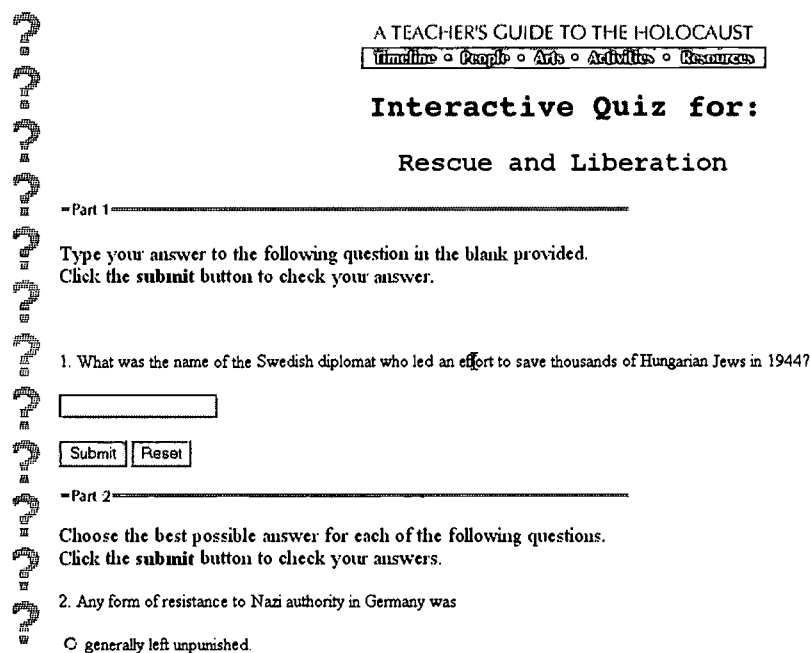
Introduction

In 1994, Florida became the first state to enact a law requiring instruction in the history of the Holocaust (Brogan, 1997). The law was championed by, among others, Stephen Spielberg, director of Schindler's List. The law requires that all public schools teach the following:

> The history of the Holocaust (1933-1945), the systematic, planned annihilation of European Jews and other groups by Nazi Germany, a watershed event in the history of humanity, to be taught in a manner that leads to an investigation of human behavior, an understanding of the ramification of prejudice, racism, and stereotyping, and an examination of what it means to be a responsible and respectful person, for the purposes of encouraging tolerance of diversity in a pluralistic society and for nurturing and protecting democratic values and institutions.
>
> The Holocaust Education Bill (SB 660)

Although the law mandated Holocaust education, very few of Florida's teachers were adequately prepared to teach this sensitive subject. To help meet the need for teacher preparation and curriculum resources, the Florida Center for Instructional Technology, along with the Instructional Technology program in the College of Education at the University of South Florida, created the online resource, *A Teacher's Guide to the Holocaust* (http://fcit.coedu.usf.edu/holocaust).

The *Teacher's Guide* is designed to provide an overview of the Holocaust through text, original source documents, graphics, photographs, art, movies, and music. This Web site allows preservice and inservice teachers to view the Holocaust through three different "lenses"--Timeline, People, and the Arts. Additional resources are provided in the Student Activities and Teacher Resources sections.

Multimedia


Multimedia is the use of several media to present information. Advances in digital technology in the last decade have led to the ability to develop multimedia more conveniently and at higher levels of sophistication than ever before. These advantages impact the field of education due in part to the richness of context that multimedia can provide and also to the range of formats in which information can be presented (i.e. text, graphics, video.) Because of its universal availability and dynamic nature, Web -Based Instruction has also grown rapidly in all facets of education. Due to the recent explosion of interest in Web -Based Instruction in education, researchers and practitioners are scrambling to find proven methods for turning Web sites into effective learning instruments.

A variety of media has been used in developing the Teacher's Guide. The site provides over 1,000 photographs, hundreds of source documents, numerous panoramas of concentration camps, music, survivor testimony videos, interactive quizzes, interactive glossaries, and many other resource materials for Holocaust instruction. All of these resources included in the site can be readily used in classrooms for instructional purposes. This paper briefly describes the design and development of the following multimedia elements of *A Teachers' Guide to the Holocaust*: interactive quizzes, digital audio and video, Java script-based glossary widows, and virtual reality panoramic pictures.

Development

Several techniques were used to create the vast array of resources available on the site. A few of these resources that will be discussed in more detail below are: Interactive Quizzes, Digital Audio and Video, JavaScript-based Glossary Widows, and Virtual Reality Panoramic Pictures.

Rescue and Liberation

▬Part 1▬

Type your answer to the following question in the blank provided.
Click the submit button to check your answer.

1. What was the name of the Swedish diplomat who led an effort to save thousands of Hungarian Jews in 1944?

[   ]

[Submit] [Reset]

▬Part 2▬

Choose the best possible answer for each of the following questions.
Click the submit button to check your answers.

2. Any form of resistance to Nazi authority in Germany was

○ generally left unpunished.

In order to provide immediate, client-side feedback and a mild level of interactivity, quizzes were developed using Macromedia's CourseBuilder ®. This software allowed items to be created quickly and easily using a variety of formats including, radio buttons, check boxes, drag-and-drop and more. Feedback was provided in the form of pop-up dialogue boxes with comments such as, "Good job," or "Try again." In some circumstances, feedback was provided in the form of correct answers provided at a prescribed time during interactions. Questions were created in a variety of formats ranging from multiple-choice to short answer and drag and drop. Question content was created and validated by a team of Holocaust and measurement experts working on *The Teachers' Guide*.

Traditional Jewish Music

The following traditional Yiddish and Hebrew selections can be played in MIDI:

Oyfn Pripetshik

This well-known Yiddish lullaby, by Mark Warshawsky (1848-1907) describes a rabbi teaching a group of kindergarten-aged boys the Yiddish alphabet. It is symbolic of the Jewish tradition of studying Torah, the Five Books of Moses, as well as the passing down of heritage from one generation to another.

Yiddish	English
Oyfn pripetshik brent a fayeri, Un in shtub iz heys;	Oh, the fire burns in the fire place, and the room has heat.
Un der rebbe lernt kleyne kinderlech dem alefbeyz;	And the rabbi teaches all the little ones all their ABCs;
Un der rebbe lernt kleyne kinderlech dem alef-beyz.	And the rabbi teaches all the little ones, all their ABCs.
Zet zhe, kinderlech, gedenkt zhe tayere, vos ir lernt do;	See now, little ones, listen children, don't forget it, please.
Zogt zhe noch a mol un take noch a mol: Komets alef o.	Say it once for me and say it once again, All your ABCs.

Paper manuscripts of music used on the site were accessed from the public domain archive at the university library. A musician was then hired from our university to create digital sound files on a MIDI keyboard. The MIDI file was then saved as a QuickTime file in order to make it universally accessible (A QuickTime installer was placed on all CDs and a link to QuickTime download on our site.) Multimedia that is created in QuickTime will perform equally as well on Windows and Macintosh computers.

Quicktime Movies

A TEACHER'S GUIDE TO THE HOLOCAUST
Timeline ○ People ○ Arts ○ Activities ○ Resources

Sylvia Richman

Sylvia Richman tells about life in a Jewish ghetto in Poland.

MOVIE "I was born in a country called Poland."

MOVIE "By being Jewish, we were threatened."

MOVIE "All the Jewish people had to move."

Holocaust survivor movie files were originally recorded by an analog video camera at the Tampa Bay Holocaust Museum. Permission was granted from each of the survivors to use the video footage on the Web site. The VHS videotapes were then transferred to a digital video camera, allowing the movies to be edited on a computer. Each one of the videos was then reduced to short one-minute clips. The clips were edited according to content. Each video clip is a stand-alone idea listed by description on the site. Finally, the movies were compressed to reasonable file sizes for use over the Web.

VR Movie: Auschwitz Gas Chamber
QuickTime VR (QTVR) allows for an immersive user experience that simulates three dimensional objects and environments. The QTVR panoramas used on the Holocaust Web site provide experiences such as standing at the Auschwitz Gas Chamber or walking through the camp grounds. To create a QTVR panorama, the photographer stood in one place, with the camera on a tripod, and took pictures in succession, as the camera was rotated 360 degrees. The pictures were then stitched together using Apple's QuickTime Virtual Reality Authoring Studio. Each QTVR was created in three file sizes for use with different Web connection speeds.

Definition of Volk - Microsoft Internet Explorer

A TEACHER'S GUIDE TO THE HOLOCAUST

Volk :

The concept of Volk (people, nation, or race) has been an underlying idea in German history since the early nineteenth century. Inherent in the name was a feeling of superiority of German culture and the idea of a universal mission for the German people.

/folk/

Definitions are provided for those words of which users might not have complete knowledge and understanding. The user simply clicks on the semiotic icon "DEFN', and a JavaScript pop-up window opens. The definition of the vocabulary word appears in the window along with a sound clip of the word being spoken in its native language. Students at the university provided the sound clips. The JavaScript was hand coded and embedded into HTML files. The Audio files of pronunciations were created in QuickTime. JavaScript is an easy to learn scripting language that enables creations of activities that have responses such as pop-up boxes, status bar messages, and validation and feedback based on form data.

Implementation

The primary vehicle for distribution of the project is the Web. The Florida Center for Instructional Technology maintains a Windows NT Web server at USF. File management and maintenance are monitored closely, and revisions and updates can be done on a routine basis. The Web site currently receives over two million hits per month, and links to it have been established from hundreds of Web sites throughout the United States, Europe, the Middle East, and other parts of the world.

Although delivery through the Web is optimal in many circumstances, there were sufficient reasons to create a version of the program for delivery on CD-ROM. One of the major restraints of Web delivery is that not all teachers have access to the Web. Another problem was that more sophisticated multimedia demands higher bandwidth than most people have at home and many have at their schools. Therefore, a CD-ROM-based version was created and distributed to every school in the state of Florida. Because of the need for distribution via the Web and CD, all of the files were client-based and all of the links were relative

Conclusion

Advances in technology in the past decade have allowed for multimedia to be developed more efficiently and at higher levels of complexity than ever before. The implications for the use of multimedia in education stem from the richness of context and variety of formats for the presentation of information that especially digital multimedia can now provide. The World Wide Web (WWW) is fast becoming the widest reaching means of communication in the world. Through the WWW, digital multimedia can be disseminated across barriers of time and space. The examples provided above are only a few of the creative ways in which specifically instructional multimedia material can be developed for and implemented using the WWW.

Successfully Integrating Technology into a Lesson Plan for a Technology-Rich Learning Environment

Christine Callahan, University of Houston at Clear Lake, USA ; Caroline M. Crawford, University of Houston at Clear Lake, USA

The successful integration of technology into a lesson plan that enhances the learning environment is a mixture of numerous significant elements. These elements build upon the strengths of numerous entities. Two significant groups of instructional designers who have come together to develop the technology-rich lesson plans are teacher candidates and inservice educators. Yet the thoughtful design of a lesson plan format with simplistic explanations and examples offers the ease of use that is necessary for persons who are working within a new philosophical world of integration. Further, the assessment module that must follow the lesson plan design and development must offer an ease of use that enriches the discussion surrounding the lesson plan assessment mode. An assessment rubric was developed that met the desires of all parties concerned.

An Adaptive Hypermedia Presentation Modeling System
for Custom Knowledge Representations

Pablo Castells and José Antonio Macías
E.T.S. de Informática, Universidad Autónoma de Madrid
Campus de Cantoblanco, 28049 Madrid, Spain

{pablo.castells, j.macias}@uam.es
http://www.ii.uam.es/{~castells, ~macias}

Abstract. We propose a generic presentation system for adaptive educational hypermedia that is highly independent from domain knowledge representation and application state management. Our approach is based on providing a) a module for knowledge representation by means of the definition of domain ontologies that best fit specific domains and/or authors, b) a module for building courses by constructing semantic networks of interrelated domain ontology instances, and c) a presentation module where presentation models (templates and rules) are associated to ontology object classes and relations. By using an explicit presentation model, separate from course contents, course designers are provided with extensive control over the generation of all aspects of presentation, at a moderate development cost. Because minimum assumptions are made about how domain knowledge is structured and updated, our presentation system can be potentially integrated with a wide range of adaptive hypermedia support tools.

1 Introduction

With the rapid introduction of web-based technology in the educational field, learners are gaining increasing autonomy, and instructional applications are reaching an unprecedented diversity of users. In this context, a growing interest has been raised for the development of hypermedia systems that are able to adapt automatically to different types of users, platforms and situation, and that take into account the evolution of each user over time (Brusilovsky 1998b). A common implicit or explicit priority concern to all research work in adaptive education is that of finding an appropriate representation for pedagogical knowledge (Murray 1998). Each courseware development tool establishes its own way to structure the domain, so that designers must describe the subject matter as the tool prescribes, and the tool takes care of the selection, presentation and dynamic sequencing of teaching materials, and the interaction with the user.

In this paper we propose a generic hypermedia presentation system, PEGASUS (Presentation modeling Environment for Generic Adaptive hypermedia SUpport Systems), that makes minimum assumptions about how instructional knowledge is represented (Macías 2001a, 2001b). It is our purpose to provide courseware designers with a simple specification paradigm for non-trivial adaptive presentation constructs, that can be used with different course management systems. In order to allow for different approaches, PEGASUS supports the definition of made-to-measure domain ontologies for the description and conceptual structuring of subject matter (as in Murray 1998). Once an ontology is defined, designers build courses by creating domain objects and relating them together using the conceptual vocabulary defined by the ontology. Course presentation is designed by defining an explicit presentation model where presentations are associated to ontology object classes and relations.

2 Related Work

The explicit representation and use of semantic knowledge about a domain to facilitate or guide the access to information has been a primary concern in hypermedia systems from the early times (Trigg 86). In the literature on adaptive hypermedia many ways to structure knowledge have been proposed. Most of them are based on a level of contents, discretized on the basis of some kind of elementary unit, and a level of semantic structure, that is used as a road map to guide navigation. There is a great variation however as to how contents are structured, how the conceptual network is organized, and how both levels are connected.

To name a few, Interbook (Brusilovsky 1998a) structures courses into hierarchical aggregate units: *chapters, sections, subsections*, and *terminal pages*, accompanied by a set of interconnected *concepts* with two types of relation: *prerequisite* and *outcome*. The relative simplicity of this two-relation model contrasts with the lexical richness of other tools like HyperTutor (Pérez 1995), where the conceptual map takes a wide variety of relations from the educational theory literature: *prerequisite, sequence, aggregation, similarity, opposite, example, specialization*, and *exception*. AHA (De Bra 1998) allows a more flexible composition of pages, based on conditional HTML fragments. Concepts have three boolean attributes to indicate the student's state of knowledge with respect to each concept: *known, read, ready to be read*, and relations between concepts have a parameter that represents a state (a boolean) or a quantitative measure (a number).

DCG (Vassileva 1997) and TANGOW (Carro 1999) are distinguished for generating the course structure, or parts of it, at runtime. In DCG a first level of interconnected concepts is defined, below which, for each concept, a tree of learning *tasks* and *subtasks* is created with the sequence of documents and actions to follow by the student to learn the concept (Vassileva 1995). Both task decomposition and the association of fragments to atomic tasks are determined dynamically at runtime by means of *rules*. TANGOW uses a conditional hierarchy similar to DCG where, unlike DCG, contents can also be associated to composite tasks which, as a consequence, can also be visited by the student. In other systems, the generation of semantic relations is even more dynamic and takes place by means of automatic search mechanisms based on metadata that are associated to information units (Wilkinson 1999). This approach is useful when the knowledge space is too large and/or volatile to define and maintain explicitly the desired relationships.

Out of the hypermedia field, Eon (Murray 1998) takes a more general approach than the preceding systems, allowing the author to define his/her own knowledge categories (*topics*), and the relations among them that s/he considers appropriate. Each topic is assigned sets of content units through different relations defined by the designer, such as *introduction, explanation, evaluation, basic level, advanced level*, or *summary*. The effective selection of contents takes place at runtime by applying predefined pedagogical strategies for content selection and ordering (e.g. choose an element randomly, or present all of them in sequence). Eon provides a graphical tool where the designer builds parameterized user interfaces, to which s/he associates units of contents, in such a way that interface widgets (buttons, tables, graphs, dialog boxes, etc.) take values from the knowledge unit being presented.

3 Knowledge Representation

Using a specific knowledge representation approach, like the ones described in the preceding section, a domain model is built. Many adaptive systems associate information about the student to domain model objects, in order to maintain an up-to-date model of the student's knowledge and goals with respect to the described subject matter (overlay model). This information is used at run-time to adapt the selection and presentation of contents and links to the user. While the cited systems provide for different forms of explicit author control over the teaching strategies (corresponding to conceptual map update mechanisms), the generation of pages, except in Eon (Murray 1998), is done according to fixed presentation patterns and styles programmed into the tool.

Our system supports the automatic generation of hypermedia documents of the type supported by other adaptive systems, with full control for the designer over the visual aspects (presentation) of the generated hyperdocuments, and without imposing a particular representation of knowledge. To do so, like Eon, PEGASUS allows the definition of taxonomies made to fit the domain and/or the author. The terminology thus defined is used on the one hand for the description of the subject matter by the author, and on the other for the construction of presentation models associated to the different knowledge categories.

3.1 Domain Ontology

The domain ontology in PEGASUS consists of a set of classes that best fit a specific application domain or that reflect the specific view of a particular author on the domain. In our approach ontologies can be defined with a high degree of freedom, with very generic classes like Concept, Lesson, Fact, or more specific, like Algorithm, Theorem, or Definition, as the designer sees fit. Ontologies include terms for subject-matter information (e.g. a theorem has a statement and a proof), pedagogical information (e.g. lessons have levels of difficulty), and run-time (user and system) state information (e.g. whether a concept is known by the student). All this knowledge is captured by defining attributes for classes, and relations between classes.

PEGASUS provides a root class, *KnowledgeUnit*, and two predefined subclasses, *Topic* and *Fragment*, for ontology designers to subclass. *Topic*'s are presented to the end-user in a separate page, while several *Fragment*'s can be inserted in the same page. A predefined subclass of *Fragment*, *AtomicFragment*, carries content media (HTML source). *KnowledgeUnit* has a few predefined attributes like *id* and *title*, to which the designer can add others like *read, known* or *visible*, and new relations like *prerequisite* and *subunit*. Among other formats, PEGASUS allows the representation of ontology classes and domain instances in XML. The following example illustrates the definition of a class *Algorithm* with three relations: procedure, examples, and proof of correction. For the sake of brevity we omit here other relations that would normally be included, such as previous definitions, problem to solve, or analysis of complexity.

```
<Class name="Algorithm" parent="Topic">
    <Attribute name="recursive" type="Boolean"/>
    <Relation name="procedure" type="AtomicFragment"
              multivalued="false" title="Procedure"/>
    <Relation name="examples" type="AtomicFragment"
              multivalued="true" title="Examples"/>
    <Relation name="correction" type="Theorem"
              multivalued="true" title="Proof of Correction">
        <Attribute name="relevant" type="Boolean"/>
        <Attribute name="difficulty" type="Number"/>
    </Relation>
</Class>
```

Relations can have their own attributes, like the difficulty of the proof of correction in the above example, that reflect properties of the relation itself. All relations have a predefined *title* attribute that is used in certain cases to generate titles or text for hypermedia links.

In addition to a domain ontology, simpler data structures are defined by the designer to describe user profiles, information about the course (plan, goals, requirements, duration, number of students, etc.), platform characteristics and other aspects considered relevant for the adaptivity of the application being built.

3.2 Domain Model

Once an ontology has been defined, courses are constructed by creating semantic networks of domain objects, using the classes and relations defined in the ontology. The following example illustrates the creation of an instance of *Algorithm* to represent Dijkstra's algorithm for the shortest paths problem (we assume that the attribute *title* and the relation *prerequisite* are predefined in the root class *KnowledgeUnit*).

```
<Algorithm id="Dijkstra" title="Dijkstra's Algorithm" recursive="false">
    <prerequisites> <Algorithm ref="relaxation"/> </prerequisites>        (1)
    <procedure>
        <AtomicFragment> <tt>Dijkstra(G,s)<br> Init(G,s)<br> Q = V[G]    (2)
        <br>  while Q not empty do<br>  u = ExtractMin(Q)<br>
          for v in Adj[u] Relax(G,u,v)</tt> </AtomicFragment>
    </procedure>
    <examples> <AtomicFragment URL="exmpl.html"/> </examples>              (3)
    <correction relevant="true" difficulty="0.6"> <Theorem ref="th1"/> </correction>
</Algorithm>
```

Elements with the attribute `ref` indicate references to other course units (for instance, line 1 refers to an algorithm with `id="relaxation"` which is assumed to be defined somewhere in the domain model). Atomic fragments can directly consist of a string, like Dijkstra's algorithm procedure above (line 2), or a web address, as in line 3.

At runtime PEGASUS maintains a copy of all domain objects for each user, where class attributes (e.g. *read*) are used to measure the user's progress. These values can be used to influence presentation (see Section 4), but a complementary update module is required to keep them up to date (see architecture, Section 5).

The domain model in PEGASUS supports the definition of adaptive elements in the model itself by means of the introduction of conditions on any part of the structure. For example, in line 3 different examples could be given to select from depending on the student's experience level. This way it is possible to build dynamic structures like TANGOW (Carro 1999) or DCG (Vassileva 1997) task hierarchies, which take their definitive shape at runtime depending on the user model. Besides these adaptive elements, PEGASUS admits, though does not include by itself, any other mechanism for dynamic construction and modification of course structure. Our system takes care of how this may affect presentation, but how course structure and state are updated is external to the presentation system.

4 Presentation Model

Existing adaptive hypermedia systems miss an explicit presentation model. As a consequence, presentation is partly intermingled with contents (as in De Bra 1998), and partly set up automatically by the system according to rigid design choices (e.g. link annotation) that the designer cannot configure (see Brusilovsky 1998a, Carro 1999, for instance). In PEGASUS, the separation of content and presentation is achieved by defining a *presentation template* for each class of the ontology. Templates define what parts (attributes and relations) of a knowledge item must be included in its presentation and in what order, their visual appearance and layout. Templates are complemented with *presentation rules*, which are responsible for generating adaptive presentation constructs involving relations between domain objects from very succinct high-level descriptions given in templates. Whereas in Eon (Murray 1998) user interface components are associated with specific units of knowledge, in PEGASUS presentations are defined for *categories* of knowledge.

4.1 Presentation Templates

Templates are defined by using an extension of HTML based on JavaServer Pages™ (JSP) (Sun 2001), that allows inserting control statements (between `<%` and `%>`) and Java expressions (between `<%=` and `%>`) in the HTML code. In these templates, the designer can use all the presentation constructs of the HTML language (lists, tables, frames, links, forms, etc.), and insert, using very simple Java expressions, the domain items to be presented. For instance, a very simple template for class *Algorithm* could be as follows:

```
<h2> <%= title %> </h2>
<h3> Previous concepts </h3>
<%= prerequisites %>
<h3> Procedure </h3>
<%= procedure %>
<h3> Examples </h3>
<%= examples %>
<h3> Proof of Correction </h3>
<%= correction %>
```

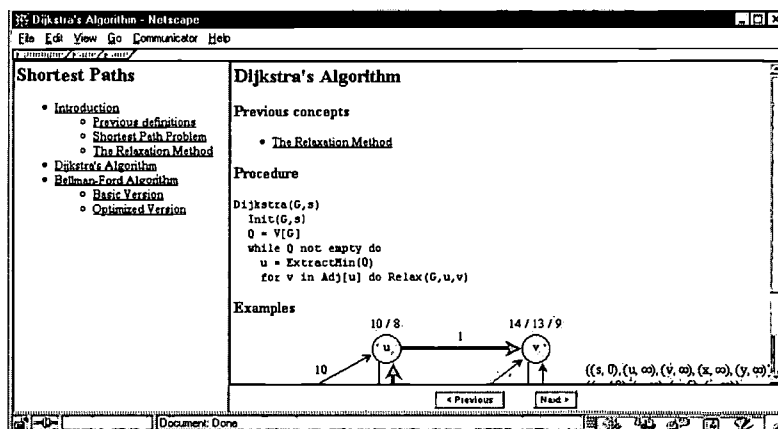
In these templates the presentation author only needs to refer to attributes and relations of the presented class (shown in bold in the example). The presentation system takes care internally of aspects like automatically handling lists (multivalued relations like the examples of an algorithm), or recursively applying templates to referenced objects according to their class (e.g. the proof-of-correction *Theorem*'s of an algorithm). The resulting page for Dijkstra's algorithm with this presentation template can be seen in Fig. 1. HTML elements surrounding the algorithm presentation (frame structure with contextual index on the left and *Previous / Next* buttons at the bottom) come from the presentation template for the root class *KnowledgeUnit*.


Figure 1: Generated web page for a topic of type *Algorithm*

The template definition language supports the introduction of adaptive elements by using conditionals. For instance, in lines 4 to 7 in the preceding example, the presented information could be conditioned to the student's level of expertise, including all available examples when the student is a beginner, and a single example for more advanced students, showing the proof of correction only if it is relevant and not too difficult for the student. The expression language for templates includes other facilities that allow, for instance, cutting down, filtering or sorting lists according to an arbitrary comparison function, generating trees and linked lists by traversing a relation, or forcing the generation of hypermedia links. The basic template language allows the specification of a wide set of non-trivial presentations by using a very simple syntax. However the designer can write arbitrarily complex Java code inside the templates themselves.

4.2 Presentation Rules

Presentation rules govern aspects like link generation, correspondence between link styles and topic states, ordering and layout of (fragment or link) lists, and the generation of built-in presentations for topic network subsets like linked lists and trees. When, like in the previous subsection, the designer refers to a relation like *prerequisite* in the template for class *Algorithm*, rules take care automatically of deciding whether to insert prerequisite details in the generated page, or to generate a link for each prerequisite, which style and annotation are used in the latter case, and how all the pieces are laid out. In doing so, the system analyzes whether the relation is simple or multivalued, the class of the involved topics or fragments, their state, and other conditions, if any, stated by the designer. The designer can modify existing rules and define her/his own. See (Macías 2001b) for a more detailed description of PEGASUS presentation rule definition and processing.

5   Architecture

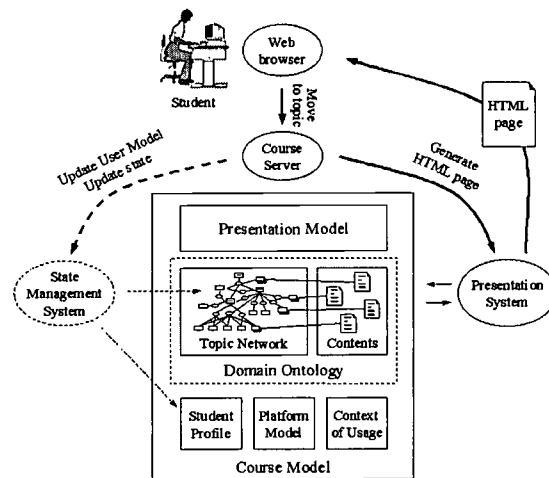
At runtime, the student interacts with the application from a web browser. The interaction with an application built with PEGASUS consists of traversing the domain object network. Each time the user moves to an object, PEGASUS responds by generating an HTML page. In doing so the system 1) resolves the user's request by determining the actual object to move to, 2) locates the instance in the domain model, 3) updates the domain and user models, 4) generates the HTML presentation applying the pertinent rules and the template that corresponds to the object class. In the generated pages links do not point to other pages but refer, explicitly or descriptively, to other domain objects.


Figure 2: Course model and system architecture

In most cases our presentation system will not work alone, since steps 1 and 3 above are external to PEGASUS. After an ontology for the subject matter is built, a runtime module is needed to set up and/or update topic networks (step 3), as illustrated in Fig. 2. Optionally, a planner can be included like in DCG (Vassileva 1997), to determine the path to follow in response to user's requests (step 1).

6 Conclusions

The proposed knowledge representation system can reproduce the domain models used in a wide range of hypermedia systems. Because the dynamic generation of presentation is a separated mechanism from the application state update mechanisms, PEGASUS is compatible with different courseware support tools like the ones described in the related work section. Our approach allows the specification of presentation independently from content construction, enhancing presentation reuse and consistency, thus reducing the development cost.

While the construction of templates is within reach of any web page designer who is familiar with HTML and JSP technologies, the definition of ontologies is a delicate task that requires the participation of an advanced designer, trained in using our system. Once the ontology and the associated presentation models are defined, the construction of the domain model is within reach of the average author. The introduction of modifications on presentation templates and rules can be an easy step for this kind of author towards a more advanced usage level.

At the time of this writing we are about to complete a set of interactive authoring tools to facilitate the construction of ontologies and domain object networks. Among our future work plans we include the development of a graphical editing tool where authors can customize presentation models by example, by editing generated HTML pages, as in (Castells 1999). The creation of this kind of tool is not possible without an explicit declarative model of presentation.

Distance Learning Pedagogy: A Staff Development Series for Faculty

Cathy Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, USA. ccavanau@unf.edu

Terry Cavanaugh, Ph.D. Curriculum and Instruction, University of North Florida, USA. tcavanau@unf.edu

Abstract:
Interest in distance learning is rising among students and professionals. The University of North Florida is preparing for students who expect technologically enhanced and delivered courses. While faculty and administrators at UNF recognize the need to offer online courses, they also recognize that the reputation of the university rests on its ability to continue to provide high quality student-centered courses. Using data that forecasts the growth in interest in online learning, and research on distance learning pedagogy, UNF has begun a program to guide faculty in effective online teaching. A series of workshops was offered to educate instructors university-wide on effective methods used in distance learning environments. The workshop series was called "Effective Teaching in Distance Education Classes." Topics were Team Building, Methods of Assessment, The Online Discussion Forum, and Distance Learning for Clinical/Internship Experiences. Workshops were structured as panel discussions with examples from various content areas and delivery platforms.

This paper focuses on an ongoing process of improvement of distance learning at the University of North Florida. UNF is a public, urban comprehensive university. The university has an enrollment of about 12000 graduate and undergraduate students in five colleges. Currently the university has hundreds of courses with on-line enhancement, and about 10 courses each semester are offered fully online. The university supports three web-based distance learning spaces beyond basic web pages: WebCT, BlackBoard, and Lotus Learning Space.

Interest in distance learning is on the rise among high school students, college students and professionals. A recent survey found that the majority of parents polled obtained Internet access for their children's education (Grunwald Associates 2000), and as of the year 2000 a full 15% of U.S. high schools offered access to online classes (Market Data Retrieval 2000). By the year 2002, over 2 million distance learning students are expected in higher education (Web-Based Education Commission 2000). The majority of working adults stated in a survey that they believe college courses offered via the Internet are the future of higher education, with 32% expressing a preference for online courses over classroom learning, given equal quality of education (CyberAtlas 2000). A survey of business managers who have used Internet-based training found that nearly 100% of respondents would recommend it, mainly because of anytime, anywhere access (CyberAtlas 2000).

Colleges and universities have begun to respond to the rapid increase in interest in distance education. In a recent survey by Framingham, MA based International Data Corporation (IDC 2000), the number of students expected to enroll in distance learning will increase by 33.1 percent annually, from 710,000 in 1998 to 2.23 million by 2002. IDC attributes this growth primarily to the use of the Internet. They see two-year colleges increasing their online offerings 85 percent by 2002, up from 58 percent in 1998; and four-year colleges are expected to increase online offerings 84 percent by 2002, up from 62 percent in 1998 (Boston Globe October 29, 2000). According to a recent EDUCAUSE e-mail survey of 464 high-ranking college information technology administrators, the greatest concern is distance education. Distance education enrollments will rise from 750,000 in 1998 to 2 million by 2002 with 6.6 million adults (age 25+) enrolling in education by 2007 (Katz 1999). More than half (55.5 percent) of the participants in the 2000 Campus Computing Survey report that their institution currently offers one or more full college courses online via the web, up from 46.5 percent last year (The 2000 National Survey of Information Technology in US Higher Education, http://www.campuscomputing.net/).

Public, private, and charter high schools offering online courses have also experienced recent popularity. During the 2000-2001 academic year Class.com offered 50 online courses to over 250 high school students (http://www.class.com). Over 3000 students attended Virtual High School (http://vhs.concord.org), and Florida

Online High School (http://www.fhs.net) enrolled 1000 students. Many other private and charter online high schools are attended by students who expect online courses in higher education. The net generation is completing high school and applying to college, and some of the nation's top high school students seek an institute of higher education that places priority on high quality web-based learning. Established colleges and universities compete for adult lifelong learners with the online schools offering a wide selection of courses in a convenient flexible timeframe.

Not only are more students entering college with distance learning experience and interest, they are also entering college with vast technology experience which alters their learning styles. Instructors face challenges when they work with classrooms of information age students who need to learn in ways that are new to many universities and instructors. Faculty need skills and tools for working with students on meaningful, authentic tasks, and in taking on the role of mentor, model, and guide. Information age students who have years of experience learning to use technology can assume more responsibility for their education. A college cannot address these challenges by applying computers to traditional education systems. To better serve students, classrooms need to adopt attributes of information-age workplaces: knowledge-orientation, flexibility, advanced skills, problem-solving, long-term projects, and communication of results. Distance learning features can be used in courses to empower students by encouraging students to pose and pursue questions while learning challenging and interesting skills, to expend long-term sustained effort for complex tasks, to learn in self-directed and exploratory ways, and to share results.

The University of North Florida is preparing for new and returning students who expect technologically enhanced and delivered courses as part of degree programs, certificate programs, or for career enhancement. At UNF, our mission is to educate students in a broad array of undergraduate and select graduate programs. Our dedication is to excellent teaching and scholarly activity and engagement of students in a personal, supportive and challenging learning environment. We seek to contribute to the betterment of society. Currently, new distance learning planning initiatives, predicated upon available technologies, commit the University to participate with local, regional and state organizations in serving as a clearinghouse for information concerning available instructional delivery options for students, employers, and residents of the community. In July, 2001, the city council of Jacksonville, home to UNF, declared that technology is the city's future," and that "technology is going to get us where we need to be" (Florida Times Union 2001). The council's report stresses the importance of education and area universities in helping the region achieve its goals.

While faculty and administrators at UNF recognize the need to offer online courses and course components, they also recognize that the reputation of the university rests on its ability to continue to provide high quality student-centered courses. Using data that forecasts the growth in interest in online learning, and research on distance learning pedagogy, UNF has begun a program to guide faculty in developing their practices in effective online teaching.

The university's Distance Learning Action Team was originally created as a temporary committee to advise the university on distance education, and to recommend policy. The action team is now a permanent subcommittee of the university's technology committee. Part of the role of the Distance Learning Action Team is to identify and support the needs of faculty as distance educators. During the 1999-2000 academic year, most faculty training in distance learning was skills-based and focused on using computers and specific course delivery technology. Workshops included setting up classes, putting tests online, managing online discussions, uploading documents in Blackboard, WebCT and Lotus Learning Space. During 2000-2001, such training continued, with an additional series focusing on the pedagogy and design for distance learning. A goal for the new workshops was to improve the quality of distance education throughout the five colleges, without using intimidating or specialized educational or distance learning vocabulary or jargon.

A series of workshops was offered to assist in educating instructors university-wide on effective methods used in distance learning situations. The workshop series was called "Effective Teaching in Distance Education Classes." The Distance Learning Action Team, working with the university's Office of Faculty Enhancement, sponsored the workshops, set up schedules and sent invitations. The Office of Faculty Enhancement is charged with providing the resources and the environment for the continuing professional development of UNF faculty. A group of experienced instructors of distance learning from several colleges worked with campus instructional technologists to determine workshop topics. A series of five workshops was developed and they were offered throughout the semester in a

digital conference room. An schedule of the workshop was disseminated throughout the university via web and e-mail. In addition to the published schedule, specific colleges were targeted with invitations, because of previous requests for assistance and instruction from those faculty. Each workshop lasted 90 minutes, with an hour for presentation and demonstration of skills, and 30 minutes of discussion with participants. Demonstrations included course syllabi, examples from current online courses, and samples of student work or student feedback about course experiences. Workshops were structured as panel discussions with demonstration of examples from various content areas and delivery platforms. Practices shared during the workshops were platform-independent, equally effective regardless of delivery system. An intended benefit of the workshop series was to provide participants with contacts who would be available for ongoing assistance. The target skills were appropriate for instructors teaching courses fully online, partially online, and enhanced with online components.

Workshop topics were Team Building, Methods of Assessment, The Online Discussion Forum, and Distance Learning for Clinical/Internship Experiences. An additional topic in development is the relationship between distance teaching and the university promotion and tenure process. A common theme throughout the series was planning for distance learning. Workshop facilitators stressed that expectations for student performance and participation must be determined beforehand, and must be communicated clearly to students at the outset of the class. All activities in the distance learning environment should be integrated into a cohesive learning process, interdependent instead of isolated. The workshop series also stressed variety of learning activities within an authentic context, as opposed to converting lectures and reading for the web. The skills and knowledge included in the most effective courses are relevant to students, either in their current lives or in their future roles. The skills and knowledge also represent the most desirable learning in the current state of the field of study (Cavanaugh 2001).

A faculty member from the College of Business Administration, where teaming is an important aspect of all courses, facilitated the Team Building session. The emphasis on team-building stems from educational research indicating that cooperative learning promotes high individual achievement. Distance education literature shows that course activities have the greatest value for students when they authentically approach the kinds of work students will experience beyond the course (Cavanaugh 2001). Students should work in cooperative groups or teams, to solve realistic problems. The instructor's role is to set up situations that approximate the professional world and require high levels of interdependence for success. Instructors must also model and require respect for student diversity and various learning styles. In the College of Business' online courses, class teams work together on projects and cases, simulating an authentic work situation. The distance learning environment includes virtual workspace where teams collaborate on drafts of assignments. Online personality inventories and learning style tests were used for student self-assessment, and the results were used to construct heterogeneous teams. Online discussions allowed team members to exchange personal stories, and to develop a collaborative team story including their goals and vision for the team. Teams developed their plan for communication and a code of conduct for team activities. Teams evaluated their performance as a group using rubrics using rubrics prepared by the instructor. The session facilitator demonstrated online examples from his classes to illustrate team-building methods, activities and goals. He also provided workshop participants access to his online teaching space and materials.

A faculty member from the College of Education led the session on Methods of Assessment. The underlying philosophy of this session was that the student-centered, project-based nature of distance education lends itself to assessment of student learning using a variety of methods. The session included demonstrations of a range of assessment techniques from the presenter's online courses. Tests and quizzes are available in most distance education environments, and offer advantages of automatic instant grading, providing students with immediate detailed feedback on short answer items. Open-ended questions may be administered in the online discussion forum, which can serve as a virtual blue book. Student participation in class discussions may be documented and used in assessment, and such assessment is streamlined using the tracking and archiving features of most distance learning delivery systems. Students may be interviewed about their progress via email. Electronic papers and projects may be submitted using email or course digital drop boxes. Instructors can use the word processor feature that tracks changes in documents to return comments to students. Student projects and presentations are most valuable when they can be shared class-wide within the distance learning course environment. An example is a student web page posted or linked in the student's or group's course web space. To give students a sense of control, instructors were encouraged to offer choices of activities and topics or they allow students to negotiate options. Control in distance learning often involves flexibility in scheduling activities and deadlines. Because students are more confident in the importance of their work when course criteria are stated clearly and are viewed as realistic, the session presenter recommended that all evaluation criteria for student performance be communicated at the outset of the course, and

suggested that posting rubrics for assignments is an effective method. Knowing the expectations up front places responsibility for learning on the student. The display of student abilities is the most important result of distance education. In the course of developing their abilities, successful students manage their learning by engaging in frequent self-assessment. Because self-assessment does not come naturally to all students, it is helpful when instructors guide and encourage students to assess themselves. Instruments such as rubrics, checklists, and journals are effective tools for helping students become independent and responsible learners. Such assessments provide information to students about their strengths and about the gaps in their knowledge. Students receive the greatest long-term benefit when they have extensive opportunities during a course to develop their skills in a realistic context, and assessment of skills should occur within that context (Cavanaugh 2001). The presenter provided participants with access to evaluation examples and rubrics.

Another faculty member from the College of Education led the session on the Online Discussion Forum. The session included discussion of the benefits and challenges of online discussions in courses, and examples of ways to include online discussions in courses. Because learning is an interactive activity and constructed socially, a key to success lies in communication between students and others. A quality benchmark is to involve students in communication during 50% of the time they spend on the course (Cavanaugh 2001). Frequent and active communication with the instructor, fellow students, or experts in the subject is essential in making students feel that they are part of the community of learners. Connection among students is vastly more motivating than isolation because students need to know that others care about them and that they are contributing to an educational endeavor larger than themselves. Valuable discussions may occur among students, instructors, subject matter experts, authors and professionals in the field. The presenter included tips for maximizing the effectiveness of online discussions, with numerous samples from current courses. This session emphasized careful planning to fully integrate online discussions with other course activities. Discussions open to all class members are appropriate for broad discussions, and other discussions may be limited to specific group members br team project work. Sample syllabi were presented to demonstrate ways to build online discussions into courses, and to help students to be accountable for the quality of their online contributions. Participants received lists of web resources, sample dis cussion topics, and sample student responses, along with student mention of online discussions in final course evaluations.

A faculty member from the College of Health presented the session on Distance Learning for Clinical/Internship Experiences. The presenter has used distance learning tools to connect students in the field with each other, with instructors and mentors, and with professionals. Students involved in field placements tend to feel isolated, and participation in a distance learning experience allows frequent sharing, feedback and questioning regarding the experience. The distance education course environment offers many tools for the clinical instructor: online discussions, digital drop box for field notes, email, shared workspace for projects, and automated testing. A valuable tool in the distance learning environment for clinical students is the adaptation of the discussion forum to serve as a personal journal. To use the discussion area in this way, a discussion topic or forum is created for each student, accessible by only the instructor and the individual student. Because students in clinical experiences are often located far from campus, contact between instructor and student is limited. The online journal allows frequent interaction. In a sense, this session brought together concepts from the previous sessions in a demonstration of a unique application of distance learning.

The session regarding the relationship between distance learning teaching and the promotion and tenure process was structured as an open forum between faculty and university administrators who understand and support distance education. In the traditional university system, promotion and tenure are based contributions in teaching, scholarship and service. Instructors have concerns about the ways online teaching will be evaluated, especially when an instructor's department chair may be unfamiliar with distance learning or opposed to distance learning. Instructors recognize that quality distance learning takes time, and they seek support from administrators ads they reach balance between time spent in distance teaching and time spent on research and publishing. At this workshop, university policies will be interpreted for distance faculty, and concerns raised about needs for new or adapted policy. The session will be moderated by the director of faculty enhancement, who also teaches in the College of Arts and Sciences.

The sessions were well attended and well received by participants, who represented colleges across campus. Participants included faculty who had already taught distance learning courses, those who had integrated distance learning enhancements into classroom courses, and those who were exploring distance education approaches for future courses. Most participants stated that they learned a great deal of information and strategies that they could

immediately put to use in their courses. The sponsoring groups are working on the schedule of sessions for the coming year. Previous sessions will likely be repeated, and will be augmented by sessions on new topics and continuations of previous topics. The series is seen as an ongoing faculty development initiative, organized in response to faculty needs.

An outgrowth of the faculty development series was a faculty distance learning handbook. The UNF Distance Learning Handbook was designed to provide UNF faculty and administration with information about the current state of the distance learning infrastructure at the University of North Florida. For faculty and administrators interested in developing distance learning courses and programs --particularly web-based -- this handbook can serve as a guide in directing interested parties to the existing support services and resources [see Appendix 1 for the Table of Contents]. The handbook will be updated on a regular basis as new campus resources are developed and as more is learned about the potential for distance learning to advance the institutional priorities of the University of North Florida. The handbook was developed by working groups of the Distance Learning Action Team as a way to collect information presented at the faculty development series sessions, along with details about distance learning at the university. The handbook is printed on paper for faculty most comfortable with traditional media, and it is posted on the Office of Faculty Enhancement web site.

Appendix 1

UNF Distance Learning Handbook Table of Contents:
- o   UNF Distance Learning Policy Statement
- o   Scheduling and Registration FAQ
- o   Student Assessment of Online Courses
- o   Listing Distance Learning Courses Beyond UNF
    1. Florida Virtual Campus
    2. Southern Regional Electronic Campus
- o   UNF Library Services In Support Of Distance Learning
    - o   Library Account Numbers
    - o   Physical Access to Books and Other Library Materials
    - o   Online Resources
    - o   Off Campus Access
    - o   Technical and Electronic Access Assistance
    - o   Other Online Resources
    - o   Online Services
    - o   Other Useful Links For Dl Faculty
- o   Computing Services Information For Students And Instructors
    - o   Services
    - o   Recommended Computer Hardware/Software
    - o   Connectivity
    - o   Training And Instructional Support
    - o   Technical Support
- o   UNF Faculty Support For Distance Learning
    - o   On Campus Support
    - o   Additional Online Resources
    - o   Periodicals
    - o   Books
    - o   Series
    - o   Organizations And Conferences
    - o   Course Developer Support
- o   Pedagogical Resources For Online Instructors
    - A. Principles Of Good Practice For Online Education
    - B. Success Factors For Teaching Online Courses
    - C. Preparing An Effective Online Course
- o   Sample letters to students

Strategies for Assessing Student Writing in a Paperless Distance Learning Environment

Terence Cavanaugh, University of North Florida, USA

Today's distance learning environments can be a "paperless" environment for student research papers and projects. The "paperless" environment can offer advantages for students and teachers in the creation and assessment of work. This paper will describe practices that have been found to be effective, through action research with web based distance learning classes, on increasing the efficiency for the submission and evaluation processes for research papers and other student work within the "paperless" distance learning environment. These practices related to structuring evaluation and using rubrics, using screen readers, performing online research and referencing, using readability analyzers, word processing collaboration tools and options for submissions.

Web Page Evaluation for Education

Dr. Terry Cavanaugh, Curriculum and Instruction, University of North Florida, USA. tcavanau@unf.edu

Dr. Cathy Cavanaugh, Curriculum and Instruction, University of North Florida, USA. ccavanau@unf.edu

Abstract
Because the web is an important source of information in schools, teachers and students need skills
for evaluating web sites. For a specific learning goal, thousands of web sites may exist, but not all
of them will be appropriate. Web sites are written at a wide range of language levels, for a variety
of purposes, and for diverse audiences. A great many web pages contain information that is not
appropriate for student needs because of misinformation or bias. A critical eye is more important
than ever. Just as students should be taught to critically evaluate print and broadcast information,
they also need to learn to judge web information. A student should make judgments about a web
page for its educational value. Students should make an assessment of its worth for the academic
endeavor by judging the page's authority and currency, its publisher and purpose, and its
objectivity and accuracy.

The use of web technology is already changing the world both beyond the school walls and within. The web can be
a powerful tool for teachers and students, so opportunities for learning about its use should be a component of all
instruction. It is important for all teachers to consider more than just the information presented on a web page.
Usually web based information is developed for a specific purpose or with a specific goal. Some web pages were
designed for educational use while others were designed for entertainment or business purposes. Teachers must be
concerned with the abilities and developmental levels of the students who are using the web. This paper will present
strategies and tools for teachers for assessing the appropriateness of web pages for student use. Additionally there
will be strategies and tools for the students who are using the web for research.

The Need

Because of the ease of publishing on the web, Web page users do not have the checks and balances associated with
traditional published material. When a web site is published, there is no guarantee that the pages have been checked
for accuracy, content, or even spelling. Published web authors range from elementary school children to government
agencies. The amount of the information available on the web has surpassed a billion unique pages and continues to
grow by the minute, without a board or organization that indexes or controls what appears on the web. As the web
continues to grow as a research and data tool, validation of web information will become even more important

A study on information literacy instruction in Tennessee, found that teachers' understanding about web based
research was not associated with traditional library reference skills, and many teachers were either unfamiliar with
information literacy or were under the misconception that it was the same as computer literacy. The teachers
themselves were unable to describe their own process of selecting web resources and, when questioned about their
students, the teachers stated that information literacy skills should be taught by the media specialist, who thought
they were being taught by the computer teacher, who thought that they were being taught by the classroom teacher
(Spearman 1999).

Evaluation of Web Sites by Students

In an evaluation the technology components within the Florida state curriculum standards (Sunshine State
Standards) across the content areas, it was found that common themes and skills existed. The recurring technology
themes and skills for students include effective information finding, evaluation of source information, and how to do
research on the web. For a specific learning goal, thousands, if not millions, of web sites may be found, but not all of
them will be appropriate. Web sites are written at a wide range of language levels, for a variety of purposes, and for
diverse audiences. A great many web pages contain information that is not appropriate for student needs because the

pages contain misinformation or bias. Just as students should be taught to critically evaluate print and broadcast information, they also need to learn to judge web information. Students should be taught that the information that is presented on a web page should be judged based upon evaluative criteria. When a student is beginning a quest for information on the web, the answers to a few fundamental questions will help to guide them to useful and reliable information. A teacher can assist the process by providing the students with questions and checklists to assist students in their evaluative process.

Students should develop the habit of asking the following questions. "What kind of information am I looking for?" Decide whether news, opinions, multimedia files, historical documents, fiction, performances, databases, or other types of information best suit your need. "What do I want to use the information for?" Whether the information is for personal, professional, or classroom use determines how appropriate a Web page will be. "How extensively will I depend on the quality of the information?" When collecting information to present in a report or proposal, authoritative fact is much more important than when surveying viewpoints on an issue." How much information and detail do I need from the resource?" Many Web pages are primary source documents, while many others summarize those sources. Depth and comprehensiveness in coverage between sites varies greatly.

Students and teachers judging web pages for educational appropriateness should consider the following factors. Consider the authority of the writers, their background, their level of expertise, their knowledge of the topic. A good practice is to look for the "Last Updated" date to learn if the information is current. In many cases, it is not crucial that information be recent, such as when learning about consistent facts, grammar or vocabulary. At other times, the timeliness of the information is very important, such as when researching world events or political geography. The researcher should find out what group or individual is responsible for publishing the web page. The teacher or student should decide how the page's domain (.com, .edu, .net, .gov, .org, etc.) relates to the topic presented in the web page. It is always important to remember that information on an education server (.edu) is not necessarily from a reputable source: it could be written by a professor who is an expert on the topic, by a student of the topic, or by a student who has created a page for fun. If the material is published on a public server source such as AOL or GeoCities, the researcher should be aware that anyone who requests space can publish any information they desire with no checks on quality or accuracy of the information. Pages from a governmental agency or other professional organization generally have quality control measures. Everyone needs to follow the example of reporters and determine for himself or herself whether the source is reliable. The person researching must judge whether the information is objective or has a bias or slant. Notice whether the style of presentation is scholarly or logical. When an issue is presented, look for multiple viewpoints and determine if they are fairly represented. It is always important to determine the purpose of the site: to educate, to sell, to persuade, or to explain, and then to consider that purpose when reading a page.

Evaluation of Web Sites by Teachers

The resources gathered from the web can help educators make choices that are appropriate for their students. For many, safety is an all-encompassing concern when students are accessing the Internet. Other concerns include the quality, accuracy, and level of the information being made available. It is important to remember that web information changes constantly, so any evaluation of a Web page will characterize the page for that particular moment in time. It is a good practice for a teacher to always test the web pages against the desired learning goal. Using the Four A's for educational web page evaluation: Audience, Authority, Accuracy, and Appropriateness an instructor can develop guidelines for the inclusion of web material.

Teachers must also ensure that materials are appropriate for the special needs of their students, such as ESE or ESOL students. In addition to the guidelines above, there are considerations for using the web with students who have a disability or impairment (physical or cognitive) and students who are nonnative speakers of English. Perhaps the main thing to consider in Web site evaluation for ESOL students is the type of skills that the site builds in the students. These skills can include: Reading; Writing; Listening; Speaking; Grammar; Vocabulary, and Cultural Knowledge.

Considerations and Suggestions as Using Blackboard to Teach and Learn

Introduction

Different instructional software is being employed in higher education to enhance and facilitate students' acquisition of knowledge. Learning with technology also promotes students' technology skills (Bazillion & Braun, 1998; Berger, 1998). Blackboard is one of the instructional applications, which allows learners and the instructor to log on whenever there is the accessibility of the Internet. Additionally, Blackboard enables learners and the instructor to teach and learn at anytime and anywhere with any means.

However, Blackboard does not guarantee the instructor to effectively administer an online course by simply filling up the pre-format template with the course content. Knowing how to mount a syllabus, homework assignments, reading requirements and/or quizzes does not ensure the instructor to hold meaningful and useful online teaching and derive desirable learning. Online education by no means includes posting syllabi, having students submit assignments, having students take online quizzes or providing online reading and homework assignments. ". . . putting up course notes and static, non-interactive course materials on the Web results in an effective virtual course—a virtual correspondence course, perhaps, but seldom a successful virtual learning experience" (Graves, 2000, p. 36).

To achieve effective learning results, it requires the instructor to motivate learners' desire to learn. With respect to infusion of technology into curriculum, the instructor preliminarily needs to build up an understanding of *meaningful* utilization of computer technology before carefully and holistically structuring a course design and strategies of its implementation (Chang, 1999). What and how an instructor performs will surely affect how pre-service teachers will manage their classroom instruction with technology in the future. Integration of technology with a little consideration and pedagogical meaning contributes only to superficial coverage of the course content and shallow exploration of learning. Facilitation of meaningful online learning calls for an instructor to implement reflection and self-analysis.

Theoretical Framework

It is a misconception that the instructor's responsibility is to prepare a course, deliver instruction, distribute assignments, and grade submissions, whereas the responsibility of a student is to attend classes, complete given assignments and submit required work. Nevertheless, "The professor, . . . is less the dispenser of knowledge and more the facilitator of it (Lambert, 2000). Teaching is, as a mater of fact, complex rather than linear. Students are pluralistic; each has unique experiences and knowledge" (Knowlton, Knowlton, & Davis, 2000, p. 54). The responsibility of an instructor is to understand how students learn, how to motivate students to learn and how to help students learn successfully (Edwards, 1993). The student's responsibility is to acquire knowledge that can be applied for problem solving and enhancing quality of education. True learning takes place as an individual learner interacts with the materials and is able to connect learned knowledge or skills with real practice (Katz, 1993).

Traditionally, students tend to forget about the content of delivered lectures after they leave the classroom (Bowers, 2001). Research has shown that technology benefits students' learning (Bazillion & Braun, 1998; Berger, 1998; Grossman, 1999; McCandless, 1998; Raschke, 1998). Bowers (2001) noted that the Internet enabled students to remember the delivered course content whenever they were (Bowers, 2001). Technology allows students to actively participate in content learning rather than to "enter courses as blank slates waiting to be filled with knowledge by the professor (Knowlton, et al., 2000). Learning via technology broadens the students' concepts, but also enhances their acquisition of learning skills, such as electronic learning skills that may be used in their future courses or later personal and professional growth (Bazillion & Braun, 1998). However, like classroom teaching and learning, instruction with technology factually imposes challenges to an instructor in respect of seeking ways to stimulate and provoke students' learning and thinking (Chang, 1999).

Considerations in Designing and Implementing an Online Course

I have taught students via the software of Blackboard in the past two semesters. In the Fall semester of 2000, there were 26 enrolled in Programs and Curriculum for Young Children. Twenty-eight students were enrolled in Nutrition and Health for Young Children. Of 26 enrolled students in Programs and Curriculum for Young Children, 23 were the elementary major of pre-kindergarten to 6th grade. Two students majored in Early Childhood Special Education with one having undeclared major. Of 28 students enrolled in Nutrition and Health for Young Children, 26 were the elementary major of pre-kindergarten to 6th grade. One was from Early Childhood Special Education with one undeclared major. In the Spring semester of 2001, I have 30 students in Programs and Curriculum for Young Children and 29 students in Nutrition and Health for Young Children. Of 30 students enrolled in Programs and Curriculum for Young Children, 26 were the elementary major of pre-kindergarten to 6th grade. Three from Early Childhood Special Education with a special student. Of 29 students enrolled in Programs and Curriculum for Young Children, 24 were the elementary major of pre-kindergarten to 6th grade. There are four from Early Childhood Special Education with one special student.　　Regardless of which major my students are undertaking, their future careers are associated with teaching and learning. As has been discussed earlier, influential modeling is of great importance. In the future, students may take on a similar mode as how they are instructed and taught previously. Additionally, for the best interest of their future children/students, meaningful and purposeful learning must be the center of attention of teacher preparation programs. In achieving this intention and taking advantage of online teaching and learning, I have been keeping field notes and other related notes in order to understand my teaching and understand how students learn. In so doing, I frequently analyze myself and solicit students' voices, based on which, I enter experimental strategies that allow shaping curriculum and employed instructional mechanisms to fit students' rights and needs while encouraging their ownership for learning. The followings provide my general understanding of what the instructor needs to carry out in designing a course via Blackboard:

(1) Acquiring necessary training for required technology: It is essential that the instructor find time to equip himself or herself with technology know-how before designing an online course.
(2) Practicing learned knowledge: Once technology is acquired, it does not mean that one is ensured to be able to manipulate given software. To enhance an understanding and familiarize oneself with learned technology know-how, the instructor is strongly recommended to take time experiencing the software.
(3) Focusing on the content of curriculum: As preparing a course design, the instructor needs to keep in mind learning goals and objectives of a course.
(4) Sketching a mental plan: Before sketching a written plan or laying out a written map, it is useful for the instructor to go through a mental map as to what are key points of a course and how this course is to be implemented.
(5) Sketching a written plan: With the formation of mental schema, the instructor may assume to process a written blueprint, which record vital learning elements and potentially employed strategies that facilitate students' meaningful and in-depth learning. In laying out this initial proposal, suggested effective learning opportunities may also be noted, which may embrace ways to encourage students' higher order of critical thinking, making connections and building relationships with their classmates through discussion, allowing reviewing one another's point of view, reflection of assigned texts, incorporation of the element of service learning experience.
(6) Refining the mapped-out design: The instructor refines the map and may consider webbing out the design.
(7) Designing meaningful and helpful assignments: Assignments are more than what is commonly understood as commodity exchanging for an instructor's lecture. It is a misinterpretation that to exit the study of a course, an assignment is a vital gatekeeper. Students attend classes for lectures and for doing assignments. In fact, submitted work from students serves as a vehicle for widening their views and for augmenting their understandings of learning content. Furthermore, required work serves the purpose of exchanging understandings and ideas among students. Assignments also can be conceived as a learning opportunity for students and the instructor, through which they are able to teach one another by providing constructive comments and recommended ideas. Moreover, assignments help

the instructor to discern how students have learned and what teaching approaches work and what requires further refinement and improvement.

(8) Considering ways to make maximal personal immediacy: Online learning deprives students and the instructor of frequent personal touches or frequent face-to-face on campus meetings that a traditional classroom usually possesses. Acknowledging the drawback, the instructor takes into account elements as he or she designs a course. The instructor contemplates of how to maximize personal immediacy. This may be accomplished by replying students' email messages, including requests, questions, and concerns and by providing immediate feedback to students followed by their online submissions.

(9) Being willing to accept challenges from students: In the process of web-based education, it is beneficial that the instructor sincerely listens to students' voices, accept students' constructive suggestions and input, which are helpful for improving the virtual classroom teaching and learning.

(10) Finding ways to deal with difficulties: Teaching and learning online is not something that has been in existence for a long time. A plethora of research studies are undertaking to discover more and more valuable understandings of effectiveness with regard to online teaching and learning. Many questions are to be answered. Given the current situation, difficulties are, therefore, predicable. The instructor needs to patiently and bravely take time to probe into emergent problems and seek as much advice from others as possible for resolutions of barriers.

(11) Finding ways to handle frustrations: Associated with unsolved difficulties, the instructor may feel frustrated and disappointed. However, writing notes and clearing ones' thoughts are essential to conquering a difficult moment. Seeking support from technological personnel or from those who have had prior experiences in online teaching may help overcome difficulties.

(12) Obtaining administrative support: Fighting alone may add to a level of frustration. Searching for administrative back up is of necessity. One's frustration may stem from limited capacity of technology equipment. In this sense, one may easily defeat the difficulty by enhancing the understanding of the administrator and by replacing the old machine with an updated one.

(13) Keeping working relationships with technology personnel: Technology know-how is soaring day by day. An instructor may encounter a series of questions that a workshop may not fully offer. Thus, technology personnel need to be contacted and consulted with.

(14) Managing time: Designing an online course is by no means easy and may eat up more time than one may anticipate. Organizing one's time is of priority. Too much time contributed to the online design may interfere with other obligations.

(15) Making online courses manageable: What to include and what to put aside need to be taken into serious consideration. The instructor has to make such teaching manageable to balance between work and personal life.

(16) Communicating with colleagues and administrators: It is essential and vital to make your initiative known to your colleagues and administrators at annual reappointment, and other relevant promotion meetings. This novice teaching and learning experience needs to be understood due to the fact that much research and trial and errors are involved. Time is devoted. Be realistic, honest and detailed.

Suggestions for an Online Design and Implementation

(1) Taking in a little at a time: Learn and practice technology know-how little by little. Don't be greedy or anxious, wishing that you would grasp all required technology skills overnight.

(2) Giving clear instructions with respect to the instructional software: Figuring out a way to help students understand the employed software. Frustration and fear can be roadblocks for students' continual learning desire. It may be a good idea that a written guidance for walking students through a web-based course can be concurrently offered with personal instruction at the first class meeting.

(3) Making clear of course expectations: Use a simple and jargon free language as the instructor elaborates the course expectation, having students prepared at the beginning of a semester.

(4) Repeating yourself whenever it is necessary: In the process of teaching and learning, grabbing an appropriate opportunity to go over what has been announced and distributed.

Sometimes, students need more than once to comprehend instruction or expected learning assignments. At times, a student's question may be considered representative of the whole class' puzzlement.

(5) Balancing your workload: Although more is better, helping students construct an understanding of the course content needs balance. Too much requirements may exhaust the instructor as well as students. A good intention may turn out to be "an evil ending."

(6) Balancing work with one's personal and family life: It is known that online teaching requires extra work and time. After all, one's personal life and significant others should also be within the arms' reach of the instructor, deserving his or her attention.

(7) Keeping in mind: Nobody triumphs his or her success with only one attempt. It is well recommended to keep trial and error since failure is the mother of success.

(8) Understanding students: Keeping in mind that students have different expectations and references. It may be a good idea to combine novel and traditional ways of teaching to accommodate different learning methods.

(9) Making commitment: Having said that online teaching requires time and extra efforts, committing to such work is critical because such teaching and learning is time consuming and may not end in expected outcomes.

(10) Soliciting students' feedback with a variety of ways: It is useful to attain students' voices and feelings toward online teaching and learning. It may be considered to obtain these by pre- and post-surveys, oral requests, and group meetings. These needs fit for a wide array of students and allow you to acquire comprehensive feedback. These methods are sensitive to students' needs and are appreciated by the students. The feedback is useful for improving online courses and does away with teaching a same course with the same set of strategies over and over regardless of needs and rights of students from year to year.

Conclusion and Implication

Teaching and learning online is the future and is not at all an easy task to implement. Thinking, designing, reflection and analysis through online classroom research are fundamental to effective instruction and improving the quality of teaching and learning. This leads to a lot of thinking and work, which calls for commitment, dedication and devotion. Balancing weight in teaching and life outside teaching is of primary importance. Researched teaching strategies applied to online learning and teaching result in merits to students' confidence in learning, students' enhancement of technology skills, reflective thinking of students and an instructor, learning from one another, promoting relationship between the teacher and students, provoking students' consideration of how they will infuse technology into their teaching and learning, controlling their learning, active learning mode, establishing ownership, promoting a productive learning community, and being willing to explore more. And yet, many studies are in demand for understanding how to make the most of online teaching and learning (Boettcher, 2001). In general, a lot of research is needed for an understanding of how to promote quality online teaching and learning.

Learning Style Differences and Attitudes Toward Web-Based Distance Learning among Pre-service Teacher Education Students

Ching-Chiu Chao
The Pennsylvania State University, USA
cchao@psu.edu

Abstract: Web-based courses with distance learning components have become popular in teacher education programs and there is every indication that the trend will continue. This paper is a brief report on the findings of a study conducted on pre-service teacher education students' learning style, attitudes toward web-based distance learning and the relationship between attitudes and learning styles in this learning environment. Kolb's experiential learning theory, Moore's theory of transactional distance and related learning theories are synthesized as a framework to investigate research inquiries. This study established a basis for better understanding theories and practices in distance education as well as pre-service teacher education student learning in web-based environments.

Introduction

Distance learning technologies are playing an important role in teacher education programs throughout the world. Web-based distance learning has greatly helped connect pre-service teachers and their college supervisors, sometimes separated by space and/or time. Distance learning also allows pre-service teachers at distant sites to network and plan cooperative activities. Literature revealed that the understanding of learners' factors, such as learning styles and attitudes toward distance education was widely considered to be important for designing and implementing distance education (Martin, & Rainey, 1993; Moore & Thompson, 1990; Starr, 1993). Despite the widespread adoption of web-based distance education technologies in teacher education programs, we know very little about pre-service teacher education students' attitude toward web-based distance learning and whether differences in learning style, if any, would influence their attitudes toward this new learning environment. Understanding the relationships between learning styles and attitudes toward web-based distance education among pre-service teachers would help us target initiative/intervention/design efforts more effectively.

The main purpose of this study was to determine if there is a difference in teacher education students' attitudes toward web-based distance learning based on learning styles. Additionally, individual learning styles of pre-service teacher education students and their attitudes toward web-based distance education were also investigated.

Method

The participants for this study were elementary teacher education students (pre-service teachers) who enrolled web-based courses that have a face to face and a distance component to the course at an eastern University in the U.S. in Spring 2001 (169 students totally). Two self-assessment instruments were employed to collect data. Kolb's Learning Style Inventory (LSI) (Kolb, 1985) based on Kolb's (1984) experiential learning theory was used to determined the participants' preferred learning styles as one of the following four types: Converger, Diverger, Accommodator, or Assimilator. *Web-Based Distance Education Attitude Instrument,* based on Moore's theory of transactional distance (Moore, 1993) and associated adult learning and distance education theories, developed by the researcher was applied to understand study participants' attitudes toward the web-based distance education in terms of teaching and learning. In addition, written responses on participants' evaluation of web-based technology as a course delivery method, and personal information, such as age, gender, student status (full-time vs. part-time), prior computer experience and Internet use, were also collected.

Results

For the learning style profile of respondents, 63 out of 157, or approximately 40.1% of study participants in this investigation were assimilators; 48 (30.6%) were divergers; 25 (15.9%) were convergers; and 21 (13.4%) were accommodators.

For the attitude survey, factor analysis using the principal components method with orthogonal rotation extracted three uncorrelated factors (Interaction, Effectiveness, Barriers) which accounted for 46% of the variance in student self-reported attitudes. Additionally, the mean and standard deviation scores, as well as score ranges of all attitudinal statements were calculated to understand study participants' attitudes toward web-based distance education based on the four types of learning styles. Results indicated that overall there was a positive attitude toward the web-based distance education among learners participating in the study.

Furthermore, an overall MANOVA and three individual ANOVA for the three attitudes scales were performed and the results indicated that in this study, there was no significant difference in elementary pre-service teacher education students' attitudes toward web-based learning for various learning style groups (F-Interaction (3, 154)=1.67, p>.05; F-Effectiveness (3, 154)=0.45, p>.05; F-Barriers(3, 154)=1.42, p>.05; p-value of Wilk's Lambda was .34).

Conclusions

This investigation found that among four types of learning styles as assessed by LSI, participating students with the Assimilator learning style were the biggest group in the study, followed by those having the Diverger, Converger, and Accommodator learning style. About one-thirds of study participants were more likely to focus on ideas and abstract concepts and less on the practical values developed as assimilators. In addition, based on the distribution of four types of learning styles, it is clear that individual differences exist among teacher education students who participated in the web-based learning setting in this study. The importance of sound instructional design that considers different learning styles as a key design element is supported.

Results of this study revealed an overall positive attitude toward web-based distance education among elementary pre-service teacher education students participating in this investigation regardless of learning style. Furthermore, the differences in students' learning styles did not have any effect on students' attitude toward web-based distance learning. These findings were consistent with other learning style-attitude research in the field of distance learning research, although emphasizing different age groups and conducted in different context of distance education (Chen, 1999; Gee, 1990; Starr, 1993). Web-based distance learning serves as a self-directed learning context with which pre-service teachers can self-pace their learning and also interact with educators, peers, and learning resources, which may in turn facilitates them in developing life-long learning skills.

An Investigation of University Teacher Education Students' Internet Use and Perceptions in Web-Based Instruction Learning Environments: A Case of Taiwan

Ching-Chiu Chao
The Pennsylvania State University, USA
cchao@psu.edu, chingchiuchao@yahoo.com

Abstract: This paper is a brief report on the findings of a study conducted on teacher education students' use of Internet in learning processes and their involvement in web-based instruction in Taiwan. Both quantitative and qualitative approaches to research were employed. Findings indicated that most students expressed positive responses toward web-based instruction especially it supports active learning. Students also expressed various concerns, expectations and barriers while participating in web-based instruction and different needs for instruction and training to effectively participate in web-based learning environments. Educators need to constant reflect on their pedagogical beliefs and practices in technology-supported classrooms and take a wary approach to implementing web-based instruction that better taps its potential for student-centered learning.

Introduction

The World Wide Web (WWW) has become a useful educational medium and provides new learning environments and experiences for students that were not previously possible. Web-based instruction (WBI) is defined as an innovative approach for delivering instruction to a remote audience using the World Wide Web as the instructional delivery system (Khan, 1997). WBI has been used not only in fully distance education programs but also in supporting face-to-face traditional classroom instruction (Cornell, 1998). In this study, major learning theories, including self-directed learning (Candy, 1991), constructivist learning (Duffy & Jonassen, 1991) and the social aspect of cognitive development (Vygotsky, 1978), collaborative learning (Bruffee, 1993), resource-based learning (Rakes, 1996), and the theory of diffusion of innovations (Rogers, 1995) are synthesized into the theoretical framework that gives a special focus in understanding teacher education students' use of the Internet and their learning in web-based instruction.

Method

The purpose of this study is twofold. First, it intends to describe the level of Internet use as a new learning tool and as a resource by university teacher education students in Taiwan, and various aspects of Internet use in Web-based instruction in which they have participated, along with their perceptions of the benefits and barriers of web-based learning environments and such Internet use. Second, it aims to examine the relationship between students' level of Internet use in their studies and selected variables.

Participants in this study were students who enrolled in the teacher education programs at two four-year, degree-granting universities in Taiwan. This study employed both quantitative and qualitative approaches to research. Two sources of data collection were used. A survey of 63 questions containing 141 specific items developed by the researcher was used to collect both quantitative and qualitative data. A semi-structured interview protocol including ten questions designed by the researcher was used to collect qualitative data through in-depth interviews with a purposeful sample (Guba & Lincoln, 1989) of participants. Descriptive statistics, factor analysis, multiple regression, and qualitative analysis including sorted, and coded themes were

employed. The follow-up qualitative analyses of this study were used to help expand, interpret and analyze the quantitative findings. In addition, the qualitative results also provide methodological triangulation for this study.

Results

Results indicated that the majority expressed positive responses toward web-based instruction in many aspects. A variety of instructional materials were available online for students' use in web-based instruction that had different instructional objectives. Technical problems (Internet traffic congestion, server down-time, and short of technical support) and personal constraints (lack of adequate knowledge or skills to use the Internet effectively for communications and online search) were the greatest barriers that students have encountered while using the Internet in web-based instruction courses. Additionally, individualistic learning approach, as opposed to social learning approach or collaborative learning, was more or less dominant when the Internet was used in web-based instruction, despite the fact that students seemed to be aware of the advantage of involving in social learning opportunities supported by networked learning environment. Findings suggested that students' overall level of using the Internet in learning was not widespread. However, they expressed expectations of involving in web-based instruction more widely in supporting learning.

Furthermore, results showed that four variables – Internet literacy, perceptions of the Internet as an innovation, access to the Internet, and perception of learner autonomy, when combined together – explained 45.8% of the variance in students' self-directed/initiated Internet use in their learning processes. Among these factors, Internet literacy was the best predictor of students' Internet use level. Gender and age did not contribute statistically to students' Internet use.

Conclusions

Students generally expressed positive responses toward web-based instruction. Although a few students' perceived benefits of the Internet use in learning processes were limited primarily to convenience, many students seem to be aware that the potential of web-based learning environment for changing the way in which they learn. Evidence from students' survey, written comments and interviews shows that web-based instruction is a powerful way of learning and instruction in terms of supporting active learning. Despite recognizing benefits, students sensed the continuing need for the human touch in teaching and learning.

This study suggests that the teacher's role in a technology-supported classroom is critically important. Students' use of the Internet in web-based instruction courses would largely depend on faculty members' constant reflection on their beliefs and practices to better support students with opportunities to collaborate with their peers and to learn together. Also, when teachers in Taiwan are able to change their beliefs about the nature of education, new technologies can be implemented in ways that better tap their potential for aiding student-centered learning.

Multiple literacies and various literacy instruction, such as computer and Internet literacy, information literacy skills, computer-mediated communication, English language literacy, multimedia presentation, using online search engines to conduct research, self-directed learning etc., are needed for students to use the Internet effectively and thus participate in the information society and communication age.

Developing Java Servlets for Web Based Teaching

Li Chao, University of Houston at Victoria, USA

The paper considers issues of Java Servelet technology and its application in Web based teaching. It discusses the usefulness of Java Servelets in business and in teaching. The discussion on the implementation of a Java Servelet with Java programming language is also given. The ease of learning Java, its reliability, and its portability make this programming language a convenient tool to implement a Java Servelet. As an assistant in classroom teaching, Java Servelets have the flexibility needed to develop classroom demonstrations and Internet enabled client-server applications. The objective of this paper is to discuss the implementation of Java Servelets in classroom teaching.

The Clipper Project: Designing Effective Web-based Courses for Pre-Baccalaureate Students

Tammy Chapman, Lehigh University, USA ; Stephen Bronack, Ph.D., Lehigh University, USA ; James DiPerna, PhD., Lehigh University, USA

The Clipper Project is a research endeavor designed to study the effects of Web-based learning on pre-college students. Using Blackboard's CourseInfo Lehigh University currently offers two online courses for students accepted early decision, calculus and economics. The professors partner with an Information Technologies consultant to incorporate technological tools into their courses that are not readily available in traditional classroom setting. The Clipper Project is a constructive step towards effective Web-based instruction that will lead to a positive learning experience for students and faculty alike.

From educational multimedia to "global digital library" development: Convergence of technology, content, and international collaboration

Ching-chih Chen
Graduate School of Library and Information Science
Simmons College
300 The Fenway
Boston, MA 02115
chen@simmons.edu

Abstract: Multimedia technology has shown its promises for educational applications at all levels of academic institutions as well as business settings for sometime, long before the Internet and World Wide Web have become commonplace. Then, in recent years, particularly the last half decade, we have witnessed how the Internet has changed our world in every conceivable aspect -- everything from how we communicate, learn, conduct research, deal with information, do business, receive health care, and dealing with our governments at all levels. Thus, desktop education has been extended to networked-based learning and education.

As to information provision, academic institutions have long been advocating the importance of their libraries and library collections. The old model is "the larger the collection and the closer it is to the users the better." But now in the Internet era, this powerful global information network has provided the kind of infrastructure and environment natural for international collaboration if only the desired information resources are "digital." Thus, the new emphases have shifted from "owning" to "sharing," from "physical libraries" to "virtual libraries," from one central library with huge collections to the federated distributed digital library systems all over the world... With the exciting convergence of technology, content, and global collaboration, we can visualize the coming of a kind of "global digital library" unattainable in non-networked environment.

In this paper, the author will share some of her own experiences in all these areas and transformations -- from the creation of the award-winning interactive videodisc and multimedia CD-ROM, called *The First Emperor of China*, in mid- and late-1980s, to her current international digital library project, called *Chinese Memory Net*, supported by the US National Science Foundation, as well as the latest China-US Million Book Digital Library Project.

Introduction

Long before the Internet and World Wide Web (WWW), multimedia technology has already been effectively utilized to develop powerful educational applications at many levels of educational institutions as well as in business settings. As the Internet and WWW proliferate to such an extend, they have truly changed the way we communicate, teach, learn, conduct research, do business, deal with government, etc. The fast- and broadband global network provides a kind of environment natural for globally collaborative learning and research. Thus, much of the existing multimedia applications have also been transformed mostly for network-based learning.

With the proliferation of digital information resources on the web as well as the growing popularity in creating digital information, as well as in converting print and non-print resources to the "digital" ones, we have sensed the fast growing interests in developing "digital libraries," "virtual libraries," and the like everywhere.

In the following few pages, this author was asked to briefly discuss these developments and transformations as they relate to her own experiences. Her projects will be used to demonstrate this exciting time when technology, content, and international collaboration are truly converging to enable us to provide access to needed human knowledge in such a way far beyond our imagination even just a couple years ago.

Vision for Universal Information Access

Prior to this digital age, the model for better information provision and services is to create larger collections at its own sites. This is why academic institutions value the large number of books and journals available in their own

libraries. But now in the Internet era, this powerful global information network has provided the kind of infrastructure and environment natural for international collaboration if only the desired information resources are "digital." Thus, the new emphases have shifted from "owning" to "sharing," from "physical libraries" to "virtual libraries," from one central library with huge collections to the federated distributed digital library systems all over the world...

This is the time we can begin to entertain a bold vision for universally accessible collections of human knowledge as advanced by the President's Information Technology Advisory Committee's (PITAC's) Panel on Digital Libraries (February 2001):

> "*All citizens anywhere anytime can use any Internet-connected digital device to search all of human knowledge. Via the Internet, they can access knowledge in digital collections created by traditional libraries, museums, archives, universities, government agencies, specialized organizations, and even individuals around the world. These new libraries offer digital versions of traditional library, museum, and archive holdings, including text, documents, video sound, and images. But they also provide powerful new technological capabilities that enable users to refine their inquiries, analyze the results, and change the form of the information to interact with it...*
>
> *"Very-high-speed networks enable groups of digital library users to work collaboratively, communicate with each other about their findings, and use simulation environments, remote scientific instruments, and streaming audio and video. No matter where the digital information resides physically, sophisticated search software can find it and present it to the user. In this vision, no classroom, group, or person is ever isolated from the world's greatest knowledge resources.*"

The Convergence of Technology, Content, and Collaboration

"Anytime, anywhere, on any device" stands strong this year as many groups' most-quoted slogan, including those of the digital libraries and networks, as well as those in commerce. Sure, this ambitious and crafty near-alliteration can only become a phrase of reality with the continued developments in pervasive computing. These include not only very-high-speed networks, but also the wireless ones. In fact, when we say "any internet-connected digital device" and "anywhere," we are or will be definitely pointing to the wireless device. Wireless LANs are maturing, offering faster speeds and interoperability with a multitude of devices. From the technology side, it seems easy to see what we need and where we are going.

But, the real challenge is not relating to "technology." When we are referring to "all of human knowledge," we are surely pointing to the enormously huge "digital contents," much more so than any current data centers, or digital libraries can possibly begin to offer. While technology is maturing rather quickly, the bigger challenge is the creation of the large quantity of high-quality digital contents. Take libraries as examples, this is why we are seeing all kind of digital library initiatives ranging from the digitization of specific collections of invaluable resources to elaborate regional, state, national, or international collaborate efforts devoted to creating digital contents, developing innovative technological tools, and introducing exciting new ways of information retrieval and service provision. Similar activities are going on in the museum and archival worlds globally.

In order to create high-quality digital contents, we need to carefully select the potential candidates for digitization. Then, we need to have proper technological tools to design, manage, preserve, and retrieve the digital contents. Yet, no one institution can possibly possess all the valuable contents of a given topic, thus, collaboration becomes essential. While in old days, and even now in its traditional ways, libraries learn to cooperate via "interlibrary loan" to share their resources. In this current digital age with its high-speed networks, it becomes a reality for institutions or individuals to collaborate regardless the distance between them. In fact, one can collaborate just as easily with collaborators in the other side of the globe as those next door to his/her office.

With this kind of exciting convergence of technology, content, and global collaboration, we can visualize the coming of a kind of "global digital library" positively unattainable in non-networked environment.

From Multimedia to Collaborative Global Digital Library Development

In the last 15 years, this author has engaged herself in a few major federally supported research and development projects. The experience gained through this exciting journey from multimedia to collaborative global

digital library development will be briefly described in the following while more detailed information on the current *Chinese Memory Net (CMNet)* can be found in Chen (2001):

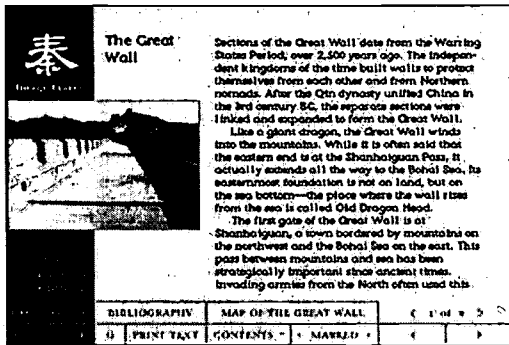
Educational Multimedia and *The First Emperor of China*

In 1984, when the Internet was still unknown to most people, and CD-ROM was not yet introduced to libraries, because of the high cost, with the help of industry such as SONY, the Library of Congress was probably the only library in the US could have videodisc technology applications. Recognizing then the potentials of the interactive videodisc technologies, I embarked on a major project, PROJECT EMPEROR-I, supported by the US National Endowment for the Humanities. This project demonstrated that this interactive videodisc technology could indeed help to overcome the barriers of time and distance by enabling educators, researchers, students, as well as the general public to gain multimedia access to The First Emperor of China's fascinating 7,000 terracotta figures of warriors and horses. In early 1990s, the project effort was expanded to use cutting-edge multimedia technology. As a result, the Voyager Company published two award-winning products (interactive videodisc and multimedia CD-ROM) in 1991 and 1993 respectively (http://voyager.learntech.com).

With numerous user-friendly multimedia courseware that provide flexibly links to needed texts, audios, still images, and videos (sample demonstration will be made during presentation, see also Figure 1 for the Table of Contents screen, and Figure 2 for sample screens); as well as interviews, the products have been widely used in various educational settings as well as by general public. As shown in Figure 1, the features include:

- Textual commentary from experts in the field of Chinese history and archaeology
- Bilingual English/Chinese soundtrack
- Dazzling photography of hundreds of life-size terra cotta warriors and horses
- Original film footage of the excavation in QuickTime video
- An "Image Index" with essays linked to photographs
- A thumbnail index to all photographs
- Reference tools, including maps, a timeline, an extensive bibliography, and a glossary with Chinese characters and audio of Chinese pronunciation

The products also received many honors and awards. Although well received by their users, they are created for use with desktop computer facilities only, and cannot be shared over the network. The interactive videodisc is an analog product, while the multimedia CD is not web-compatible.

Figure 1: "Table of Contents" screen of *The First Emperor of China*'s multimedia CD


A tour of the Great Wall   Photos detail the terracotta army

The First Emperor of China

Figure 2: Sample screens from *The First Emperor of China*'s multimedia CD

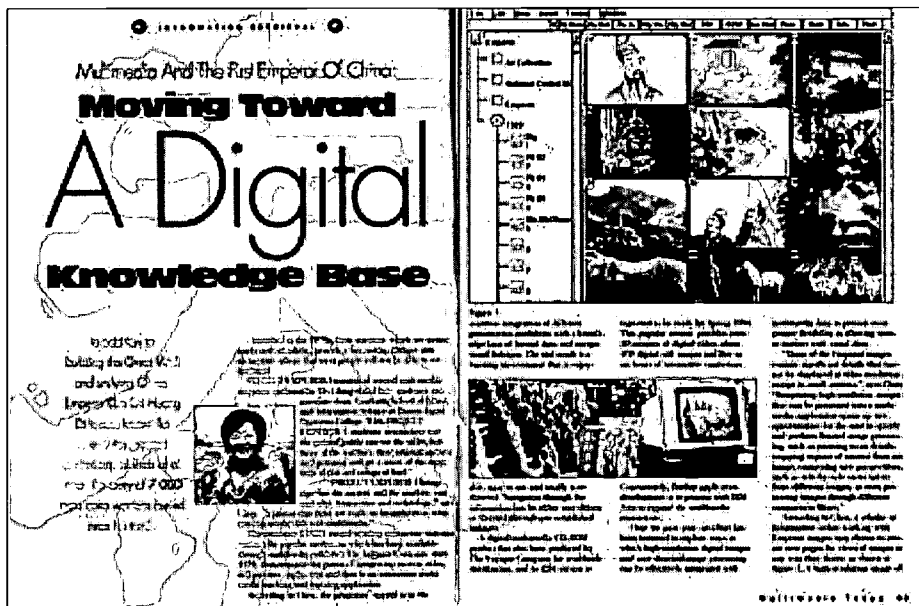
With the advent of communications and information technologies in the early 1990s, and the anticipation of the coming of the Internet, it became clear to me that in order to promote better information sharing in the coming "digital" age, there is a real need to work toward a "digital knowledge base." Again, *The First Emperor of China* was a perfect example used to prepare several feature articles including that in the 1994 issue of IBM's *Multimedia Today* (Figure 3) (Chen, 1994) to advocate such a concept.


Figure 3: Images of the first two-pages of the featured article on "digital knowledge base"

The power of current technology supports sophisticated systems for connecting people to all kinds of old and new forms of knowledge. It also links between the expanding physical and intellectual universes. Thus, looking at a traditional library, for example, throughout history, its mission is to facilitate the free flow of information. While this mission remains unchanged, yet the ways in which information and knowledge workers (including librarians) used to fulfill this mission is constantly changing due to the advent of technology. In other words, the tools they use to create, collect, transmit and preserve recorded information sources, and the ways they organize, store, retrieve and use all types of available information have changed. The coming of digital knowledge age has profound impact on the kind of information services available for people and institutions.

Hypermedia on Learning: A Literature Review

Abstract: This article reviewed the literature from hypermedia research. Several perceived problems are identified, which include: (1) irrelevant assessment of outcome variables, (2) weak methodological design in conducting experimental research, (3) lack of theoretical foundations in designing hypertext systems, (4) lack of specification of precise learning outcomes and (5) lack of learner's prior knowledge in the content area. Furthermore, suggestions are made to reform the future hypermedia research agenda. The suggestions include: (1) future research should focus on assessing relevant student's learning outcomes (knowledge acquisition, knowledge integration and knowledge generation), (2) researchers should develop reliable and valid instruments and methodology of experimental design (reporting reliability of criterion measures), (3) hypermedia design should reflect hypotheses derived from established learning and instructional design theories, and (4) future studies should consider learner's prior knowledge and varied learning styles.

Introduction

Hypermedia learning environments are currently being employed as major components for designing and implementing educational and training learning environments. This fact can be validated by the increasing number of online courseware in school settings and corporate environments as well as by the number of articles and journals in hypertext-related literature.

Several theorists and researchers in the field of instructional technology have made strong arguments for integrating hypermedia technologies into educational and training environments. They have argued that hypertext structures match with human mind's cognitive structure, and that this congruence can facilitate learning. For examples, Kearsley (1988) has indicated that "hypertext matches human cognition; in particular, the organization of memory as a semantic network in which concepts are linked together by association" (p.23). Jonassen (1993) clarified Kearsley's statement by indicating that "hypertext provides an electronic environment to facilitate knowledge exploration via links created by the course experts. Because hypertext is a node-link system based upon semantic structures [as opposed to a sequential access system], hypermedia can map fairly directly the structure of knowledge it is presenting" (p.14). Based on these two statements, it would seem that hypermedia, properly conceptualized and implemented, would be a very effective instructional tool for facilitating

learning.

However, in reviewing the existing research of hypermedia on learning, the results are quite disappointing (Astleitner & Leuner, 1995; Tergan, 1997). Specifically, there is little empirical evidence showing that a hypermedia learning environments improve learning outcomes (See Beeman et al., 1987; Gordon & Lewis, 1992; Hammondm & Allinson, 1989; Jonassen, 1993; Jones, 1989; Marchionini, 1990; Marchionini & Shneiderman, 1988; van Den Berg & Watt, 1991). Additionally, it is still questionable as to whether hypermedia learning environments can be designed to be effective and efficient learning environments for different kinds of learning objectives (Astleitner & Leuner, 1995; Balcytiene, 1999; Spiro & Jehng, 1990; Tergan, 1997). The purpose of this paper was to review the existing literature related to hypermedia learning environments and to point out some of the inadequacies that may be limiting its potential usefulness in facilitating student learning. As a result of this review of the literature, suggestions for future research in the field of learning with hypermedia are provided. The ultimate goal of this article was to examine the research base in hypermedia on learning in order to identify existing limitation inherent in existing research and to provide a research agenda, the results of which would assist instructional designers in producing appropriate instructional materials to facilitate student achievement of the varied levels of performance outcomes.

Problems Associated with Learning with Hypermedia

Astleitner and Leutner (1995, p.389) have identified three basic problems on learning with hypermedia. They are:

- Goal attainment: which comes from distraction caused by the huge amount of information in a hypermedia system. Under this circumstance, students will miss the most important information and spend too much time on browsing unnecessary information.
- Spatial disorientation: which comes from the complex node-link structure of hypermedia. Students do not know where they actually are, where they come from and where they should go next. This is the famous so called lost-in-hyperspace problem when they learn in a hypermedia environment.
- Knowledge acquisition: which comes from learner's cognitive overload when they confronted with a high memory demand.

While the first two problems deal with the information retrieval process, it has little to do with learning. The third problem related to human information acquisition process related to the learner's cognitive overload when they are confronted with a high memory demand guides the literature review of this article. This contention is supported by Whalley's statement, claiming that "the concerns of the developers of hypertext systems have always primarily focused on information retrieval rather than learning" (1993, p.8).

By reviewing the existing literature of hypermedia on hypermedia learning, several potential problems are summarized as follows:

- Assessment of irrelevant outcome variables: The majority of the hypertext research focuses on the navigational behaviors on information retrieval instead of evaluating learning performances as the related to different types of learning objectives (See McKnight et al., 1990; Schroeder & Grabowski, 1995; Senn & Horton, 1996; Simpson & McKnight, 1990).
- Weak methodological design in conducting experimental research: Astleitner and Leutner (1995) observed that research in the field of learning with hypermedia is still dominated by computer scientists by charging that they "do not dispose of that high-quality methodological repertoire concerning empirical investigation which is usually common to social scientists. Often studies are based on weak designs with only few persons and without experimental control" (p.395). Similarly, Tergan (1997) contends that the major problem in the hypermedia research over the past ten years was that it was too technologically oriented and not so well grounded in the knowledge of applied cognitive science.
- Lack of theoretical foundations in designing hypertext systems: Many of the current hypertext applications are designed with no instructional theoretical foundations, emphasizing technical features or simply designing by intuition (Astleitner & Leuner, 1995; Balcytiene, 1999; Spiro & Jehng,

1990; Tergan, 1997).

- Lack of attention to learner prerequisites: Learner's prerequisites (prior knowledge, aptitude, reading comprehension, etc.) have been established to be a critical learning variable that influences hypertext learning. However, most empirical studies on learning with hypermedia do not take into account individual differences and learning styles. Researchers fail to consider that "novice learners are not typically familiar with the procedures associated with constructive self-regulative learning" (Tergan, 1997, pp. 227-228).

Future Research Agenda

In acknowledging many of the problems associated with the hypermedia research reviewed, several suggestions are made to guide future research in the field of learning with hypermedia.

- Future research should focus on assessing relevant student's learning outcomes that would include facts, concepts, abilities of comprehension, problem solving skills and other higher critical thinking skills. Student's authentic learning capabilities cannot be completely understood by simply looking at their browsing behaviors, such as numbers of mouse clicks or time spent on a single hypermedia page.
- Different types of hypermedia routines need to be examined in terms of their differential effects in facilitating achievement of different types of educational objectives.
- Hypermedia routines need to be examined in terms of their ability to create learning environments conducing to facilitating achievement in terms of knowledge acquisition, knowledge integration and knowledge generation.
- To overcome the methodological drawbacks, researchers should develop reliable and valid instruments for measuring student's performances in hypermedia learning. More importantly, the studies should be conducted in experimental settings with cognitive psychological background and also grounded in existing research base. Reliabilities of all dependent measures should be reported.
- For hypermedia courseware designers, the design should be based upon instructional theories. For examples, elaboration theory developed by Reigeluth and his associates (1978) helps select, sequence, summary and synthesize course contents, which can serve as a good design model for organizing hypermedia materials (Chou, 1999; Hoffman, 1997); cognitive flexibility theory developed by Spiro and his colleagues (Spiro et al., 1988; Spiro & Jehng, 1990) can be used as a prototype for designing complex and ill-structured knowledge domains by providing multiple perspectives, cases and examples.
- Future studies should consider learner's different learning prerequisites and learning types, for instance, various characteristics such as high/low prior content knowledge/skills, field dependence/ independence and so on. Additionally, many of the independent variables associated with the study of aptitude-treatment interactions should be taken into account in the design of hypermedia learning environments (Tergan, 1997).

Conclusion

As we continue to investigate how hypermedia learning environment may be manipulated to positively influences student's learning, it is crucial that particular attention be given to guidelines derived from instructional theory and experimental methodology as well as consideration of leaner characteristics and learning styles. Only by initiating a systematic program of investigation where independent variables are judiciously manipulated so as to determine their relative effectiveness and efficiency of facilitating specifically designated learning objectives will the true potential inherent in hypermedia be realized

Making Sense of Search Results by Automatic Web-page Classifications

Ben Choi

pro@BenChoi.org

Abstract: This paper reports the development of a system for automatically organizing Internet web pages into meaningful categories. The aim of the system is to allow Internet users to find useful information in less time. The current problem with using the Internet is how to find the information that we need. With the explosive growth in the Internet, the information overload situation is getting worse. The proposed system automatically classifies web pages based on three types of information: (1) The system analyzes organizational information among web pages (inter-web-page relationship), such as an URL and links within a web page. (2) It analyzes the meta-web-page information such as data contained in META tags and formatting data of a web page. And (3), it analyzes web-page-content information such as keywords and phrases in the content of a web page. Our results show that combining all three types of information provides better accuracy.

Introduction

Although we know that "information is power," the current problem with using the Internet is how to find the information that we need. With the explosive growth in the Internet, the information overload situation is getting worse. Since currently the Internet technology is one of the most important sectors in our economies, it is of central importance for our society that we take action to address this information overload problem. Nowadays, a simple keyword search on the Internet may return thousands of web pages (even up to a million in one of our tests). To find the right information, one may have to scan the outlines of the first hundred web pages (and usually give up after that). To decrease the amount of time spent searching for the right information, it is of central importance that we take action now, before the situation becomes unmanageable.

One technique for managing vast amounts of information on the Internet is to arrange web pages into categories. From the point of view of web-page classification, search engines can be grouped into three classes: manual classification, non-classification, or automatic classification. The current status is that there is one search engine providing manual classification (www.yahoo.com), one providing automatic classification (www.northlight.com), and the rest of them either provide not classification or rudimental manual classification (AltaVista, Excite, Go, DirectHit, Google, and Lycos). Although there is already one automatic classification system available in the market, the proposed system addresses new issues (such as inter-web-pages analysis) and provides enhanced implementations (such as object-oriented data organizations and distributed processing).

The automated categorization of web documents has been investigated for many years. For example, Northern Light received a United States patent on July 13, 1999 for their classification mechanisms (Krellenstein 1999). Mladenic (1998) has investigated the automatic construction of web directories, such as Yahoo. In a similar application, Craven et al. (1998) intend to use first-order inductive learning techniques to automatically populate ontology of classes and relations of interests to users. Pazzani and Billsus (1997) apply Bayesian classifiers to the creation and revision of user profiles. WebWather (Joachims et al., 1997) performs as a learning apprentice that perceives user's actions when browsing on the Internet, and learns to rate links on the base of current page and the user's interests. For the techniques of construction of web page classifiers, several solutions have been proposed in the literature, such as Bayesian classifiers (Pazzani & Billsus, 1997), decision trees (Apte et al., 1994), adaptations of Rocchio's algorithm to text categorization (Ittner et al., 1995), and k-nearest neighbor (Masand et al., 1992). An empirical comparison of these techniques has been performed by

Pazzani and Billsus (1997). The conclusion was that the Bayesian approach leads to performances at least as good as the other approaches.

Our Approaches

Our project addressed the following four major issues for automatic classification of web pages:

(1) Develop a process and a database system to allow arrangement and storage of hieratical categories: Our strategies include using Object-Oriented database and storing the hieratical categories in a tree structure.

(2) Develop an analysis system to determine whether a web page belongs to a specific category. The system analyzes the follow three types of information: (a) Inter-web-page relationships including URL (Universal Resource Locator) and links contained in a web page: the analysis includes going down the links pointing out of a web page and checking the given URL of the current web page for information such as the type of resources and web site organization (e.g. www.cnn.com/health indicates that the web pages contained in the health directory may be health related.). (b) Meta-web-page information including HTML Meta tags and formatting data: the analysis includes checking META tags such as tags for description, keywords, section, subsection, and date. In addition, the formatting data of the web page are also analyzed (e.g. table of content or resume usually formatted in certain way). And (c), web-page-content information including keywords and phrases: the analysis includes matching keywords within a web page to keywords for a specific categories. Words appeared within some HTML tags carry more weight than others.

(3) Develop a mechanism that can learn from training web pages to identify attributes of a specific category. The learned and programmer provided attributes are then used by the analysis system. Training web pages and their categories are provided to the learning mechanism. All training web pages are initially tokenized, and tokens shorter than three characters are removed. The set of tokens (words) is filtered to remove HTML tags, punctuation marks, numbers, and stop words, such as prepositions, articles and conjunctions. Moreover, a stemming algorithm is applied to remove suffixes such as -s, -es and -ies, to preventing separate frequency counting for those words that differ in the number (e.g., computers and computer). Separate counting leads to flattening frequency histograms and has the effect of making relevant and irrelevant features less distinguishable. A selection criterion is developed to select the tokens that are best representative of the categories. Normalization methods are also used to account for difference in the number of words in the training web pages. Methods to learn from inter-web-page relationships and from meta-web-page information do not yet exist, but are being developed in this project.

(4) Develop a strategy for the proposed system to be able to port to parallel and distributed hardware platforms: Our strategies include using CORBA (Common Object Request Broker Architecture) interfaces. CORBA specifies the functions and interfaces of an object Request Broker (ORB), which act as an object bus that allows remote and distributed objects to interact.

Automatically organizing Internet web pages into meaningful categories is only a small step toward addressing the information overload problem due to explosive growth in the Internet. Other promising strategy includes using intelligent agents that learn user's behaviors and preferences. Based on the profile of the user, the intelligent agents then automatically gather information for the user.

E-coBrowse: an Extensible Web (Co-)navigation Framework

Ng S. T. Chong‡ and Masao Sakauchi†

Institute of Industrial Science/University of Tokyo†
chong@ias.unu.edu ‡
sakauchi@iis.u-tokyo.ac.jp†

Abstract: We have developed e-coBrowse, a cross-platform architecture and toolkit for augmenting Web client capability, external to the browser, by dynamically rewriting page contents. With this system, developers can incrementally add a wide range of feat ures to a popular browser, including those, which have been difficult to realize without resorting to native code or browser/protocol customization, such as telepointer, radar view, collaborative form filling, and synchronized page scrolling. Furthermore, it also provides support for state persistence, which is essential to the development of asynchronous collaborative applications.

Introduction and Motivation

Widespread use of the World Wide Web, together with the accelerated growth in bandwidth, has made the Web attractive as a platform for interpersonal communication and collaboration, even in real-time. Today many multi-user applications have been developed to run inside a Web browser. Ironically, despite longstanding interest in extending browsers with groupware features, which can be traced back to the early days of the Web (e.g., Woo & Rees, 1994, Greenberg & Roseman, 1996, Trevor, 1997), browsers continue to be supported mainly as single-user applications. The most interesting groupware extensions to browsers are related to co-navigation (e.g., Hipbone), collaborative form filling (e.g., Kobayashi et.al., 1998), and synchronous group annotation (e.g., Pacific & Youssef, 1999). Although these group features can be found in a number of research and commercial instances, none of them are extensible systems. In particular, they do not allow users to create features which meet a specific need or decide which features to add to their browsers for the page they are visiting.

Our primary goal is to address the lack of extensibility support found in today's browsers, while meeting the need for a solution that will work for the leading browsers, Netscape and Internet Explorer. Solving this problem not only will users be able to dynamically augment their browsers with a range of network features (e.g., co-navigation), but also local features (e.g., a dictionary or translation utility), as they browse the Web together or independently.

In order to realize this goal, we have developed e-coBrowse, a web co-navigation system that supports extensibility and development of new features for Web browsers, without using plug-ins. The system has been tested successfully on Internet Explorer 5.0 (IE) and Netscape Navigator 4.7 (NN). Since e-coBrowse is implemented using a combination of JavaScript and Java, it is less susceptible to platform differences. But, due to diverging browser designs (e.g., event model), browser-specific code is necessary. Extensibility is realized by dynamically augmenting retrieved documents with system and user-defined add-ins before passing them to the browser. Add-ins can be just about anything that can display or run inside a Web browser. Hence, they can be client-side features (e.g., scripting languages), server-side features (e.g., servlets) or a combination of both. Add-ins can also interact with local applications that are outside the browser from the client file system. In this way, e-coBrowse can tap into many existing applications and help harness advances in Web infrastructures and programming languages (e.g., JavaScript and DHTML) in order to support collaboration while browsing. For example, chat and telepointers can be inserted in every page you visit. In addition to this flexibility in development, e-coBrowse provides programming abstractions and support for building groupware add-ins (e.g., a shared data model). When add-ins are carefully designed, they can operate across browsers. Moreover, because e-coBrowse extensions are external to the browser, modification to the browser is not necessary, apart from configuring it to use a proxy server that runs on the client PC. When these extensions are not in use, the client-side proxy can be controlled to work as a normal caching proxy (i.e., HTTP streams are not rewritten). Thus, there is no need to reconfigure the proxy setting in the browser when switching to normal browsing.

The remainder of the paper is structured as follows: First, some examples of how e-coBrowse might be used as the basis of different collaborative services are presented. Second, the design of the system architecture is described. Third, the key features of the e-coBrowse toolkit are introduced along with the workflow of how a complete add-in application can be built. The last section contains our concluding remarks and an outline of the ongoing work.

Prototypes based on e-coBrowse

E-coBrowse is part of a larger project, the Virtual University Initiative – a multi-mode learning platform under development at the United Nations University (Chong & Sakauchi, 2001). We are currently using e-coBrowse to develop Web-based collaborative learning tools and study human computer interaction issues in the domain of multi-user browsers. Beyond URL synchronization, a wide variety of other applications can be built with the framework. To illustrate the potential of e-coBrowse, we describe some of these applications below:
Figure 1: Samples of multi-user add-ins running on top of e-coBrowse

Figure 1-a describes an application where custom forms can be sent to users on the fly. Although the scenario depicted corresponds to a job interview, it can also be used as a quiz tool in distance education. The interviewer has access to a set of form templates, which can be used to generate customized interview questions. The form is sent to all the job applicants joining the interview. After filling out the form, the job applicants return it to the interviewer. At that time, the interviewer's screen is updated with the names of those who have just submitted the form and their responses can be reviewed.

Figure 1-b demonstrates a slightly more advanced form-based application. The form implements the semantics of a real-time poll. The application consists of a vote counter and a number of clients that act as voters.

Figure 1-c showcases another interesting application we have developed. It is a Web annotation tool featuring a pointing device that connects any DHTML-compliant portions of a Web page to a variable number of annotation effects (e.g., bookmarks and chat) known as X-pointer (Chong & Sakauchi, 2000). These effects are merged into the original document as separate layers at document retrieval time. The pointing device can behave either as a tele-highlighter (region focus) or tele-pointer (point focus). The annotations can be for personal use or sharing in a group.

System Architecture Design

There are many ways to extend browsers with extra capabilities, all of which either modify or extend some aspects of the client-server model of the Web infrastructure. The changes vary with different degrees of transparency to the server, browser, and user. These can be broadly classified into three categories: Web server customization, browser customization, and external extension. This problem has also been the subject of study, most notably in the context of Web annotation systems (Yee, 1997, Vasudevan, et.al, 1999, Zohar, 1999). We show that some of the proposed solutions can be adapted and applied towards the design of e-coBrowse. The main idea behind e-coBrowse is to allow users to dynamically incorporate new functionality in arbitrary web pages while browsing together or individually. This would have the same effect as if the browser were augmented with new capabilities. Our design rationale is given below.

The requirement that the custom features should work with any page accessible from the Web renders the first category impractical. CoNote is an example of using this approach (Davis, 1994). Browser customization affords developers complete control of the custom features. Current implementations are based on plug-ins, native-code browser interface calls (e.g., ThirdVoice and JotBot (Vasudevan, et.al., 1999)), proprietary/new browsers (e.g., Greenberg & Roseman 1996), or modified mainstream browsers (e.g., Netscape Conference). The main problem with customized browsers is their dependency on a specific browser and platform. Since a large installed body of browsers already exists, many users might not want to change their current browsers (or lose their bookmarks). Arguably, a different plug-in could be prepared for each browser and platform, but it would not be a very practical solution, particularly when plug-in programming is in general complex. This narrows the design space to extensio ns that are external to the browser. The variations within this category include application sharing and proxy intermediation. In application sharing, the sharing-enabling environment needs to be started before the browser can be shared, e.g., NetMeeting. Additionally, sharing-enabling environments that are cross-platform, like Disciple (Li, et.al., 1996), require that the browser be written in a language compatible with the system. This severely limits the choices of browsers that can be shared.

Proxy intermediation can be used to achieve both cross-platform extensibility and seamless integration with existing browsers. Since current browsers already support connection to a proxy, browser modification is not necessary. Proxy intermediaries lie along the path between the browser and Web server (Barrett & Maglio, 1998). They can access and modify the Web transaction data (HTTP request/response streams) to synthesize the desired functionality. E-coBrowse is based on this approach. Previous proxy-based solutions replace every URL with customized functions. This adds performance overhead to page loading. Instead our current implementation merges code into the original document at retrieval time. For this method to work for any pages, interference of our code with user's code must be handled.

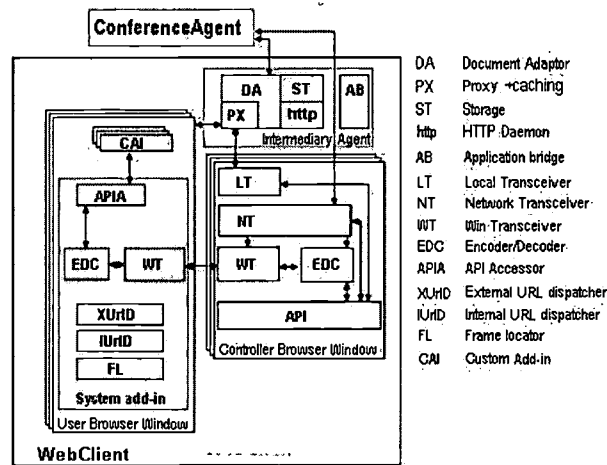
Figure 2 shows the software components of e-coBrowse and their interconnections. Proxy intermediation is realized through the client-side intermediary agent in the architecture. Similar to annotation systems, browser requests are used as triggers to actions for modifying the default behavior of page retrieval. But, the similarity ends here. We take this idea a step further to support not only annotation, but also a range of browser extensions by providing a runtime infrastructure and a development toolkit. These extensions can be written in any language as long as they can be included as part of a HTML document.


Figure 2: Software architecture of e-coBrowse

E-coBrowse Toolkit – an Overview

With the e-coBrowse toolkit, developers can easily build add-in tools and applications that enable users to participate in a community network while browsing. The key idea in the toolkit is a shared data model based on the metaphor of virtual rooms (VR). A VR is instantiated every time a conference session is started. VR interconnects the web client states and participants' file systems together. Participants can share a document by copying the file to a directory that is reserved for e-coBrowse. The shared directory automatically appears as a home directory under 'user' in the VR created for the session, much like a file system mounted on the file system hierarchy in Unix. The directory structure of VR is shown in Figure 3.
Figure 3: Logical view of the e-coBrowse community that integrates web clients' states and portions of their logical file systems in a single namespace that resembles the Unix file system.

At the root of VR, the 'bin' directory contains the ecoBrowse functional extensions that are visible to all the users in the session. These extensions can be accessible as add-ins that are merged into a retrieved web page or commands that run inside a shell console. The 'etc' directory contains configuration information about the current VR, such as session profile and sharing policies. Likewise, the private per-user counterparts can be found in the 'user' directory. At the top level of the shared data model is the e-coBrowse community that bridges the distributed VRs together in a single Unix-like namespace for accessing and manipulating data within and across VRs. Similar directory structures also exist at the community level.

Toolkit Architecture

The toolkit is still evolving, but it already contains quite a few high-level primitives that bring simplification to writing many forms of groupware add-ins. Furthermore, through the Application Bridge local applications external to the browser can also access the various APIs defined in the toolkit. Figure 4 shows the main layers of the toolkit architecture. The complete documentation of the toolkit is available at:
Figure 4: Architecture of the e-coBrowse toolkit

http://vulab.ias.unu.edu/e-cobrowse/developers/toolkit/. Here we give a summary of the key development support features.

VR Runtime Environment

The VR runtime environment provides mechanisms for managing extensions and a shell console where traditional Unix utilities such as ls, cd, mv, cp, more, cat, and rsh, can be used to navigate through the ecoBrowse community, and access the state or change the behavior of local/remote web clients directly. In addition, an add-in or a command can use the shell console to print out information useful for debugging purposes. Figure 5 shows a snapshot of the default GUI of the VR runtime environment. Using the extension manager, developers can query, update, share, and
Figure 5: End-user view of the VR runtime environment, where extensions can be shared locally inside a VR or globally across the e-coBrowse community

upload individual add-ins and commands. Each add-in can have its own configuration interface and startup parameters. The control panel provides direct access to these settings. At the minimum, users need to login through CA before they can access the VR runtime environment. Subsequently, users can be directed to an application-specific session manager. Using the session package in VRX, developers can write their own session managers (e.g., public or invite-only subscribe policies). There is only one control panel per Web client. Even in the case of a session containing multiple spawned browser windows and pages with several frames, it is only shown once. However, add-ins can be launched in a specific window and a specific frame.

Packages in VRX

A developer will find the VRX layer as the main entry point to the e-coBrowse toolkit. The packages in VRX are organized into the following programming abstractions:
- Awareness. This provides supports for realizing group awareness through automatic event notification (e.g., peers' cursor positions) and on-demand event monitoring of user actions ((e.g., peek at someone's screen) and browser operations. A participant's presence (e.g., someone who just joined a session) and current view (e.g., when a particular DOM object has changed) are some of the events that can be trapped.
- Browser. This enables programmers to manipulate behaviors of remote browsers (e.g., replace the URL in a certain browser window).
- Communication. This provides programmers with a common data path, VRBus through which they can share data, methods, and events among members joined to a same VR.

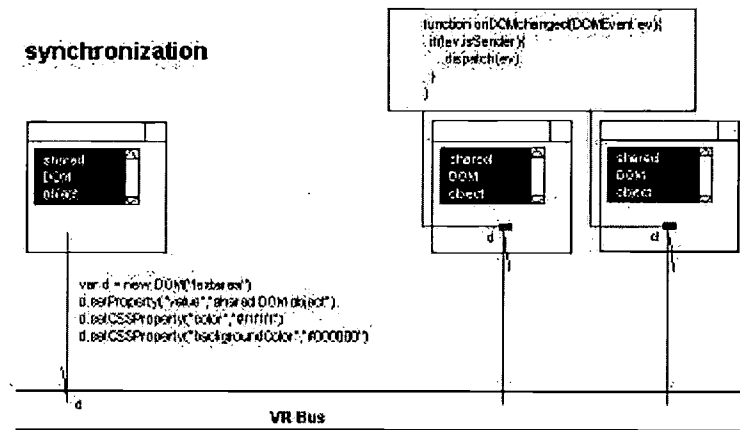
- Synchronization. This supports client-to-client synchronization within the same VR. VRX understands five different types of events, which can be monitored and processed with default or user-defined handlers. Browser events include page change, page scroll, window resize, and input events. DOM events include explicit changes made in DOM objects from program code (e.g., propagate the changes in a textarea element inside an HTML form, see Figure 6) and input events on focused DOM objects. Session events are generated when joining/leaving a session and requesting the floor control. Message events are user-defined events that can be pushed to the peers via message passing mechanisms. Method events are the last type and allow methods to be executed at the specified peer clients' browser windows (e.g., insert a dynamically generated DOM object and place it anywhere on a remote page). In addition, the package provides support for redirecting input events targeted to a (possibly remote) DOM object   to another web document. This feature finds many uses in client-server programming. The client-server poll application described in Figure 1-b is an example of using remote event monitoring.


Figure 6: An example of automatic notification and propagation of explicit changes in a DOM object to peer browsers connected to the VR Bus.

- Serialization. This provides a structure-preserving uni-dimensional abstract data type for save and restoration of object or application state. In particular, recursively nested lists are used to assist programmers with their needs for passing complex data across the network or store them in a file system.
- System. This contains methods to access the VR runtime environment.
- Bridge. This provides the means to start a local application and maintains two-way communication between the local application and add-ins.
- Utility. This includes general data abstract types such as hash tables.
- Security. This allows programmers to assign custom security policies to each file and transfer data using secure communication.

How to write an add-in? – an example

Figure 7 traces the sequence of steps for sharing and executing the poll add-in from the VR runtime environment. The application semantics dictate that there should be exactly one central counter in a session. Because the same poll add-in program is running on each connected browser, the view and behavior need to be differentiated based on the role assigned to the individual add-ins. Step 3 shows how the role for the local instance and peer instances of the program is initialized through the custom 'execute' handler. In this example, pressing the 'execute' button only starts the local copy of the poll program. The user enters the poll question and choices in step 4. When the user presses the 'send' button, a separate copy of the poll program starts in the peer browser windows. The annotated source code in figure 8 shows the implementation details of the remote execution and client-server logic of the poll program.

Two methods from the VRX package greatly reduce the programming complexity. The remote execution is based on the exe() method from the System package. The votes are directed to the counter by using the redirectBrowserEvent() from the Synchronization package. This method intercepts mouse-click events originated from the 'send' button on the voter clients and directs them to the central counter client. The result is that these events are processed on the central counter, but not on the voter clients.

1. put the poll program into add-in folder

2. share the poll add-in
3. configure and execute the poll add-in

4. customize the form and send it
5. poll appears in all of the peer documents

Figure 7: Snapshots and code show how the poll add-in can be shared and executed in e-coBrowse

how events are handled ?

Conclusions

At this point Web browsers have not found a satisfactory transition into the realm of groupware applications. This is in contrast with the relative success of the Web for running these applications. In this paper we have described a methodology to turn a common Web browser into an extensible browser with capabilities for supporting a range of custom single-user/multi-user enhancements, combined with synchronization of Web pages and users' actions inside browser windows. Our main contributions are threefold. First, enhancements are available through a cross-platform and browser independent infrastructure that runs alongside an unmodified standard browser. This will facilitate widespread deployment. Although the current implementation requires users to configure the browser to communicate through the intermediary agent, this does not interfere with regular browsing since the intermediary agent can also function as a normal caching proxy. Second, new features can be

dynamically added to and removed from shared Web pages being visited during a session through an intuitive runtime infrastructure. Even when a website is not originally designed with groupware features it can be shared in a very customized way. As the rewriting process does not place any restrictions on the language or programming model (client-side, client-server, or both), a wide range of features that can take advantage of the evolving web infrastructures can be incorporated in any web page. Furthermore, the support for sharing add-in applications fosters the formation of online communities of developers. Third, the framework provides a toolkit that supports the development of groupware tools and applications that can be closely coupled with page sharing and co-navigation. The toolkit also provides a serialization API that can be readily used to support latecomers. We expect that this tight integration will give rise to new usages of the Web and help maximize the connective potential of the Internet.

We are currently investigating a new architecture to realize the features of e-coBrowse without the need of a proxy and evaluating the framework in the further development and testing of our Web annotation system (see Figure 1-c). In the future, we will continue to evolve the toolkit and adapt the framework to new Web technologies.

Transcending Distances and Differences with E-learning Technologies

Norman Coombs, Ph.D.
CEO of EASI (Equal Access to Software and Information)
Professor Emeritus Rochester Institute of Technology
22196 Caminito Tasquillo
Laguna Hills, CA. 92653
Nrcgsh@rit.edu

Abstract: E-learning is the fastest-growing technology tool both in university education and in business training. Universities are doubling the number of distance learning courses and degrees they offer. Many businesses are finding anytime, anyplace training more convenient and less costly in terms of lost employee time than onsite workshops. Asynchronous systems overcome the problem of involving participants from different time zones and distant countries.

Web-based learning technologies create an environment that minimizes many of the differences between learners and, as never before, provides a level playing field for everyone. Status, gender, age, race, religion, learning styles and even physical disabilities all fade into the background. The speaker will share from his fifteen plus years of teaching some 6,000 people online in over forty different countries for seven separate organizations. The presentation will cover both tips for teachers and trainers in content design and delivery as well as describing some of the technological considerations that software programmers and web designers need to keep in mind to ensure that their design does not create new and needless barriers for users with disabilities.

Introduction

Different E-learning Systems

What began as correspondence courses and then graduated to telecourses broadcast before sunrise has been transformed into satellite telecasts with or without two-way interactivity and increasingly has become web-based courses delivered over the Internet. They may use video, audio, telephone, text on the web, graphics on the web, synchronous or asynchronous, and more. In some cases it means connecting two rooms of students across many miles by telecommunications. In other systems, each student is located at a different place. The problem for a discussion about E-learning systems is that the speaker and audience may have very different systems in mind and may not actually be communicating with each other. For this presentation, we will limit the discussion to web-based systems with the addition of e-mail. The web-based material may include text, graphics, video and audio. It may be either synchronous or asynchronous. Learners, in our model, will not be working together from a classroom setting but rather each learner will be connected from different locations. This is not independent learning as courseware facilitates groups interacting and working together.

The Medium is the message

In face-to-face learning situations, body language enriches and enhances the communication. How something is said may be as important as what is said. Besides so-called body language, the tone of voice itself is frequently an important part of the message. Some people compensate for this by adding pictures of smiling or frowning faces to help clarify their words. I can't imagine Johnson or Boswell drawing cute pictures on their extensive and rich correspondence. Masters of the language in the past were able to convey subtle meanings by carefully selecting their words, but a media generation such as ours has lost that kind of verbal finesse. Linguists have found that the writing style of e-mail and other electronic writing such as discussion boards fall somewhere between written and

oral language. Rather than lamenting a decline in writing sophistication, E-learning instructors need to understand the medium and find its strengths and weaknesses. This informality actually reflects how it is used. It tends to encourage spontaneity and a more relaxed, somewhat personal interaction. While it is not usually used for long thoughtful communication, it does permit editing and permits reading a message before sending it. It is usually more thoughtful and considered than is a purely oral exchange. It can be used for group discussion similar to a classroom, but it also allows students to think at least briefly before participating. Shy students frequently are not as intimidated as in a face-to-face situation. It permits anyone reading and rereading someone's comment before replying which a face-to-face setting does not. An instructor can answer a particular question at length even though most of the students understand the topic and do not need that detailed explanation. Those students can skim or skip material they understand and move ahead quickly to the topics they find most relevant. I am assuming that most of these ideas are familiar to most people, but I want to touch on it as a backdrop for talking about the inclusion of people with disabilities.

E-learning Systems and Students with Disabilities

Types of Disabilities

People all have a wide spectrum of abilities and disabilities. In a discussion of E-learning we will focus most on people who have been seen as print disabled—people who have severe problems in reading typical printed materials. When the material is transformed from print to a digital format, it lends itself to a wide variety of display formats and systems which has the potential of practically eliminating the print disability altogether. Those who have been print disabled usually includes those who are blind, who have very low vision, people with various types of learning disabilities and people with some motor impairments which prevent their holding books and turning pages. In that modern computers are all becoming multimedia machines, and in that video and audio is becoming more common on the web, we need to add the Deaf and the hearing impaired to those impacted by E-learning systems. There are, of course, a number of other disability types, and I do not want to minimize their problems. However, these are the groups that are most impacted positively and/or negatively by E-learning systems.

Adaptive Technologies

The display independence of digital information is the key to providing access to users with disabilities. Students who are blind can use screen-reading software with speech synthesis to "speak" what is on the computer screen. This provides access to textual materials, but confronts problems in providing access to graphics and images. Screen enlargement software can let a user with severely limited or low vision manipulate the size of text and images on the monitor and also alter its colors when the color presents a problem. Students with learning disabilities. may also benefit by enlarging the material and thereby limiting the amount of distracting material on the screen and enabling the person to focus on a small portion of the information at a time. There are alternative input systems to permit users with little or no hand use to control the computer and navigate through text and pictures without assistance. Alternative input systems include keyboard alternatives, mouse alternatives and, perhaps most popular, voice recognition. The Deaf and hard of hearing have problems with audio and video on the web. However, we have not yet reached the point where voice recognition software can take an audio or video and automatically output a text transcript. This still requires considerable human intervention to create and post the transcript.

Textual material can readily be used in web-based E-learning courses and be fully accessible with the use of standard adaptive technologies. There may be some problem for the Deaf if they are primarily sign language users. ASL is not signed English but another language, and English text is, in effect, their second language. Of course, because electronic communication tends to be less complex than most written language, this in itself is a help. Graphics and images are certainly useful for the Deaf and for many learning disabilities. Unless the vision of a low vision person is too bad, screen enlargement should provide reasonable access. Screen reader users have a problem and require either a text label identifying the image or sometimes a longer description of the graphic. Audio on the web works well for the users who are blind or low vision. It works well for most people with learning disabilities. It is a significant problem for the Deaf requiring making a transcript available. Video is a complex medium, and it creates more or fewer problems depending on what it is. If it includes someone speaking and conveying important information, then there must be streaming captions to accompany it. (Putting a captioned videotape on the web does

not work as the compression on the web renders the original captions unreadable.) If the video has a lot of action and complex images, it may be problematic for many with learning disabilities. If it includes a number of important and small items, someone with low vision may miss those. It is not very feasible to combine screen magnification and video. While the user was scrolling the screen magnification to focus on an item, the video would have moved to another image. Finally, students who are blind will have no trouble in following the voice track on the video, but if there is a lot of activity that is not directly reflected in the sound, you may need to add an audio description of those parts of the video for them to understand its content.

Courseware Interface

Choosing for Accessibility

There are many reasons to select one package or even creating your own system. The system needs to be easy for faculty to create their courses, and it must meet the needs of the administration to run on existing platforms and to interface with other record systems. It must also be easy for students to use and navigate. One group of students who have been frequently forgotten in making the selection are students with disabilities. Courseware vendors frequently justify their previous lack of attention to these needs by saying that no one ever requests it of them. Colleges and universities can do a lot by becoming noisy consumers and demanding that courseware products be made fully accessible. In the past year vendors are taking accessibility for students with disabilities more seriously. Asking the vendor to explain which parts of their system are accessible and which parts are not and demanding to know when the process will be completed is the first and easiest step. Like in many other software and hardware purchases, buyers need to check for themselves. Have someone on campus or a consultant check accessibility for you. One other simple test is to turn images off in a browser and to navigate using the tab key rather than the mouse and walk through several pages.

Who's Responsible?

If the courseware you purchase is not actually accessible, who is legally responsible if, in fact, it is found to be a civil rights violation? The correct answer for me to give is that you should consult your lawyer. As most people seem to read the law, however, the school, university or provider of the online training is responsible to give training that is accessible. There is legislation about providing equal education. There presently is no legislation requiring creating accessible software. The revised section 508 of the Rehabilitation Act mandates federal agencies to only buy accessible software, but it does not itself prohibit creating inaccessible software. This would seem to mean that you could end up purchasing inaccessible software, and you might be required to make your online training accessible but not even have access to the software code. If you won't be able to fix it, making the correct selection in the first place is the only meaningful alternative.

Web Accessibility

The World Wide Consortium has established the Web Accessibility Initiative to establish guidelines for making web pages accessible to a variety of users with different disabilities. It has developed a set of content guidelines, a set of quick tips and is also developing guidelines for the designers of authoring tools. Reading these materials will help you in selecting courseware and in helping your instructors post course materials that also are fully accessible. These materials are on the web at http://w3.org/wai. In the summer of 2001, the Federal Access Board's standards for web design developed under the Federal Rehabilitation Act revised Section 508 came into effect. While these are similar to the Web Accessibility Initiative's guidelines, they have some differences and have the force of law for any agency covered by Section 508. The major differences from the WAI guidelines is that these are standards that need to be stated in terms suitable to adjudication rather than merely being guidelines. These can be found at http://www.access-board.gov. WebAIM is a Learning Anywhere Anytime Program project with a number of useful resources at http://www.webaim.org.

Accessible Course Content

My Experience

This field is so new that there are no real experts. I have been teaching online since the early 1980s and have taught some 5,000 students in over 40 countries and have taught for five different university distance learning systems as well as teaching extensively for EASI. Others will have different experiences, and their insights are equally valid to mine. I can only share my experiences and what I have learned from them. IT'S ABOUT PEOPLE, NOT TECHNOLOGY. When you first start using technology to deliver material, the temptation is to focus on technology and how to use it and to almost forget the student. Find the simplest way to use the system and try to make it as invisible as possible for yourself and, above all, for your students. Remember the student with a disability is interfacing your material through two layers of technology, the courseware and the adaptive technology. The more you do to show off the technology and your use of it, the more likely that the student will focus on it and not on your content. Also, in thinking of your students with disabilities, think of them as STUDENTS with disabilities. Do not think of them as a disability but as a student. The National Science Foundation found that the major barrier to student success in science courses was not the material but social attitudes. KISS: KEEP IT SIMPLE STUPID! Simple and simplistic need not be identical. Do not dumb down the content, but present it in as simple, clear and straight forward a way as possible. Frequently being overly pedantic is a way to hide lack of content. Saying something complicated in a non-complicated way takes more work, but clear communication is good teaching. While this should help everyone, it can be of special value to Deaf ASL users and to learning disabled students.

Be Accessible

Some instructors are naturally relaxed and friendly while others seem formal and intimidating. I don't advocate that you try to create a false computer personality, but even teachers who are somewhat socially inhibited can find ways to let students know they are approachable. A student with a disability may well be shy about their situation and may fear rejection or prejudice from a faculty person. Find ways to reach out so that students with problems will not be afraid to ask for special help when they need it. At the same time, however, there are students with disabilities who exploit their disability to manipulate people around them. You should not be their social worker, and you need to know where you will draw legitimate boundaries.

Use Redundant Communication Modes

Different student have different learning styles. Universal teaching is teaching that seeks to reach everyone or as many people as possible. Frequently, education as aimed at a segment of learners, the middle ability students or the above or below average. One advantage of asynchronous online learning is students can skim over what they know or repeat some information several times. Learners can work according to different styles and different abilities. This makes it possible to design content differently than for a live classroom. It is difficult to have people working at differing paces in a room, but it is quite easy to do online. Instead of having to aim at a segment of the class, the teacher can design for a much broader ability spectrum. Besides accommodating learning styles, it can assist users with disabilities and with adaptive technology interfaces that may make learning slower or harder. Besides modularizing the material, use text, graphics, and when possible include audio and video media.

Designing for Accessibility

Most of the web design issues relate to the courseware interface itself. Much course content can be posted to the system without much concern about web accessibility issues. Whenever an instructor begins including graphics, media and some more complicated format items, problems may arise. While faculty or instructional technology people may not need to be web designers, it will help if someone involved with course production has an awareness of the most basic problems and knows where to find solutions. Perhaps the simplest introduction to the subject of accessible web design is WAI's ten quick tips, which are duplicated here.

1. **Images & animations**. Use the alt attribute to describe the function of all visuals.

2. **Image maps**. Use client-side MAP and text for hotspots.

3. **Multimedia**. Provide captioning and transcripts of audio, descriptions of video, and accessible versions in case inaccessible formats are used.

4. **Hypertext links**. Use text that makes sense when read out of context. For instance, do not use "click here."

5. **Page organization**. Use headings, lists, and consistent structure. Use CSS for layout and style where possible.

6. **Graphs & charts**. Summarize or use the longdesc attribute.

7. **Scripts, applets, & plug-ins**. Provide alternative content in case active features are inaccessible or unsupported.

8. **Frames**. Label with the title or name attribute.

9. **Tables**. Make line by line reading sensible. Summarize. Avoid using tables for column layout.

10. **Check your work**. Validate the HTML. Use evaluation tools and text-only browsers to verify accessibility.

Special Solutions for Special Problems

There are three areas that cause more serious accessibility problems. These are captioning of streaming video on the Internet; complex graphics, drawings and maps; and complex mathematics.

Video captions cannot be done by streaming captioned videotapes. The process of providing Internet captions first requires getting a verbatim transcript. Then using SMIL (synchronized multimedia integration language) you create a file with time stamps in it. This file controls the synchronization of blocks of text with the audio on the video. This is a time intensive process especially for someone with limited experience. It is a job you might want to outsource.

Providing access to complex graphical material for students who are blind will require providing hard copy tactile graphics. If you have enough need to do this, you may want to set up a process to do this. If your needs are more limited, you may want to outsource this too.

Complex math is another problem for students who are blind. It is almost impossible to render complex formulae verbally either with audio or with a text description. Presently many symbols can only be represented on the web by a graphic. While this may change in the future, presently providing hard copy Braille is the only true way to provide full access. There are Braille embossers and software translators to assist with computer generated Braille. For literary Braille this is quite simple. However, math requires a special Braille code, Nemeth Braille and producing complex Braille math demands human intervention and control. For large amounts of Braille math, you may want to develop these skills. For smaller quantities, you may consider outsourcing.

Conclusion

Adaptive computer technology has opened the world of information for many people with disabilities like nothing before in history. Because E-learning is accessed by computers, it can provide a more level playing field for learners with disabilities as nothing else in education. In its early years, E-learning has frequently contained many needless barriers for these students. With its growing use across more courses on all campuses both on campus and in distance learning, these problems can no longer be ignored. They will have to be rectified. Retrofitting can be expensive. Therefore, institutions need to consider accessibility issues as soon as possible in the creation of their E-learning infrastructure. They also need to provide some awareness training and technology support for faculty and instructional technologists.

EASI is the premiere provider of online training on how to provide a barrier-free learning and workplace. Many of EASI's leaders have had their lives transformed by these technologies. Others have worked in support positions where they have watched this impact on others. We are dedicated to extending this power to others like ourselves. EASI has recently partnered with the University of Southern Maine to provide a Certificate in Accessible Information Technology all delivered online. Courses include Barrier-free Information Technology, Beginner Barrier-free Web Design, Advanced Barrier-free Web Design, Barrier-free E-learning, Business Benefits of accessible Electronic and Information Technology, Accessible Internet Multimedia Production, Accessible Information Technology for persons with learning disabilities and Train the Trainer. Information is on the web at http://easi.cc/workshop.htm. These courses are designed to cover all the on campus and Internet facilities of schools, colleges, universities and of other information providers.

VIRTUAL CAMPUS CONTRIBUTION
TO THE EMERGENCE OF A NEW PARADIGM IN
E. LEARNING

We are living the end of employment and the need of a strictly qualified hand labor and the beginning of "employmentship" and the need of a dynamic and thinking worker (solution creator brains). In this context, it is essential to "learn how to learn", making academic qualification continuous and perennial, not limited to the schools' borders. In what concerns to the relationship with knowing, facing the amount of available information, it is more important to create knowledge to new problems through existing information than to simply know how to absorb it in an accurate way.

How to include these new necessities in the teaching-learning process?

How to promote knowledge accessibility to a broader amounts of people, continuously, making flexible space-time boundaries?

The work done by the Universidade Gama Filho (UGF)'s Virtual Campus will be discussed. It offers on-line courses and virtual libraries to teachers and students from *educação básica* based on a new paradigm of the teaching-learning process.

E-learning or e-Lemmings? Who pipes the tune?

Tony.clear@aut.ac.nz

Abstract: This paper urges a rather more critical view of e-learning than that taken to date. It is argued that strong forces are converging to redefine education as a commercial rather than public activity, of which e-learning is one element. Inherently different perceptions of the teaching and learning process, based upon a commercial rather than a public model, combined with a certain amount of naïve technological progressivism are challenging the role of higher education. Poor implementations based upon flawed assumptions are also likely to lead to an e-learning bust in much the same way as the dot com phenomenon has collapsed under the weight of its own hype. The case is argued for diverse and informed models of education (including e-learning approaches) that nurture local cultures and values, and produce socialized, adaptable and capable citizens rather than captive globalised consumers, colonized by monoculture online.

1. Introduction

A powerful and persuasive set of forces are converging to reinforce the spread of e-learning across the globe. These imperatives do however beg the question, is the distinct role and contribution of Universities and academic education programmes being lost? Are E-training and E-education being confounded in the e-learning space? Who is driving the agenda and to what end?

2. The Case of IT education

If we take as one example the issues facing computing and Information Technology (IT) education, they may serve to illustrate the point.

A global shortage of IT professionals means that companies in many parts of the world cannot fill positions. Hughes (2000) observed this *inability to meet demand* and the *growth of consumerism* in education as two key challenges for IT education. Others have noted that increasing diversity in the computing student body brings with it "changing modes of study: more re-education, more mature students, more non majors, more hybrid degrees and study programmes" (Daniels et al., 1998).

Adapting to these needs has generated strategies such as greater immigration, more specific skills based commercial courses, wholly work based learning, increased private commercial training provision, combined academic and certification programmes being offered in academic environments e.g. The UTS Master's in Internetworking as a by product of which graduates gain CISCO certification, (Hughes, 2000).

E-learning is an obvious method addressing the need for flexible modes of delivery. E-learning is being promoted as a strategy for IT training by companies such as Smartforce (2001), and "Information technology companies such as Microsoft, Oracle Cisco, IBM and Hewlett Packard do most of their training online" (Baer, 2000), while an increasing range of web based course delivery approaches are also being adopted in academic environments. It has been suggested that for many commercial organizations "moving from online training to higher education is a natural extension" (Baer, 2000).

3. Combining Information Technology and Pedagogy

Before further exploring the question of e-education, the relationship between information technology and sound educational practice will be reviewed.

Leidner and Jarvenpaa (1995) in the MIS literature have discussed educational uses of IT and proposed a theoretical framework within which to position certain technologies and pedagogical strategies for IT use. This framework identifies some key assumptions about knowledge, theories of learning, reality of context and the learning environment, within which educational practice and technology can be positioned. An overview of the framework is depicted below as Figure 1. These approaches to learning are quite varied both in style and outcome.
Figure 1. The Dimensions of the Learning Theories (Leidner & Jarvenpaa, 1995)

The traditional instructor-led learning style (Dale Spender's (1996) *sage on the stage)*, resides in the dimension of *Objectivism* and underpins many largely teleological theories of instructional and curriculum design (Bruner, 1966, Gagne et al., 1988), namely the pre-packaging and doling out of parcels of measurable and assessable knowledge by the expert to the learner. This model might be termed *"education as knowledge transfer"*.

Much work in interactive and multimedia design has been concentrated upon the dimension of *Constructivism* (Reeves, 1992), to design and create virtual worlds with which the learner can interact in order to create their own forms of knowledge in ways that are meaningful to them. This model might be termed *"education as knowledge construction"*.

In my own work involving international collaborative learning (Clear 2000, 2001), I have experimented with the dimension of *Collaborativism,* using web-based groupware as a compatible combination of IT and pedagogy to support this form of learning. This model might be termed *"education as knowledge sharing or co-creation"*.

I will now suggest that much of what is called e-learning, especially that based upon the commercial pre-packaged learning management systems such as *Blackboard Course info* and *Web-CT* tends to be objectivist in pedagogical style, that is it is based largely upon the model of "education as knowledge transfer". Thus content management is given undue emphasis, and the educational focus is restricted, being based upon a limited view of teaching and learning. This form of e-learning might be better termed e-training.

I would suggest that moving from e-training to true e-education and e-learning presents a far harder challenge, and one with which those who possess different world views and perceptions about the teaching and learning process will struggle. While we have made some progress in our understanding of what might work online, combining truly transformative models of education with the transformative capability afforded by information technology, is the challenge that e-learning has still to address.

4. The Discourse of Enterprise versus the Discourse of Community

4.1 The Nature of Information Technology

In wrestling with the educational and social issues arising from my own work with international collaborative learning (Clear, 2000), it occurred to me that one needs to look far wider than the technology itself to comprehend some of the conflicting forces that contend in the e-learning space.

I was given cause to reflect through a critical incident, in which an email was sent to me, prior to an international collaborative trial, from a student in the class. The relevant comment is excerpted below:

Do not forget that students are the customer, [AUT] is just lucky that we are more locked in to the degree by the time that we get to the professional studies that to not come back would mean that the time you have spent at [University] was a waste.

This increasingly common student view certainly does not reflect my own, nor that of the University. For instance Horsburgh (1996) has stated clearly, "Education is a participative process, students are not products, consumers or customers. They are participants".

So, is the simple act of introducing technology into the teaching and learning process one with neutral impact? To what extent do technology, individuals, organizations, and society interact? An interactive perspective on information technology (Orlikowski, 1992), recognises that technology is not separate and distinct from society and culture. We often fail to appreciate that the systems we create with software are merely subsystems within a wider nexus of overarching social systems. Software based systems merely represent a set of cultural patterns frozen for now into a reproducible and constraining form. Likewise from a systems view of education, we see again a set of educational subsystems operating within the overarching set of social systems of the culture in which the education is taking place. So the education of Christians, Jews, Hindus, Muslims is very different, representing their different cultures and religious heritages. The education of those within traditional indigenous cultures is different again, with the primacy of oral as opposed to written communication being asserted, and the emphasis placed upon collective rather than individual achievement, community and kinship ties and one's place within the tribe.

4.2 The Concept of a Discourse

One way of relating these contesting values to higher education and e-learning is through the concept of a "discourse". A discourse operates as a mechanism in society to define social interaction, prescribe certain rules for that interaction, specify the boundaries of what can be said in a given context and "prescribe which actors within that discourse may legitimately speak or act" (Davies & Mitchell, 1994). In society we could be said to inhabit "discourse webs" in which different cultural perceptions and agendas are advanced. It is like a contest between different stories, either jousting to be told, or to define the rules dictating which stories are permitted to be told.

In the E-Learning environment several discourses contest for space. One key dichotomy for higher education is that between the "discourse of enterprise" and the "discourse of community".

4.3 The Discourse of Enterprise

The discourse of enterprise comes from a neo-liberal interpretation of society, in which the economically rational or self-interested human being is primary.

In the discourse of enterprise humans are defined in a wholly economic frame, with individual lives as an enterprise of the self, like individual businesses engaged in developing their own human capital. The language of the market takes over, and civic culture becomes consumer culture. The citizen is reconceptualized as the sovereign consumer/customer. This discourse, for some time popular with western governments, has now permeated into the areas of social service provision. Patients, parents, passengers and pupils are re-imaged as customers. The power of this discourse is that it links the political, the technological and the ethical by aligning "the politico-ethical objectives of neo-liberal government..., the economic objectives of contemporary business and the self actualizing, self regulating capacities of human subjects" (Du Gay and Salaman, 1992).

Globalisation is part of this same discourse with the enterprise vision of capturing bigger markets, and the use

of technology as a vehicle to deliver services on a global scale. E-Learning aligns well with this discourse and the globalisation agenda. We even see arrangements such as the World Trade Agreement prescribing rules for free trade in educational services, (Bridgeman et al., 1999), so that global barriers to education delivery can be broken down. E-learning if viewed in this context can be seen as one strand in the rise of a new religion, that of *globalisation*, based upon a belief in the value of "free markets" and their ability to deliver global prosperity. The difference here is that the culture being asserted is global western culture, not local and unique forms.

4.3 The Discourse of Community

By contrast the discourse of community asserts the right of citizens to function collectively to maintain and build their communities. As opposed to the single utility model of economic rationalism, we see a concept such as Etzioni's (cited in DeSanctis, 1993), of dual utility both to ourselves and to one another. This discourse has a moral dimension which requires us to make our choices constrained by values such as fairness and justness. The duties we owe one another are emphasised, such as to care for our elderly and educate our young not as isolated individuals but for the wider social good. E-Learning based upon this discourse would not be about grasping bigger markets, but about supporting community building initiatives, and enabling diverse initiatives tailored equitably to the needs of learning communities.

5. Differing Perceptions and the Role of Higher Education

In the *"sovereign consumer"* model the teacher becomes subservient to the students' whims. But a sound higher education teaching and learning model is not one of tailored individual instruction, or the commercially efficient version of *mass customisation* (cf. Mathieson, 1998), where the teacher is ruled by several tyrannies of one. While each individual is unique and must be acknowledged as such, the needs and interests of the group must also be balanced, teaching and learning are social processes, and the role of the teacher is to guard carefully the trust of diverse stakeholders. Against this essentially moral role of the teaching professional, is the dilemma that Hinchcliff (1997) poses: which stakeholders do we serve, are we "educators of students or trainers for industry?" Universities have multiple stakeholders – parents, students, employers and the wider society. "The demands of serving the needs of an industry may conflict with our need to serve educational ideals" (Hinchcliff, 1997.).

Mass customisation in E-Learning while superficially promising to better meet the needs of all learners, does not meet the requirements of a community discourse. This model of education delivery is based upon the discourse of enterprise, on the "education as knowledge transfer" model, and a teleological pedagogy of staged goal-driven units for individuals to complete. The advantage of this model of education is that the learning units can be tidily packaged and the courses "sold" commercially as products, while leveraging economies of scale. However, mass delivery of custom product with self-paced learning options is an individualised instruction model, which devalues group and community learning modes and brings the danger of homogenisation of culture.

There is scope for complementary diversity in the E-Learning space, but if we ignore the community discourse we run the risk of having our culture and communities usurped by the juggernaut corporate models eating inexorably into community space. And let's be honest, in a marketing sense they see an opportunity – in the US the higher education "market" is said (Baer, 2000) to be worth about $230 billion, mostly delivered by community institutions. The training market by contrast is said to be worth $75 billion, and mostly delivered by the for-profit sector (Baer, 2000).

Higher learning cannot afford to ignore this discourse. Dennis Tsichritzis (1999) in as significant an academic journal as Communications of the ACM has asserted vigorously, "today's university is at a turning point, and turn it must. The time has come to recognize that education is a business and students are the customers". Regarding the role of the University teacher he further asserts that "professors are personnel who produce and evolve content". Harris (2000) in contrast to this view refers to "the threat to the traditions of scholarly enquiry within the academy".

A model of education in which education is a transformative process for the student is hugely at odds with Tsichritz's construction of the student's or the professor's role. Sound pedagogy informing teaching and learning is not about students as passive customers, but as active participants in a process of personal and social change and enquiry. The educator's role is not to simply provide content but to structure the learning opportunities for students, and as far as possible to engage them in that process.

The several roles of the University must also be acknowledged, among which may be numbered: to generate critical thinkers, to contribute to the creation of new knowledge, to offer equitable access to those able to take advantage of higher learning, to develop capable and adaptable citizens ready for the demands of an uncertain future world, to develop the potential of learners, to serve as a critic and conscience of society.

These goals will not be readily met by a commercial model, and will often be quite at odds with commercial goals. Generating docile labour units to participate in today's jobs, while happily paying for the privilege, will do little to address the broader needs of society.

6. E-Lemmings?

However there are some signs in early E-Learning venture failures that the core competencies that are required in the higher education sector are very different from those in the commercial training sector. Poorly implemented educational solutions, with weak business models have led several providers to collapse, or revise their strategies (Parkinson, 2000). Courses designed with restricted and wooden objectivist pedagogies, based upon mass delivery of packaged content are unlikely to enthuse many students. Low completion rates and the challenges of motivating distance learners are well known factors in traditional distance learning, why should they differ in online environments?

However "the naïve technological progressivism" (Harris, 2000) which has led many University administrators to join in virtual University consortia, purchase learning management systems, grandly pronounce e-learning strategies, appears to offer little more hope from the University sector.

7. Conclusion

While many may be rushing headlong to disaster, the Open University (OU) in the UK is one example of a successful Mega University, where the scale of activity has enabled significant reductions in the cost of servicing each student. Costs have been quoted as "less than $400 per student compared to over $10,000 in the UK and USA" (Harris, 2000). Nevertheless the OU still serves the greater social purpose of a University being research-led in its teaching and learning activity, and enabling significant access to higher education from groups formerly excluded. While the OU as a networked bureaucracy (Harris, 2000), has the expertise in both education and distance learning to adjust to a move towards greater online provision, this will prove a far greater challenge for other institutions, who lack the economies of scale, the reputational strengths or the expertise to succeed with such an educational model.

My own view is that most institutions can most productively experiment with hybrid delivery models – partly online, partly web-supported, using what Harris (2000) terms an "interstitial model" involving "investment in new learning technologies combined with conventional methods". There remain nonetheless real concerns about the "moves towards cartelization and learning consortia, many of whom operate on a multinational basis. Homogenization of learning content is a risk in these developments" (Harris, 2000).

Baer (2000) proposes several ways in which the academic and for profit sectors may productively collaborate, and these approaches may help preserve the best of public education while meeting some of the commercial pressures towards profitability and growth in market share. The broader role of the public institutions must be acknowledged and preserved, while we search for appropriate pedagogical combinations and effective ways to use the new technologies to meet the increasingly diverse needs of learners.

In the end maybe we can find effective accommodations where communities can provide customised, unique and local forms of education to meet their own needs, augmented by links to other online learning communities and resources in ways which enhance diversity and build local communities rather than create bored captives to globally delivered cheap product creating monoculture online.

Tools to Foster Course and Content Reuse in Online Instructional Systems

John W. Coffey and Alberto J. Cañas
The Institute for Human and Machine Cognition
The University of West Florida
United States
jcoffey@ai.uwf.edu, acanas@ai.uwf.edu

Abstract: A significant issue for the success of an e-learning system is making course creation and maintenance cost-effective. The creation of electronic course content has historically been extremely expensive and time-consuming (Klingenstein, 1998; O'Donnell, 1999). One way to make online course delivery less expensive is to avoid starting over every time new courses and instructional materials are needed. The creation of reusable course content is one way to break out of the cycle of recreating instructional materials from scratch. This paper contains a description of LEO – a Learning Environment Organizer. The use of LEO plays two helpful roles in fostering the reuse of existing course specifications and instructional content. It fosters the creation of course templates that can be tailored to specific audiences and that foster reuse of instructional content. It also provides an automated means of cataloguing content that has been used. This cataloguing facilitates identification of content in order to foster its reuse.

Introduction

The Internet is revolutionizing the delivery of education and training with the introduction of on-line, e-learning systems. With the rapid evolution of the Internet as a delivery system comes an increased focus on the need to make highly flexible, tailorable training and education program creation and maintenance simpler. These tasks have historically been expensive and time-consuming (Klingenstein, 1998; O'Donnell, 1999). One way to make e-learning content development less expensive is to avoid starting over every time new materials are needed. The creation and cataloguing of reusable course content modules is one way to break out of the cycle of recreating instructional materials from scratch. The goal of fostering reusability of course content gives rise to two major issues:
- cataloguing and identifying potentially useful materials, and
- being able to reorganize entire courses, topics, and content simply and easily.

It is time-consuming to produce content itself, and even more time is required to catalogue the completed product. At present, no universal standards exist regarding how to catalogue data. Groups such as the Dublin Core Metadata Initiative (Dublin Core, 2001) are attempting to develop interoperable online metadata standards that support a broad range of purposes. International standards are emerging within individual disciplines, as in the case of ISO/DIS19115, an international standard for geographic data (ANZLIC, 2000). Other organizations such as the Advanced Distributed Learning Initiative (ADL, 2000) have established their own standards for documents to describe on-line instructional content. Currently, ADL has created standards in conjunction with the IMS Global Learning Consortium (IMS, 2001) to catalogue entire courses, topics within courses, and individual pieces of instructional content. As the products of these initiatives are deployed, they will ultimately make possible searches that return fewer spurious matches than are produced by current search engines and strategies.

Assuming that content has been created and identified, it can still be time consuming to identify reusable subsets of the content and to reorganize them for special purposes or audiences. A system of hyperlinked Web pages could require the editing of links in all the pages to reuse the content. A better way to foster reuse would be to have an organizing component that presents course templates that can be easily rearranged and that can tie appropriate instructional materials together in varying combinations in order the reuse the material.

This paper contains a description of a demonstration software program named LEO, a Learning Environment Organizer, that provides a graphical editor used to create, edit, and archive course layouts that provide structure to course content. LEO may be used to produce reusable organizers that can be rearranged to meet the needs of various audiences. LEO also supports the flexible reuse of content that may be assembled in various combinations, as well as the generation of metadata records for content that has been used. This paper presents a

basic description of LEO and a description of how this software fosters reorganization of courses and topics for reuse of instructional content. The paper also describes how LEO can be used to catalogue instructional materials.

LEO: A Learning Environment Organizer

This section describes a Learning Environment Organizer (Coffey, 2000) that is part of a distributed knowledge modeling system named "CMapTools" (Cañas, et al., 1998; Coffey, 1995; Ford et al., 1996). An Organizer is a graph that takes the form of a modified concept map (Novak & Gowin, 1984) with two different types of nodes: instructional topic nodes that correspond to the topics in the course, and explanation nodes that explain about the topics. Figure 1 presents a view of an organizer pertaining to the computer science course named Data Structures.

Figure 1. A typical organizer, showing place and explanation nodes.

As can be seen in Figure 1, the organizer presents a context and focus view of the course organization. The context view is the small square box in the upper left that contains a view of the entire organizer, and the focus is the large, readable area that fills most of the window. The smaller rectangle that appears in the context view can be dragged around that view in order to scroll the focus along arbitrary trajectories. The display status panel in the top-center of the window allows subsets of the focus view to be either shown or hidden.

Topic and explanation nodes are visible in the focus view. Topic nodes correspond to the topics in the course. Figure 1 depicts topic nodes as those surrounded with shadowed boxes, populated with icons, and containing a rectangle that color-codes the status of the topic. Explanation nodes elaborate the relationships among the topic nodes and have no adornments. For example, "Introduction to Data Structures," "Linked Lists," "Arrays," and "Recursion" are topic nodes, whereas "Data Structures," "RAM," and "Statically Allocated" are explanation nodes.

Double lines that indicate prerequisite relationships connect the topic nodes. They are hyperlinked (as indicated by the icons beneath them) to the instructional content that can be used to study the topic under consideration, and to media that describe the tasks, activities, or completion requirements associated with the topic. When the user clicks on the icon beneath a topic, a pull-down menu appears that presents choices of links to online instructional content or to the tasks, assignments, activities, etc. that are associated with the selected topic.

Reusing Course Descriptions and Course Content

LEO fosters the reuse of both course descriptions and course content. The editor provides capability to create, edit, sequence, or delete entire course descriptions, or individual topics within a course. It is also simple to select media that will serve as content for a course and to associate it with the topics. LEO's incorporation into CMapTools allows knowledge models to be used as course content. LEO allows different subsets of a CMapTools model to be organized into a course with a specific goal. Once content has been imported into CMapTools (which an be done with a simple drag-and-drop operation), it is available to be linked to a topic or explanation node in LEO.

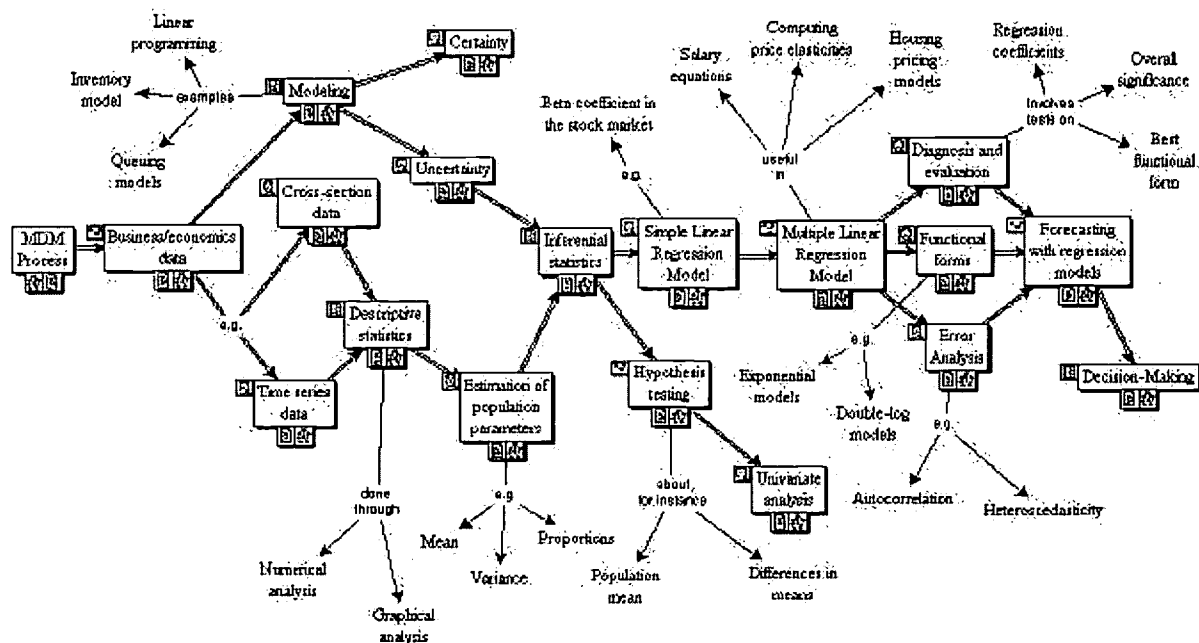
The editor is a modeless drawing tool with a variety of capabilities. The editor allows the user to create topic and explanation nodes, to create arcs between the nodes, and to place linking phrases on any of the arcs. It also allows the developer to browse through local or remote content and to create hyperlinks between topic or explanatory nodes and content that has been identified. The editor provides the capability to select completion criteria and to associate the criteria with a topic. The software is easy to use because the user does not have to switch between modes to perform these various operations. Within an existing course description, it is possible to create, edit or delete individual topics. It is also possible to change a topic into an explanatory node or an explanation node into a topic. The editor provides functionality to add or delete links between topic and explanatory nodes and to change the names of the nodes and linking phrases themselves. The layout of the entire graph may be re-arranged using standard drawing package functionality that permits the selection and relocation of one or more items.


Figure 2. An organizer for a course on Regression Analysis

233

Figure 2 presents an example of a course on regression models for decision-making. This course starts with an introductory topic (on the left-hand side of Figure 2) that is followed by the topic "Business and Economic data." In turn, that topic is followed by several topics on modeling, two types of data, and "Descriptive statistics." Following these introductory topics, the course progresses through a series of topics on various regression models, leading to a discussion of how to make decisions based on the forecasts that these models provide. The links to content are indicated by the icons beneath the topics.

Figure 3. An organizer for a Time Series course that reuses content from the Regression Analysis course.

Figure 3 presents an organizer for a course in time series models. This course utilizes some of the same introductory material as the course presented in Figure 2, in particular, topics covering modeling, types of data, and descriptive statistics. The starting point for development of the course presented in Figure 3 was the introductory material from the course depicted in Figure 2. The topics and explanations on time series models that are specific to this course were added to the general introductory material. The links to content for the topics that were reused were already established and retained.

```xml
<?xml version="1.1" encoding="UTF-8"?>
<!DOCTYPE record SYSTEM "IMS_METADATAAv1p1.dtd">
<record xmlns = "http://www.cs.uwf.edu/jcoffey/metadata/"
  <metametadata>
    <metadatascheme>
      ADL SCORM 1.1
    </metadatascheme>
  </metametadata>
  <general>
    <title>
      <langstring>Introduction to Data
                Structures</langstring>
    </title>
  </general>
  <description>
    *****Place description here********
  </description>
  <keywords>
      <langstring>Static structures</langstring>
  </keywords>
  <keywords>
      <langstring>Dynamic Structures</langstring>
  </keywords>
    . . .
</record>
```

Instructional content could be added to or deleted from any of the reused topics by selecting the topic and choosing to edit the resources associated with the topic. This form of organizer facilitates recombining previously created content. If a variety of media exist on a topic, these media can be included in varying combinations, depending on the audience. If a course on a different subset of a domain is desired, explanatory items can easily be made into topics and topics can be made into part of the explanatory component.

Cataloguing Content for Reuse

LEO provides capabilities to create metadata records for the entire course and to scan through the list of course topics, creating records for them as well. Figure 4a presents a part of the metadata record for the first topic in the Data Structures and Algorithms course presented in Figure 1. This metadata record is structured according to the format described in the ADL/IMS specification, as presented in the Sharable Content Object Reference Model (SCORM) (Dodds, 2001). Although the current demonstration software has been coded specifically to produce metadata records that comply with the ADL/IMS format, future work will lead to the creation of a code generator generator (Glanville & Graham, 1978; Henry & Damron, 1989) that will automate the creation of a metadata record generator from a BNF or other context-free grammar description of the requisite format.

As the metadata records for individual topics are being created, the links to course content are read, and metadata records for the content are created. The course metadata record is placed in a subdirectory that contains all the metadata for the course. A subdirectory within that directory is created for each of the topics in the course, and a topic metadata record is placed in the subdirectory. The metadata records for the individual course content items that are linked to the topic are placed in the subdirectory for that topic. Figure 4b illustrates the directory structure that is created for the metadata records associated with the Data Structures course.

The metadata records contain a variety of information that can be automatically determined from the system. The names of the course, topics, and individual media are taken from the filename of the course organizer, the topic labels in the organizer, and the names of the media that are used in the link to the content. When individual media is imported into the system, the media can be annotated with a description that can be used in the metadata record. The metadata generator software uses that description or prompts for one if none exists. The generator reads the directory entry for the file to determine the creation date of the file. The software provides editable default values for copyright status and placeholders for keywords that might be associated with the media, topic, or course. These values may be edited at any time.

Summary and Discussion

This paper contains a description of a demonstration software program entitled LEO. This program contains an editor that can be used to create modifiable courseware description templates. A depiction of the course layout is created as an annotated graphical representation. Metadata records describing the course, the topics in the course, and the content associated with the topics can be automatically generated from this graphical depiction. This capability has been demonstrated with the addition of the capability to generate automatically ADL/IMS compliant metadata descriptions. In this way, LEO makes it possible to catalogue and reuse content, and to archive and update course descriptions for presentation to various audiences.

The editor provides for point-and-click selection or substitution of content, topics and their sequences, for the specification of completion requirements, and for the automatic generation of the metadata records. The software also provides capabilities for the automatic creation of metadata records for content that has not previously been catalogued when that content is included in a course organized with LEO. The structuring of subdirectories containing metadata records and the capture of a global path to those directories make their placement on a server of choice simple. As standards emerge for the cataloguing of data in various domains, these capabilities will make it possible to do more accurately targeted searches for requisite educational content based upon metadata records of the sort that can be generated with this software.

Future work will involve adding a program generator to the system that will take a format description in a context-free grammar, process the rules, and automatically generate a module that will translate the graphical representation into the specified grammar. The value of this capability is seen specifically in its application to the generation of potentially rapidly evolving courseware descriptions of the sort described here, and more generally for

the automatic creation of a translator to produce descriptions of any sort of annotated linear, tree-like, or graph-like structure.

Living Science On-Line

Dr. William A. Tyler III
Department of Biological Sciences, IRCC

Dr. Raymond H. Considine
Associate Dean of Arts & Sciences, IRCC

I.   Project Summary

Through advanced web-based technology, Indian River Community College (IRCC) is bringing "living science" to teachers and students interested in science. Research scientists from Smithsonian Marine Station, U.S. Department of Agriculture, Harbor Branch Oceanographic Institution, and other Treasure Coast research facilities interact with IRCC faculty and with area high-school and middle-school math and science teachers in specialized training programs to improve science and math education. These local research scientists also are working with college faculty from IRCC and local science and math teachers to create a web-based "Scientific Community."

The Scientific Community serves as a resource for teachers, students, and professional scientists. It creates a web site that contains information on scientific experiments or other scientific information that assists science and mathematics educators and students. In addition, advanced distance learning technology has been used to offer science and mathematics courses to students through an innovative approach that brings the scientists to the students and the students to the scientists electronically.

This presentation will describe the unique characteristics of this program, will discuss the on-going developmental process for the on-line Scientific Community, and will display innovative on-line course delivery systems used in the Introduction to Ecology course.

II.   Project Description

Indian River Community College (IRCC), through an Earmark Appropriation from the U.S. government, is working to increase student interest in science using advanced web technology to bring "living science" into classrooms and homes. Through web-based technology, IRCC provides the opportunity for teachers and students interested in science to interact with science professionals. Research scientists from Smithsonian Marine Station, U.S. Department of Agriculture, Harbor Branch Oceanographic Institution, University of Florida Institute of Food and Agricultural Sciences, and other Treasure Coast research facilities interact with IRCC faculty and with area high-school and middle-school math and science teachers in specialized training programs to improve science and math education. These local research scientists also are working with college faculty from IRCC and local science and math teachers to create a web-based "Scientific Community."

The Scientific Community serves as a resource for teachers, students, and professional scientists. It creates a web site that contains information on scientific experiments or other scientific information that assists science and mathematics educators and students.

We recognize that the best content providers are the very teachers who will use the Living Science Program's web site as a resource for teaching materials, information, and fresh ideas. The teachers know what types of materials and information are needed and what will be useful in the classroom. They also can provide classroom-tested materials and activities. To assist their learning, students have access to the majority of the educational content developed.

Science and math teachers from Treasure Coast middle schools and high schools submit project proposals for the content that they would like to contribute to the web site in three broad disciplines: physical sciences, biological and marine sciences, and mathematics. An appropriate IRCC faculty member supervises each discipline.

Projects range widely in their content. The most common types of projects are detailed lesson plans, activities and problem sets designed for classroom use. Such lesson plans provide beginning teachers with valuable resources from which to build their own courses and provide more experienced teachers with fresh ideas for teaching. The lesson plans contain sufficient

background information to familiarize teachers with the topics, classroom activities, worksheets, exam questions and answers, and appropriate Internet links.

Other projects include:
1) science- and math-oriented games and crossword puzzles,
2) potential science fair projects for students,
3) detailed instructions for submitting a science fair project,
4) raw data and summaries of student research projects,
5) a student written online magazine covering human biology and health issues, and
6) online interactive lessons in mathematics, chemistry, and biology.

In addition to development of the Scientific Community web site as a resource, we also used advanced distance learning technology to offer physical and biological science courses and mathematics courses to students through an innovative approach that brings the scientists to the students and the students to the scientists electronically.

The Internet offering of "Introduction to Ecology" is an example of the type of course developed as part of Indian River Community College's Living Science Program. The Internet Ecology program employs several unique and innovative techniques to reach out to the distant student. In addition to providing the typical reading assignments, on-line testing, and instructor contact over the Internet, Internet Ecology attempts to overcome some of the difficulties of distance learning by providing on-line mini-lectures that are downloaded through the Internet via streaming video. These mini-lectures help students identify and understand the major topics typically addressed in an ecology course

The mini-lectures are designed as overviews of each chapter. They are also used to discuss important aspects of ecology not adequately covered in the text, and to provide a different perspective from that of the text's authors. The mini-lectures also create a more personal relationship between the instructor and students, in essence, taking the classroom to the students. Students can ask questions asynchronously of the instructor via e-mail or the on-line bulletin board provided by the course software, WebCT. This method of on-line instruction appeals to students who respond positively either to visual or to auditory stimuli.

Sixteen 10-18 minute streaming video lectures have been produced covering 24 text chapters. Each mini-lecture was developed using PowerPoint to provide visual information which include many of the instructor's own photographic images, public-domain images downloaded from the Internet, and text notes to highlight important concepts. The instructor conceived, wrote, recorded and coordinated the audio and visual portions of the mini-lectures. The Distance Learning Department assisted with the audio recordings using Sound Forge. Distance Learning personnel overlaid audio recordings on the PowerPoint visual presentations using Flash. On-line students access the mini-lectures through WebCT and view the mini-lectures using a free RealPlayer viewer on their own computers. The PowerPoint file, with images and text is also viewable without RealPlayer through the course web site as a student study guide and review.

In addition to the mini-lectures, streaming video clips of a variety of research topics are also available to the Ecology students. The Research Summary videos are designed to communicate to students how scientists actually conduct science in the laboratory and the field. The focus on local research projects is meant to emphasize the local relevance of science and ecology to students. The Summaries also provide scientists with an avenue to engage students, communicating the excitement of discovery and the process of science to potential future scientists and voters.

These short 5-10 minute video productions feature scientific researchers from the Treasure Coast area talking about their own work and the excitement it brings them. The Research Summaries are similar in format to the course mini-lectures except they also include video clips, so students can view the researchers in action. Current videos include research material from scientists at the USDA Horticultural Research Laboratory in Ft. Pierce and other researchers at the Harbor Branch Oceanographic Institute, the Bureau of State Parks, and Florida Atlantic University.

The Research Summary videos contribute to our expanding on-line library of streaming videos that is accessible through IRCC's Scientific Community, the Living Science web site. This web site provides area teachers and students with state-of-the-art resources to improve science education on the Treasure Coast. The purpose is to enhance the learning experience of distance learning students taking a non-major's Ecology course such that they successfully complete the course.

Partners in the Living Science program include IRCC; Florida school districts in Indian River, Martin, Okeechobee and St. Lucie counties; and the scientific research facilities of the Smithsonian Marine Station, Perry Institute/Caribbean Marine Research Center, Florida Oceanographic Research Society, US Department of Agriculture Research Laboratory, Harbor

Branch Oceanographic Institution, Florida Atlantic University School of Marine Science, and University of Florida Institute of Food and Agricultural Sciences.
The Living Science Program addresses several needs identified by these partners.

Training programs for Treasure Coast teachers provide interaction with professional researchers and educators. Internet courses in general, including Introduction to Ecology, provide equal access to a quality-learning environment to all IRCC traditional and dual-enrollment students through electronic delivery. The inclusion of mini-lectures further enhances the experience of more visual and auditory learners than is normally available in the on-line format. The finished Research Summary is in partnership with the local scientific community. The research addresses agricultural, economic and natural history topics that are an important part of Treasure Coast culture. The Research Summary currently available is the beginning of a library of such summaries that will be used for Internet Ecology and also made available to the Living Science Program's community of students, educators and scientists.

Learning in the Palm of Your Hand

Robert Cook
Dept. of Math & Computer Science
Georgia Southern University
United States
bobcook@gasou.edu

Abstract: The contributions of the National Classroom Project are based on the author's extensive experience with a web-based testing environment for college classes and the development of K-12 learning applications for Palm hand-held computers. The paper describes the technology developed by the author and discusses the lessons learned in the classroom.

Introduction

Can technology have a fundamental impact on human learning? Not just making teachers more efficient or off-loading manual tasks like grading, but actually saving those children whom the "system" currently loses. Are we on the threshold of a revolution in education in which the goals are to instill a love of learning and then to guide each student through an individual voyage of discovery?

The National Classroom Project (NCP) [1,2] is attempting to explore the answers to those questions from the perspective of a technologist, who is not a trained education professional. Thus, the focus of the Project's research is creating learning applications. We use some of the applications on a regular basis for college courses in a Department of Computer and Information Science. Other applications have been developed for use as enrichment activities in grades K-12 in the local school systems (public and private). Students use Palm computers (currently Palm IIIs or Handspring Visors) or a web browser.

Originally, the project was based on the assumption that network connectivity would be pervasive using wireless technology, such as Bluetooth or IEEE 802.11b, which turned out to be a reasonable assumption for the college environment. Thus, the first part of the paper discusses our experiences with network-based learning services. However, in trying to implement this model in the local school systems, we discovered that off-site access to our servers was not reliable.

As a result for K-12, we are investigating a model in which students intermittently "sync" to their teachers PC, which serves as a control station to monitor students' progress and to distribute activities. The second part of the paper discusses our experiences with this model in K-12 classrooms.

Web Testing

The web-testing server gives tests, which are taken using a web browser, and then grades them. It is implemented using the author's object-relational database system [3]. The system was first used to give tests to computer science students. The students were given several days to complete each test. Basically, each student entered a user name and password and a test id. Then they would be given the test questions as part of a web page form. Upon completion, the student would select the SUBMIT button to execute the grading program at the server. The system has now been in use for several years. Some of the courses include Computer Organization, Operating Systems, C++ and Java Programming. The students really liked being able to take the tests at their convenience and the absence of the time pressures of an in-class exam. The disadvantages included technical problems (i.e. ISP disconnect) and the lack of help if there were questions about the questions.

The system supports the ability to set both the start time and the stop time for each test. It also records the time at which each student retrieves and submits his test. For example, tests due at 9am tended to have a cluster of activity around midnight and an even bigger cluster in the hours preceding the deadline. We use the testing system to give out-of-class exams because that generates additional lecture time. Of course, having out-

of-class exams raise the challenge of cheating prevention. We address this issue by guaranteeing that each exam is unique. Thus, copying as a cheating technique is eliminated. Two students can still cheat, but one of them has to complete two exams!

The question format is tabular so that questions can be stored in a database system. We believe that in the future it will be desirable to select questions by executing queries that are conditioned on a student's past performance and other criteria. The NCP testing system supports embedded HTML within questions so that there is considerable flexibility in formatting. Further, test generation can involve the permutation of the answers for each test and the random selection of questions from test bank sets. Random question generation does raise the issue of accountability. Students like to know why they missed a question. Thus, the system has to record the id of the question that was asked as well as the correct answer and the student's answer.

Parameterized questions make it much easier to generate tests that can be altered to accommodate different skill levels among the students. Having parameterized questions created an opportunity to enhance learning by making practice tests available to the students. The answers are hidden in a drop-down control so that a student can first fill in their answer and then check it against the correct choice. The response from students with respect to the practice tests has been very positive.

Palm Applications

As mentioned earlier, we were never successful in trying to set up an ad hoc laboratory of networked computers in K-12 classrooms. As a result, we scaled back our solution to one that was technically and economically feasible for local schools. The K-12 NCP laboratory is a small suitcase of Palm computers, a small Canon IR printer, and an IBM ThinkPad laptop with a USB synchronization cradle. The learning applications are distributed either by syncing with the laptop or by having the students "beam" the applications to each other. Students of all ages get excited about beaming data back and forth.

We have developed a simple scripting language, EduScript, which has been used to code the various applications. The language supports the basic data types and provides interfaces to the functions of PalmOS. Figure 1 illustrates some sample EduScript applications.

Abstract: This paper outlines a collaborative e-learning model that has been developed to connect students, teachers and organizations in the learning outcomes of stage three courses in a Bachelor of Business Management Degree. The model adopts a broad approach to e-learning principles and comprises four components that contribute to the learning experience. They are "Business 2 Education", and "Education 2 Business" initiatives, a flexible learning environment, integrated assessment practices using a threaded live case study, and mentoring and student supervision. The paper concludes with a critique of the model from the perspective of the various stakeholders with comment on future directions.

Introduction

Background

The Christchurch College of Education has a tradition of tertiary education that spans almost 125 years. During that time it's main focus has been teacher education and professional development for teachers. In the past ten years however, the institution has broadened and diversified, and now offers qualifications in Performing Arts, Sports Coaching and Business.

The School of Business at the Christchurch College of Education was established in 1991 and initially offered diploma level business qualifications with an applied focus. The New Zealand Qualifications Authority in its Regulations and Prescription Handbook (2001), provides a graduate profile that describes the nature of an applied diploma as developing graduates who will demonstrate "the ability to apply a broad range of generic business skills, principles and practices" as well as having "the ability to apply technical knowledge and skills particular to specific business fields". This has provided the context for qualifications offered within the school.

In 1996 the College affiliated with Griffith University Australia, an institution with a similar reputation for innovation, and a willingness to embrace new approaches to teaching and learning. Griffith University (2001) describe themselves as providing "degrees that are strategically focused for our particular time and place - degrees that lead to the careers of today and tomorrow". This common emphasis on offering current and relevant qualifications presented an apparent fit between the two institutions.

A major initiative of this partnership was to develop a Bachelor of Business Management Degree to be jointly conferred by the Christchurch College of Education and Griffith University. This makes the qualification a trans-tasman qualification with significant advantages to students. Study options are available within New Zealand and

Australia, and on graduation, employment opportunities are enhanced as the qualification is recognized in both the New Zealand and Australian labor markets.

The Bachelor of Business Management

The Bachelor of Business Management is a 3-year under graduate degree program. As an applied business degree it is a significant movement away from the more traditional, theoretical degree program. It has an emphasis on:
- Giving students an applied business experience, including workplace internships, while presenting current and relevant theory and research.
- Delivery to relatively small groups, emphasizing inquiry, communication and teamwork.
- Providing web-based materials for courses to support learning. (School of Business Prospectus, 2001, p.16)

In-order to achieve these outcomes experiential learning and live case studies are employed throughout the teaching of the Bachelor of Business Management. This includes a variety of real life case studies and guided practical work with organizations' actual business issues.

Within the Bachelor of Business Management, students will identify a subject major from the fields of:
- Business Communication
- Employment Relations
- Enterprise Management
- Information Systems
- Managerial Accounting
- Marketing

Flexibility within the degree structure allows a student to complete a double major, by filling their elective courses with those that satisfy another major. Students must also complete a compulsory element within their degree. Figure 1 illustrates the current structure.

Threaded Live Case Study

Waguespack (1997) describes the difference between a live case study and a threaded live case study. He sees both of these approaches as utilizing the "learning by doing" experiential model and states that this "is the most effective pedagogy in preparing IS professionals". The key difference between these two case study approaches lie within the

question raised by Waguespack. How can students be equipped with broad knowledge principles when the sequencing of learning units in business and information technology may be independent of one another? This is the premise for a threaded live case study, where the case study provides a context surrounding several application problems.

In this paper we discuss how an e-learning model has been designed to provide collaboration and an experiential learning opportunity between two courses. The two courses are Applied Management Project (MGT3001), and E-Business (MGT 3041). These are 3rd year papers for students completing the Bachelor of Business Management Degree.

A core paper, Applied Management Project focuses on the research process with a management perspective. Students work with an organization researching a current issue faced by them and are assessed on the key elements of a research project from an initial research proposal, through to the completion of appropriate research, and finally to a presentation of the research findings to the organization.

E-Business is an optional paper in the Information Systems major. It provides students with the strategies, tools and techniques to analyze new E-Business opportunities, to identify the issues and risks of these opportunities and then manage the expansion process. Students also learn about the development of the dot.com business and the processes required in this development.

To activate the threaded live case study students are permitted to select one case study for which it will be possible to complete the learning outcomes for both of these courses. Figure 2 illustrates how the case study maps to different assessment outcomes for each course.

Figure 2: Threaded Live Case Study Assessment Outcomes

A Collaborative E-Learning Model

Rosenberg (2001) argues that "e-learning" is a learning transformation that is poised to take off if it encompasses the following factors:

- Meaningful and motivational goals that reflect the "real job situation," not merely passing the course.
- Simulations that focus on learning by doing and learning from mistakes.
- Coaching and feedback, preferably from managers and supervisors who are held accountable for the learning process.
- "Expert modeling" and "stories" that reinforce learning.
- Authenticity, which requires continuous revision of training programs to focus on real situations.
- Reuse of the material and links to other sources.

Ismail (2001, cited in Martin 2001) has an equally broad view of e-learning. He says: "Related to the need for learning and e-learning to complement each other is the growing awareness that formal education cannot be separated from informal learning. The domain of learning, therefore, can no longer be confined to formal education institutions".

In the collaborative e-learning model we have developed for the MGT3001 and MGT3041 courses respectively, we have encapsulated these broad e-learning principles to develop an apparently unique approach for the teaching and learning process. The model developed comprises four components. "Business 2 Education" and "Education 2 Business" (B2E / E2B) initiatives, a flexible learning environment, integrated assessment options and mentoring and student supervision.

B2E / E2B

B2E /E2E is an initiative that has been incorporated into our e-learning model. This initiative involves direct interaction and involvement in the learning process between our Educational Institution and the Businesses who agree to be the "Live Case Studies" for the students' research and learning. Arnott and Atchison (1997) said that the links between research and practice could be collectively termed "professional engagement". Professional engagement falls into two main categories- teaching by direct instruction, in which student learning is based on teacher centered delivery of the material, and "teaching by doing", where students embrace experiential learning techniques and learn by carrying out activities and reflecting on their experiences.

Bonwell and Eison (1991) and Dabbour (1997) said experiential learning techniques are characterized by: -
- Student involvement in many activities (e.g., discussing, persuading, writing, critiquing) rather than just listening.
- Emphasis on development of student skills rather than information transmission and
- Higher-order thinking on the part of students.

In this case study, as part of the B2B and E2B initiatives, students are required at the start of the course to identify an organization that would be suitable for their research project in MGT 3001 and also for their E-Business Strategic Plan for MGT 3041.

Students were required to spend time working in the selected organization. This provided students with an opportunity to work alongside practitioners, and complete a project where they could apply their learning to real life practice. Research with a strong practical focus provided the students with a great opportunity to explore the adequacy of theoretical models within the context of the constraints that are often imposed in a real world environment.

Flexible Learning Environment

Flexibility was provided so that students could meet the learning objectives of both courses while retaining control as much as possible of "when", "where" and to some extent "how" the learning took place (Janicki and Madey, 1997).
A flexible learning environment was necessary as: -

- Conflicting and other more important priorities often affected timeliness of response by contact people within organizations.
- The case study was a staged learning process and deliverables at the end of the chain could not be completed until research data had been collected and analyzed.
- Constraints and difficulties not anticipated at the outset of the project could arise requiring last minute changes to the "game plan".

Flexibility was provided in a number of ways. Individual assessment arrangements were negotiated with students to fit with their specific case study. In most cases changes were minor, and generally involved re-negotiation of submission dates in response to circumstances relating to the project.

In addition to relaxing deadlines, a web site was provided for both courses. This enabled access to key information by students and supervisors from organizations. Each web site contained a discussion board, notices, frequently asked questions and links to course notes and relevant readings. As students were required to balance commitments between College and the organization, the web site provided an excellent online resource.

Integrated Assessment

The organization case study is a common thread between the MGT3001 and MGT3041 courses. This provides the context for the students learning, however the assessment requirements also needed to be woven. The idea of one case study for two courses had to also work well for the assessment requirements of each individual course in addition to providing a valuable tool for seeing the real life application across more than one academic discipline.

Assessment in the two courses took on an integrated approach where the overall study undertaken by students in the case study allowed different assessment outcomes for each course. Each course had quite specific learning outcomes that were complementary to those within the other course but were not mutually exclusive. Outcomes identified within one course often provided students with a vehicle for working towards further outcomes within the other course.

Example 1: Merrin Street Café and Bar
The first example is a neighborhood café and bar, which is currently a traditional "bricks and mortar" business. Research was undertaken to determine the feasibility to transform the business into an e-business using a staged implementation process. The student was required to undertake primary and secondary research, analyze the findings and prepare recommendations to meet the learning outcomes of MGT3001. The recommendations were presented to stakeholders and formed the basis of the e-business strategy to transform the business and prototype web site that was developed to meet learning outcomes of MGT3041.

Example 2: Institute of Chartered Accountants of New Zealand (ICANZ)
Members of the Public Practice Committee of ICANZ were interested to research the online information requirements of Chartered Accountants with a view to establishing a "Portal" web site with relevant links and services. Learning objectives within MGT3001 required students to complete a literature review that related to the research question they had identified. This provided the students with essential secondary research data, providing a greater understanding of what research had been completed in the area previously and some direction for working towards their research findings. The outcomes from the literature review helped in putting together a research questionnaire to be distributed to Chartered Accountants on the shape and form that an industry related dot com web site should take. As with Example 1, the literature review, research findings and recommendations met the learning outcomes of MGT3001 and the dot.com development strategy and prototype web site met the learning outcomes of MGT3041.

The level of integration in the two examples provides an indication of the careful management required in this approach not only by the student, but also by the lecturing staff and academic supervisors involved in the process.

Mentoring and Student Supervision

In order to be accepted into the Applied Management Project paper, a student must have completed two entry prerequisites, a second-year compulsory paper Management and Decision Making, (MGT2001), and at least two second or third year papers within their specialized major. These prerequisites are designed to ensure students have an adequate understanding of management principles as well as some knowledge of their major, which will be encompassed in their research project.

The Course Examiner oversees all students. Each student will identify a Supervisor at the organization they are working with. This person is a key contact point at the organization. Any resource requirements that may arise through the research process can be directed to this person, while they also provide a medium for discussing the direction the research may be taking. Students will also be assigned an Academic Supervisor within the School of Business. The Academic Supervisor is a subject specialist who has knowledge and experience in the field of research being undertaken. As Doran, Daigle and Robertson (1997) highlight in their overview of mentoring within Computer Information Systems courses, "although a solitary faculty member can be expected to provide guidance for the project a team's project may require technical or domain knowledge unfamiliar to the instructor." Together the Supervisor from the Organization and the Academic Supervisor look to provide the practical and theoretical support to students completing a first time research project. Further the Course Examiner ensures critical research milestones are reached throughout the project.

Critique of the Model

B2E / E2B

The Students Perspective

Students enjoyed the experience of working on a "live case study" within a real organization. In most cases students sourced their own case studies and often had some prior connection or relationship to the organization they were working with. This ensured an interest in the topic and a willingness on the part of the student to do a good job.

The Lecturers Perspective

Convening a course where students are working with a variety of different industry based case studies is both challenging and rewarding. Positive aspects are the enthusiasm that is engendered in the students and satisfaction when outstanding pieces of work are submitted at the end of the semester. The difficulties include trying to match the "wish list" of the organization with student's ability to deliver. Realistic expectations are necessary by all concerned to ensure a happy outcome. Another difficulty is in trying to manage many projects simultaneously while ensuring that dialogue and communication with organizations are appropriate and timely. In some cases, students do not observe standard business etiquette and practice, leaving the lecturer to "pick up the pieces".

The Organization's Perspective

Feedback received from Organization Supervisors has been positive. There was a perception that the input required by them was realistic and not over burdening and the research undertaken was valuable and useful for the organization. Supervisors viewed the process as a "win win" situation with one commenting "in addition to free research, they obtained an excellent opportunity to test a prospective employee before they were employed".

Flexible Learning Environment

The provision of a flexible learning environment is a key component of this collaborative e-learning model. Students are required to be flexible and adapt to the changing needs of the organization that they are working with and therefore need some "latitude" in the College environment in order to mesh everything together.

One case study applied to two courses requires students to juggle deadlines and carefully balance their time between the organization and course work. A key aspect of the flexible learning environment is that students are encouraged regularly, to gage how well things are going and to communicate problems early. A certain amount of sympathy is extended for extenuating circumstances provided they have been communicated prior to assessment deadlines.

The web site as an online resource is beneficial as it makes it easy for students and organization supervisors to access information and allows the lecturer to publish key information in a timely manner.

Integrated Assessment

A student who used one case study across two different courses does not receive an easier road to the completion of each course and was required to meet the same learning outcomes as all other students completing these courses over the same time period. The key difference in terms of assessment for these students was the negotiation of dates for deliverables within the courses. Students using the one case study approach tended to negotiate lengthier periods for completion of assessments thereby disadvantaging themselves nearer the end of the course where assessment workloads tended to get heavier regardless.

Additional effort required to manage the assessment process for a case study spread across two courses takes nothing away from the pedagogical process involved. It is our position that a student can enhance their understanding in one course by supplementing it further with work completed in another. This we believe is an advantage to the students as they can see the various aspects that feed into an issue within business, and it improves the outcomes for the businesses involved.

Mentoring and Student Supervision

The mentoring process has a time cost with Organizational and Academic Supervisors meeting regularly with students to help guide them through their research. To ensure quality outcomes this mentoring role is vital.

Industry feedback on student's research and recommendations has been positive and they have been impressed at what students can actually do and the knowledge they can draw upon.

Future Directions

This collaborative e-learning model was implemented in this format for the first time in Semester One 2001. We have gained considerable knowledge as a result of our experiences and intend to further refine the processes undertaken in Semester Two. We have some concerns regarding "liability" when students are involved in industry based case studies and we intend to seek legal advice to ensure that all our documentation and procedures are adequate.

The component of the model that presented the biggest challenge was integrating the assessment between the two courses and ensuring that the learning experience for the students in each course was not diminished. We considered this particularly important, as both papers are stage three completing papers in the degree. We were satisfied that our objectives were met in Semester One, but plan further refinements to the assessment tools used.

The next stage in the process will be to further promote the applied case study model to the business community. A brochure is to be produced to advertise the benefits of B2E / E2B initiatives. On the B2E side examples will be provided of how business can link in with education providers. For example as members of advisory committees or as guest speakers. On the E2B side what education can provide for business will be outlined including work placements, research projects, just in time training etc.

Future challenges are to adopt the model in other courses where appropriate. We are excited by the future possibilities with collaborative and integrated learning techniques and are keen to explore the opportunities in other stage three papers.

Conclusion

A collaborative e-learning model that involves students applying management principles learnt in class to real life problems faced by organizations leads to a better learning outcome. Student work produced in this setting displayed an ability to analyze a business situation, and find best-fit solutions in "real" but supervised environment.

This model is a further extension of student-centered flexible learning practices that have been incorporated at the Christchurch College of Education over the last decade. The lecturing staff involved in the experience found the broad definition of e-learning to fit well with the philosophy and culture of the Institution.

Many institutions have embraced a narrower definition of e-learning and proceeded to develop online courses with web-based instruction and self-directed learning techniques. The preference at our Institution is not to follow this route. Instead we believe that the best learning outcomes are achieved by offering students a collaborative e-learning environment with applied courses where students are interacting with Teachers and Organizations through threaded live business case studies.

Ethnographic Approaches in the Design and Implementation of a Web-based Information System

Edwin M. Cortez, Professor
School of Library and Information Studies
University of Wisconsin, Madison
United States
corter@slis.wisc.edu

Abstract In contrast to conventional methods for Information Systems (IS) design, and development, an anthropological/sociological perspective is used through the application of various ethnographic techniques to the information system's development cycle. This methodology is described in the context of a U.S. Department of Agriculture applied research project called REEIS (Research Education & Economic Information System) whose aim is to build the world's most comprehensive web-based information system in the field of agriculture. The focus of the paper is a description of IS development methods that can be associated with an ethnographic design, and the utility, effectiveness and limitations of these methods.

Background

From the fieldwork of Margaret Mead in the 1920s to the study of romance readers in the 1980s, ethnography has emerged as a critical lens in many disciplines, a way of seeing, of knowing. Ethnography is now shaping the way information systems (IS) are designed and documented. In critiquing the use of ethnography for information systems development Blomberg et.al. (1993) write:

> The languages of design and of ethnography evolved in quite different contexts and in relation to different concerns. While the ethnographer is interested in understanding human behavior as it is reflected in the lifeways of diverse communities of people, the designer is interested in designing artifacts that will support the activities of these communities. The current challenge is to develop ways of linking these two undertakings (p.123).

This paper is presented with this challenge in mind and describes the application of ethnography to an information system's development cycle, including eliciting system requirements, and creating a prototype. The methodology was developed as part of an ongoing applied research project that is building ostensibly the world's most comprehensive web-based information system in the field of agriculture. The name of the project is REEIS (Research, Education & Economic Information System) and is commissioned by the Research, Education, Economic (REE) mission area of the U.S. Department of Agriculture. Various phases of the project and its components have been previously reported in the literature and the reader is referred to it rather than being repeated here (Cortez, 1999; Cortez & Kazlauskas, 2000).

Rationale for Ethnography in Information Systems Development

Organizational and social issues associated with the development, implementation and use of computer-based information systems have increasingly attracted the attention of information system researchers' interest in qualitative research methods such as action research, case study research, and ethnography, all of which focus on understanding social phenomena in their natural setting (Drake et.al., 1998).

Ethnography, in particular, is useful in IS research when the focus of the study is participants information behaviors, especially regarding how users capture and process meaning from situations. Potentially ethnographic analysis is able to identify personal sense making that include cognitive, affective and conative (action instinct) elements (Solomon, 1997).

Ethnography derives its impetus from three major schools of interpretative sociology and anthropology (Beyon-Davies, 1997).

1. Symbolic interactionism where the ethnographer takes on the 'role of the other'. In the context of the research reported here, the 'other' is the end-user of REEIS.
2. Phenomenology, as derived from the phenomenological school of sociology, which emphasizes the individual's perception, where the ethnographer attempts to understand the individuals' construction of reality, their definitions, their views of the world.
3. Ethnomethodology that refers to the 'methods' people use in every day affairs to construct their social world, including their interactions with one another, and with the artifacts around them.

The ethnographic research approach is qualitative and interpretive whereby the researcher, cautiously and within certain parameters, interjects a subjective point of view. Good ethnography, in projects such as REEIS, requires more than just 'hanging out' waiting to see what unfolds. The researcher, relying on accepted precepts of the field, and on his or her record of experience, manages the collection of data from a particular perspective determining what data are needed for analysis, where to look for them, and how best to obtain these data from relevant sources. This practice is rooted in good fieldwork where the ethnographic records are formulated by finding out what is significant, then targeting one's observations to all that is around the object of significance, including documents (memos, minutes of meetings, reports, policy statements, etc.) and artifacts (equipment, furniture, physical layout, etc.). In the REEIS project part of the formulation of these ethnographic records was also guided by the use of basic precepts found in library and information science (LIS), organizational behavior, and open systems theory literatures, see [Table 1].

Precepts from LIS Literature	Precepts from Organizational Behavior and Open Systems Theory Literature
1) People avoid information overload by using information channels because they are convenient and accessible rather than because they are high quality.	6) What is included within an organization's boundary and its relevant environment varies from organization to organization on the basis of the nature of the organization's goals, its internal structure, and relationships with other organizations.
2) Most people prefer "talk" channels to publications and electronic databases for this reason.	7) Internal structure enables the organization to cope with uncertainty; the more the organization interacts the stronger the internal structure, and the better it is able to deal with uncertainty.
3) When people turn to recorded sources of information, they tend to prefer ones they already know and are comfortable with, rather than those that require new learning. This hold for learned professional, as well as the lay public.	8) Changes in organizations often result from changes in the organization's environment so that "openness to its environment facilitates an organization's innovativeness".
4) Because of the voluminous amount of information available, it can be said that most people are unaware of what they don't know.	9) One impetus for innovation in organizations is provided by "performance gaps"—discrepancies between an organization's expectations and its actual performance.
5) The mere presence of new information system capabilities does not guarantee use.	10) There is a correlation between the diversity of information gathering, analysis, and distribution activities, and the richness and diversity of information services an organization can offer.

Table 1: Precepts for the REEIS Project

Writers representing these precepts, and associated concepts, in their work include, Dervin (1977), Belkin (1980), Blair (1990), Taylor (1991), Kuhlthau (1993), Katz and Kahn (1966), Zaltman (1973), Churchman (1971), Kanter (1988), Schon (1971), and McGuire, et. al. (1996). These precepts not only guided the direction for data collection, but from an ethnographic perspective, also informed the process for organizing and presenting data.

Ethnography in Relation to Activity Theory and Joint Application Design

It was the intention of the researchers to arrive at a system design that would be driven by behavioral models so as to understand the individuals in the particular context of their work, organizational culture, and very importantly, in the context of the REEIS development project. The procedure for turning the initial set of the REEIS system requirements

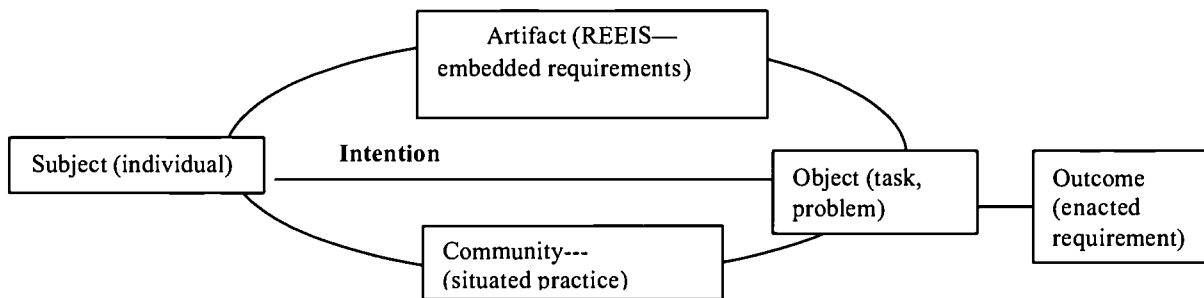
was based on an "activity theory" model that has ethnomethodological elements. Activity theory models link individual human acts with all of their influencing factors in a given environment. The model that was adopted in the REEIS project is called Joint Application Design or JAD, and like other activity theory models has been used successfully in studies relating to human-computer interaction. The objective of the model is to understand the intersection between an activity and the consciousness of the individual engaged in that activity. It considers all social/cultural aspects of the intersection, and very importantly the unique meaning that a subject (individual) brings to an object (goal). The matrix surrounding the activity also involves the use of artifacts. These artifacts may be physical tools or sign systems such as language. As applied to this project REEIS is considered as the artifact, and its value is revealed with each of its use. The value depends on the intention of the user and the resulting outcome, or stated another way, the utility and value of REEIS is determined within the context of the activity in which it is used within a specific community (Ryder, 2000). The model in figure 1 illustrates this theoretical framework and shows a subject moving toward an object with a specific intention, working within a specific user community, and selecting a tool to meet the objective. This is an iterative process that continues until the 'correct' tool that satisfies the objective is selected. The tool represents functionality derived from the system requirements. The final tools (functionality) to be part of the prototype are those that are actually selected (enacted), and not necessarily those that are available (embedded). In other words the prototype is designed around those functions that the user actually draws upon to arrive at a solution, leaving behind those that were part of the initial design of the system.


Figure 1: Joint Application Design

The techniques described above are characteristic of JAD sessions. Each session is made up of a community of users with common use traits and work requirements. Each session is designed around a specific use-case (the individual use-case is constructed from the initial set of system requirements derived from ethnographic records), involving human intentions, information problems, goals, tools, context and outcomes; in this case the outcomes are those REEIS functions that are actually called upon to reach a solution. From these selected functions a prototype is developed for further testing and demonstration (alpha mark).

The further testing and demonstration prototype continues until all communities (administrators, scientists, USDA program leaders, members of congress, etc.) of REEIS are able to satisfactorily complete all use-cases (beta mark). Examples of the use-cases include such activities as an end-user conducting a bibliographic search concerning forest sustainability, or for an intermediary to query the system for statistical /factual data on the 10 top commodities in each State, or for an administrator to aggregate/dis -aggregate data for decision making. On the technical side use-cases might additionally include, for example, providing technical search assistance, excavating for data, submitting query statements to the system, manipulating, synthesizing and reformatting data, etc.

The overall approach for developing the prototype is to establish a taxonomy of user tasks in order to visualize user/system interactions that will guide the final development of REEIS (Hert & Marchionini, 1997). The process is cyclical, iterative and one of logical deduction that produces an ongoing reduced set of problems until a permanent solution is reached (e.g. Carey & Mason, 1986; Naumann & Milton, 1982).

Discussion

The discussion section of this paper is partially framed around two constructs reported by Duane Truex and his colleagues. In one of their papers Truex, et.al. (1999) present a cogent argument for considering new assumptions about developing IS in organizations that are today in constant flux due to reinvention initiatives, the pressure for performance and accountability, the global economy, and the need to rapidly adjust to innovation. They call these organizations "emergent" suggesting that they are constantly seeking stability without ever arriving at it. The organization in which REEIS is being developed can be easily characterized as emergent.

In a second paper Truex, et.al. (2000) present another construct that leads to a deeper understanding of the 'method concept' in IS design, development and implementation, questioning basic assumptions underlying conventional wisdom and methods in information systems development. In an interesting analysis the authors use postmodern deconstruction to present deferred definitions and assumptions of IS development methods that they call 'amethodical'. Table 2 identifies these definitions and assumptions.

Privileged methodical text	Marginalized amethodical text
• Information systems development is a managed, controlled process	• Information systems development is a random, opportunistic process driven by accident
• Information systems development is a linear, sequential process	• Information systems development processes are simultaneous, overlapping and there are gaps
• Information systems development is a replicable, universal process	• Information systems development occurs in completely unique and ideographic forms
• Information systems development is a rational, determined, and goal-driven process	• Information systems development is negotiated, compromised and capricious

Table 2: Assumptions and Ideals of Methodical and Amethodical Text. Modified from *D.* Truex, et.al., (2000)

Together these two constructs lend themselves to a critical analysis of the methods used in the development of REEIS as presented in this paper, and go to the heart of three questions: 1) Do situated IS development methods, such as ethnography, lead to a more effective understanding of user system requirements? 2) In contrast to qualitative methods what are the advantages/ disadvantages of ethnographic methods, specifically applied to IS development? 3) Is it possible to construct templates, formulas, and frameworks around ethnographic approaches to the design, development and implementation of IS.

The short answer to these questions, in the context of the REEIS project being grown in an emergent organization, is that any methodology for IS development that requires lengthy analysis and detailed procedures are poor investments. As Truex notes (1999) large-scale analysis and design projects are not cost effective in organizations that are constantly evolving, because they inevitably lead to obsolete system requirements that are largely imaginary since they point to a target that can never be reached in an emergent organization. Also, users engaged in large-scale analysis, often feel frustrated and trapped by a situation in which they are expected to articulate information needs that are yet and always evolving in an unstable environment.

A longer answer could involve the use of Truex's amethodical lens to take a retrospective look at REEIS' development to date, and determine, as the negative construct would suggest, that REEIS is being built "without a predefined sequence, control, rationality, or claims of universality" (2000, p. 54). The data and this researcher's experience with the project indicate that this is not entirely the case. However, there are a number of related tangents to the Truex argument that are relevant to this discussion and to the questions posed above. They also relate to issues and limitations in using ethnographic methods in IS development, and point to the idea that the methodology, as Truex would no doubt agree, cannot be reduced to a rule-based IS development practice. This perspective complements some very important observations made by Beynon-Davies in his discussion of ethnography, for and within IS development (1997).

The following is a summary of the Beynon-Davis observations in the context of the REEIS project. Ethnography is dependent on explicated knowledge underlying cooperative work, yet people all the time perform activities and skills without being able to articulate how they do them, what is called tacit knowledge. In the REEIS project an attempt to capture tacit knowledge was made by inspecting non-human sources, such as procedure manuals and documentation for defining tasks and operations. While this was generally an adequate strategy it would have been better to also construct artificial situations to trigger and elicit tacit knowledge from REEIS users, such as asking users to think about how they execute a particular information related task while they are doing it, then document their thoughts, feelings and behaviors as specifically as possible. The objective in ethnographic studies is to explicitly ground the investigation around observations, checking and modifying back and forth until the proposed explanation accounts for the data, and until new observations fail to inform previous observations. The JAD session plan described earlier does incorporate some of these strategies.

While the ethnographic account provides robust discourse, its lengthy and unstructured nature makes it difficult for modeling and analyzing. Contradicting the reflective theme of ethnography, its use in IS development must be accompanied by an organized schema tailored to the specific study in order to manage and make sense of the data. The schema used in this study was derived from the precepts presented in table 1. These precepts come from a variety

of disciplines. The adequacy and accuracy by which these precepts are identified is therefore dependent on the depth and breath of the researchers interdisciplinary domain. In venturing into an ethnographic study structured as this one was, careful consideration should be give to this potential limitation.

The ethnographic approach is a time-consuming and costly methodology. Justifying its cost-effectiveness must include evidence that the organization is so unique and complex that it warrants an approach that is exploratory rather than prescriptive. However, with increased complexity also comes the need to cross-check and verify findings. The level of complexity in the REEIS project was increased when it became known that the project's stakeholders included Congress, the White House, other federal agencies, and the public at large. A purely quantitative study would have been inadequate given this complexity, and the number of variables needing to be examined. (Not reported in this paper are findings of a survey of REEIS users that quantified the study).

An additional potential limitation to the use of ethnography in IS research relates to the fact that the ethnographic record is nothing more than a snapshot of the workplace displaying a particular user behavior at a particular time, and does not necessarily speculate beyond that. Implementation of new IS should provide the potential for innovating work practices and for adapting new uses for technology. A challenge for the IS ethnographer, hence, is to effectively and objectively gaze into the crystal ball in order to speculate beyond what the data reveals, looking for new patterns and indicators all the while. These new patterns and indicators for each concept are sought until common instances are found repeatedly so that the concept can be considered saturated. For this reason the ethnographic record should be as detailed as possible referencing observed behaviors, documentation, and artifacts.

Of concern to the researchers in the REEIS project was, that unless conscientiously sought out, functionality requirements would be over shadowed by system design constraints. In the REEIS study, therefore, questions and probes specifically addressed what users liked or did not like about the use of current information technology, and what they desired for its use in the workplace. The researchers carefully looked for shared patterns of behavior specifically in terms of information creation, processing, storage, retrieval and use. In writing the ethnographic records explicit attention was given as to how effectively they would ultimately yield functional and technical system requirements.

Finally, a danger for an ethnographer coming from an information technology background used to a 'naturalistic account' rather than a 'reflective' one, is that of resorting to logical or rule-based explanations. Yet, as mentioned earlier, there is a need to have exactly this kind of logic and rules in place if sense is to be made from the collected ethnographic records. It is a slippery slope that the information system ethnographer maneuvers.

Conclusions

This paper concludes that while there is no unified method to the ethnographic approach, the construction of an analytical framework, based on anthropological/sociological theoretical schools, is an effective way of identifying personal sense making that include cognitive, affective and conative (action instinct) elements. In using ethnography for IS development work the emphasis should be on the kind of analytical framework that will explicate (or make observable) the real-world organization in which the information system will live. Ethnography, unlike other conventional qualitative methods, supports the kind of facetted analytical framework necessary to do good IS development work, but is not without limitations.

The paper describes how ethnography is used to plan the design, development, and implementation of a modern comprehensive web-based information system in the field of agriculture called REEIS. Each design/development/implementation component of the REEIS project is situated in one or more of the qualitative research traditions, depending on the data collection and analysis requirements, as well as on the orientation needed. Throughout the IS development work the research orientation has focused on ethnography as a way of taking account of the "reality" of the information retrieval situation. For example, in order to formulate REEIS system requirements in the context of the REE mission agency needs, it was necessary to view how users derive meaning from the experience they encounter. By applying ethnographic methods the real-world character of workplace activities was revealed, and hence system design goals (requirements) could be appropriately established. Without these pre-determined goals, or with the wrong goals in place, the system development work fails. The use of ethnography hopes to ensure that system development resonates with the circumstances of the system's use. In this project there was significant reliance on ethnographic records, constructed throughout the project, in order to generate initial system requirements and to build 'use cases' for prototyping REEIS. This heavy reliance on the ethnographic approach is a significant departure from conventional IS design methods that do not concentrate on social activities and the individual's construction of reality. As an extension of the ethnographic method, JAD sessions are being used to build a 'rapid prototype' of REEIS, where the 'proof of concept' is achieved through prolonged interaction between users and those engineering the system. Here

the research framework is based on activity theory where, with each iteration of the system, focus is on users and what they are attempting to achieve. This approach leads to understanding the intersection between an activity and the consciousness of the individual engaged in that activity.

Developing an ethnographic methodology for IS development is not an easy task. Nor does such an approach guarantee ultimate success, solve all design problems, or revolutionize IS implementation strategies. The full impact of ethnography for IS development can only be imagined for now. It will take many more projects such as REEIS and some time to pass before understanding the full potential of the methodology. Meanwhile, what is certain is that sociological/anthropological based approaches to IS development resonate well with the relatively new user-centered paradigm which has reconceived and fortified the IS specialization, particularly within the library and information science field. The main conclusion to be drawn is that information system design work must include user participation, and that the objective of the design is to empower the workforce through the expansion of knowledge. As Juup Esser and Jos Schreinemakers suggest this is particularly true today where knowledge can be considered an independent production factor next to (physical) labor, capital and natural resources (Esser, 1997). Accompanying the expansion of knowledge in the workplace means devising effective means for its management, as evident with the emergence of a variety of knowledge management practices and programs. These include the ability to capture and share explicit and implicit information in the organization, to focus on content, and access to content, and to develop organization information policies that relate to ethical and legal issues, such as confidentiality and intellectual property. The main conclusion to be drawn is that we should focus on the role of knowledge in the workplace and as Shoshana Zuboff writes, "not knowledge for its own sake, but knowledge that comes to reside at the core of what it means to be productive" (Zuboff, 1988). And, I may add, at the core of what it means to be a reflective practitioner in the field.

Using Online Tools to Enhance Classrooms:
A Case Study with MaSH (Making Serendipity Happen)

Dan Cosley
Department of CS&E, University of Minnesota [1]
4-192 EE/CSci Building, 200 Union Street SE
Minneapolis, MN 55455 USA
cosley@cs.umn.edu

Abstract: The middle ground between distance learning and standard-issue classroom education is ripe for exploration. In particular, the Open Directory Project shows that groups of people can create their own portals onto the Web. MaSH (Making Serendipity Happen) is a system similar to ODP that also allows users to rank and comment on information, allowing students and teachers to quickly create course-specific resources, with the best information found by one shared by all. A case study using MaSH to support a computer science course for pre-majors suggests it encourages students to spend more time and learn more about course topics while providing an easy way for instructors to get feedback and assignments from students and learn more about their interests.

Introduction

A middle ground exists between distance learning and standard-issue classroom education where tools for computer mediated communication (CMC) could supplement the traditional classroom. Tools from e-mail lists to integrated course environments such as WebCT support dynamic learning environments tailored to the task at hand and to the student performing it. However, many classes do not use these tools. Even in computer science, they often serve only as a one-way conduit of information from teacher to student (and much of this information is electronic copies of paper documents). One likely—and valid—reason that teachers avoid using these tools is the mindset that using such tools gives them even more responsibilities. *Someone* needs to find and organize the information; *someone* needs to answer the students' questions; and *someone* is busy already.

Assumed above is that *someone* is the teacher but this does not have to be so. The World Wide Web is a ready-to-reap garden of information. The Open Directory Project (ODP), a Web directory similar to Yahoo! but built by volunteers, is one tool for the harvest. Teachers and students could use a similar tool, working together as a group to create course-specific resources. Making Serendipity Happen (MaSH) is such a tool, allowing groups of users to explore the Web and share their discoveries. Group members can create directory topics specific to the course and fill them with Web sites focused on their needs. In addition, students can discuss what they find and rank the sites within a subtopic, allowing everyone access to the most useful and interesting information. Students can use this information to learn more and do better work while teachers can use it to learn more about their students. By creating a focal point for common interest, students might event become more interested in the course.

This paper presents a case study in which MaSH supported a pre-major computer science course. It begins with work that contributed to the development of MaSH, then outlines the software itself and some design considerations in building such software. It then presents the results and lessons learned from the case study.

Related Work

The inspiration for MaSH came from the field of CMC and the observation that education is often viewed as a one-way transaction of knowledge from teacher to students. Computers provide a number of tools that could support education (Hiltz & Wellman, 1997, Khan 1997). However, "most course-based or learning sites simply post course

---

[1] This work was completed at James Madison University.

materials. Use of the Web as merely an 'electronic book' falls far short of the potential the medium affords" (Hill 1997). MaSH's vision is to use the Web as a resource that students can mine, organize, and share. To this end, it borrows from other solutions to the problem of finding information on the Web. In particular, it draws on The Open Directory Project (Skrenta & Truel, 1998), a Web directory similar to Yahoo! but created by volunteers and with no centralized editorial control. In ODP, the editorial control rests at the level of categories. To promote the feeling of a truly shared, dynamic resource, MaSH allows any student to edit any part of the directory.

The notion of quality is a notable omission from ODP; apart from a "cool site" indication, links in a category appear in alphabetical order. It would be better if students had tools to find the most useful information. Obviously, the directory will be more useful if the best information is readily available. More important, students should learn the skill of evaluating information (for quality, authenticity, etc.). Programs that provide these facilities already exist. A number of "recommender systems" take user input and ratings for a set of documents and then use that input to filter or rank other documents. The first such system, Tapestry, used text annotations, which MaSH uses to facilitate discussion (Goldberg et al., 1992). Most later systems use numeric ratings that are both easier to give and to process. Even so, users are notably reluctant to rate (Konstan et al., 1997). MaSH attempts to counter these problems by modeling ratings as moving links up and down in a list. This strategy requires minimal effort from users, and fits well with the Yahoo!-style interface to the directory.

Landon (2001) maintains a comprehensive directory for courseware tools, such as WebCT and CourseInfo, which support integrated distance learning environments. These tools are not as well suited for enhancing traditional classroom settings, however. Their power comes with a steeper learning curve that is another factor discouraging teachers from using computers to supplement their classrooms. Running a class involves a number of distinct tasks (Hartley et al., 1997). MaSH can support or enhance a number of these tasks, including increasing (and possibly measuring) student participation, allowing for submission of assignments online, facilitating discussions, and supporting collaborative research and learning.

The MaSH Interface

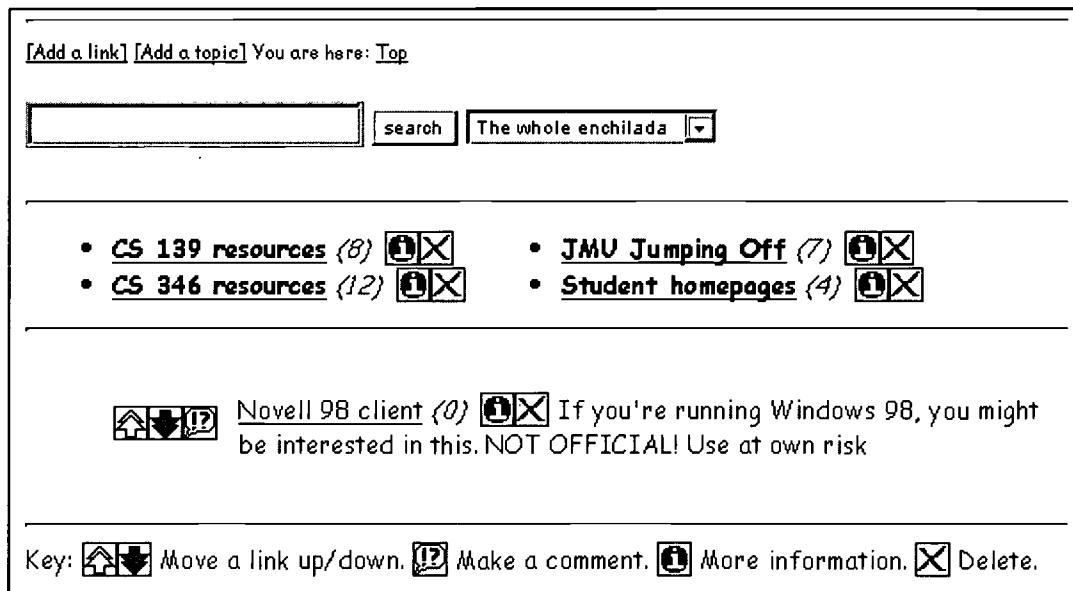
The MaSH interface is similar to Yahoo!'s look and feel (Fig. 1).


Figure 1: The primary MaSH interface.

Controls for moving, discussing, editing, and deleting links are readily accessible, and updates take place immediately. Simple keyword searches, within either the current category or the entire directory, are available. The controls for adding links and topics are not as prominent (see the top of Fig. 1). The icon legend appeared after some students found the icons confusing, particularly the icon for adding comments. Since Yahoo! has no public interface for adding links or categories, MaSH had to come up with its own (Fig. 2). Users can submit a title, URL, keywords, description, and parent topic for the link.

One concern was that the group would not come to a consensus on what was good and useful. Since the combined acts of all users determine the order of links, a link might yo-yo up and down as its champions and critics battled. The most difficult design decisions, however, involved identity and security. In the end, MaSH chose neither. Users can add links with their names, under an alias, anonymously, or even as other users. Nor are links owned—any user can edit or delete any link. In the small-group scenarios MaSH is intended for, the I believe that the gains in ease-of-use, simplicity, and shared ownership outweigh the cost in potential disruption and inability to collect detailed per-user statistics (which could be useful for certain educational applications, such as measuring participation).

Figure 2: Changing or adding a link.

Case Study

MaSH was used to support a course called "Being Productive With Computers" taught at James Madison University. The course targets students interested in becoming computer science majors but do not have enough experience using computers to go directly into the computer science program. The range of assignments for the course is broad, including a generous helping of Internet use, research, and exploration. About 140 students, mostly first-semester freshmen, took the course. Most students were able to use MaSH almost immediately, even though students received minimal instruction and some students had only minimal prior exposure to computers.

A number of course assignments involved MaSH. For the following assignments, it was required:
- *Neat Sites*: students were required to find an interesting Web site and add it to the directory with a comment. This assignment was to familiarize students both with the Web and with MaSH.
- *Areas of Computing*: students were required to populate a number of subtopics representing areas of study in CS (databases, theory, etc...), in order to learn what computer scientists do besides "program".
- *Submitting assignments*: students were required link to Web pages they created for two assignments, a My First Homepage assignment and a position paper on an ethical issue in computer science.

In other cases, use of MaSH was optional (but encouraged):
- *Supplementing lectures*: several subtopics pertained to lecture topics that students on which students needed more help (in particular, units on *HTML* and *number* systems).
- *Sharing links for research*: students wrote several papers throughout the semester; students were encouraged to use and add links to topics created for these assignments.
- *Discussions*: students could post comments in Q-and-A and course feedback topics.

Overall, MaSH received 54,916 hits (Tab. 1), with students viewing Web sites (the "View Link" action) 12,394 times (22.6% of total activity), navigating the directory (the "View Topic" and "Welcome/Help" actions) 38,329 (69.8%), and modifying the directory 4,193 times (7.6%). Sites visited and links added varied greatly by assignment (Tab. 2). In particular, the four assignments that had over 50 links added all required students to add links to MaSH.

Action	Count	Pct.
View Topic	38284	69.7%
Visit Link	12394	22.6%
Request Add/Edit	2150	3.9%
Add Item	1259	2.3%
Edit Item	416	0.8%
Rank Item	240	0.4%
Delete Item	128	0.2%
Welcome/Help	45	0.1%
Total	54916	100.0%

Table 1: Overall activity frequencies.

Topic	Hits	% Hits	Links	H/L
Homepage	7125	57.5%	189	37.7
Neat Site	1987	16.0%	236	8.4
Projects	1009	8.1%	53	19.0

Position Papers	78	0.6%	23	3.3
Other	13	0.1%	3	4.3
Total	12389	100.0%	702	17.7

Table 2: Hits and links, by assignment.

In some instances, students used MaSH beyond the course requirements. For example, in the *Homepage* assignment, each student was required to post a personal Web page and to visit and grade the pages of three fellow students. The goal was for each student to learn about HTML, to practice evaluating others' work, and to learn more about a few of their fellow students. Students were enthusiastic about this assignment. Some created very ornate pages, and many students visited each other's pages far more often than required, as evidenced by the average of 40 visits per homepage. A similar pattern prevailed for the *Neat Sites* assignment, which was the first assignment of the semester. Many students contributed more sites than required, and students both contributed and visited links from this assignment throughout the semester. For the *Projects* assignment, groups of students had to post an informational Web site devoted to a computer science topic (e.g. DVDs, computer security). They were not required to visit other groups' pages—but many students did. All of these cases point to students learning and experiencing more than they otherwise could have if the course had not used MaSH.

Students also made heavy use of MaSH topics that contained supplemental information related to assignments. These topics included *HTML, Position Papers, Numbers,* and *History of Computing.* In each case except for *Numbers,* the instructor posted a few links. Students used these links heavily and added several of their own, particularly for the *HTML* and *Position Papers* topics. This suggests that students did more research about course topics and perhaps learned more about them than they otherwise would have.

Students used the evaluation features of MaSH (link ranking and comments) infrequently, ranking links 240 times and making around 300 comments. Several factors probably contributed: the icons were confusing, no assignments explicitly required evaluation, and there was no easy way to add a comment when submitting a new site. Even if these issues had not arisen, however, Avery and Zeckhauser (1997) argue that people will in general require some sort of external compensation in order to provide ratings in a recommender system. Ideally, teachers could design assignments that would help students internalize the value of providing ratings; however, tying them to grade is more likely to actually garner ratings. Students did use the comments to give course feedback in the *Discussion* topic, showing that MaSH can be a lightweight tool for adding asynchronous discussions to a class where the instructor wants to use the system for its primary purposes of sharing information.

Students occasionally made spontaneous use of MaSH. One student (who asked first) posted a link relevant to the take-home final exam. Another pair of students created and populated the *Numbers* topic. Students made heavy use of both topics. "Anonymous" created a topic that got some play, *Interracial Interaction.* It originally appeared with eight links. Most of the titles and descriptions were vague, like the link titled "Interesting: definatly [sic] worth looking at." The links mostly pointed to sites with racist views (e.g. the KKK). One might expect complaints, or perhaps angry discussion and comments attached to the links. This did not happen—the links received around 100 hits total with no comments added and no complaints received. Two of the links, however, disappeared, and anonymous students altered the rest to point to innocuous sites such as Microsoft. One link, originally described as "White Power", was changed to "white flower" and redirected to the Betty Crocker home page.

Lessons Learned

The most practical lesson learned from the case study is that MaSH can improve a classroom. MaSH gave students a way to find and share information on difficult topics and topics they cared about. Students used MaSH a great deal for these purposes, suggesting that many students spent more time learning about course topics than they otherwise might have. MaSH also gave students an outlet to comment on the course in a safe, anonymous way. For the instructor, it provided a means to receive honest and direct feedback, a convenient way to collect and review assignments electronically, and a way to let students help each other learn the course material.

The case study strongly suggests that use of the system depends on how, and how interested, students are in a topic. Three patterns of use emerged (Tab. 3). The first pattern includes high volume topics with many links and a moderate to high hit per link ratio. A second pattern covers topics that have a high average number of hits per link, but few links. The third pattern contains relatively inactive topics, which had a very low number of hits per link.

Pattern	Topics	Hits	Links	H/L
High volume	Homepages, Neat Sites, Projects, Discussions	10306	483	21.34
High hits per link	Numbers, History, Sources, Final, HTML	1676	24	69.83
Inactive	Areas, Position, Other	407	156	2.61

Table 3: Three distinct patterns of use indicate kinds of student interest.

The reasonable explanation is that these three patterns correspond to why a topic matters to users. High volume topics are those where users had an intrinsic or strong interest in the subject, such as publishing *Homepages* or visiting *Neat Sites*. High hits per link topics suggest an operational interest: the material was useful for some task, such as learning about *HTML* or getting help with the *Numbers* and *History* assignments. Students used these topics in a markedly passive way, with few contributions but many hits. The inactive topics appear to be topics that students did not see as useful or interesting. The *Areas of Computing* topic is a fine example. Students were required to add several links each in order to get credit for the exercise, but few used these links. Instructors could monitor the ratio of hits per link added to check the "health" of the system—too few or (when student contributions are solicited) too many hits per link suggest a topic that is not faring well.

The case study also supports the decision to forgo security and identity. At least in a small-group setting, problems involving deliberate sabotage of the directory or impersonation of identities were not severe—even in a computer science setting, where at least some of the students might have greater-than-normal skills at causing mischief. The one potential incident, the *Interracial Interaction* episode, showed a community policing (censoring?) itself: objectionable material went into the directory and was gone shortly thereafter. Hiltz and Wellman (1997) describe a similar incident while discussing the social dynamics of online communities, which they feel are much like those of communities in general—including having an unstated but clear social norm for behavior. MaSH enables these norms to form by providing every member of the community the ability to make comments, move links around, and delete links. Students can vote low-quality links downward, attack them in annotations, or just remove them.

Several conditions in the case study were necessary to the success of MaSH. Students must have access to computers, which would limit its use in low-budget settings. The course topic must be amenable to using information available on the Web. This is becoming less and less of an issue, as information from all disciplines migrates to the Web, but is still a consideration. The instructor must have access to a system on which to run MaSH (a Web server with CGI scripts enabled and the Perl language is sufficient). Finally, the instructor must ensure that students understand the value of the course topics and the value of a shared information repository.

Future Work

Although not needed in the case study, features for security and identity might be worth adding to MaSH. Imposing a short (5 to 10 second) delay when responding to users deleting or editing links would discourage all but the most dedicated miscreant from random sabotage. Moderation is already possible, simply by using the system as any group member would. Collecting recent activity in one place for review in a "what's new" page would make moderation easier and allow instructors to quickly get a feel for how students were using the directory. One caution, however, is

that moderation might have a chilling effect on participation from students whose contributions were deleted. Adding identity to the system would allow instructors to track and reward contributions, and to learn more about the interests of individual students. Again, however, this route is fraught with danger—the quality and use of conscripted contributions is uncertain, as shown by the Areas of Computing failure.

The interface has room for improvement. The "what's new" page described above would be useful for everyone, not just moderators. Better icons would help users, while controls for adding to the directory should be more prominent. Another way to solicit more content would be a small second window that made it easy to submit links while surfing, similar to the itList online bookmark manager's PuppyDog (Frankovitz, 2001). Finally, students would probably comment more if they could add a comment at the same time as they add a link.

Conclusion

MaSH was useful in teaching the course. It helped students share information and learn more about the course topics and about each other, while providing the instructor with feedback and easy access to student work. Further studies would show useful it is in other domains and at other levels of education, but MaSH can be a useful addition to the teacher's toolkit. MaSH can give members of any online community the power to benefit from each other's knowledge and effort—making serendipity happen.

Effective discourse styles in asynchronous online collaboration

Extended Abstract

Instructors use the online collaborative group process for individual classes and whole curriculums. Facilitators often base their practice on face-to-face group process theory. Yet, online communications seem to change the way people think, problem solve and interact (Abdullah,-Mardziah-Hayati, 1998). Telecommunications redefine the spatial and temporal parameters of the interaction they mediate so that online discourse is taking new directions, particularly in the way people write. (Tomow, 1997, p.1) Kimball states faculty need to learn the dimensions of the new instructional medium. "New technology requires us to rethink these dynamics because we don't have the option to use familiar approaches" (Kimball, 1998, p.1). Several research projects conducted at a large private university give insight into facilitating online discussion and the differences with face-to-face facilitation. Very effective discourse styles for online collaboration have emerged from these studies.

Method

The presentation will report on the following studies: face-to-face collaborative group process conducted in a technical writing class and based upon Collaborative Problem-solving Theory by L. Nelson (1999); a qualitative study of an online fifteen-week family nursing project where 1179 electronic mail messages were analyzed for categories, concepts, and constructs; a comparative study of two online groups judged by three facilitators as producing the best and least effective outcome products; and an action research study conducted of the fifteen-week nursing project.

Findings

Although successful face-to-face and online groups share a lot of similarities, the differences are significant. The differences include the choice of subject matter, the time allowed for problem solving, facilitator behavior, and even group process.

Nelson has documented the naturally occurring steps that expert collaborators go through in successful face-to-face collaborative problem-solving. These steps are (1) Build readiness for the collaborative process, (2) Form and norm groups, (3) Determine a preliminary problem definition, (4) Define and assign roles, (5) Engage in an iterative collaborative problem-solving process, (6) Finalize the solution or project, (7) Synthesize and reflect, (8) Assess products and processes, and (9) Provide closure. The qualitative study of group processes in a face-to-face collaborative environment shows that successful groups did indeed follow these steps.

The studies of online groups, though, show the need for adjustments in the electronic setting. Complex subject matter works well in a problem-based learning or cooperative environment. The online group requires more time than do face-to-face groups to develop cohesion so the online group can't be used for short-term assignments. Tasks without fixed starting and ending points, and requiring the participation of all members to define the learning process adapt well to the online format. Facilitators of f2f groups can allow groups time to form their own heterogenous groups. The online process, on the other hand, takes more time and can benefit from instructor formation of the groups.

The environment established by the facilitator and group impacts the process and product. Online language and metaphor create the ambience. The facilitator focuses on the outcome desired and then builds the imaginary space that produces the type of communication needed to produce the emotions and process. For example, some groups projects may need a kitchen table metaphor to produce informal discussions and debate, while other projects require a boardroom metaphor to encourage formal presentations.

The comparative study of two online nursing groups found the mental metaphor used by group members affected how participants used the media and the quality of the product. The most effective outcome product group sent twice as many messages with 3 times as much content. Their metaphor described the group as an informal place to go and problem solve before producing the assignment. Ninety-four percent of all messages included validation of each other and the group: encouraged, praised, addressed individuals and their issues, agreed with each other, and built on each other's ideas.

The lack of visual presence contributed to several differences in group processing between the face to face and online groups. Interviews of online participants indicated time was needed to develop cohesion among

members. The first and last paragraph of email often contained sentences sharing life experiences and giving an emotional picture of the writer (Molinari, 1998).

The greeting and conclusion paragraphs acted as substitutes for visual cues. Students announced their communication purposes, defined boundaries, asked for social support and tried to create a shared reality before and after the message body. During the project students rarely used threading in the subject line. The subject line announced substance, purpose, priority and emotions. Further study of these adaptations may give clues for understanding the psychological cyberspace climate.

The online groups struggled with the time taken between sending and receiving messages. A "democratic abbreviated discussion" form developed. Students reflected before writing their opinions. Their message substance began with a thesis statement and was followed by supporting statements. Group members used organizing elements from both written and verbal communication. Numbering supporting ideas is often seen in document while verbal cues like "Well" and "uhm" were used to change topics.

Conclusion

Facilitators need to understand collaborative group process research and how to adapt it to online settings. Online participants create a mental metaphor for the group, which impacts process and outcome products. Online members adapt past experiences and invent new methods of communication to the online setting.

Abstract: The Institute for Computational Discourse Technologies is developing a user-friendly, web-based information retrieval system designed to minimize platform requirements and maximize usability, while employing readily available technologies. The system consists of three components: a user interface in the form of a web browser with an avatar; a digitized library organizing the data in a standard relational data base; an application server that accepts input from the user and interacts with the digitized library to dynamically compose web pages. The Human Use Regulatory Affairs (HURA) Advisor gives the user strategic advice aimed at optimizing information retrieval. The knowledge base of the HURA Advisor includes various documents on Institutional Review Boards taken from federal, civilian, and military sources. This paper focuses on the web usability of the HURA Advisor, how its avatar serves as a navigational guide, and how the system manages interactions that occur between a user and the system.

Introduction

The Human Use Regulatory Affairs (HURA) Advisor is being developed by researchers at the Institute for Computational Discourse Technologies, an interdisciplinary team of cognitive psychologists, computer scientists, and engineers at Thoughtware Technologies, Inc. The HURA Advisor is designed to help users learn the policies and regulations that pertain to using human subjects in research that is funded by the U.S. Department of Defense. While developing the HURA Advisor, we encountered both psychological and technological challenges. The psychological constraints required that we develop a web-based help system that was accurate, efficient, and user friendly. The technological constraints demanded that our system be scalable and compatible with industry standards and the Advanced Distributed Learning Initiative, such as the Sharable Content Object Reference Model (SCORM). We also wanted to minimize computational requirements performed locally, in order to allow the user's platform to perform as a thin client.

The current version of the HURA Advisor addresses these challenges. Four requirements were implemented to meet the psychological constraints. First, the curriculum is organized into a hierarchical format that reflects the relevant federal regulations (i.e., 45 CFR 46; 32 CFR 219). Second, the avatar (taking head) provides navigational guidance in each of six learning trajectories. In order to avoid navigational uncertainty, the talking head is under the control of a Dialog Advancer Network (DAN). Thus, the talking head is always available to offer advice to the user concerning what to do next. Third, a point and query feature is included in selected learning trajectories. By simply mousing over specified parts of bulleted information, the user is presented with lists of context-sensitive questions that experts deem critical to illuminating the important information contained in the particular contents. Finally, latent Semantic Analysis (LSA) is always available to provides an intelligent search of the database anytime users choose to generate their own questions and submit them in English.

To meet the technological challenges, we organized the curriculum into a relational database that is structurally equivalent to SCORM. An intelligent learning management system (ILMS) provides a server application that works with the relational database. This IMLS manages interactions between the user and the HURA Advisor. Because the workloads of both the curriculum (database) and management system are located on separate servers in remote locations, the user's platform functions as a thin client, requiring only the Windows ME operating system, or some of the equivalent software. This architecture was adopted because the

HURA Advisor is too computational intensive to run in real time on most platforms functioning as thick clients, that is, on platforms that have downloaded much of the architecture of the HURA Advisor itself.

Using the HURA Advisor

At the HURA Advisor web site the user provides a user name and password and then selects from a list of user profile categories and purpose-of-visit options, before logging on. The first time a user logs on, a page listing minimum platform requirements is presented (e.g., Pentium 200 or higher), along with software programs (e.g., Microsoft Agent core components) the user would need to download if the standard installation of Windows ME is not available. Any software programs needed to support the HURA Advisor architecture can be downloaded directly from this page by simply selecting appropriate links. This page also specifies the size (e.g., 395 KB) and approximate download time (e.g., two minutes on 56K modems) for each of the programs available to download. Once the user hits "click here when you are ready" a brief flash-movie introduction begins. This movie, created in Macromedia Flash 5.0 (www.macromedia.com), provides some historical information and describes the importance of the three Belmont principles: beneficence, justice, and respect for persons participating as subjects in research. Some of history's worst cases of human subject abuse, such as Nazi concentration-camp research, the Tuskegee syphilis study, and the Willowbrook study are highlighted in this part of the movie. The purpose is to grab the user's attention and then concentrate on the three Belmont principles. The remainder of the introduction is designed to reduce the volume of text the user has to read and to explain how to use the interface. The end of the movie takes the user to the first page of the interface.

The User Interface

The functionality of the interface, created in the Delphi 5 Enterprise Version for rapid prototyping, will be described from the user's perspective. The first page of the multimedia interface, which includes an avatar created in Curious Labs Poser 4.0 (http://www.curiouslabs.com) that is controlled by Microsoft Agent (http://msdn.microsoft.com/workshop/imedia/agent/default.asp), can be seen in Figure 1. The avatar, or animated agent, with a female persona, remains on the upper left part of the screen throughout the interactive session. As indicated earlier, the agent is an omnipresent navigational guide offering suggestions to the user on what to do next in order to optimize information retrieval (Johnson, Rickel, & Lester, 2000). Depending on the user's needs at the time, the agent's interactions are under the control of a generic dialog advancer network (DAN), or several context sensitive DANs. These networks will be described in the next section of the paper.

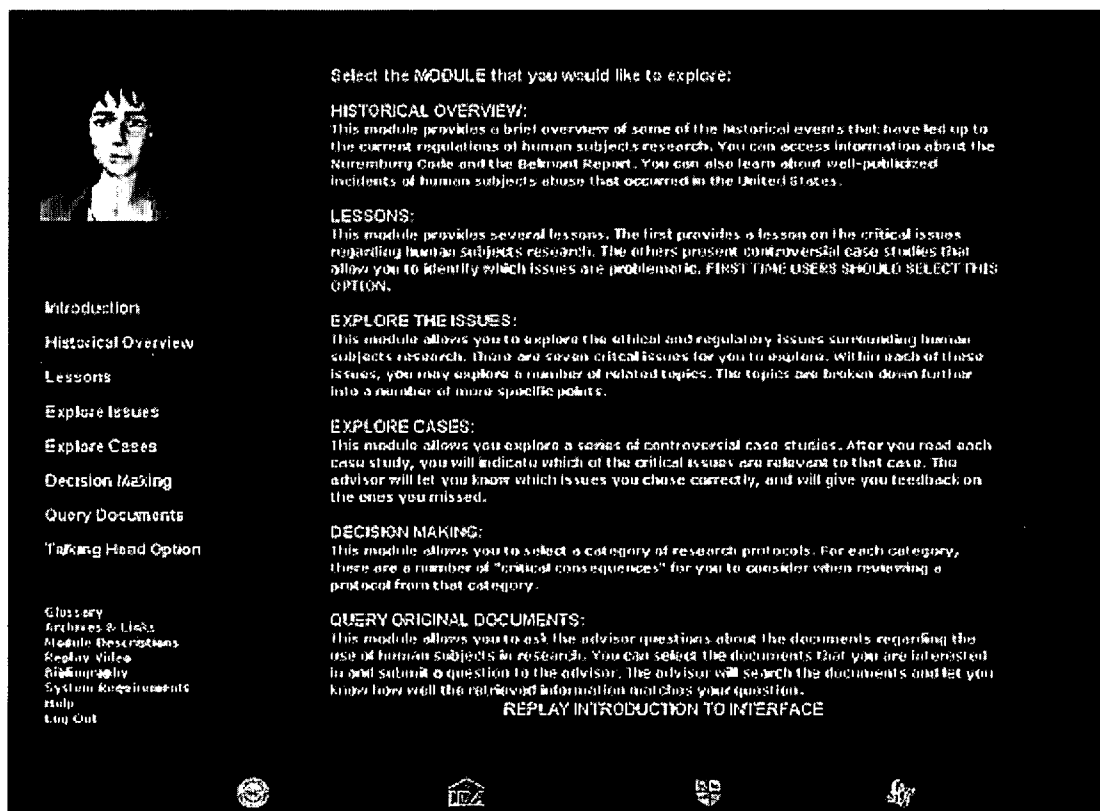
Located directly below the agent on the interface are an Introduction option, which simply replays the movie, six learning trajectories, and eight other options. All of these options are always available to the user throughout the session (see Figure 1). Each of the learning trajectories is described in a later section of this paper. Some of the learning trajectories are designed specifically to get users to actively engage with the contents (i.e., Lessons, and Explore Cases). Others simply present the user with hierarchically structured texts, and users are encouraged by the agent to "drill down" through the contents of the information. In addition the agent reminds the user of other exploration options. For example, the agent might suggest that the user submit a question about the contents, or that the user review a case relevant to the issue being explored. The system tracks the progress of each user. This feature permits the HURA Advisor to decrease probabilistically the frequency with which the agent gives various kinds of navigational information or makes suggestions, either as the user interacts with any given learning trajectory, or when the user returns to the HURA Advisor web site at a later date.


Figure 1: Opening page of the HURA Advisor's Multimedia Interface

The other eight informational options are provided directly below the six learning trajectories (see Figure 1). These options are as follows: Glossary, Archives and Links, Module Descriptions, Replay Video, Bibliography, System Requirements, Help, and Log Out. When the user mousses over any of these options, the agent gives a brief description. Like the learning trajectories, these eight options are available for users to select at any time during the session.

The remainder of the interface, basically the center and right side of the screen, is the content window. This is where all the content-sensitive information is presented to the user when one of the learning trajectories or other options, such as Glossary or Archives and Links, is selected. Two navigational options are always available on the content window, "Next" and "Previous." These buttons, standard on most web browsers, take the user to the next page or the previous one.

Dialog Advancer Networks

A Dialog Advancer Network (DAN) is a mechanis m that manages interactions between the user and the HURA Advisor. A DAN allows the agent to micro-adapt each dialog move to the user's navigational choices. The HURA Advisor contains several DANs with customized pathways that are tailored to the special requirements of each of the six learning trajectories. The purpose of the DANs is to prevent navigational uncertainty for the user by always having a dialog move available that presents options to the user concerning what to do next. In earlier automated tutoring research we found that learners were frequently lost, not knowing what to do next, in the absence of a DAN (Person, Bautista, Kreuz, Graesser, & TRG, 2000).

The generic DAN encourages the user to select one of the learning trajectories; once a trajectory is selected one of the context-sensitive DANs takes over. Because each of the learning trajectories involves a

BEST COPY AVAILABLE

distinct way of presenting information, it was necessary to create the various context-sensitive, or trajectory-sensitive DANs. This was done in order to provide maximal navigational guidance (e.g., Johnson et al., 2000).

Six Learning Trajectories

Historical Overview.

One learning trajectory, located directly below Introduction (see The User Interface, Figure 1), is Historical Overview. As indicated earlier, selecting Introduction (the first option directly below the agent) simply replays the movie described above (see The User Interface). When Historical Overview is selected, a bulleted list of historical documents and access to several notorious cases appears (e.g., the Nuremberg Code, Well Known Cases of Human Subject Abuse, the Belmont Report). Selecting any of these bullets "drills down" to the next level, which contains specific information about the document, and an opportunity to ask an English language question to directly query the documents themselves. This trajectory also includes a point and query feature. Each of the bullets has a highlighted question mark in front of it. If the user mousses over the question mark, it pops up a list of two to five questions.

For example, if the user mousses over the question mark to the left of The Belmont Report bullet, a list of three questions is presented: "What is the Belmont Report?", "Why is it called the Belmont Report?", and "How is the Belmont Report related to the Nuremberg Code?". When any one of the questions is selected, a pop-up window containing the answer is presented. In addition, if the Belmont Report bullet itself is clicked, it has the effect of drilling down to the next hierarchical level, where further information on the Belmont Report is provided, along with other point and query options. There are two reasons for the point and query option: to allow users to easily submit questions that will then produce information experts deem critical to the particular contents, and to minimize demands on the user. The DAN for this trajectory contains dialog moves that always keep the user informed about what to do next. The agent might say, for example, "Learn more about the Nuremberg Code by clicking here," or "Select a question by mousing over the question mark to the left of the bullet."

Explore Issues.

When the user selects Explore Issues, a page is presented containing bullets that correspond to seven critical issues derived from the Belmont Report (Emanuel, Wendler, & Grady, 2000). The information in this trajectory is presented in a three-level hierarchy. The seven critical issues are presented at Level 1. When one of these is selected, a list of Level 2 'Topics' related to the specific critical issue is presented. Level 3 contains very specific 'Points' related to the Level 2 topics. Like Historical Overview, Explore Issues also includes a point and query feature. When the user mousses over the highlighted question mark to the left of the bullets at all three levels, a list of questions experts deem important to the bullet's contents pops up, and selecting any of the questions brings up the answer.

Lessons.

First time users are encouraged to work through the Lessons trajectory first. When this option is selected, the agent tells the user to select "Lesson 1." In Lesson 1, the user is introduced to the seven critical issues discusses in the previous section. The agent then suggests that the user select a specific historical case (i.e., the Tuskegee Syphilis Study) to read after the seven critical issues are read. When the user indicates the case has been read, information is presented that delineates how each of the seven critical issues was violated in the historical case. The agent then tells the use to select the next lesson (Lesson 2). After reading about a new case, the user is asked to select which of the seven issues were problematic in the case. The HURA Advisor then provides feedback concerning the issues the user has selected and not selected. The feedback is based upon experts' evaluations of the cases. Lesson 3 continues in this manner: the user reads the case, the user selects problematic issues, and the HURA Advisor then provides feedback to the user. Lesson 4, the last in this trajectory, is selected dynamically based upon the user's performance during Lessons 2 and 3.

Explore Cases.

When Explore Cases is selected, bulleted options that correspond to ten controversial cases are presented in the content window. The agent tells the user to "Select a case study to read, and then test your knowledge of the

seven critical issues by selecting the 'Test Your Knowledge' option." On the Test Your Knowledge page, the seven critical issues (see Explore Issues) are presented, and the agent instructs the user to select the problematic issues for the specific case. Once the user finishes the issue selection, the HURA Advisor provides feedback on the selections.

User choices consistent with expert opinion are denoted with explanation marks; choices not consistent with expert opinion are highlighted in red and denoted with question marks. Following both misses and false alarms, additional feedback is provided if the user mousses over a particular issue. After the feedback phase, the HURA Advisor presents a "Summary of Issues" option. At that point, the agent might say, "You can select the 'Summary of Issues' option to review the problematic issues in this case."

Decision Making.
This option is designed to help the user make a decision about a particular research protocol. When this trajectory is selected, a bulleted list of nine distinct research areas appears in the content window. The nine research areas included in this trajectory are General Consequences, Basic Biomedical Research, Drug and Vaccine Trials, Radioactive Materials and X-rays, Epidemiological Research, and Training and Weapons Development. Once a research area is selected, a bulleted list of typical ethical problems that occur in that particular type of research is presented. When any one of these bullets is selected, the HURA Advisor presents information concerning how to avoid the ethical problem, along with the potential consequences of specific ethical violations.

Query Documents.
The final learning trajectory in the current version of the HURA Advisor is Query Documents. When this option is selected, the user can select a number of specific types of documents that are related to the use of human subjects in research (e.g., the IRB Guidebook, Department of Defense documents, Army, Navy, Air Force regulations, various Codes of Federal Regulations). The agent tells the user, "You can search any of these documents by clicking the box next to the document." The user can search one, or any combination of documents by entering a question in English. When the search is completed, the agent might say, "Look below the dialog box for the results of the search."

Latent Semantic Analysis (LSA)

At any time during a session, the user may ask a natural language question in English. The knowledge in the HURA Advisor pertaining to Institutional Review Board practices and procedures is represented by LSA (Hu, Graesser & TRG, 1998; Landuaer, 1999; Landauer & Dumais, 1997; Landauer, Foltz, & Laham, 1998). This is a statistical procedure that compresses a large corpus of texts into a space of approximately 100 to 500 dimensions. This N-dimensional space is used to evaluate the similarity between any two bags of words. The relevance or similarity values vary from 0.00 to 1.00.

In most applications of LSA, a geometric cosine is used to evaluate the match between the N dimensional vector for one bag of words and the vector for the other bag of words. In the HURA Advisor, one bag of words is from the user's input (e.g., specific issue, case, or typed text). The bag of words it is compared to is the documents. The LSA space for the domain of IRB procedures was derived from a variety of documents (i.e., IRB Guidebook, Codes of Federal Regulations, DoD documents, Army, Navy, and Air Force documents), plus a corpus of approximately 15,000 questions probing these documents. The questions were created by the Institute for Computational Discourse Technologies.

An LSA analysis requires the preparation of a document by word (D x W) co-occurrence matrix. Each cell in the matrix specifies the number of occurrences of word W_i in document D_j. The computation of the N dimensions is then derived from a statistical procedure called singular value decomposition. In order to prepare the D x W matrix, the researcher needs to define what constitutes a document unit. A single document was defined as a paragraph in the various IRB, DoD and military documents, and as a single sentence in the corpus of 15,000 questions.

Summary

The HURA advisor was designed to meet both technological challenges and psychological constraints. In order to meet our technological requirements, the bulk of the system is located on remote systems that contain relational databases and an intelligent learning management system (ILMS). By integrating these two modules, we have used already existing technologies to create a thin client that produces minimal resource drain on the user. Furthermore, the relational database and the ILMS are SCORM compliant in that their content can easily be shared with other SCORM compliant programs. These technological challenges allowed enough flexibility to meet the psychological constraints on the system. The system provides a user-friendly, web-based interface with an avatar that is controlled by the system and provides navigational guidance through six different learning trajectories.

Abstract: The University of Pretoria presents a masters-level degree in computer-assisted education, incorporating a module on Internet -based learning. This module uses creative, constructivist and collaborative learning techniques via the Internet to simulate the communicative aspects of a real classroom in a web-environment. Using the Hexa -Metamodel as an evaluation perspective, the paper shares successes (good), and problems experienced (bad & ugly).

Introduction

The University of Pretoria, a contact -teaching institution, presents a two-year masters' degree in Computer -Integrated Education, yet one of its modules, RBO-880 has, since 1995 taught *Internet-based Learning* using the Internet as medium (Cronjé 1997, 2001; Cronjé & Clark, 1999). The idea is to give the learner-educators first-hand experience of constructivist distance-learning and collaborative tasks, so as the better to manage Internet -based learning and communication with their own target learners. This paper presents the results of our ongoing formative evaluation research into the dynamics of learning theory and instructional design -and- practice in this novel Web-based learning environment. As an evaluation toolset, elements of the Hexa-C Metamodel (De Villiers, 1999, 2000, 2001) are applied to investigate:

- Can a "classroom" and its activities be successfully simulated on the Internet/World Wide Web?
- From the viewpoint of learning theory, to what extent does the instructional design of the *RBO* classroom implement the following three elements of the Hexa-C Metamodel:
  (i) creative instruction, (ii) constructivism, (iii) collaborative learning?

RBO has progressed through the five levels of web use (Harmon and Jones (1999) and is currently *immersive*, namely a constructivist *virtual learning community* with all its content and interaction online. In this context, we evaluated the *RBO* presentations of 1999 and 2000 using the Hexa-C Metamodel (HCMm), a concise set of theories/characteristics of contemporary learning design and practices from the cognitive-family. Of its six elements: creativity, constructivism, collaborative learning, cognitive learning, customisation, and components, we used the first three as tools of enquiry. The paper summarises some of *RBO*'s (i) good - (ii) bad and/or ugly features and experiences. Under each header, an investigation was conducted using the three 'C' tools.

The Good

The RBO web-classroom uses the metaphor (Branscomb, 1996) of a junior school classroom. The instructor-designer set out to mimic, in a *creative and innovative manner*, objects/events of its real -world counterpart. There is no face -to-face communication, nor any meetings, but rather a system comprising a *web -classroom* (*http://hagar.up.ac.za/rbo/ 2000/index.htm*) to represent a physical classroom (see Fig 1) and a mailing list for interpersonal interaction (*talking*), together forming a *virtual settlement* (Jones, 1997).

Figure 1 presents the 2000 website, simulating attributes of a physical classroom. The buttons link to objects such as tasks, timetable, classmates, and instructor's desk - which branches to his personal home page. References (resource cupboard and tool box) link to literature and construction programs such as HTML editors, graphics utilities, and website construction tools. Others access academic information, such as the course topics, grading system, required outcomes, and the practical competencies learners should acquire. The *poster wall* links to students' projects, and the *blackboard* is implemented as a graphics file. As a challenge, students may access and edit this chalkboard, which simulates a graffiti wall. Classroom objects proliferate as the course proceeds. From learners' perspectives the most important area is the central region for their self-constructed, auto-customized *desks*. Each mini-desk in Fig 1 links to a full-scale desk (or study), two of which are shown in Figure 2. They represent the *scholar's* personal traits, formality/informality, web-skills, etc. The creativity of the theme *engendered creativity among learners*, in both their desks and in the content and presentation of the deliverables they generated as their tasks.

The artefacts on/around each desk – objects typically found in a school desk - are hyperlinked to the learner's own *RBO* site. These are a *utility bag* (links to useful sites, e.g. editors, search engines, clipart libraries); *books* (useful resources); my *hobbies* (links to sites of personal interest; my *class work*(including links to joint projects); and my *portfolio* (a link to the major individual examination project).

RBO is highly *constructivist* in ethos. Not only did learners find information on the WWW, but also generated web pages as part of individual and collaborative projects. Construction is transparent, in that the developing artefacts are accessible to peers. There is active participation, discovery-learning and no direct instruction. Learners with initial low web -skills tackled independent learning, using peers or links to tutorials - termed *extra lessons* - analogous to a class in school. RBO led to transfer, as skills were later used in real -world employment.

Figure 1 Website of the RBO electronic classroom
Figure 2 Desks of two of the *Class of 2000*
Regarding *collaborative and communicative* aspects, the tasks are designed to provide Johnson & Johnson's (1991) key elements of co-operative learning: a mutual goal, positive interdependence and individual responsibility. Role allocation and work distribution under distance-collaboration have unique characteristics and entail different media, such as discussion and debate via a dedicated mailing list. In line with the metaphor, some students *down -aged*, addressing the instructor as "Teacher" in emails. They tattled on one another, made jokes, and one played truant, replacing her desk with a beach and surf kit. This role-play and humour contributed to team spirit, in keeping with Baym's (1995) contention that "... humorous performance can be used to create group solidarity, group identity, and individual identity in CMC". Initial RBO classes lacked synchronous interaction and its associated urgency, a matter that has been partially addressed by *Chat* sessions.

An analysis of the messages sent through the class discussion list (Cronje & Clarke, 1999) indicate that the most frequent actions of the instructor were to make suggestions, give encouragement, explain how to do something, and give directives. The main actions of the learners were to provide information, ask questions, present their problems, initiate/contribute to discussion, and offer humour – typical scholar-behaviour. It appears that the communicative acts in the Web-class are similar to speech acts in a face-to-face classroom, indicating that "Computer-mediated groups can create solidarity through developing interpretive consensus" (Baym, 1995).

The Bad and the Ugly (issues and solutions in constructivist collaboration)

Students with a skills-gap experienced *constructivist frustration* and *cognitive conflict* (Perkins, 1991). The distance-variant of constructivism and challenge exacerbated the problem, causing feelings of isolation.

True self-paced work - a *constructivist* ideal – cannot be fully implemented in a formal teaching instituation, nor is it compatible with collaborative learning. Individual projects are impacted by time factors, particularly where the adult learners are interrupted by professional demands or personal commitments. Learners who do surveys as part of their projects experience response delays. It must be stressed, however, that *RBO* is more about learning, than about finishing a project. Projects and tasks are a means to an end. Hands-on exposure to the issues and problems of distance-collaboration is a prime purpose of the course.

Communication and distance-collaboration raise further issues. The class of 2000 generated a joint virtual opera, *Phantom of the Internet*. There were complexities due to role allocation, schedules, and unequal workload; yet the final artefact (*http://hagar.up.ac.za/catts/learner/2000/opera/index.htm*) was a resounding success, as learners made contributions that synergistically capitalized on strengths - management, technical and multi-media skills, research, writing, etc. The groupsize of eight appeared to be cumbersome for distance teamwork, and the subsequent two-man co-operative tasks proceeded more smoothly.

At times interpersonal dynamics are stressful - in 1999 conflict arose between two learners, due to varying perceptions on the use of HTML coding. Acrimonious messages were posted on the mailing list, intimidating some students, who threatened to withdraw. The instructor *creatively* put the duelling students in a 3-person co-operative team with a mediator. They built a *Flames & Internet wars* website, using a *Calvin & Hobbs* theme to show how differing views cause conflict *(http://hagar.up.ac.za/catts/learner/projects/flames/index.html)*.

Conclusion

RBO appears successfully to have simulated a real world class, its actions and ethos, in a way that creatively implements constructivist learning and distance-collaboration.

Abstract: This paper addresses the popular contention that multimedia-rich, web-based courseware increases learning. Research is reviewed that addresses issues relevant to interactivity and visualization from educational and human-computer interaction perspectives. The results suggest that some characteristics of multimedia may actually interfere with learning and should be taken into account by educators, designers and researchers when planning web based learning environments.

• Educational Research and Interactivity: A Retrospective

The proliferation of highly interactive and visually appealing educational multimedia and software, particularly in Web-based environments, reflects the prevalent belief that these features are associated with improvements in learning. Despite increasing commercial appeal, several basic research questions remain. Do multimedia-rich environments facilitate learning, and under what conditions? More specifically: Are increases in graphical and interactivity truly constructive in the sense that they facilitate learners' developing their own mental models of phenomena or do they merely present others' conceptualizations, providing learners with endlessly appealing graphics but little opportunity to puzzle out and form representations of their own? In this paper we examine these issues by providing a preliminary framework for examining the potential of interactivity and visualization devices in Web-based environments, both from educational and computer science perspectives. Iding (2000) derived principles for effective multimedia reflecting these theoretical perspectives relevant to the design of effective multimedia for learning science.

• Relevance to Web-based environments

Heightened interactivity appears to be implicit in constructivist educational models. However, these sorts of models need a means of measuring the students' ability to construct knowledge through interaction. Furthermore, is there any transfer from the training situation to the classroom situation? There is a fine line between formative evaluation of this type and research in that it is an iterative process. In the case of Web-based environments, assessment of learning needs to be redesigned to maximize the effectiveness of the learning environments because traditional pencil-and-paper type testing are not likely to at all tap into the kinds of representations that students may have developed. A primary consideration in the design of these environments for distance education is that interactions that are possible in regular classrooms are not available in distance education environments.

• Some Ideas from Usability Engineering

The field of human-computer interaction (HCI) offers examples of the application of psychology and computer science to the presentation and manipulation of information. There is particular interest in HCI applied to the development of educational software (Berg, 2000). Two of the many relevant examples are studies on the use of graphics and text in web pages, and expert-novice differences understanding visualizations of technical information. In particular, *usability studies* of web pages have implications for the design of web-based distance learning environments. Of the objects on a web page, users initial tendency is toward textual flags such as headings. Thus not only might designers of web-based courses pay particular attention to textual headings and captions, designers

should plan for students to switch focus among simultaneously open pages. Second, there is substantial computer science research on expert-novice differences both in general and specifically applied to visual representations of technical information such as schematic diagrams and visual programs (Petre 1995; Kiper et al. 1997). Diagrams are most commonly used in computer science to illustrate the structure of data or code (module interdependencies) or control (flowcharts). A common belief is that graphics and animation "must be better than text". Berg (2000, p. 363) echoes this optimism for animation: "effects such as animation can be very effective in establishing mood, in increasing sense of identification, for persuasion, and for explication." However, research comparing static graphics and text disputes common sense. Petre found that in graphics versus text tasks, subjects completed tasks more quickly when using text representations than using graphics. The illustrations were technical designs as Petri nets and schematic diagrams. Not only does it take longer to understand technical information presented as a diagram, novices are most negatively affected. Some expert-novice differences are remarkable – experts tended to use their fingers on the screen to augment their working memory. Novices lack skills in understanding their fields' conventions for illustrations, and they tend to be mislead by mis-cues. Novices' fledgling understanding of conventions and secondary notations cause not only mis-interpretations but also mis-production of technical diagrams. Petre suggests that a constrained environment that minimizes secondary notation might be better for novices

• Summary and Conclusion

In this paper, we began by speculating that the heightened interactivity and visualization capabilities afforded by multimedia and software in Web-based environments may not be consistently associated with learning gains, although they may be popularly presumed to be effective and are certainly commercially appealing. To determine the validity of this contention, we reviewed some of the educational, psychological and user modeling research that can relate to the design of Web-based educational environments. Results of this review indicate that interactivity and visualization, by themselves, may not be simple determinants of increases in learning and may under some circumstances, actually interfere with learning. Therefore, specific aspects of interactivity, as well as user characteristics and purposes, need to be taken into account when assessing and conducting further research on the efficacy of these features of Web-based environments.

Abstract: The Emergency Department and Poison Information Centre have both been challenged with providing educational opportunities that will allow all staff to participate in the same experience. The very nature of the work in these areas, providing care for unplanned health events seven days a week, 24 hours per day, makes scheduling educational opportunities an exercise in frustration. To date learning needs have been addressed by planned face to face experiences that require the department to be "quiet" and the majority of staff to come into the hospital on their day off. Such efforts are often met with limited participation. All team members from both departments now have access to the world wide web through two terminals. An increasing number of team members also have internet access at home. Access, coupled with the availability of user-friendly authoring software to create web based learning environments, makes the web a viable option to present learning opportunities to team members. This present will describe the findings of a study examining the use of a web based learning environment as a means to increase access to and interaction in learning opportunities for Emergency Department and Poison Information staff.

Introduction

Participation in continuing education is a professional responsibility for all members of a health care team. However, health care professionals face unique barriers in participating in educational experiences that meets their learning needs. Focus on patient care in a hospital environment, shift work, personal and professional obligations outside of patient care and reduced education funding are just some of the challenges faced by learners in the health care field. Emergency care providers face additional challenges with the unpredictable flow of patients. Staff are often interrupted or unable to participate in scheduled learning sessions due to an unexpected crisis. It is generally impossible for health care teams to come together as a team to share knowledge and participate in discussion around patient care. Video recorded learning sessions and self-directed learning packages present possible alternatives. However, these modes of delivery present limitations. There is usually very minimal or no opportunity for collaborative learning through dialogue with peers or content experts. In addition, content is generally focused on objectives created by the presenter as opposed to the real needs or questions of the participant.

Constructivist learning theory provides a framework which challenges our current pedagogy. The framework identifies interactivity as one of the key elements in developing a successful learning opportunity (Jonassen, Davidson, Collins, Campbell, & Hagg, 1995; McVay, 1998) . The learner must be actively engaged in the learning process, actively constructing their own knowledge as opposed to being a passive recipient of information. Interactivity incorporates three distinct components; learner-learner interaction, learner–content expert interaction, and learner– content/resources interaction. This type of a collaborative learning environment is key to the development of critical thinking skills essential for providing emergency care (Boyer, 1999). Constructivist teaching also places a strong emphasis on the learning needs of individual participants. Educational opportunities should be leaner focused as opposed to content driven.

Emerging informational and instructional technologies provide an alternative to the traditional mode of face to face delivery and hold great promise as a tool in a constructivist paradigm. This medium provides learners with an opportunity to not only selectively view content but also dialogue with their peers as well as local, national or international content experts. All participants can contribute to an asynchronous discussion on an electronic bulletin board contributing to the development of a collaborative learning environment. Several discussions can take place at the same time. Participants can choose any or all discussion threads depending on their individual need. Participants can also tap into any number of links on the web related to the topic of discussion. This type of a learning environment enhances the reflective process, allowing for constructive learning. This ability to engage in a discursive, adaptive and an interactive process provides the adult learner with a more meaningful educational experience (Driscoll, 1998).

The number and type of resources available to health professionals on the internet is on the rise (Pinkowish, 1999; Drake, 1999) Access, interactivity and learning outcomes have been the focus of many studies evaluating web based learning environments in formal academic settings (Ryan, Carlton, & Ali, 1999; Woo & Kimmick, 2000,). While there is a scarcity of evidence indicating the usefulness of this type of a learning environment to provide continuing education for interdisciplinary health professionals. Furthermore, there is no evidence pointing to the transfer of learning to practice from a web based environment.

Questions

1.   Is a web based learning environment more accessible than a structured face to face session?
2.a   Do participants feel they have a greater opportunity to interact with the content expert, peers and the content in a web based learning environment as compared with a structured face to face session?
2.b   Do participants interact more with the content expert, peers and the content in a web based learning environment as compared with a structured face to face session?
3.   Do participants feel that they learn as well in a web based learning environment as compared with a structured face to face session?

Method

This study was a randomized control study with the multidisciplinary staff members of the Emergency Department and Poison Information Teams (75 staff). Team members were informed of the purpose and nature of the study and interested participants were asked to complete a consent form. Participants were assigned a number upon completing the consent form and randomly assigned to a structured face to face intervention or a web based intervention. Randomization was facilitated with a computer generated table of random numbers.

During the month of August, 2001 Dr. Connie LeBlanc conducted a 45 minute face to face presentation on Street Drugs. The presentation consisted of an oral presentation with Power Point slides, with the opportunity to ask questions during and at the end of the presentation. Participants were asked to sign an attendance sheet when entering the room. Participants were also asked to complete a questionnaire immediately following the session which captured demographic data as well as satisfaction and self perception of interaction opportunities and learning.

A web presentation containing the same Power Presentation narrated by Dr. Ross was available two weeks following the face to face presentation. Participants were provided with an information sheet describing how to access and operate the website. This session was accessible to users with a valid password. Access to the site was available through computers in the Emergency Department and Poison Information. Participants with internet access at home were able to access outside of the Health Centre. The web site was built using web authoring software called WebCT with links to an electronic bulletin board for asynchronous discussion and external links to relevant internet resources. The site was accessible to participants for a three week period. A content expert checked the bulletin board twice per week for three weeks to address participant questions and correct any inaccuracies in the ongoing discussion. At the end of the three week period participants were asked to complete Questionnaire A as above.

Analysis

For the purposes of this study access was defined as the availability of the experience to the individual participant. It was represented by attendance at the sessions. Attendance at the face to face session was tracked using an attendance sheet. Access to the Web site was tracked using the electronic tracker built into WebtCT. All participants were asked to comment on accessibility to their assigned intervention in the post study Questionnaire

Interactivity was defined as the active engagement of the learner in the learning experience. Interactivity was measured on three levels; participant-participant, participant-content, and participant-content expert. A research assistant attended the face to face session and counted the number of participant generated questions as well as the number of participants who responded to content expert generated questions. A second researcher reviewed the audio taped session to validate the number of questions counted. In the web intervention an electronic bulletin board captured participant discussions. Transcriptions were reviewed and participant generated threads of discussion as well as participant responses to others (peers and content expert) were counted. WebCT also provided for tracking of participants viewing of content pages. Participants were asked to comment on the three levels of interactivity on Questionnaire A.

In keeping with the principles of adult learning and a constructivist paradigm, participants were asked to comment on their own level of learning during the intervention. This approach acknowledges that individual participants come to the intervention with varied educational and clinical experience and will identify their own personal learning outcomes for the event.

During this presentation we will describe the findings of the study as it relates to access, interactivity and learning in a health care environment. We will also describe the plan to incorporate expanded use of a web based environment to support learning and practice.

The Web Project Readiness Checklist:
Five Key Components That Must Be In Place for a Web Project to Succeed

Abstract: The goal of this paper is to introduce a tool that will help you and your team overcome common problems that frequently cause web projects to miss deadlines, exceed budgets, or be put on permanent hold. Called "The Web Project Readiness Checklist," this planning tool is the outcome of over seven years of multimedia and web development work at The Ohio State University. The checklist was designed to expose and eliminate problems in five key areas before much time is invested in a project. This tool is most helpful for project managers or subject matter experts developing web-based learning applications that are new implementations of existing classroom curricula. However, if you are an experienced web developer you will still find the checklist useful, it will give you new ways to solve many of the difficult problems you have encountered in the past.

The goal of this paper is to introduce a tool that will help you and your team overcome common problems that frequently cause web projects to miss deadlines, exceed budgets, or be put on permanent hold. Called "The Web Project Readiness Checklist," this planning tool is the outcome of over seven years of multimedia and web development work at The Ohio State University. The checklist was designed to expose and eliminate problems in five key areas before much time is invested in the project. This tool is most helpful for project managers or subject matter experts developing web-based learning applications that are new implementations of existing classroom curricula. However, if you are an experienced web developer you will still find the checklist useful, it will give you new ways to solve many of the difficult problems you have encountered in the past.

There are five key components that, combined, form the foundation of any web development project: content, vision, insight, time and support. Technology is not included in this list because it is seen as the next layer, it is built on top of this foundation. When teams rush into planning, programming and designing without addressing fundamental questions, their projects become susceptible to the problems associated with weak foundations, namely rushing to keep things "propped up" when "cracks" appear, or watching projects collapse altogether. The common problems associated with these components include:

1. *Content* — The amount of content currently in hand, and the amount of content processing work that must be performed by someone with subject expertise is grossly underestimated.

2. *Vision* -- The project vision is blurred or superceded by discussions about "cool" web gadgets (i.e. Flash movies), "innovative" instructional designs, and technology development/delivery issues. Yes, all of these things should be discussed but only after more fundamental vision questions have been answered. Otherwise, projects move in unproductive directions that ultimately waste valuable time.

3. *Insight* -- The team does not review or critically evaluate other web sites that are similar in content or approach to the project at hand. Skipping this step results, again, in projects moving in unproductive

directions.

4. *Time* -- The amount of time required to develop the web application is vastly underestimated. Based on our experience, this is the number one cause of projects being put on permanent hold—a key member of the project team simply runs out of time and a competing priority takes over.

5. *Support* -- Project "champions" do not have the support they need from those who control resources the project requires: content, staff time, funds, equipment, etc.

Laying a solid foundation: The Web Project Readiness Checklist

In order to eliminate the problems described above, our application development group designed the "Web Project Readiness Checklist" and we use it as a planning tool for every project request we receive. In our case, this checklist has helped many "champions" make the pragmatic decision to not proceed with their web project ideas after realizing the time and resources that would be required. Conversely, this same tool has enabled us to secure over $100,000 in recent funding because we had the evidence we needed to support our confidence the projects would succeed.

The checklist contains five items, each one with associated questions and tasks. Answer the questions and do the tasks. You will be amazed at the level of clarity your project will reach just by using this one simple tool.

☑ 1. You Have Content to Work With

What we mean by "have" is just that, "have," .... as in, "I have those 35mm slides in my course file," or "I have a VHS tape with that segment we'll use in my office." We do NOT mean "have" as in, "I have to write that part, but it's no big deal" or "we have to go out and shoot some footage, but it's easy, we can do it in a day."

"Have content to work with" means:
- 50-80% of the content you imagine will be a part of your program is in your possession (much of it will need to be edited and some of it will still need to be written, photographed, taped, etc.; the point is that most of it should already be in your hands)

- you own or your organization owns the copyright for the content OR

- you have or your organization has permission from the copyright holder to use the content in the program.

It is not necessary at this point to have the content in digital form, just keep it as it is for now--Microsoft Word documents, databases, spreadsheets, CAD drawings, glossy brochures, photographs, 35mm slides, video tapes, audio tapes or CDs, DATs, etc.

Before you check this item off as "done," clean out a filing drawer or a shelf or somewhere in your office and bring all of your existing content together. It doesn't matter if it is odd-sized, in electronic format or on 16mm film reels, just gather all of the content you will possibly use in your program and organize it in a way that is meaningful to you.

☑ 2. You Have a Clear Vision Of Who the Web Application's (Program) Users Will Be and How They Will Benefit From the Program.

Your answers to the following questions will help you clarify your vision for the project. Please go through them one-by-one and complete all of them before checking this item off as "done."

1. What three main problems are you solving by developing this program?

   Some kinds of problems might include: eliminating time and space barriers for users, enabling users to experience something that would be otherwise inaccessible to them (i.e., a simulation or "virtual tour"), making administrative data tracking of some kind possible and/or more efficient.

2. For whom are the problems being solved?

   In other words, who will your primary users be? Are they the company's employees? the school's students? the sales force? managers?

   Rule #1: "general public" or "all employees" is not specific enough, but "students in Arabic 101" or "all new-hires" or "women 18-24 with computers and internet access at home" would be specific enough.

3. Why are YOU solving these problems (emphasis on the "you")?

   Your job requires you to take responsibility for it? If you don't nobody else will? You think it will save time/money? You believe it will generate revenue? You have expertise and/or content that few others possess? You have funding to do "something" and if you don't spend the money now you risk losing it?

   It is important that you be honest with yourself here, it will give you clarity when we reach another item in the checklist about resources available to you. It is also important to keep in mind that technical skills have little to do with answering this question. If you are the world's expert on Japanese Noh Theater and you are frustrated by the lack of materials on the market that will help students learn about it, then this is a valid reason.

4. How will you determine whether the project has been successful?

   Your supervisor liked it and gave you a bonus? The web site was accessed by 4,000 employees in 6 days? You were able to demonstrate an impact on learning or an impact on the company's bottom line? Others working on similar projects hold yours up as an example of "best practice"?

5. How clear is your overall vision? The "elevator ride" test.

   Imagine you step into an elevator with a colleague, someone who could be a big supporter of your project idea, who says, "I heard through the grapevine that you have a new web project idea—what's it all about?" You have 30 seconds to explain your vision to him/her based on your answers to 1-4 above. What will you say?

   Rule #1: Write down your 30-second description and then say it aloud. Time yourself. Keep modifying the statement until you can say it in 30 seconds.

   Rule #2: In your description you must answer the questions: what problem is being solved, for whom, what's your role, how will you know whether it's been successful?

   Rule #3: You may NOT talk about the technology to be used in the program as a part of the description. Remember, technology comes AFTER the vision, it SUPPORTS the content and the message and, thus, must be chosen after decisions about the content/message have been made.

6. Now, go back to the previous item in the Readiness Checklist, "You have content to work with," and add or remove items to/from your pile of source materials --the one you've gathered in your office in a filing cabinet drawer or on a bookshelf--based on your refined vision.

☑ **3. You have seen how others have implemented similar projects and you have learned from their mistakes.**

It is important to remember that developing any web application is a labor of love. It requires a lot of work on your part, not to mention your programming and design colleagues. Mistakes are costly in terms of time and resources. Know what you want, but also know what you DON'T want. Help your team understand your vision by SHOWING them examples and non-examples of it rather than just talking about it.

The best way to do this is to review similar multimedia products or web sites with a critical eye. Granted, there may not be another product on the market or on the web that is exactly like yours, but there are certainly ones that have features or content areas in line with your goals.

Your task is to *review five web sites and/or multimedia products* that have something in common with the vision you have for your project. Don't just spend a few minutes skimming them over, actually use each one to accomplish something: buy something, learning something, find something, use the site/product to accomplish something for which it was designed.

Spend 30 minutes reviewing each site/product:

- 10 minutes jumping around in the program to gain a bird's-eye view of it

- 10 minutes working through a specific task (if it is a shopping site, buy something; if it is a learning application, go through a lesson; if it is a digital library, find a resource of interest to you)

- 10 minutes answering the following questions about the site:

  1. Who do you think the intended audience is for this product? Try to find some kind of overview or introduction and read it to help answer this question.

  2. What problem do you think the program is attempting to solve for them? Look at the way the program is structured, the kinds of input requested from users and the feedback provided.

  3. What are 3 things you like MOST about this site/product? Why?

  4. What are 3 things you like LEAST about this site/product? Why?

  5. If you were the person in charge of revising this site/product, what 3 things would you do differently in the next version that would make it really useful?

  6. What does this site/product have in common with the one you aim to develop?

  7. How many people participated in the development of this site and what were their roles? Try to find a credits screen somewhere on the site.

Once you have reviewed five similar multimedia web sites/products, go back to the previous item in the Readiness Checklist, "You have a clear vision of who the program's users will be and how they will benefit from the program," and modify your 30-second description, if necessary.

☑ **4. You Have Enough Time to Work on This Project**

In our experience, lack of time is the number one reason projects get put on permanent hold. It is crucial to be realistic about your expectations for the web application, as well as your level of commitment to the project.

1. What is the release date for this program, or the deadline for the "final" version to be ready?

2. Between now and the release date, how many hours per week can you personally dedicate to this project? In our experience the minimum is 10 hours per week, preferably 25-30.

3. Who else might be able to help you with this project and in what capacity, and how many hours per week can each person dedicate himself/herself to it between now and the release date? Don't assume—ask each person!

4. Between now and the release date, are there any major events happening in your life or the lives of those above that will put this project on the back burner (i.e., major holidays, someone gets married or buys a house, you move offices, you must prepare for end-of-quarter reports, a big training event or conference presentation to prepare for...)?

5. Given the hours you are available, the people/groups that may be able to help, and the range of block-out dates between now and the release date, are you confident you can get this project done on time? If yes, check this "readiness" item off. If no, what additional staff and/or time would you need?

☑ 5. You Have Support for This Project

- Someone influential supports your goals and vision without reservation. This could be your supervisor, your unit/division vice president, your publisher...someone who has the power to keep your project moving ahead or to block it.

- You have funds to work with and some level of autonomy in allocating those funds.

- You have resources to work with including some equipment, software, people, content and time. Even if you decide to outsource the technical production work, you will still need enough equipment/help to work effectively with the production team (i.e. TV/VCR to review video-based segments that will ultimately be digitized; color printer to print scanned images for notations, someone to help collate and organize all the content, etc.).

To Begin or Not to Begin: Interpreting The Results

Congratulations! Through a few hours of work you have hopefully gained a new level of clarity in thinking about your project. If you were able to meet all the requirements and check each item off, then move ahead into the exciting and exhilarating design phase. If you have four of the five items in place, still move ahead but be sure to complete the last item before getting to deep into design. If you have three or fewer of these items in place, it would be best to not begin the project right now. This does not mean the project should never be done, it just means you need to make some additional arrangements before it can get underway.

How did The Multimedia Readiness Checklist work for you? Please help us refine it by sending your comments, suggestions and examples to Diane Dagefoerde, dagefoerde.2@osu.edu.

Procedural Terrain Visualisation for Internet-Based Games

Maurice Danaher
School of Computer and Information Science,
Edith Cowan University, Mt Lawley,
Western Australia 6050
Email: m.danaher@cowan.edu.au

Abstract: In this paper a method is presented for dynamically generating landscapes in Internet-based games and other graphics simulations. Current systems that use large datasets to represent the terrain have a number of drawbacks including large storage requirements, low level of detail and overcrowding in multiuser games. Here an approach is described in which the terrain is procedurally generated as required. The terrain is produced in the form of blocks and displayed using a spherical page management technique. This approach allows for the generation of a detailed environment, participation by a very large number of players in multiplayer games and easy download of the environment generator via the WWW.

Introduction

Terrain visualisation typically renders a dataset that represents a terrain. These datasets consist of height values sampled at regular grid intervals. By constructing a lattice in three-dimensional space, and using the values in the datasets to displace the intersections of the lattice, a renderable mesh of triangles is created.

Creating landscapes based on large datasets results in a number of limitations for games applications including: (1) in multiplayer games the environment quickly becomes overcrowded when more than a dozen or so players join; (2) these environments demand a lot of storage space and they are usually distributed by CD ROM rather than via the WWW; (3) in order to display relatively large terrain areas and to maintain reasonable display rates the detail must be kept within certain limits; (4) user/player participation is reduced because the environment cannot be downloaded via the WWW.

The main problem with the use of simple triangular meshes is the large number of triangles involved. Modern hardware is not capable of rendering in real time the amount of triangles necessary in a mesh to accurately depict a landscape over a reasonably large area. Many present solutions to this problem involve rendering only objects that are close to the user's position and using a fog effect to hide the missing detail. Another common solution is to decrease the resolution at which the terrain is sampled and hence produce a larger, less detailed mesh. Lindstrom et al (1997, 1999) developed techniques for creating meshes that involved different triangle sizes. These meshes use smaller triangles near the user's viewpoint where detail is important, and larger triangles at areas distant from the user. These are known as continuous level of detail meshes, abbreviated to CLOD, or, more commonly LOD meshes.

Page Management Approach

The approach presented here is based on the assumption that the terrain to be visualised is a terrain of fantasy, one that does not exist in real life. The solution involves the creation of a viewing system that procedurally generates all the graphics that are to be displayed in real time. The terrain is created only around the user's position.

To maintain a terrain around a user's position the terrain is created in small blocks. These blocks, referred to as terrain pages, join together to form the terrain the user sees. A page management approach is used to display these blocks as required. The advantage of this paging approach is that as the user travels across the landscape new pages can be created and added. This is considerably faster than reproducing the entire scene around the user's point of view. The work presented here involved developing and implementing methods for (1) creating the terrain blocks and (2) performing the page management. The terrain blocks are created from height field data and level of detail (LOD) algorithms. The page management system is based on a spherical page wrapping approach.

The goal of a LOD algorithm is to simplify the landscape mesh in appropriate places so as to reduce the number of triangles used while maintaining the quality of the scene as much as possible. The LOD algorithm devised for this work is based on an adaptive quadtree refinement algorithm (Wright, 2000). This recursive

algorithm utilises a data structure that stores a square that is optionally made up of four other squares which in turn are optionally made up of four other squares.

The approach to page management is termed the spherical offset method. It is named thus because of the manner in which pages are wrapped (as if the terrain forms a planet). This novel approach is very efficient and produces very good results. A map represents an entire landscape and a submap represents the user's visual vicinity. The LOD algorithm operates directly on the submap and the terrain is produced as a collection of tessellating pages. As the user moves a distance equivalent to one page the submap is adjusted around the user's position. New pages are created as the user comes within viewing distance of them, and, pages are removed as the user moves away from them. It is important to note that the user moves across the submap rather than remaining centred in the submap with the pages changing.

An example of a user moving to the right is shown in Figure 1. As the user moves from square 5 to square 6 new pages are loaded into 1,4 and 7. The user can always see one page ahead. As the user moves off square 6 he/she moves onto square 4 which is displayed in front, i.e. the view has wrapped around to the other side of the submap.

| User at initial position | After movement 1 page right. | After moving another page right. |
Figure 1: Spherical offset page management

The page swapping in this spherical offset page management technique is highly efficient. It is the efficient page management and the easy integration with the other components of a terrain simulation that make this approach to terrain visualisation highly desirable.

Conclusion

An approach is described here for producing a graphical simulation in which the virtual environment is continuously produced without the need for a large terrain dataset. At all times the environment is procedurally generated in correlation with other users.

This technology allows for graphically intensive Internet-based games and virtual environments to be downloaded easily. The approximate download size is 1-2 Mbytes as opposed to current systems that can be in the order of many hundreds of Mbytes. This easy distribution of the virtual environment encourages user participation.

The constrained size of current environments limits the number of participants in multiuser games. Simulations using the methodology described can be extremely large in size and allow thousands of players to participate without overcrowding.

Introduction (Gordon Davies)

The discussion last year at the annual convention of the American Federation of Teachers and the subsequent resolution that was passed highlights the concern felt by many about the quality of distance education programs. There are many who feel that the quality of the teaching, the support that students receive and the information provided to students is not as good in a distance education environment as in a conventional face-to-face situation.

The panelists come from varying backgrounds, coming from a variety of academic institutions and industry. The panelists will explain how quality is assured at their institutions and claim that students who do learn at a distance receive as good an education as those in the face-to-face environment. Evidence to justify the claim will be produced. Factors such as the cost of the provision and the scalability of the operation are factors that will also be discussed.

C. Fay Cover

Distance Education, The web, Industry based competencies and fundamental knowledge, can they all be achieved while maintaining quality? As we embrace the World Wide Web and the associated technology, ensuring that we have enhanced student learning and met all course objectives can be a daunting task. Can we make it work? For example, one concern is centered on how to provide the appropriate interaction with the professor and other students. Exploring a variety of technologies being used today by various educational and industry alliances. The quality of distance education depends upon a variety of factors, such as; technologies used, professor training, reliability of the equipment and data communications networks, and many others. Finding the right mix and delivering up-to-date curriculum is a challenge that can be overcome.

Wendy Lawrence-Fowler

At the University of Texas-Pan American, we deal with quality in three aspects of distance education: the quality of course materials, the quality of presentation, and the quality of student services. While we address each aspect independently, we also try to capitalize on the synergistic interplay among the aspects. It is this synergy that defines the quality of a program and can be evaluated via the outcomes of the learning experience.

We use an approach to course materials development that matches the faculty member's level of expertise and comfort with technology, as well as their teaching style, to the level of development support provided by the Center for Distance Learning. Support levels range from the Center simply providing server space and maintenance to a level, which entails a team of

individuals including a faculty content expert, an instructional designer, a media specialist, a graphic designer, and one or more courseware technology assistants. The Center also provides training for faculty in both technological and pedagogic issues (including an online course titled "Teaching Online in Higher Education") and provides a rubric which faculty use to complete a self-assessment of their course materials.

The training and rubric help faculty match the presentation of the materials they develop with their preferred interaction or presentation style. Presentation style and course materials are tested at three levels: first the materials are used to augment the traditional classroom. As material design and presentation are honed, the faculty moves to what we refer to as a reduced seat time course (traditional seat time is traded for web based learning experiences.) Given that the materials and presentation meet a strict set of standards, including the application of sound online pedagogic practices, the course is taught completely in a web-based environment.

Various factors are tracked to evaluate a course or program including short-term and long-term outcomes (retention and satisfactory completion, performance in subsequent courses, and job placement).

Finally, the Center for Distance Learning provides online and dial-in helpdesk facilities for students. Through the University of Texas System and a consortium of Hispanic serving institutions (HETS), distance learning students are provided access to web-based information/library resources as well as advisement and mentoring programs.

I will talk more specifically about our training programs for faculty, the rubric used for evaluation of materials and presentation as well as the challenges of providing students support services to the distance student .

Mark Guzdial

The Role of Technology in Distance Education

When people say "Web," there's often a reaction of "Distance Education!" as being a potential killer app. Yet, many large-scale distance education efforts rely much more on paper and less on Web-based or other computing technologies. Some of the problems of current technologies for distance education include cost, lack of robustness at large scales, and inferior quality and educational effectiveness compared to other technologies. For example, we know that lectures are among the least effective educational interventions, and putting lectures in a postage-stamp size streaming video window certainly doesn't make them better. At the same time, there are opportunities for computing and network technologies to help solve problems in distance education that paper can't solve alone, like having a mentor handhold a student through a difficult problem, or working through multiple iterations of a design in a studio environment. Finding the right role for the right technologies in distance education is an open problem. when marking more traditional assignments.

AHA! Adaptive Hypermedia for All

Paul De Bra[*], Jan-Peter Ruiter
Department of Computing Science
Eindhoven University of Technology (TUE)
PO Box 513, Eindhoven, The Netherlands
debra@win.tue.nl

Abstract: There are roughly two types of (Web-based or other) Adaptive hypermedia systems (AHS): *special-purpose* systems, geared towards one specific application or application area, and *general-purpose* systems, designed with different applications in mind. Most existing systems are *special-purpose*, with a majority aiming at educational applications. Previous developments on the AHA system (De Bra & Calvi, 1998) and the AHAM model (De Bra et al, 1999) have shown that *general-purpose* AHS can be designed and implemented, but also that such systems tend to be too complicated for non-technical authors. This paper describes the "third generation AHA", called Adaptive Hypermedia for All, which is being developed as an open source project sponsored by the NLnet Foundation. AHA aims at bringing adaptivity to all kinds of Web-based applications, through a simple but powerful adaptive engine. In this paper we focus on the authoring interface for creating the conceptual structure of an adaptive application. But we also briefly describe how the AHA system can be used for some typical constructs found in (adaptive) Web-based applications.

1. Introduction and Background

In (Brusilovsky 1996) an overview is given of adaptive hypermedia systems (AHS) and of the methods and techniques these systems employ. In 1996 many AHS were not yet Web-based. Most were stand-alone (or locally networked) software systems aimed at a single *specific* application or application area, such as learning or information retrieval. Virtually all newer AHS are Web-based but still serve a single application area. This has important advantages: 1) A *special-purpose* AHS can be made easy to use for an author, through an authoring interface that is tailor made for the designated application, and 2) the interaction with the end-user can be optimized through a well-designed browser interface. A prime example of such a system is Interbook (Brusilovsky et al, 1998), a tool for creating adaptive textbooks. It offers users a frames-based presentation that includes a partial (and adaptive) table of contents, an overview of required prerequisite ("background") knowledge for the current textbook page, and an overview of "outcome" knowledge (concepts to which this page contributes). It offers some special features for learning as well, including a glossary and a "teach me" guided tour generator to learn about a specific concept. The special features of Interbook for educational applications may not be desirable in other application areas such as an adaptive search engine, on-line information systems (or information kiosks), on-line help systems, corporate websites, shopping sites (mail order catalogs), etc. The AHA project aims at creating a Web-based environment for creating very different types of adaptive applications.

Authoring usable hypermedia documents (Web-based or not) is always difficult. On the one hand an author wants to offer a lot of navigational freedom, with short paths to every page. But on the other hand an author wants to avoid overloading the user with too many links, which would make the selection of appropriate destinations difficult. Many adaptive hypermedia systems (AHS) tackle this problem by automatically selecting or emphasizing those links that are considered "appropriate", based on a model of the user's state of mind. Similarly, an author also wants to provide the "appropriate" information on each page, thereby including prerequisite explanations for users who need them, by providing additional information for the truly interested user, etc. See (Bruvilovsky 1996) for a long or (De Bra et al, 1999) for a short overview of AHS techniques. Such *personalization* is beginning to appear on websites, usually through a *My* suffix (like in "My Yahoo!", "My Excite", "myCNN.com", etc.). However, in most cases the personalization is based on a user profile that is created through an elaborate registration process, and not adapted to the changing interests and knowledge of the user that can be seen by observing the user's browsing behavior. The goal of the AHA project is to create a simple environment for making websites that adapt themselves to the user. It builds upon the adaptive engine in the AHA system (De Bra & Calvi, 1998, De Bra et al, 2000).

---

[*] Also at the "Centrum voor Wiskunde en Informatica" in Amsterdam.

The structure of this paper is as follows: in Section 2 we show the overall architecture of the AHA system. We explain the role of the different structures that together provide all the information the adaptive engine needs to perform adaptation. In Section 3 we show how an author can create and manipulate the conceptual structure of an adaptive application, and how web-pages are linked to that conceptual structure. Section 4 shows examples of common navigation structures seen in (adaptive) Web-based applications and how these can be realized using AHA. The final section indicates the planned future stages of the AHA project.

2. Architecture of the AHA system

The overall architecture of AHA is inspired by the AHAM reference model (De Bra et al, 1999), an extension of the Dexter model (Halasz & Schwartz, 1994). This model was constructed to capture the structures and functionality of most existing (and future) AHS. In this model an AHS consists of four parts that work closely together:

- The *domain model* describes the application domain in terms of *fragments*, *pages* and (abstract) *concepts*. In the AHA system pages are simple XML files containing fragments of HTML text (possibly with embedded images, JavaScript, etc.). XML tags are mainly used to delimit the boundaries of the fragments and to provide *conditions* on the inclusion of fragments. (We shall briefly describe these conditions later.) Pages are connected through hypertext **links**, using the HTML *anchor* tag (<A>). In AHA pages are at the bottom of a *concept hierarchy*. (In the full AHAM model the fragments are at the bottom.) In Section 3 we describe how the concept hierarchy is visualized in the authoring interface. Pages and higher-level concepts are also connected through **generate** and **requirement** relationships that play an important role in the processes of *updating the user model* and *performing the adaptation*. (See below.)

- The *user model* in AHA mainly consists of a table with for each page or concept an attribute value that is updated when the user browses through the Website. The updates are partially determined by the **generate** relationships. Currently for each concept AHA maintains an integer attribute with a value between 0 and 100. (Different attribute types are planned for the future, but for the most part having 101 possible different values for each concept is more than enough.) When a user accesses a page there are two possibilities:

  o If the page was *desired* (according to the requirement relationships we describe later) the attribute value for the page is increased to 100. In a learning context this means that the system thinks the user has full knowledge of this page.

  o If the page was *not desired* the attribute value is increased to 35 or left unchanged if it was already 35 or higher. This value 35 was chosen arbitrarily. In a learning context it represents that when a user reads a page for which the system thinks she is not (yet) ready, she only gains partial knowledge of that page.

Updates to (the attributes of user-model) concepts are propagated to other concepts through the **generate** relationships. For each (page or) concept there is a list of relationships with other concepts. The relationships also have attributes associated with them that indicate how an update to the "source" concept's value defines the desired update to the "destination" concept's value. The update can be the assignment of an *absolute* value to the destination concept's value, but it can also be a *relative* update, meaning that a fixed *percentage* of the update to the source concept's value is propagated to the destination concept's value. In AHA all generate relationships for one concept are grouped into a structure like the following:

```
<genitem>
        <name>de_koninck</name>
        <item concept="belgian_beer" absolute="no" perc="10"/>
        <item concept="alcohol" absolute="yes" perc="5"/>
        <item concept="chocolate" absolute="no" perc="-3"/>
</genitem>
```

A possible interpretation would be that the system's confidence that the user is interested in Belgian beers increases by 10 when the user visits the "de_koninck" page (assuming that in the user model the value for de_koninck goes from 0 to 100). The system's confidence that the user is interested in chocolate decreases by 3. The system also registers that the user is accessing a page on beer with 5% alcohol. This information can be used to conditionally include information in other pages, specific for beers with 5% alcohol content.

The way updates are implemented in AHA allows the further propagation of *positive relative* updates, such as the one for "belgian_beer" (De Bra et al, 2000). This is useful to allow an interpretation of the user-model values as *knowledge*. Reading pages contributes to the knowledge of a section, which contributes to the knowledge of a chapter, etc.

- The *adaptation model* is a part in the AHAM model that is defined as a collection of rules that define how the adaptation must be performed. (Strictly speaking in AHAM the rules we described above for updating the user model through the generate relationships also belongs to the adaptation model.) In AHA the adaptation is defined through **requirement** relationships. For each fragment, page or concept we can define a relationship that indicates under which circumstances this fragment, page or concept is *desired*. Such a requirement relationship links the "source" fragment, page or concept to one or more "destination" pages or concepts. Whether or not a fragment, page or concept is *desired* may not only depend on which information the user has read before, but also on which information the user has *not* read. (All user-model values are initialized to 0.) In the current AHA system for each (fragment, page of) concept there can be one requirement relationship, written as a Boolean expression in (user-model) pages or concepts. The requirement relationship for a fragment appears in the XML/HTML page that contains the fragment. Requirement relationships for pages and concepts are stored together in one XML file (typically named "xmlgenlist"). In the previous (non-existing) Website on Belgian products we can imagine a paragraph (fragment) describing special characteristics of beer with more than 10% of alcohol, and which is aimed at people who have shown great interest in the topic of beer. The Boolean expression for the requirement relationship for this paragraph could then be something like:

  belgian_beer > 70 and alcohol > 10

  As this example already shows that the simple user-model structure with just one (bounded) integer attribute per page or concept already enables the creation of adaptive applications based on knowledge (0 means *unknown* and 100 means *well known*), interest (by reading different pages on beer the user expresses her interest in the topic of beer) or anything else that can be expressed through a number (or an enumerated type simulated through numbers).

- The final element in the AHAM model is the *adaptive engine* that performs the actual adaptation. While the adaptation rules indicate the *desirability* of fragments, pages and concepts, the engine generates the pages in such a way that the user can distinguish desired from undesired information. Many techniques for adapting page content and link presentation exist (Brusilovsky, 1996). The AHA system currently uses the following techniques:
  - *Conditional inclusion of fragments*: desired fragments, i.e. fragments for which the *requirement* Boolean expression is true (or for which there is no condition) are included in the page; undesired fragments are omitted.
  - *Hiding or annotation of links*: AHA presents link anchors as colored text (not underlined). AHA uses three link colors: "good" for links to previously unread desired pages, "neutral" for links to desired pages that were already read, and "bad" for links to undesired pages. The default colors for "good", "neutral" and "bad" are blue, purple and black. Assuming that normal text is black this color scheme corresponds to the technique of *link hiding*: links to undesired pages are present (and fully functional) but not clearly visible. In AHA the user can change the color scheme. Another well-known color scheme, used e.g. in Interbook (Brusilovsky et al, 1996, Brusilovsky et al, 1998) uses the traffic light metaphor: green, yellow (or orange) and red. Such a scheme results in the technique of *link annotation*. (Interbook uses other annotations in addition to this.)

AHA supports "pure" Web-based applications. On the server side the adaptive engine consists of Java Servlets that are activated when the Web-server receives HTTP requests from the browser. Whenever the user clicks on a link the requested page will be "filtered" by the adaptive engine and the user-model will be updated by taking into account the page visit (and the associated generate relationships). Requests may also be generated through JavaScript code that is embedded in the HTML pages, e.g. for updating Web-pages that consist of several frames. For the AHA engine all these requests are treated equally and handled separately. It is thus possible to create frames-based as well as non-frames-based applications with AHA. AHA is also a "pure" Web-based system in the sense that it *only* reacts to HTTP requests. There are no special tools or protocols to interact with the adaptive engine, no user-model updates based on timeouts, etc. AHA can be installed on any Web-server supporting Java Servlets. (Currently we have a "production" version running on W3C's Jigsaw server and on Sun's JSWDK and are experimenting with the emerging Servlet support on the popular Apache server.)

The architecture, and even the current implementation of AHA is sufficiently powerful to support a wide variety of adaptive Web-based applications. We show parts of a few possible examples in Section 4. The biggest shortcoming until now has been the lack of authoring support. In the next Section we discuss the automatic generation (and maintenance) of the XML file(s) that represent the conceptual structure of an application, from a user-friendly and (partially) graphical authoring interface.

3. The authoring interface

In order to develop any non-trivial Web-based application one needs to first design (or "draw") the overall conceptual structure. Traditionally, in hypertext applications, a "conceptual" diagram shows how pages are connected through links. The link structure normally contains a *hierarchy*, which corresponds to a book structure (with chapters, sections, subsections and paragraphs), some special structures such as table of contents, index and glossary, and a set of carefully chosen cross-reference links between pages. See e.g. (Botafogo et al, 1992) for an article on metrics for link structures. Many Websites even offer the hierarchical part of the link structure as a navigation aid for end-users, through a so-called *site map*.

For an adaptive application (at least when developed for AHA) one needs to consider not only the **link** structure but also the **generate-** and the **requirement** structures. In this paper we concentrate on the creation of the **generate** relationships. (The creation of link structures is well known, and the requirement structures can be pretty arbitrary. We plan to study special types of requirement relationships such as *prerequisites* later.)

In most cases the application domain will have some kind of hierarchical structure. Figure 1 shows a small part of such a structure, from our imaginary Website on Belgian products. Such a hierarchy normally corresponds to generate relationships that have a positive, relative value. Reading about "de_koninck" shows interest in beer and also means you learn something about beer. Learning something about beer means you also learn something about Belgian products. And learning about Belgian products means you're learning something about Belgium. To keep the overview simple and readable the graph does not show the *percentage* of each generate relationship. The interface shows the percentage when you move the mouse over the icon that precedes the concept name.

```
⊟ belgium
  ⊟ products
    ⊟ beer
    │  ├ de_koninck
    │  ├ hoegaarder
    │  └ duvel
    ⊟ chocolate
    │  ├ callebaut
    │  ├ meurisse
    │  └ godiva
    ⊟ french_fries
       ├ potato
       └ mayonaise
```
Figure 1: concept hierarchy shown through generate relationships

When building an application the other, more arbitrary generate relationships must also be entered, and can be shown in the same graphical way. Figure 2 shows the generate relationships between different beers and the concept "alcohol". To indicate that the concepts "de_koninck", "hoegaarden" and "duvel" have a hierarchical and therefore prime place somewhere else in the graph their names are preceded by an icon like that for a windows "shortcut" (equivalent to a Unix symbolic link).

```
⊟ alcohol
  ├ ⊠ de_koninck
  ├ ⊠ hoegaarden
  └ ⊠ duvel
```
Figure 2: structure of positive and negative generate relationships

Figure 1 can be extended with negative relationships from the different beers to the concept "chocolate" and negative relationships from the chocolates to the concept "beer". Reading about "de_koninck" not only increases the interest (and/or knowledge) in beer but also decreases the interest in chocolate. If both updates would propagate then "products" would receive a positive update through beer and a negative update through chocolate. This is clearly not a desirable situation and explains why the AHA system does not propagate negative updates.

289

The graphical overview in the authoring interface shows a *top-down* view on the generate relationships. Using the book metaphor the top-level element will be the book, with the chapters at the next level, then the sections, etc. This metaphor is so common (especially since everyone knows the Windows Explorer) that we expect authors to easily understand these overviews. For defining the generate relationships however we take a *bottom-up* approach. When an author enters a concept (or page) into the structure he must specify the influence of this concept on other concepts. Using the book metaphor again, when entering a subsection the author identifies to which section it belongs. When entering a section the author says to which chapter this section belongs, etc. Therefore we have created an authoring interface for entering the generate relationships for which the given concept is the source. Figure 3 contains (part of) the interface that shows the generate relationships for "de_koninck" in our imaginary example. Each time the author adds or updates generate relationships the graphical (explorer-like) presentation of the overall structure is updated accordingly.

GenList: New   Load   Save   Verify

Concept: Add   Modify   Delete   Add Root

Concept

The Name of the selected Concept is:de_koninck

This Concept is Changeable.

The GenItems are :

Name	Percentage	Absolute
belgian_beer	10	false
alcohol	5	true
chocolate	-3	false

Figure 3: interface for entering and updating generate relationships

The first entry in the table in Figure 3 is interpreted as the hierarchical position of the concept. So it is the order of the items that determines where "de_koninck" is shown with and where without the "shortcut" icon. And in case there is a cycle in the generate relationships the order in which the concepts were created determines which concept gets the highest position in the hierarchy.

Figure 3 also shows another feature of AHA: for each concept the author can indicate whether or not it is "changeable". The user of an AHA application can manually alter the user-model by means of a form. For each concept the author marked as "changeable" the user can view and alter the value in her user-model. We realize that adaptive Web-based applications can only work with unreliable input (the page requests made by the user), and therefore it is best to allow end-users to manually update (or "correct") their user-model.

4. Examples of AHA applications

In this section we briefly indicate how to realize some common constructs using the AHA system. We first look at the most popular application area for AHS: learning by reading, and possibly verifying knowledge through multiple-choice quizzes. The author must decide for each page how much knowledge it contributes to each course topic. This determines the *percentage* to use in the generate relationship that links pages to topics. In order to allow users to skip parts of the material the author can choose the numbers such that reading most (but not all) pages about a topic already results in 100% knowledge. Topics can be grouped into larger units, and knowledge of topics is accumulated in the larger units because AHA propagates positive relative updates.

The AHA system contains a module for multiple-choice tests. That module allows for randomized tests that make cheating somewhat difficult and that are thus suitable for student evaluation. Simple fixed multiple-

choice quizzes can be created in plain HTML by using links to pages that explain whether an answer is right or wrong. When the user chooses an incorrect answer, the answer-page can explicitly decrease the knowledge value for some topics and reset the value of pages that must be reread to 0. When the user reads the material again knowledge about the pages and topics is augmented again.

Another popular construct is that of a "table of content" frame, showing a menu and possibly also one or more submenus. Basically, this *navigation frame* acts like the left frame in the Windows Explorer. Submenus can be opened in the navigation frame, or when a page that belongs to a different submenu is opened by clicking on a link (anchor) in the *information frame*. The (sub)menus in the navigation frame can be implemented as conditional fragments. Each menu is assigned a unique number, and a global "concept" *menu* must be defined. Each page is connected to the appropriate menu by adding a generate relationship between the page and the *menu* concept. This generate relationship must define an *absolute* update to the number of the (sub)menu that must be opened when this page is displayed. Whenever the page is loaded in the information frame the *menu* concept is set to the correct value. A one line JavaScript program in the HTML page can instruct the browser to reload the *navigation frame*. Because the request for the page precedes that for the menu the menu is retrieved with the appropriate submenu opened up. Such Explorer-like menus are used in our on-line course text about graphical user-interfaces, at http://wwwis.win.tue.nl/2R350/. (The whole system is so fast that you hardly notice that the menu is refreshed *after* loading a page and not *simultaneous* with loading the page.

A final example is that of verbosity levels. In the same course on graphical user-interface, there is a one-to-one correspondence between the Webpages that are available for the students and the viewgraphs that are used during the lectures. The same topics are treated and the overall style of the presentation is the same. But for each item the on-line text is much longer than the one-liners on the viewgraphs. The pages and viewgraphs are always in sync during updates to the course because they are actually the same pages. A global "concept" *verbose* is used to guide the conditional inclusion of fragments. In the course only the levels 0 and 100 are used, but by using more values one can create a Web presentation that exists at different levels of verbosity.

5. Conclusions and Future Work

Web-based adaptive systems need not be geared towards a single application or application area. AHA (the Adaptive Hypermedia Architecture) was originally built to make an on-line (hypermedia) course adaptive. For this purpose a user-model was introduced with for each page (or concept) a knowledge value. We soon realized that there was nothing in the way AHA treated this knowledge value that actually required the value to represent knowledge. We have developed applications (and shown examples in this paper) in which the AHA engine performed arbitrary types of adaptation based on the user's navigation (De Bra & Calvi, 1998). In this paper we have presented (most of) the interface for creating and manipulating the *generate relationships* that define how user actions result in user-model updates (and thus indirectly also in adaptation that is based on the user-model). We continue to improve and extend the functionality and usability of AHA, especially for authors, through a research grant of the NLnet Foundation (see www.nlnet.nl). In this AHA project (or Adaptive Hypermedia for All) we are developing open source software that will be made available from our Website http://wwwis.win.tue.nl/. (Preliminary software is already available at this time and we welcome feedback.) Among the planned developments are analysis tools for detecting potential problems with the *link, generate* and *requirement relationships*. These tools will warn an author about pages that never become *desired*, or that can never even be reached, fragments that are never included, etc. Apart from improving the usability for authors we will also create more applications using AHA in order to be able to evaluate the user acceptance of adaptive Websites in general and adaptive AHA applications in particular.

Discussion Topic

Hypermedia systems have enabled authors to break free from the linear presentation structure enforced by the world of physical (paper) books. The Web has further enabled authors to bring hypermedia documents on-line, so that they can reach a much wider audience. As a consequence, documents also reach an audience with widely varying interests, background, (hypermedia) experience, etc. In order to provide the most appropriate information to all users, and present it in the most suitable way, documents must be *adapted* to target user groups or even individual users. Adaptive hypermedia provides the methods and techniques to perform this adaptation automatically (instead of purely based on a questionnaire to be completed by every user).

Adaptive hypermedia has been applied in many application areas, but a large majority of all adaptive hypermedia applications is used in education. While it is not often named as such, most learning material that is available on-line can be viewed as an extension of the concept of a textbook. (Extensions may include search facilities, automatic evaluation of exercises or assignments, progress feedback, etc.) The panelists have all been involved in the creation and use of *adaptive* on-line textbooks. The panel discussion focuses on the experience with different adaptive methods and techniques used in these applications. Experience with a single specific adaptive application cannot lead to conclusions that are guaranteed to carry over to a different application area or the use by a different type of audience. Therefore the aim of this panel discussion is to find common experiences that suggest a more generally applicable pattern (that should be verified through future research) as well as contradicting experiences that suggest that the perceived influence of adaptation might actually be something that was specific to the application area, the audience, or the course topic. Although the four panelists together will present different angles of adaptive textbook creation and application, active participation of the panel attendees is needed to collect and discuss more different experiences with adaptive educational course material. Because the WebNet conference proceedings are produced in advance, the outcome of the panel discussion, including the expected participation of the audience, cannot be included here.

Background: Methods and Techniques for Adaptive Web-based Textbooks

Most textbooks have a structure that appears to be hierarchical (with chapters, sections, subsections, etc.) but that also provides one clearly suggested reading order. Of course it is possible to dive right into chapter 4, but most readers will not be surprised when this chapter uses terms and concepts they are not familiar with. The reader will automatically assume that the difficulty in understanding chapter 4 is caused by not having read chapters 1 through 3 and that it is really the reader's fault. Very few people expect a textbook to be clear for readers who ignore the suggested reading order. Learners have very different expectations from a hypermedia or Web-based textbook. When the reader sees a table of contents in which chapter and section titles are links, he or she expects that the author has intentionally made these links available to enable users to start (or continue) the reading process in any desired chapter or section. This not only sounds but actually is too good to be true. It is virtually impossible to write a textbook in which the chapters and/or sections can be studied in any arbitrary order. And in a rare case where it would be possible, it is certainly a lot of work to write the textbook with many different reading orders in mind. Adaptive methods and techniques come to the rescue. An Adaptive Web-based textbook can monitor what the learner reads, possibly also which tests or assignments the learner completes, and can adapt the presentation accordingly. This adaptation is generally done in two ways:

- **Adaptive presentation:** the information and/or the way it is presented is adapted to the user. When the system notices that the user visits a page in which a concept is used that the user does not yet know about, it may insert a (short) explanation to compensate for the missing foreknowledge. This adaptation method is sometimes referred to as adding a *prerequisite explanation*. Likewise, it is possible to provide an *additional explanation* of certain details to advanced users, or to show a *comparison* with other concepts, for users who are already familiar with these other concepts. Different techniques are used to create adaptive presentations. A simple technique is to use variants of information pages. Unfortunately this leads to duplication of the information that is common to each variant. An alternative technique is to use conditionally included fragments. For the inclusion of additional details one may also opt to always include the material but "shade" it for users who should probably skip these details. Techniques are plentiful, but it remains to be seen how useful they are, and whether the help they provide outweighs the potential problem that different users receive a different presentation of the same page, or even that the same user gets different presentations of a page at different times.

- **Adaptive navigation:** the links and/or the way links are shown is adapted to the user. When the system detects a link on the "current" page, leading to a page that requires prior knowledge the learner does not yet possess, it may alter the link or its presentation so as to warn the user that the link's destination is not (yet) desirable. By suggesting which are "good" links to follow and which are "bad" links, the system offers *guidance* to the learner. Different techniques have been tried to offer such guidance. A commonly used technique is *link annotation*, which means that good and bad links are presented in a different way. The "traffic light metaphor" uses a green link anchor or icon to indicate that a link is recommended, red to indicate that the user is not well-prepared for visiting the link, and yellow to indicate that the link does not lead to new information. Another technique uses *link hiding*. It is similar to annotation, but "bad" links are presented without a visible link anchor. The link may still work, but because it does not look different from normal text the user will not notice it. Yet another technique, mostly used with lists of link anchors, is to sort the links from most to least relevant. Web users know very well that a list is a suggestion to first follow the topmost link and work your way down. More techniques exist, but here also it remains to be seen how useful they are in general. (Research has shown they usefulness in specific cases already.)

The interested reader can find more information on adaptive hypermedia and adaptive web-based systems in the two references below.

About the Panelists

Prof. dr. Paul De Bra received his Masters degree in mathematics (1981) and Doctorate in computer science (1987) from the University of Antwerp. He is full professor in Databases and Hypermedia at the Eindhoven University of Technology. He has been researching database theory, hypermedia models, browsing semantics, and adaptive hypermedia principles and systems. He is author of an adaptive course on hypermedia that is offered (through the Web) to students of different universities in the Netherlands and Belgium. He is currently investigating a model for "general-purpose" adaptive hypermedia, and developing the "general-purpose" AHA! (adaptive hypermedia architecture) system. He also hosts the (global) Adaptive Hypertext and Hypermedia Homepage (at http://wwwis.win.tue.nl/ah/) and the Adaptive Hypermedia mailing list. He is program chair of the second International Conference on Adaptive Hypermedia and Adaptive Web-based Systems (AH2002, Malaga, Spain).

Dr. Peter Brusilovsky graduated (with honour) in applied mathematics (1983) from the Moscow State University, where he later obtained a phd in computer science (1987). He is now an assistant professor at the University of Pittsburgh (School of Information Sciences) and an adjunct research scientist at the Human-Computer Interaction Institute of Carnegie Mellon University. His research interest include adaptive web-based systems, intelligent tutoring systems and shells, student and user modelling, human-computer interaction and artificial intelligence. He is author of the (adaptive educational) Interbook system and the influential overview article "Methods and techniques of adaptive hypermedia" (User Modeling and User-Adapted Interaction, vol. 6, nr 2-3, pp. 87-129). He was program chair of the first International Conference on Adaptive Hypermedia and Adaptive Web-based Systems (AH2000, Trento, Italy), and is considered one of the leading experts in the field of adaptive hypermedia.

Dr. Tom Murray has degrees in education (EdD, MEd), computer science (MS), and physics (BS). He has been researching, publishing, consulting, and leading workshops on the subjects of authoring tools, knowledge acquisition, and knowledge representation for advanced technology instructional systems since 1985. He is currently visiting professor of instructional technology at Hampshire College, and director of the Hampshire College Digital Design Center. His research interests include adaptive hyperbooks (the MetaLinks project), Intelligent Tutoring Systems (ITS) authoring tools (the Eon project), and glass box simu lation based learning environments for inquiry learning (the SimForest project). In general his research has focussed on designing systems that allow practicing educators and instructional designers to participate more completely in the design of advanced technology instructional systems. He has also published papers in the areas of ITS ontologies, ITS interoperability and reusability, distributed models of curriculum, exploratory evaluation of software, example-based strategies for teaching concepts, and the representation of instructional strategies.

Dr. Marcus Specht received his Diploma in Psychology in 1995 and a Dissertation from the University of Trier in 1998 on adaptive learning technology. Marcus Specht currently works as a senior scientist at the GMD German National Research Center for Information Technology. His main background is in the field of cognitive science, intelligent tutoring systems and the integration of ITS and Web-based tutoring. He was involved in the design, the implementation, and the evaluation of personalized eLearning technologies and adaptive hyperbooks in several projects in the last years (ELM-ART, Interbook, ACE). Currently he coordinates the group on personalized eLearning in the department on Information in Context (ICON) in GMD-FIT. The group develops a highly scalable eLearning platform for design and architecture in the European WINDS (http://winds-university.org) project of the IST program of the 5th framework. Furthermore he is involved in the concertation activity on learner modelling for personalized instruction in the 5th framework of the European commission and contributes to the developments in the Learner Technology Standardization Committee of the IEEE (IEEE-LTSC). Recently he co-founded bureau42™, a spinoff company of GMD providing personalized eLearning and education brokerage solutions (http://www.bureau42.de). His main research interests are adaptive learning and training systems, knowledge management, contextualized computing, and intelligent interfaces.

Leading Technological Change through Paradigm Shifts

Robert Dean

Leading technological innovation involves significantly more than using the best equipment or software. Human considerations are of major importance. This paper presents a very successful approach to leading faculty and administration through the difficult period of curriculum assessment and the development of the best approach to integrating technology into the curriculum. With over three years of innovative technology implementation, this university presents its chosen implementation strategy and methodologies as a prototype for others to follow.

The presentation outlines successful methods for leading faculty and administration through decision-making and technology implementation in a setting that is both supportive and rewarding. Potential pitfalls are discussed, and approaches are outlined which being about a collaborative university-wide solution to a proper solution despite significant paradigm shifts occurring in higher education.

Extension of RDF(S) with Contextual and Definitional Knowledge

Alexandre Delteil, Catherine Faron-Zucker, Rose Dieng
INRIA, ACACIA Project, 2004 route des Lucioles, BP 93,06902 Sophia Antipolis, France
{Alexandre.Delteil,Catherine.Faron,Rose.Dieng}@sophia.inria.fr

Abstract: RDF(S) is the emerging standard for knowledge representation on the Web. However, in the context of the European IST project CoMMA dedicated to ontology-guided information retrieval on a "corporate Semantic Web", the RDF(S) expressiveness is too much limited. CoMMA stands for "Corporate Memory Management through Agents". The corporate memory is materialized by the company's Intranet whose documents are semantically annotated in RDF. These RDF descriptions then enable an information retrieval based on the semantics of the documents. However, when compared to object-oriented representation languages, description logic, or conceptual graphs, RDF(S) has a limited expressiveness: in particular it does not enable to declare class or property definitions, nor axioms in an ontology. We propose an extension of RDF(S) to express this kind of definitional knowledge, and more generally contextual knowledge on the Semantic Web. We hope that DRDF(S) will contribute to the ongoing work of the W3C committee for improving RDFS.

Introduction

The need of a Semantic Web is now well recognized and always more emphasized (Berners Lee, 1999). The huge amount of information available on the web has become overwhelming, and knowledge based reasoning now is the key to lead the Web to its full potential. In the last few years, a new generation of knowledge based search engines has arisen, among which the most famous are *SHOE* (Luke *et al.*, 1997) and *Ontobroker* (Fensel *et al.*, 1998). They rely on extensions of HTML to annotate Web documents with semantic metadata, thus enabling semantic content guided search. For interoperability on the Web, the importance of widely accepted standards is emphasized. *Resource Description Framework* (RDF) is the standard proposed by the W3C for the representation and exchange of metadata on the Semantic Web (RDF, 1999). *RDF Schema* (RDFS) is the standard dedicated to the representation of ontological knowledge used in RDF statements (RDFS, 2000).

Our work takes place in the CoMMA European IST project. CoMMA stands for "Corporate Memory Management through Agents". The corporate memory is materialized by the company's Intranet whose documents are semantically annotated in RDF. These RDF descriptions then enable a knowledge-based information retrieval based on the semantics of the documents by using the inference engine *CORÈSE* developed in our team (Corby *et al.*, 2000). However the expressiveness of RDF(S) appears too much limited to represent the ontological knowledge of a corporate memory. Axiomatic knowledge or algebraic properties of relations are crucial for intelligent information retrieval on the Web: they are the key to discover implicit knowledge in Web page annotations (Heflin *et al.*, 1998). Martin (2000) claims the need for additional features and conventions in RDF.

When compared to object-oriented knowledge representation languages, description logics, or conceptual graphs, RDF(S) provides no way for representing axioms, class or property definitions. We propose to extend RDF(S) with these features. We call it DRDF(S) for *Defined Resource Description Framework*. DRDFS more generally, enables to express contextual knowledge on the Web. The RDF philosophy consists in letting anybody free to declare anything about any resource. Therefore the knowledge of who and in which context a certain annotation has been stated is crucial. DRDF(S) enables to assign a context to any set of annotations, in particular for definitional contexts. We first present the RDF(S) model. The RDF(S) extensions with contexts, existential quantification and coreference are then described. The RDF(S) extensions for axioms, class and property definitions are then presented. Finally DRDF(S) is summarized.

RDF(S)

RDF and RDFS

RDF is the Web standard for annotating resources with semantic metadata (RDF, 1999). Everything named by URIs can be considered as a resource and described by annotations. An RDF description consists in a set of statements; each one specifying a value of a property of a resource. A statement is thus a triple (resource, property, value), a value being either a resource or a literal. The RDF data model is close to semantic nets. RDF assertional knowledge is positive, conjunctive and existential. A set of statements is viewed as a directed labeled graph: a vertex is either a resource or a literal; an arc between two vertices is labeled by a binary property. RDF is provided with an XML syntax. Figure 1 presents an example of RDF graph and its XML serialization. It is the annotation of the Web page of T-Nova which is a subdivision of Deutsche Telekom.

subdivisionOf		<rdf:Description about='www.T-Nova.de'>
www.T-Nova.de ——— www.Deutsche Telekom.de		<subdivisionOf rdf:resource='www.DeutscheTelekom.de'>
	type	<rdf:type rdf:resource='#TelecomCompany' />
	TelecomCompany	</subdivisionOf>
		</rdf:Description>
Figure 1: An example of RDF annotation.

RDF Schema (RDFS) is dedicated to the specification of schemas representing the ontological knowledge used in RDF statements (RDFS, 2000). The RDF(S) model thus distinguishes between ontological knowledge (in RDF Schemas) and assertional knowledge (in RDF annotations). A schema consists in declarations of classes and properties. RDFS properties are declared as first class entities like RDFS classes. This feature opposes RDF(S) to object-oriented approaches, where properties are defined inside of classes. Multi-inheritance is allowed for both classes and properties. A property is declared with a signature allowing several *domains* and one single *range*.
The RDFS metamodel is presented in Figure 2.
Figure 2: The RDFS metamodel.

To represent domain specific knowledge, a schema is defined by refining the core RDFS. Domain specific classes are declared as instances of the *Class* resource and domain specific properties are declared as instances of the *Property* resource.

RDF Limitations

A Triple Model. The RDF data model is a triple model: an RDF statement is a triple (resource, property, value). When asserted, RDF triples are clustered inside annotations. An annotation can thus be viewed as a graph, subgraph of the great RDF graph representing the whole set of annotations on the Web. However, "there is no distinction between the statements made in a single sentence and the statements made in separate sentences" (RDF, 1999). Let us consider two different annotations relative to two different research projects which the employee 46 of T-Nova participates to:
{(employee-46, worksIn, T-Nova), (employee-46, project, CoMMA), (employee-46, activity, endUser)} and
{(employee-46, worksIn, T-Nova), (employee-46, project, projectXX), (employee-46, activity, developer)}.
The whole RDF graph does not distinguish between these two clusters of statements. Employee 46 is both endUser and developer: the knowledge of which activity he is implicated in inside of a project is lost.
DRDF(S) will enable to represent independent clusters of RDF statements through the *context* feature.

RDF Reification. The RDF model is provided with a reification mechanism. A statement (r, p, v) is reified into a resource s described by the four following properties: the subject property identifies the resource r, the

predicate property identifies the original property p, the object property identifies the property value v, the type property describes the type of s; all reified statements are instances of rdf:Statement. Figure 3 presents the reification of 'Observer-3002 says that the rating of Newsletter-425 is seminal'.
Figure 3: An example of RDF reification.

However, the reification of a set of statements requires the use of a container to refer to the collection of the resources reifying these statements. This leads to quite complicate graphs. Moreover a statement containing an anonymous resource can not always be reified: the values of the properties *subject* and *object* must have an identifier. The notion of context we introduce in DRDF(S) will enable to reify a set of statements much more easily.

Existential quantification. The RDF model focuses on the description of identified resources but allows a limited form of existential quantification through the anonymous resource feature. Let us consider the following RDF statements describing an anonymous resource:
Figure 4: An example of anonymous resource.

This existential quantification is handled by automatically generating an ID for the anonymous resource. However, such a handling of existential knowledge through constants is a limited solution and a graph containing a cycle with more than one anonymous resource can not be represented in RDF. DRDFS will enable to represent every existential, positive and conjunctive statement, without any restriction.

The roots of DRDF(S) stand in the correspondence between RDF(S) and the conceptual graph (CG) model (Sowa, 1999). The CG model provides a direct way of expressing independent pieces of knowledge through graphs. It thus enables the representation of contexts for various applications (quotations, viewpoint, ...). CGs are particularly useful as definitional contexts enabling the definition of concepts or axioms (Delteil *et al.*, 2001). An in-depth comparison of both models is studied in (Corby *et al.*, 2000).

Extending RDFS with contexts

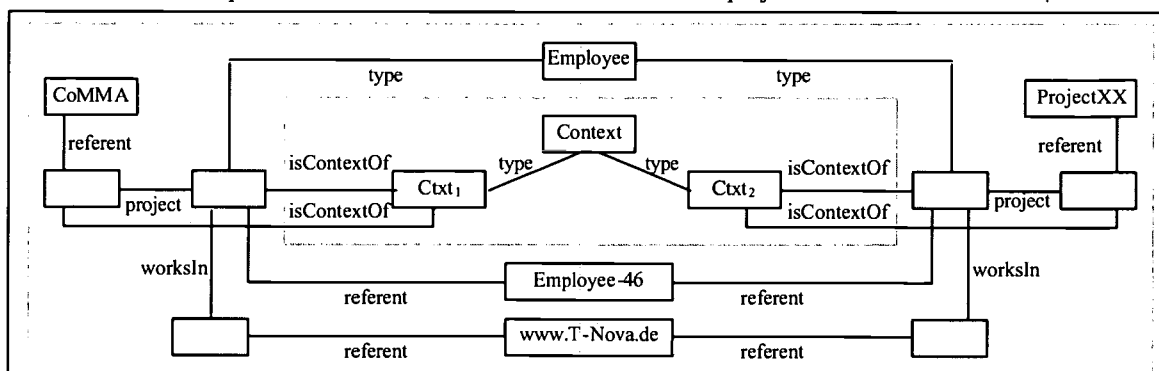
DRDF(S) is provided with a notion of context to express the clustering of statements much more easily than RDF reification. A context identifies a sub-graph of the whole RDF graph. Let us consider again the two projects of T-Nova which Employee-46 participates in. The statements relative to one project can now be clustered in a context and then separated from the statements relative to the other projects.


Figure 5: Two contexts about the same resource Employee-46.

The rules for extracting the set S of triples belonging to a context from the RDF graph are the following:

- Select a resource G of type Context; S ← {(G, type, Context)}.
- Select all the anonymous resources $c\emptyset_i$ for which the value of the *isContextOf* property is G; for each i, S ← S ∪ {(G, isContextOf, $c\emptyset_i$)}.
- Select all the identified resources r_j values of a *referent* property of a $c\emptyset_i$; S ← S ∪ {($c\emptyset_i$, referent, r_j)}.
- Select all the properties p_{ik} between two resources $c\emptyset_i$ and $c\emptyset_k$; S ← S ∪ {($c\emptyset_i$, p_{ik}, $c\emptyset_k$)}.

A context is defined from a resource G of type Context as the largest subgraph of the whole RDF graph whose all internal nodes excepted G are anonymous resources $c\emptyset_i$. A context is an abstraction that enables to talk about representations of resources (through anonymous resources) rather than directly about resources. For instance, in Figure 5, the resource Empoyee-46 is referred to by two distinct anonymous resources in two different contexts. Anonymous resources are "externally identified" by the *referent* property.

This general notion of context will appear of particular interest for expressing definitional contexts.

Extending RDFS with existential quantification and coreference

DRDF(S) is provided with a general mechanism for existential quantification handling. An existential quantification is represented by an anonymous resource described by a *referent* property whose value is an instance of *Variable*, a new RDF class we introduce. Figure 6 presents an RDF graph that could not be represented in the standard RDF. The cycle is resolved by two *referent* properties sharing the same value.
Figure 6: An example of existential quantification.

The scope of a variable is the context it belongs to, just like in FOL, where the scope of a variable is the formula it belongs to. We introduce a *parameter* property to link two resources of types *Variable* and *Context*.

Extending RDFS with class and property definitions

Extending RDFS with class definition

DRDF(S) class definition is descended from type definition in the CG model. A class definition is a monadic abstraction, i.e. a context whose one resource of type Variable is considered as formal parameter. To extend RDFS with class definitions, we introduce the following new RDF primitives:

'*DefinedClass*': A defined class is of type *DefinedClass*. *DefinedClass* is a subclass of *rdfs:Class*.

'*hasDefinition*': A defined class is linked by a *hasDefinition* property to its definitional context.

'*FormalParameter*': The variable linked to the definitional context by a *FormalParameter* property corresponds to the formal parameter of a monadic lambda abstraction.

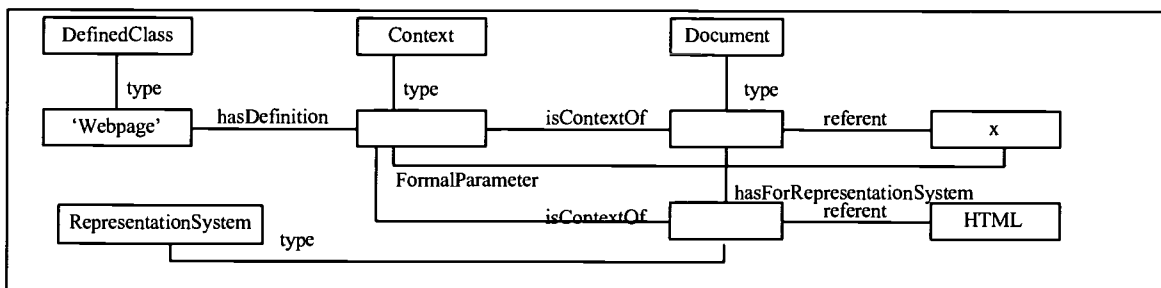
Figure 7 describes the definition of the 'WebPage' class as a document represented in HTML.


Figure 7: Definition of the 'WebPage' class.

Extending RDFS with property definition

DRDF(S) property definition is descended from type definition in the CG model. A property definition is a diadic abstraction, i.e. a context whose two resources of type Variable are considered as formal parameters. To extend RDFS with property definitions, we introduce the following new RDF primitives:
'*DefinedProperty*': A defined property is of type *DefinedProperty*. *DefinedProperty* is a subclass of *rdf:Property*.
'*FirstFormalParameter*' and '*SecondFormalParameter*': The variables linked to the definitional context by these properties correspond to the formal parameters of a diadic lambda abstraction.

Extending RDFS with axioms

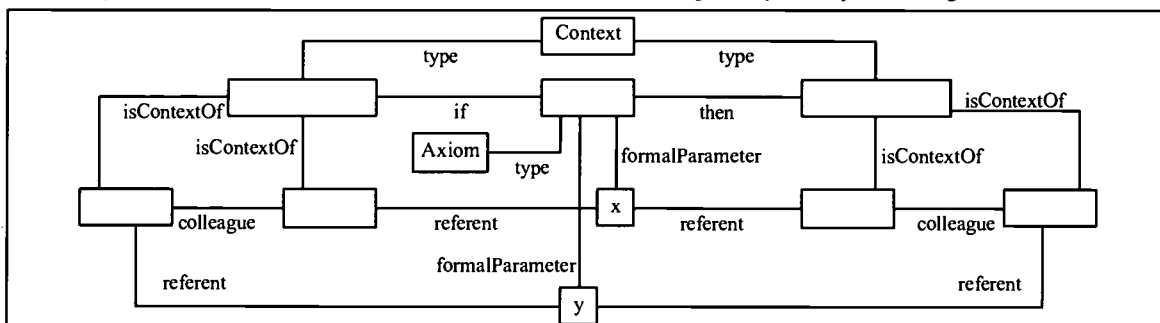
DRDF(S) axiom definition is descended from axiom definition in the CG model. An axiom is a couple of lambda abstractions, i.e. two contexts representing the hypothesis and the conclusion. To extend RDFS with axiom definitions, we introduce the following new RDF primitives:
'*Axiom*': An axiom is a resource of type *Axiom*. *Axiom* is a subclass of *Context*.
'*if*': An axiom is linked by an *if* property to the context defining its hypothesis.
'*then*': An axiom is linked by a *then* property to the context defining its conclusion.
The variables linked by a *FormalParameter* property to the resource of type *Axiom* correspond to the common formal parameters of the two lamb da abstractions.
Figure 8 describes the definition of the axiom "If x is colleague of y, then y is colleague of x".


Figure 8: Definition of an axiom.

The Defined Resource Description Framework Schema (DRDFS)

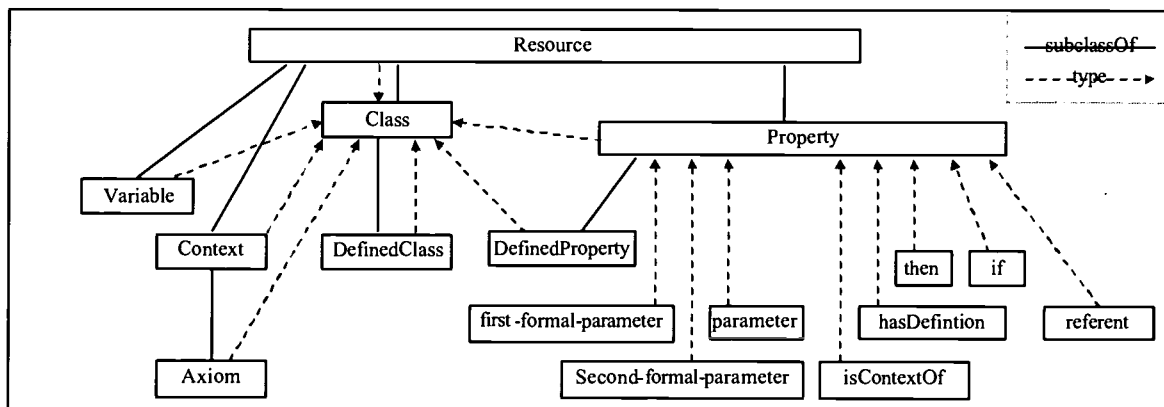
We call Defined Resource Description Framework Schema (DRDFS) the set of RDFS primitives augmented with the ones we introduced in the previous sections. DRDFS is an RDF Schema and remains compliant with the triple model. The metamodel of DRDFS is presented in Figure 10.


Figure 9: The DRDFS metamodel.

Conclusion

DRDF(S) is an extension of RDF(S) dedicated to ontology representation on the Semantic Web. It enables the representation of axioms, class and property definitions in ontologies. More generally, it provides a way to represent contextual knowledge on the Web. We hope that DRDF(S) will contribute to the ongoing work of the W3C committee for improving RDFS.

Since DRDF(S) is an RDF Schema, it is compliant with existing RDF parser. However, the semantics of the new introduced primitives can not be understood by them. A DRDF(S) interpreter is currently under implementation. It is based on the existing platform *CORESE*. In the framework of the CoMMA project, DRDF(S) will enable the representation of rich domain ontologies for intelligent information retrieval in the Intranet of companies.

Several languages for ontology representation and exchange are existing, among which *SHOE*, RDF(S) and *OIL* are dedicated to the Web (Corcho *et al.*, 2000). RDF(S) is the emerging standard proposed by the W3C. Like DRDF(S), OIL (Fensel *et al.*, 2000) is defined by an RDF Schema. Compared to OIL, DRDFS provides the Semantic Web with the notion of *context*: by enabling the representation of contextual knowledge, it is of special interest to identify the origin of an annotation on the Web; it also enables the representation of existential knowledge. Finally, it enables the representation of defining graphs for classes, properties and axioms through definitional contexts.

Abstract: As more information is made available online, users collect information in personal information spaces like bookmarks and emails. While most users feel that organizing these collections is crucial to improve access, studies have shown that this activity is time consuming and highly cognitive. Automatic classification has been used but by relying on the full text of the documents, they do not generate personalized classifications. Our approach is to give users the ability to annotate their documents as they first access them. This annotation tool is unobtrusive and welcome by most users who generally miss this facility when dealing with digital documents. Our experiments show that these annotations can be used to generate personalized classifications of annotated Web pages.

Introduction

Organizing Web pages collected in our bookmarks is a long and highly cognitive task. Most users would be happy to delegate this activity to an automatic classifier (Abrams 1998). User studies also show that the number of bookmarks grow linearly with time and that most users do not organize their bookmarks at creation time. Because they do not classify at creation time, they have to organize a large number of bookmarks and typically do not remember what was interesting in a particular page. Remembering what was interesting can also be impossible when the Web page has been modified or is not longer available, which is typical on the Web. One solution used in Vistabar is to index every Web page loaded in the browser (Marais & Bharat 1997, Li 1998). The other approach is to store a signature of each page which can help to retrieve the page from the Web when its URL has changed (Phelps & Wilensky 2000). But indexing or being able to retrieve the same page on a different location does not necessarily help the user to remember why this page has been saved as a bookmark. We believe that being able to annotate the document would certainly help users remember their activities around this document and thus help them classify it.

Even if marks can help users remember what was important in a document, there is still a need to help them automatically classify these documents. Automatic classification has been applied to cluster bookmarks (Maarek & Shaul 1996). The results do not show if these automatic classifications fit user expectations. We argue that since a Web page can contain several topics like home pages, listings and online news papers, using all the words to classify this Web page will probably lead to bad classifications because only a subset of this page might be of interest to the user.

In this paper, we use a Web annotation system to let users highlight and possibly annotate the Web pages they access. Annotating on paper is ubiquitous and some annotation systems like ThirdVoice, iMarkup and eQuill are now available to mark Web pages. In our experiences, we have used Yawas, a Web annotation system prototype that supports the creation of annotations in a fast and effective way using Dynamic HTML and the Document Object Model (Denoue & Vignollet 2000).

By annotating Web pages, users select words which can then be used to represent each document. This paper is organized as follows. In the first part, we present a pilot study which tries to understand the utility of annotations to help someone understand the topic of a document. In the second part, we present the results of applying an automatic classification algorithm to classify the documents, first using the traditional approach which indexes the full text of the documents, and secondly using only the annotated passages in each document to represent the documents. We show that representing the documents by their annotations provides more personalized classifications than when the documents are indexed with their full text.

Pilot Study: Manual Classification of Web Pages

Experimental Method

To gain an insight into the usefulness of annotations to classify Web pages, we asked two subjects to manually classify 333 annotated documents. Subjects were also asked to name the groups of documents. No time limit was imposed. The first subject is the author of the annotations, while the other subject was not familiar with the documents. Each subject had to complete two classifications. In the first setting, the original document was downloaded into a Web browser so the subject could see the complete page and manually classify it. In the second experiment, each document was represented by the list of annotated passages in this Web page.

Results

When accessing the original documents, the subjects took approximately 3 hours to classify the documents, and 2 hours and 30 minutes to classify them when using the annotations. This difference is primarily due to the time required to retrieve the documents from the Web and browse them. Subjects could not classify 10% of the documents because their URLs were broken. On the other hand, all documents have been classified when using the annotations.

For a given subject, the number of classes is not significantly different. However, the author of the annotations created 60 classes, while the other subject created 40 classes. This is not surprising since the author of the annotations is more apt at differentiating topic amongst the documents. For both subjects, the names created when considering the highlighted texts were more precise. For example, "conference" was used instead of the more appropriate "classification", and "home page" was used instead of "annotation". Using the annotations, subjects have then been able to generate more precise group names.

To test how annotations can help an automatic classifier to build a classification that better fits a particular user, we used the classification provided by the author of the annotations as a reference and compared it to the classifications produced by the second subject. The second subject misclassified 35 documents when using the full text of the documents, but only 5 when using the annotations to represent each document. This result suggests that an automatic classifier could also take advantage of the annotations to generate a personalized classification.

Moreover, we observed that most documents contained about 10 annotated words (after the indexing step). This further suggests that the annotations could be used to generate concise representations for documents, similar to the representations used by current search engines on the Web.

Second Study: Automatic Classification

Since the manual classification of the documents showed encouraging results, we conducted a second experiment using an automatic classification algorithm.

Classification Algorithm

Numerous algorithms are available to classify data and most of them can be applied to document classification. Each document is represented by a vector of features. Features are typically words, but other data could be used like the date of creation, the author, etc. Since most users tend to classify their documents by topics, we represented the documents by their words. Basically, two approaches can be used to classify a set of documents: supervised classification using machine learning techniques and unsupervised classification (also known as clustering).

Supervised classification requires a set of pre-classified documents where each document is associated to a predefined class. A machine learning algorithm like decision trees or Naïve Bayes is used to find a function which maps documents to their class (Mitchell 1997). This function is then used to predict the class of a new document. Classifying bookmarks with this approach would require users to pre-classify a subset of the bookmarks. Some authors have avoided this step by using the Yahoo! classification scheme where thousands of Web pages are already classified (Chen & Dumais 2000, Li 1998, Marais & Bharat 1997). In this experiment, we didn't use this approach since we wanted to discover a personalized classification. Yahoo! would have given us a more general classification which we believe is not necessarily adapted to every user.

On the other hand, unsupervised classification does not require a set of pre-classified documents. Documents are compared to each other and the algorithm tries to structure them. This structure depends on the nature of the algorithm. Some of them - like the single pass algorithm - produce a flat classification of the documents. Others like the hierarchical agglomerative clustering (HAC) induce a hierarchy of classes. Although flat classifications can further be split to create a hierarchy, we chose to use the HAC algorithm because it does not require a priori knowledge about the number of classes and does not require a threshold when comparing two documents (see (Rasmussen 1992) for details).

In the first step of the HAC algorithm, each document is put in one class. At each subsequent step, the two most similar classes are merged. The algorithm typically ends when there is just one class. There are 3 basic alternatives to compute the similarity between two classes, also known as "single link", "complete link" and "group average" described in (Rasmussen 1992). We implemented all of them in our experiment. Documents were indexed by removing common words from a stop list and by further applying the simple Porter stemming algorithm (Porter 1980).

Experimental Method

We used the 400 annotated documents used for the pilot study. We have implemented the 3 most common variants of the HAC algorithm "single link", "complete link" and "group average". We ran the classifier for each variant, first using the full text to represent the documents, and then using only the annotated words in each document. To compute the quality of the classifications, we compared each of them to the reference classification obtained from the author of the annotations using the quality measure used by Zamir and al. (Cutting et al. 1992):

$$Quality(C) = \sum_{g \in C} \sqrt{t(g)} - \sqrt{f(g)}$$

where $t(g)$ is the number of pairs of documents in one cluster which have also been classified together in the reference classification, and $f(g)$ is the number of pairs of documents in one cluster which have not been classified together in the reference classification.

The global quality sums the difference between $t(g)$ and $f(g)$ for every cluster in the current classification. In our experiment, each document has been indexed by removing common words from a stop list and by further applying a simple stemming algorithm (Porter 1980).

Results and Discussion

(Figure 1) shows that the quality is always better when using the annotations. The graphic show the quality of the classification at different merging steps as the HAC algorithm is running. At the first step, the quality is null since no documents are merged: the number of correctly classified documents is equal to the number of misclassified documents. Using the full text of the documents, the quality never goes far above zero, meaning that the classification is never useful for the user: the same number of documents is correctly of incorrectly classified.

On the other hand, the quality reaches a maximum above zero when the annotations are used, suggesting that at some point the classification becomes useful (more documents are correctly classified). Determining this point can be useful but this is not crucial since the HAC algorithm never modifies its previous merges as it runs, thus preserving the quality of the classification obtained at the previous steps. However, the classes become populated with noisy documents and it might be desirable to stop the HAC algorithm before. On our sample of 450 annotated documents, we found that this maximum was reached when there was only one word left to represent a class. In our implementation, each class is represented by the intersection of the words included in the documents of this class.

One typical problem with HAC algorithms is that they tend to produce a deep hierarchy, which is not desirable if users need to browse it. A maximum of 5 levels is usually recommended (Larson & Czerwinski 1998). One solution is to arbitrarily slice the hierarchy into 5 or more levels (Maarek & Shaul 1996), but it is not clear how this threshold fits all tasks and how valuable distinctions among documents is lost with this simplification. In our sample of annotated documents, the deepest level is about 4 in the classification when the curve reaches a maximum.
Figure 1: Quality of the classification at different steps of the HAC algorithm; Dashed lines represent results when the full text is used and solid lines represent results when the annotations are used; 3 variants of the HAC algorithm are shown in different gray scale for the full text and for the annotation.

Using the intersection of words contained in one class to name this class, we found that annotation-based classification generate better and more concise names, typically varying from 10 to only 1 word. This is consistent with our preliminary findings and in sharp contrast with the names obtained when the full text is used. In this later case, class names are useless and further filtering based on TFIDF would be required. To browse the hierarchy, users also need to see document representations. Since our pilot study suggested that annotation-based document representations were useful to understand the meaning of a document, we chose to use this representation in the classification as well.

Concluding Remarks

We believe that being able to annotate digital documents like Web pages can dramatically improve the user experience of accessing information online. Annotating is very natural on paper and few tools are currently supporting this activity for digital documents (see Xlibris in Schilit et al. 1999). But digital annotations have the potential to push the limits of their paper-based counterpart. Our experiments suggest that they can

support users in other activities like the classification of personal information. Using the same approach, annotations can also be used to improve information retrieval (Golovshinsky et al. 1999). Annotation tools will play an increasing role in personal information management systems by helping users to filter and organize vast amounts of information they collect in their personal spaces. Email and Web pages are current examples. More importantly, by annotating their documents, users build personal profiles which could be used to retrieve documents out of the personal space.

Abstract: Universities teach computing mainly in terms of computer science, software engineering and information systems, and, also, as computer engineering and networking, both at undergraduate and graduate levels. Teaching Web Development does not fit neatly into any of these categories. This paper outlines our experience in teaching Web development at the undergraduate level and then argues that this area, which we have called Web Engineering, is best taught at the master's level, for several reasons. The justification rests on factors such as the multidisciplinary nature of Web development, the strong influence of non-IT disciplines on it, the maturity levels of the developers themselves, and their awareness and understanding of legal and socio-economic factors affecting Web-based applications. The paper presents a brief outline of the master's course in Web Engineering that we have offered since 1999, reviews our experience and makes recommendations for curricula.

1. Introduction

Universities organise undergraduate and graduate courses in computing and Information Technology (IT) focussed on traditional disciplines such as Computer Science (CS), Software Engineering (SE), Information Systems (IS), Computer Engineering and Networking. Web site and applications development do not fit well within these boundaries and yet, given its multidisciplinary nature, impact and complexity, it is essential that Web development be treated in a serious, academic manner. Web development requires not just the technical skills but, more essentially, ability to understand and deal with its global impact and the additional responsibilities that must be discharged by the developers in social, ethical and legal terms.

We (at the School of Computing & IT, University of Western Sydney, Australia) have been teaching Web development to the undergraduate students since 1997 and the graduate students since 1999. Over the years, other institutions, academic and commercial, IT and non-IT, have developed various courses to teach parts of Web development. However, their focus very often is on imparting specific skills required for the current technologies and packages. They do not prepare students to face a whole gamut of issues, life-long learning or to discharge their social, legal, ethical and professional responsibilities. These areas require a level of maturity, ability and willingness to think through and beyond the boundaries of traditional disciplines.

Our experience and analysis of the Web environment and developmental activities have led us to the conclusion that Web development, which we have called Web Engineering (for reasons explained below and elsewhere), is best taught in all its complexity at the graduate level. This paper offers rationale for this conclusion and, in the process, outlines a curriculum that we have used at the master's level since 1999.

The paper is organised as follows. Section 2 describes the motivation for teaching Web development. Section 3 deals with traditional disciplines and why formulation of Web Engineering as a discipline makes sense. Section 4 describes our experience in teaching Web development at the undergraduate level. Section 5 explains the rationale behind the master's course, its nomenclature, aims and objectives, and structure. Section 6 reviews our experience in running the master's course. Section 7 concludes with recommendations.

2. Motivation for Teaching Web Development

308

It is a truism that what we teach our students has to be relevant to the world in which they will live and work. They also have to understand the world they have inherited, and learn to anticipate how it is changing, even as they shape parts of it for themselves. Our world is going through a very rapid change in the way people live, work and organise themselves. New technologies are being introduced in all spheres of life at such a rate that 'information explosion', 'information overload' and 'information management' have become terms of common usage and are seen as problems for all professions and professionals. Curriculum development and updating existing curricula, therefore, assume a high importance and are of concern not only to the students, parents and educationists but also to governments, business and industry, and professional bodies.

The World Wide Web, and all its associated developments, is a phenomenon that has confounded everyone. All disciplines and professions, and the general public, are trying to understand and explain it in their own ways. It seems only logical that universities take up the challenge of understanding its development and all the implications, both in terms of teaching and research. We started two undergraduate course units in 1997 to teach students Web site construction and Web-applications. These were and remain technically oriented.

However, there are now millions of Web sites and thousands of Web-based applications useful to a greater variety of people than ever before. In many cases, the development approach used for Web-based systems has been ad hoc, lacking in rigour and a systematic approach. As Web-based systems grow more complex, a failure in one system can and will propagate broad-based problems across many. Furthermore, the global reach of the Web imposes upon Web developers a much greater responsibility in social and professional terms. The Web developers cannot live in cocoons that have generally enveloped the IT professionals. It is not enough to have only or mainly technical virtuosity where Web development is concerned.

We became aware of the complex and multidimensional nature, both in IT and non-IT terms, of the Web through the work we started at what was the University of Western Sydney Macarthur in 1996 (Murugesan et al 1999,). We reached a conclusion that a new discipline had to be formed to encompass the true nature of Web development and called it Web Engineering (see below). The graduate course arose out of this experience.

3. Traditional Boundaries in Computing and IT and a Paradigm Shift

In the Information Technology (IT) arena, universities and training colleges typically develop their own niches to attract students from different demographics. Academics draw boundaries around disciplines such as CS, SE and IS and debate the validity of these boundaries and their natural habitat. There are also other, more hardware oriented disciplines such as Computer Engineering and Networking. Professional organisations such as the Association for Computing Machinery (ACM), the Institute for Electrical and Electronics Engineers Computer Society (IEEE-CS), the Association for Information Systems (AIS) and others reinforce the distinctions among these disciplines even as they have started to emphasise commonalities between them. Their recommendations for curricula over the years are evidence of all the forces at play in deciding the undergraduate and graduate curricula across the globe. For an excellent overview of these developments, see (CC2001, 2001).

The arrival of the World Wide Web and the explosion of activities around and based on it caused a stir and controversy (Pressman, 1998). For many computing professionals, the Web was only about presentation, justifiably. HTML was not even a programming language. The Web, therefore, was not to be taken too seriously. To the computer science purists, the Web was "just an application of distributed systems". To the software engineers, developing Web-based applications presented no shift in paradigm and software engineering methods and techniques were just as applicable and useful in the new environment. The Web and Web development were treated with benign neglect by these groups.

It was in this context that Web Engineering was first proposed as a new discipline (Murugesan et al, 1998, 1999, Deshpande et al, 1999, and 2001). By Web Engineering, we mean: use of sound scientific, engineering and management principles and disciplined and systematic approaches to the successful development, deployment and maintenance of high quality systems and applications. The basic tenet of the argument is that developing Web-based applications requires not only understanding of and skills from CS, SE and IS but also information architecture, navigational design, hypertext, graphic design, multimedia, document management, legal, social and ethical issues and diffusion of innovations. Developing Web sites and Web-based applications, thus, was different from and went beyond CS, SE and IS (Deshpande et al, 1999, 2001). We named this as Web Engineering,

The validity and relevance of the new discipline has been tested now over four years through one-day workshops at the World Wide Web conferences (1998-2001), two two-day workshops at the International

Conference on Software Engineering (1999-2000) (see online proceedings listed in among the references) and special tracks on Web Engineering at the Hawaii International Conference on System Sciences (2001 and 2002 to come). See also, Murugesan and Deshpande, 2001.

The paradigm shift brought about by the Web has to be adequately reflected in the academic courses. The next section describes our early efforts at the undergraduate level.

4. Teaching Web Development at the Undergraduate Level

The introduction of course units in Web development at the undergraduate development has been mentioned before. These are in the form of two subjects at second and third year undergraduate levels. The two subjects together take students from basic Web development to interactive site building, client and server-side scripting and building prototype e-commerce and other applications. The students are expected to be fully conversant with programming, database design and SQL. Both subjects are very popular.

Again, based on our experience in developing and running real-life Web applications, as also on analysis and constant feedback from IT and non-IT colleagues, we tried to incorporate the non-IT aspects of Web development that are absolutely vital for the success of any Web site and application. These deal with, in a very limited way, graphic design, usability, document management, legal, social and ethical responsibilities and others briefly mentioned before.

Not surprisingly, the undergraduate students thought of Web development mainly in technical, computing or programming terms. For them, the new technology itself was fascinating and the rest either irrelevant or a waste of time. Questions of copyright, privacy laws, accessibility, document management, maintenance or how to deal with information explosion were not seen as part of the overall Web development. We realised that there had to be a shift of focus to more mature, experienced students in order to rise above the merely technical, and also with an appeal to non-IT graduates that they could and had to contribute to Web development.

We also found that a majority of CS, SE and IS academics were not inclined to think in terms of incorporating Web development in their own areas. In any case, their appeal would have been to only IT students. The master's course in Web Engineering and Design was formulated out of this experience and based also on wide discussions with other IT and non-IT colleagues and professionals.

5. Master of Information Technology (MIT) in Web Engineering and Design

5.1 Rationale

Previous sections have outlined part of the rationale behind the master's coursse. In specific terms, back in 1998, the educational programmes did not cater to the wide-ranging issues raised by the nature of Web and related developmental activities, even at the Master's level. Many institutions had typically taken much more restricted programming-oriented or graphic design-oriented approaches when dealing with the Web or almost completely ignored the Web's influence and potential when dealing with IT/IS curricula, except in flexible delivery.

However, a thorough and systematic exploration of the topics/subjects and issues connected with Web-based systems, and mentioned above, is best carried out at a level which rises above the undergraduate level. The undergraduate courses typically concentrate on the technical competency and it is mainly at the master's level that students start to ask the difficult questions about what works in specific situations, what does not, why and what can be done about it. It is at that level, with a certain degree of maturity that they start to devise and systematically experiment with their own solutions.

5.2 Nomenclature

Given the line of argument above, the name for the course had to be specific to convey the. IT orientation but general enough to suggest to non-experts that there was possibly some difference between this course and those dealing with CS, SE and IS. IT is sufficiently generic to suit the purpose.

Similarly, although engineers contend, with reason, that engineering includes design, the general perception among non-engineers is that the design aspect is often overwhelmed by the standard engineering practices. "Web Engineering and Design" as the name for the specialisation overcomes this perception.

5.3 Aims and Objectives

The MIT in Web Engineering and Design course aims to produce graduates who are able to understand and deploy the rapidly developing and evolving Web Technology through sound scientific, engineering and management principles and disciplined and systematic approaches to the successful development, deployment and maintenance of high quality systems and applications. In the process, the students will learn to correlate these developments and practices to the needs of the global, social and political economy.

Specifically, this course aims to:

1. provide graduates with a critical appreciation of IT/IS methodologies, the Web technologies, innovation, and their roles within an organisation;

2. enable graduates to build Web-based applications using multimedia and hypermedia based upon sound methodologies in project management and people management;

3. impress upon graduates the links between their professional work and social, legal, ethical and professional issues through case studies and on-going analysis of current developments;

4. enable graduates to acquire skills and expertise in quantitative and other methods of performance analysis, capacity planning;

5. cover new developments in intranets, extranets and Internet;

6. build up graduates' expertise in quality and security management;

7. provide a global business and IT perspective to the graduates;

5.4 Course Structure

The course comprises 8-units (subjects) delivered over two semesters. It consists of four core subjects, a 2-semester IT project and two electives.

The main eligibility criteria for admission are a 3-year degree course, preferably in Computer Science or Business Computing or equivalent. However, In keeping with the philosophy behind the programme, and especially that of Web Engineering and Design, students showing considerable potential for successful completion without full, prior qualifications in computing are also eligible provided they complete a one-year graduate diploma in IT. Figure 1 presents the course structure. A short description of the subjects follows.

Semester 1			
Web Technology	IT for Virtual Organisations	Project Management	Elective
Semester 2			
Web Site management and Security	Web-based Application Development	Project	Elective

Figure 1: MIT in Web Engineering and Design – Course Structure

Web Technology is the foundation of Web Engineering and Design. The subject focuses on Web page design and authoring tools, HTML, individual site development and management, database connectivity and ODBC, authoring and legal issues, and browser side scripting. It also includes the design, development and implementations of server-side applications, the use of multi-media, the principles of intranets and extranets, security, and access rights.

IT for Virtual Organisations challenges students to think outside the current practices and boundaries and prepare for the now already almost-cliched 'virtual' organisations, technologically and in other ways.

Web-based Application Development covers new technologies associated with the Web, such as XML, ASP, JSP and others and analyses the technological, organisational and other important factors behind their successful adoption. It examines the current methodologies and their appropriateness for the Web, the trends in

311

End-User Computing and user interfaces and how organisations may cope with complex demands of information management including the issues of security, privacy and copyright.

Web Site Management and Security introduces students to the management aspects of the running and the implementation of Web services in an organisation. It includes the development of a working knowledge of current legal, copyright, privacy and intellectual property rights issues with the corresponding obligations and responsibilities; the implementation of network/server and data communication security along with the respective policy generation and management; the integration with an organisation's information systems; a working knowledge of standards and certification bodies; a working knowledge of current e-commerce financial and ethical issues; and an operational view of web development and development team requirements.

IT Project is a 2-semester long project wherein students pursue specific topics and their own interests related to Web development and in the process not only develop an application but also learn project management, communication skills and aspects of innovation

6. Review of the Course

The course has now run for more than two and a half years with two intakes per year. The experience of starting a new course, with its different emphasis from other courses, and seeing it grow has been gratifying, baffling and sobering, all at the same time. Here, we briefly report on five main areas of experience.

6.1 Growth

The first intake for the new course was about 15, in the first (southern hemisphere) Spring semester of 1999, starting in March. Since then the demand and the quality of applicants have both gone up. In the Autumn 2001 semester intake, 60 new students enrolled in the course. Now that the dot com crash has created headlines, it is a moot point if this growth will continue in the short term. It is also uncertain if this popularity is because of the specific nature of the course or due to the high demand for IT courses overall. This ambiguity is further heightened by the following observations.

6.2 Predominance of non-IT Students

Most of the students for Web Engineering and Design have come from non-IT background. Students with computer science or information systems tend to gravitate to the familiar and standard offerings. Again, it is debatable whether this is symptomatic of narrow specialisms engendered by IT with its emphasis on technical and technological know how or the lack of perceived need for Web Engineering and Design, since there are no comparable courses to our knowledge.

6.3 Levels of Maturity

In proposing the course, we had argued that the study of Web Engineering required certain maturity and technical nous. The course had to be at the graduate level and would appeal to the non-IT graduates as well, especially since it acknowledged and tried to build upon the contributions from other disciplines. There were indeed some outstanding successes among the non-IT students, especially among those who understood what the course aimed at and worked on those aspects. A large proportion, however, seemed to be satisfied by, and wanted, only well-defined, technical details and problems.

6.4 Narrowly Focussed Training vs Liberal Education

A large percentage of students wanted, and argued for, training in specific technologies, Oracle 8i or ColdFusion or DreamWeaver or multimedia or Java and so on. This narrow, technological fixation, if it is a wider phenomenon, will need to be tackled on a much wider front.

6.5 Motivation

In any endeavour, motivation is a big factor behind success. The students' motivation levels, as always, varied significantly. As implied in the observations above, there were many who were simply driven by the 'market forces'. However, there were others who have gone on to lead Web development at a higher level, more quickly. Their feedback to us about Web Engineering has been gratifying.

7. Recommendations and Conclusions

This paper has reported on our experience in teaching Web development at the University of Western Sydney. This has been an innovative and in many ways pioneering experience. Other universities also teach Web development but generally in terms of programming, client-server computing, Web design, e-commerce and internetworking. Some have also started, or plan to start, teaching Web Engineering. Although the Web is world wide, the experiences, expectations and performance of people involved in teaching and learning Web development are bound to be have significant variations.

We started the master's course in Web Engineering and Design by learning from experience and by reasoning out that Web development can be taught at the undergraduate level only on a limited scale and that it is best pitched at more mature and experienced developers at graduate level. Our experience over the last two and a half years seems to bear that out, but is inconclusive, especially in the context of a volatile environment.

Web Engineering is a forward looking, evolving discipline and like the discipline itself, its practitioners have to be broad-based and future oriented. The Web engineers need broader perspective and maturity of outlook to avoid the pitfalls of narrow specialisations, hype, and confusion of new technologies. They have to acknowledge that Web development is multidisciplinary and respect the contributions other disciplines and people can make to any Web project. They need the humility to admit their own limitations and develop abilities to work in a really multidisciplinary team where the work or the project takes precedence and individual egos and preconceptions have to be subsumed. These are the challenges that good curricula have to address to do justice to the potential of the Web.

Maintaining Semantic Constraints in Web Sites

Thierry Despeyroux
Inria, France
thierry.despeyroux@inria.fr

Brigitte Trousse
Inria, France
brigitte.trousse@inria.fr

Abstract: Many tools already exist to help in creating Web sites, but there are more concerned by the external appearance of the sites than by their content. How can we help in designing and maintaining semantically coherent sites ? Using software engineering technics, and more exactly *Natural Semantics*, a framework coming from the world of the semantics of programming languages, we propose a way of specifying and verifying the semantics of a Web site during its life time.

Introduction

As Web sites tend to become ordinary products, it is necessary to better explicit the notion of quality of a Web site. Most of the time, Web sites are updated very frequently by many authors and in this context, proof-reading is a real challenge. The quality of a site may be linked to the easiness of accessibility and also to other criteria such as the fact that the site is coherent or up to date.

Many efforts aim to facilitate data representation and data mining. This is done most of the time by a syntactic formalisation of knowledge or information using languages such as XML or RDF. We claim that this is not sufficient and that we need to provide a way of specifying semantic (i.e. global) constraints over Web sites to be able to mechanically perform some verifications and proof-reading during the life time of the site.

After presenting some examples of semantic constraints in Web sites, we present the main ideas of *Natural Semantics*, a framework used to specify the semantics of programming languages, and some experiments done with it to specify and verify different Web sites.

The Meaningful Content of a Web Site

Nowadays, tools dealing with Web sites (that we define simply as a set of pages) are mainly concerned by the appearance of the pages, their physical location on a file system and some structural problems such as dangling links. Two ideas are now broadly accepted to better take into account the content of Web sites:

- The first idea is to separate the content of a site from its presentation. This leads mainly to XML, XSL and related formalisms such as XML Schema (W3C, 2001). The objective here is to choose a syntax that suits not only the structure, but also the semantics of the information that is presented by means of syntactic tags and DTDs. This technique corresponds to the notion of abstract syntax in the world of programming languages.

- The second idea is to annotate the content of the pages, most of the time devoted to human consumption, by a more computer-oriented form. This may be done by using meta-tags or RDF annotations (W3C, 2001), or can be disseminated in the text (van Harmelen and van der Meer, 1999; van Harmelen and Fensel, 1999). Using shared ontologies is, at this stage, a reasonable option (Fensel et al., 1998; Berners-Lee, 1998).

However, this is not because a document is well-formed (i.e. respecting a particular DTD) or correctly annotated that it is semantically correct. It is of course impossible to guarantee that the content of a page or of a site reflects the exact idea of its creators. But it should be possible to check, using a large set of tools involving text analysis, picture analysis, thesaurus, etc. that the content of the site is coherent, that the annotations are coherent, that the annotations and the contents are coherent. These constraints are no more syntactic but semantic. By describing such constraints, we want not only to be able to specify constraints, but also to generate the appropriate tools to mechanically verify that these constraints are fulfilled and to provide error messages or warning when it is necessary.

Semantic Constraints in Web Sites

In everyday language, there is an unprecise barrier between meaning, knowledge and semantics. In software engineering, semantics of programming languages may be strongly defined, with a distinction between the static semantics (the rules that a program must respect to be legal) and the dynamic semantics (formalising what happens when a program is executed). For a Web site, we can also try to define static semantics (rules that must be checked before publishing), and dynamic semantics (formalising what happens when a user navigate inside a site).

Static semantics really exist for natural languages: in the literature, we can imagine that the names of the characters appearing in a play must be defined in a global list of characters in the same way that the objects used in a program must be declared. The same feature exists in institutional Web sites in which we can think of the organisation chart (people, departments, etc.) as a declarative part against which some other informative parts must be checked. The three following sections illustrate this point.

Coherence in an Academic Site

Our first example is taken from the official Web site of Inria (http://www.inria.fr) as it was in July 2000. Research at Inria is organised in so called *research projects* (i.e. teams) that are classified by thematic areas (called *themes*). At this point, it is important to know that the organisation of research at Inria is dynamic: new teams are created, others are split or disappear rather frequently.

Figure 1 is a part of a Web page (translated here in english) presented as the official list of research projets at Inria in July 2000. We can see only a small part of this page that contains two columns: the first one contains a list of team names, and the second some brief descriptions of the research activities performed in the corresponding team.

THEME 1 : Networks and Systems

Programm 1A : Parallelism and Architecture

A3 (1) :	Advanced Analysis and Code Optimization
APACHE(2) :	Parallel Algorithms and Load Balancing
CAPS (3) :	Compilers, Parallel Architectures and System
COSI (3) :	Codesign of Silicon Systems
ReMaP (4) :	Regularity and Massive Parallelism
TROPICS :	Program Transformations for Scientific Comp

Programm 1B : Networks, Systems, Performance Evaluation

ARMOR (5)	Networks Architectures and Modeling
HIPERCOM	High Performance Communication
MASCOTTE (6)	Algorithms, Simulation, Combinatorics and OpTimization for TElecommunications
MEVAL	Modelling and Performance Evaluation of Con Systems
MISTRAL	Modelling in Parallel Systems and Communica Networks
PARIS (3)	Programming pArallel and distRibuted system scale numerical sImulation applicationS
RESEDAS (7)	Software Environments and Tools for Telecommunication and Distributed Systems

Figure 1: Official list of research projects in July 2000

Figure 2 is taken from a page devoted to the first thematic area and is older than the previous one. As we can see, the list of names is not the same as the one in the previous figure. Differences have been emphasised using a little bullet in front of the team name as the result of an experimental mechanical process. The names SLOOP and REFLECS, that appear on the second page, do not appear in the first one. This is because the activities of these two research teams have been reorganised. Most of researchers of the ex-SLOOP team belong to the newly created MASCOTTE one. The spelling of the name MEVAL is not uniform.

About other research themes

● Theme 2:
Software Engineering and Symbolic Computing

● Theme 3:
Human–Computer Interaction, Image Processing, Data Management, Knowledge Systems

● Theme 4:
Simulation and Optimization of Complex Systems

About development activities

● Development initiatives

Theme 1A: Parallelism and Architecture
A3 – Advanced Analysis and Code Optimization
APACHE – Parallel Algorithms and Load Balancing
CAPS – Compilers, Parallel Architectures and Systems
COSI – Codesign of Silicon Systems
ReMaP – Regularity and Massive Parallelism
●SLOOP – Simulation, Object Oriented Languages and Parallelism
TROPICS – Program Transformations for Scientific Computing

Theme 1B: Networks, Systems, Performance Evaluation
ARMOR – Networks Architectures and Modeling
HIPERCOM – High Performance Communication
MASCOTTE – Algorithms, Simulation, Combinatorics and OpTimization for TElecommunications
●MÉVAL – Modelling and Performance Evaluation of Computer Systems
MISTRAL – Modelling in Parallel Systems and Communication Networks
PARIS – Programming pArallel and distRibuted systems for large scale numerical sImulation applicationSs
●REFLECS – Distributed Real–time Fault–Tolerant Computing Systems

Figure 2: Presentation of the first thematic area

As we can see with this example, the parallel with programming languages is easy. The first page (figure 1) can be considered as truthful and used as a declarative part to check the names that are used in the second page.

A Thematic Directory

Our second example concerns a thematic directory as it can be found in an internet guide: knowledge is classified using categories and subcategories. This tree structure can be presented in a single page or spread on many pages. In any case, an XML DTD can specify a syntactic structure in which categories and subcategories will fit.

But there is also a semantic relation between these categories: a subcategory must make sense in the context of its mother category, maybe by reference to a particular thesaurus. For example it seems reasonable to have air as a subcategory of travel, when chocolate is not. This cannot be specify by a DTD, but this constraint is in fact the one that gives sense to the global construction. In the same way, the content of a page that is referenced by a directory must fit the selected category. This means that, for example, a certain number of keywords in some metadata are related to the category or that, by text analysis, the document seems relevant in that category. This property is context-dependent: the same word may have very different meanings in the context of different upper categories. For example a slug in the context of animals does not have the same meaning that a slug in the context of arms manufacturing.

If it seems feasible to proof-check a thematic directory, it is quite difficult to maintain such a site. For some reasons, maybe by analysing the behaviour of users, one may have to modify not the syntactic structure, but the classification itself. If the semantics constraints have been formalised, a mechanical support should be possible.

Hypermedia and Annotated Documents

Semantic constraints are not limited to textual information. When information about a document exists (an RDF annotation for example), one may want to verify that this is coherent with the document itself. By comparing captions with some annotations on images, or by using some image recognition

programs, many errors can be detected. In the same way we may also verify constraints on video or audio material. Note that, unlike in the domain of programming languages or in mathematics, proofs can not be completely formal.

Specifying and Verifying Semantic Constraints

As we can see, semantic constraints are very often global constraints (implying many pages and annotations), may use external resources (thesauri, ontologies, databases), and may use complex software (image recognition).

That is not the case for syntactic constraints that involve (for example in DTD) only local constraints (between a tag and its father). Moreover, semantic constraints concern the values of some parts of the documents, not only its literal representation neither its structure. To follow the parallel with programming languages, we can say that the authors of a Web site have not only to define the syntax they want to use (as a set of syntactic tags by means of a DTD), but also its semantics.

Some works take global constraints into account: WebMaster (van Harmelen and van der Meer, 1999; van Harmelen and Fensel, 1999), or works using attribute grammars (Psaila and Crespi-Reghizzi, 1999) for example. There are also specific programming languages to manipulate XML documents (Hosoya and Pierce, 2000; Meijer and Shields, 1999). We chosed to explore the *Natural Semantics* framework (Kahn, 1987) that is presented in the next section to specify and evaluate global constaints.

In our view, there is no fundamental difference between a Web site and a program. Proof-reading a Web site can be assimilated to program checking and it seems reasonable to investigate how works done in the software engineering area to prove and compile programs can be applied to the Web. The main difference is found in the data that are manipulated. When manipulating integers one can invoke some formal representation of the mathematical natural numbers. When we have to manipulate words or images, the underlying basement is more weakly defined.

Natural Semantics

Natural Semantics (Kahn, 1987) has been developed to specify the semantics of programming languages and to allow mechanical generation of compilers. It has two main goals: providing an executable semantic specification (Despeyroux, 1987) and allowing proofs. Its name comes from the fact that it is inspired by the Gentzen's sequents (Szabo, 1969) and the natural deduction style.

Natural Semantics manipulates an environment (a set of assertions, the hypothesis) and a set of inference rules or axioms that explain how to deduce some properties (known as consequents) using the hypothesis, mostly in a structural way.

The following two rules illustrate the example given in the previous section.

$$\frac{Name \in TeamList}{TeamList \vdash \texttt{<project>}Name\texttt{</project>}}$$

In this rule, we used some concrete syntax for the XML part. *Name* and *TeamList* must be understood as logical variables, not textual values. The tag project gives a syntactic type to the variable *Name*. The rule may be paraphrased as "if *Name* appears in the *TeamList*, then the text <project>*Name*</project> is correct in the environment *TeamList*". A more operational reading can be "Given a *TeamList*, the piece of text <project>*Name*</project> is correct if *Name* appears in the *TeamList*".

$$\frac{\text{makesense}(Name, CurCat) \qquad CurCat \cdot Name \vdash SubTree}{CurCat \vdash \texttt{<subcat><catname>}Name\texttt{</catname>}SubTree\texttt{</subcat>}}$$

This rule makes a call to an external predicate, **makesense**, to specify the semantic constraint between subcategories. It is not mandatory to specify everything by means of inference rules: an existing program can be used to manipulate a thesaurus for example.

A complete specification may manipulate many arguments, and must explain how one will construct the environment, not only how one will use it. In the context of Web site verification, one may distinguish

two main parts in this environment. The first one is information collected from the top (root) of the page to the current location (upper tags, arguments value etc.) and this functionality is very close to what is possible with XSL. A second part may contain information collected (or computed) not only in the current page, but also in the rest of the site. It can also contain references to external resources.

The specification is compiled into Prolog code to be executed. During this generation of Prolog code, new arguments are generated to be able to provide error messages and warnings.

Experiments

We have validated the *Natural Semantics* approach presented in this paper (Cherfi, 1999; Rai, 2000; Rineau, 2000; Despeyroux and Trousse, 2000) using the Centaur system (Jacobs and Rideau-Gallot, 1992) and Typol, the specification formalism that implements *Natural Semantics*. The initial goal of the Centaur system was to generate programming environments from programming language specifications: it has been used to study the semantics of many languages such as Fortran and Java or to generate environments for them. As we have already seen, there is not many differences between a programming language and any other formal language. As *Natural Semantics* manipulate abstract syntax trees (let's say typed terms) and logical variables, one will easily understand that the implementation language choice for Typol has been the language Prolog.

To relax some constraints due to the Centaur system, we have also made experiments using directly a Prolog system connected to a SAX XML parser. We made experiments both with XML documents and HTML (XHTML) documents in which the syntactic tags do not have any semantic meaning.

These experiments are positive, showing four main differences between the world of programming languages and the world of the Web that must be taken into account in future developments:

- Dissemination of information: in a Web site the information is much more disseminated over pages that it is the case in a program. In particular, cross-references are very frequent and declarations (facts) can be spread over many pages. A linear process of verification is not possible and this lead to specific incremental verification problems as we have to manipulate a great number of pages, taking into account that a Web site may evolve very rapidly.

- Use of external resources: the complete specification of a programming language can be done using Natural Semantics and Typol. This is not the case when dealing with the Web as we will need to use external resources and programs that must be easily combined with the formal rules.

- Use of heterogeneous objects: we need not only to manipulate Web pages, but also metadata (instances or schemas), images etc.

- Role of authors: a programmer needs to understand the semantics of the programming language that he or she is using. That does not imply that he is able to specify such semantics: this is the job of the programming language creator. In the world of the Web, the authors and webmasters are directly concerned by the meaning of their documents and by their semantic constraints. This means that the specification language must be easily accessible.

We have also to take into account the three following features that seem important in the context of Web sites specification:

- We need only to specify what are the points of interest. Using an inference system as *Natural Semantics*, we need at least to give one (recursive) rule for each tag; this should be a default rule. On the other hand, when several constraints are attached to the same tag, we would prefer to give several rules, not having to combine them in a big unique one.

- The environment (i.e. the set of assumption that can be used at a certain point) may be split into a local context (local to a page) and a global set of assertions. This feature can be used to perform an incremental verification of a large set of pages.

- The Constraints may be global to a site or limited to certain set of pages. It should also be possible to have some rules or constraints directly in the document itself and to group them according to multiple points of view, performing some partial checking.

Conclusion

Checking semantic constraints is crucial in designing and maintaining Web sites and thus in improving their overall quality. Our *Natural Semantics* approach was successfully applied to hypertext and semi-structured documents as Web sites (i.e. sets of XML or XHTML documents). It could also be applied to help in maintaining metadata, in particular RDF descriptions (that are also XML documents), and to verify the coherence between these metadata and the related documents. Future directions concern the design of a userfriendly specification language and its associated environment devoted to the specification of semantic constraints in Web documents taking into account the remarks listed in the previous section.

Abstract: The Web is huge, unstructured and diverse in quality, which makes searching for information difficult. In practice, few of the documents returned by a search engine are valuable to a user. Which documents are valuable depends on the *context* of the query. Some adequate context information provided in addition to keywords can improve significantly search precision. In this paper we propose a framework for dynamic conceptual clustering of web documents based on clusters of users that share common interests. The basic assumption is that the search results would be more relevant to a user when provided within the context of semantically related documents marked as 'interesting' by a sufficiently large group of users with similar interests. This framework can support personalization of a search based on a search engine that 'knows' the context of the user information needs and uses it to tailor the search results.

1 Introduction

The Web is huge and ubiquitous, unstructured, diverse in quality, dynamic and distributed, which makes searching for information principally difficult. General-purpose search engines that use keyword matching are notorious for returning too many matches of little relevance or quality in response to user queries. For example, if you submit the keyword "centroid" to Google almost 60,000 documents will be found. Which documents will be valuable to the user depends on the *context* of the query. The context depends on a number of factors, such as information related to the current request, user's interests, background, education, present professional activities, hobbies, travel and entertainment habits, etc. Search engines, however, treat each request independently from previous requests of the same user and of other web users making similar requests. Therefore the ranked list of documents received in response to the same queries is typically the same and depends neither on the user nor on the context in which the query is made. Some adequate context information provided in addition to keywords can significantly improve the search results. The question is *what type of context information is practical, how to infer that context information* and *how to use it* for improving search results?

Web users typically search for diverse information. Some searches are sporadic and irregular while others might be related to their interests and have more or less regular nature. An important question is then how to filter out these sporadic, irregular searches and how to combine regular searches into groups identifying topics of interest by observing the user behavior on the web. The fact that a user makes an isolated search for the size of Mars when solving a puzzle does not apparently indicate for any pattern of behavior while regular searches for papers on "Contextual reasoning" are more stable because they identify the user's current interests. Since the causal relations between the user's interests and actions for resource discovery are more stable, the latter are more predictive of user's future behavior. If we are able to identify *topics of interest* for a given user we can infer relevant contextual information associated with that user. Such contextual information when available to search engines could support personalized searches. Our approach to topic identification on the web is based on observations of the searching behavior of large groups of users. The intuition is that a topic of interest can be determined by identifying a collection of web documents that is of common interest to a sufficiently large group of web users.

In the present paper we present a resource discovery framework based on a contextual topology. A problematic point in the original web architecture is that there is no explicit conceptual partitioning of the web

information space. Present web communication assumes mainly *passive information* vs. *active users*. The framework we propose suggests dynamic conceptual partitioning of a portion of web information space into meaningful and more straightforwardly manageable units of information. Such partitioning of the information space would reflect the presence of groups of users that share common interests and possibly some common patterns of behavior. So, it assumes a parallel partitioning of users into groups corresponding to the overlapping objects of interest for each user group. Thus a partitioning of the *user space* into groups of users generates corresponding partitioning of the web *information space* into matching groups of documents. From these user groups we could derive the individual interests of their members to model a context of user's information needs. The partitioning of both spaces is viewed as dynamic and automatic clustering of web documents and users. Since the clustering of documents is based on overlapping interests shared by a sufficiently large group of users, we can assume that such a partitioning reflects the opinion conveyed to the information space by a typical member of each group.

2 Our Approach

Keyword queries cannot naturally locate resources relevant to a specific topic. Keywords perform poorly especially in situations in which the search index covers multiple subject areas, as is the case with "Internet" where Google returns 75,000,000 web pages. A promising technique is to guess the context of the user queries. Situations where a search is limited within a group of web documents (a topic) collectively selected by a user and his peers as 'appropriate' illustrate a *context* that is relevant to the current user's information needs. This type of context is also retrospective, because it reflects a portion of the history of the user requests. The fact that all users in a given group like a certain collection of articles is more stable and therefore more predictive than the fact that a particular user likes a given article. We can predict which articles would be of interest to a user based on the articles interesting to the other members of his group. One of the benefits of an explicit representation of a context is that it would enable us to localize the search within a relevant domain and thus to improve the search quality.

Typical search engines can be viewed as 'one size fits all' - all users receive the same responses for the same queries. This model is not always efficient. For example, when searching the web it is not always clear from a request such as "George Harrison" whether the user is looking for the famous "Beatle" or for the owner of the "Menswear of Quality" company. The ambiguity is due to the fact that the context of the search is not generally derivable from the request especially when each request is taken independently from other requests made by the same user. The major questions are: what type of context information is valuable and practical at the same time, how to infer the context information, and how to use this information for improving the search results? The framework for modeling context of user information needs suggested in this paper is based on the observations of documents being viewed (indicated as interesting) by web users. For a given group of users we refer to the collection of documents that are of common interest to all users of that group as a *matching group of documents*. Assume now that on the web there are user groups, from one side, and matching groups of web documents, from another. Then each user searching for information can perceive the web as a personalized list of search results ranked according to the current users' interests. Such a view is inherently *dynamic* as new documents arrive continually and the user groups are dynamic themselves. By synthesizing a conceptual context structure on the web specific to the interests of user groups, this framework provides a ground for a context-based resource discovery. For example, a contextual approach can support personalization of search based on a search engine that knows the contexts of user's information needs and uses that information to tailor the search results. Thus, a request for "George Harrison" may rank links to the owner of "Menswear of Quality" higher than links to the famous pop star for a user interested in stylish dressing.

Our method for topic identification on the web is based on observations of the searching behavior of large groups of web users rather than of a single user. The basic intuition is that a topic of interest can be determined by identifying a collection of web documents (articles, objects) that is of common interest to a sufficiently large group of web users. The assumption is that if a sufficient number of users $u_1, u_2, ..., u_m$ driven by their interest are searching independently for a collection of documents $a_1, a_2, ..., a_m$, then this is an evidence that there is a topic of interest shared by all users $u_1, u_2, ..., u_m$. The collection of documents $a_1, a_2, ..., a_m$ characterizes the topic of interest associated with that group of users. While the observation on a single user u who demonstrates interest in objects $a_1, a_2, ..., a_m$ is not entirely reliable judgment, the identification of a group of users along with a collection of documents satisfying the relation *interested_in(u_i, a_j)* is a more reliable and accurate indicator of an existing topic of interest.

In our approach contexts provide support in two aspects: *personalization* and *community formation*. Personalization refers to both individuals and groups and is based on automatic identification of communities with clustered topical interests. In contrast to directory services such as Yahoo where the web pages are assigned to categories manually, in the suggested framework the notion of context is viewed as a *self-organized* and *dynamic* structure. Self-organization means that the process of identification of existing groups of users and matching groups of documents is based on mining the users web experience for relevant data. Thus contexts are driven by inner dynamics, reflecting the fact that both user groups and matching groups of documents can grow and shrink over the time.

In a practical perspective the proposed approach for identifying a topic of interest is particularly appropriate for *specialized* search engines. First, specialized search engines are focused on finding information within specified fields, for example, Cora (http://cora.whizbang.com) is a search engine for computer science research papers. As a result the number of users of specialized search engines is considerably smaller compared to the number of users of general-purpose search engines. Second, specialized search engines use some advanced strategies to retrieve documents. Hence the result list provides typically a good indication of the document content. Therefore, when a user clicks on one of the documents the chances to get relevant information are generally high.

The question is: *how to gather realistic document usability information over some portion of the Web?* One of the most popular ways to get Web usability data is to examine the logs that are saved on servers. A server generates an entry in the log file each time it receives a request from a client. The kinds of data that it logs are: the IP address of the requester; the date and time of the request; the name of the file being requested; and the result of the request Thus by using log files it is possible to capture rich information on visiting activities, such as who the visitors are and what they are specifically interested in and use it for user-oriented clustering in information retrieval.

The following assumptions provide a ground for the proposed framework. We assume that all users are reliably identifiable across multiple visits to a (search engine) site. We assume further that if a user clicks (saves/selects) a document it is likely that the document is relevant to the query or to the user's current information needs. Another assumption is that all relevant data of user logs are available and that from the large set of user logs we can extract a set of relations of the type: (user_id, selected_document). The next step is to derive from the extracted set of relations meaningful collections of documents based on overlapping user interests, that is, to cluster the extracted data set into groups of users with matching groups of documents.

3 A Formal Perspective

Given a set of users U, a set of articles (documents) A and a binary relation uFa (user u is interested in article a) determine a pair of subsets $U_I \in Pow(U)$ and $A_J \in Pow(A)$ such that

$$U_I = \{u \in U / (\forall a \in A_J) \, uFa\}, \quad A_J = \{a \in A / (\forall u \in U_I) \, uFa\}$$

That is, a topic of interest (U_I, A_J) is defined by a binary relation uFa (*interested_in(u,a)*) and is characterized by the set of all articles A_J that are common objects of interest to all users in U_I.

From a formal point of view, the suggested contextual structure on the web can be interpreted as a binary relation between a set of users (U) and a set of articles (A), called *context*. Thus a context is a triple (U,A,F), where $F \subseteq U \times A$. Based on an analogy with formal concept analysis (FCA) (Carpineto & Romano 96; Wille 82), a topic of the context (U,A,F) can be defined to be a pair (U_I, A_J) where $U_I \subseteq U$, $A_J \subseteq A$ and,

$$U_I = \{u \in U / (\forall a \in A_J) \, uFa\}, \quad A_J = \{a \in A / (\forall u \in U_I) \, uFa\}$$

that is U_I is the set of all users interesting in all articles in A_J and A_J is the set of all articles that are common objects of interest to users in U_I. Exploiting further the analogy with FCA, A and U can be interpreted also as a set of *objects* and a set of *descriptors* correspondingly. Then A_J is the set of all objects possessing all the descriptors in U_I and conversely U_I is the set of descriptors held by all objects in A_J. We may think of the set of articles A_u associated with a given user $u \in U$ as represented by a bit vector. Each bit i corresponds to a possible article $a_i \in A$ and is on or off depending on whether the user u is interested in article a_i. The advantage of this interpretation is that now we can characterize the binary relation between the set of users and the set of articles in terms of *topic lattice*. Let us denote the set of all topics of the context (U,A,F) by $T(U,A,F)$. An ordering relation is easily defined on this set of topics by

$$(U_1, A_1) \leq (U_2, A_2) \leftrightarrow U_1 \subseteq U_2 \quad \text{or} \quad (U_1, A_1) \leq (U_2, A_2) \leftrightarrow A_1 \supseteq A_2.$$

The set $T(U,A,F)$ along with the "$\leq$" relation form a partially ordered set that can be characterized by a *concept lattice* (referred here as *topic lattice*). Each node of the topic lattice is a pair composed of a subset of articles and a subset of corresponding users. In each pair the subset of users contains just the users sharing common interest to the subset of articles and similarly the subset of articles contains just the articles sharing overlapping interest from the matching subset of users. The set of pairs is ordered by the standard "set inclusion" relation applied to the set of articles and to the set of users that describe each pair. The partially ordered set can be represented by a Hasse diagram, in which an edge connects two nodes if and only if they are comparable and there is no other node - intermediate topic in the lattice, i.e. each topic is linked to its maximally specific more general topics and to its maximally general more specific topics. The ascending paths represent the subclass/superclass relation. The bottom topic is defined by the set of all users; the top topic is defined by all articles and the users (possibly none) sharing common interest in them. A simple example of user and information spaces is presented in (Tab. 1). The corresponding lattice is presented in (Fig. 1).

	a_1	a_2	a_3	a_4	a_5	a_6	a_7	a_8	.
u_1	1	1	1	1	1	1	1	1	.
u_2	1	1	1	1	1	0	1	0	.
u_3	1	0	0	0	0	1	0	1	.
u_4	0	1	0	0	1	0	1	0	.
u_5	0	0	1	1	0	0	1	0	.
u_6	1	0	1	1	0	0	1	0	.
u_7	0	0	0	0	1	0	1	0	.
u_8	0	0	0	0	0	1	0	1	.
.	.	.	.	.	.	.	.	.	.

Table 1: An example of user and information spaces.
Figure 1: A lattice corresponding to the user and information spaces presented in Table 1.

In contrast to conceptual clustering (see Balabanovich & Shoham 97) where the descriptors are static, in the suggested approach the users who play a role of descriptors are *dynamic*: in general, a user's interest can not be specified completely and his topical interests change over time. Hence, the lattice describing the topical structure is dynamic too. This induces some results based on the following assumptions. A collection of articles

A_J from an existing topic (U_I,A_J) can only be expanded. This is implied by the conjecture that documents, which are interesting for a user u remain interesting to him. Therefore, an expansion of the collection of articles with respect to a topic (U_I,A_J) will not impose any change of existing links. Indeed, an expansion of A_J to A'_J results in an expansion of all parent (descendent)collections A_m, A_n, such that $A_J \subseteq A_m \subseteq A_n$, i.e. from $A_J \subseteq A'_J \rightarrow A'_m \subseteq A'_n$ and therefore $(U_n, A_n) \leq (U_m, A_m) \rightarrow (U'_n, A'_n) \leq (U'_m, A'_m)$. Analogous relations hold with ancestor nodes. That is, an expansion of an existing collection of articles preserves the structure of the lattice. The next assumption is a formal support of our intuition that the search domain relevant to the user $u \in U_I$ includes a subset of articles to which other members of the group U_I have demonstrated interest. These are collections of articles A_K of the topics (U_M,A_K), such that $u \notin U_M \cap U_I \neq \varnothing$.

One of the main factors in a page ranking strategy involves the location and frequency of keywords in a web page. Another factor is link popularity - the total number of Web sites that link to a given page. However, present page rank algorithms typically do not take into account the current user and specifically user's interests. Assume that we have partitioned users into groups associated with their topics of interest (as collections of documents). A modified ranking algorithm can be obtained by extending the present strategy with an additional factor involving the number of links to and from a topic associated with a given user. In this case the page ranking strategy takes into consideration user's interest encoded in the number and the levels of links to a topic associated with a given user. So, for a user $u \in U_I$, where (U_I,A_J) is a topic, the page rank of an article a should depend on the linkage structure to the articles $a_i \in A_J$ representing the topic of interest of user u .We can interpret a link from page A to page B as a vote of page A for page B. Thus votes cast by pages that are from the users topic weigh more heavily and help to make other pages 'more-important'. This strategy makes page-ranking *user oriented*. Such a strategy promotes pages related to users' topics of interests. From an "active users" perspective this approach enables us to recognize a community of users for which a given article is most likely to be interesting.

This approach suggests also an ordering relation $(\prec)$ for ranking articles returned in response to a request from a user u, assuming that U_I is the maximally general group such that $u \in U_I$. Thus $a_1 \prec a_2$ if there exist collections A_1 and A_2, $a_1 \in A_1$, $a_2 \in A_2$, where A_1 and A_2 are components of existing nodes (U_1, A_1) and (U_2, A_2), such that $U_1 \cap U_I \neq \varnothing$, $U_2 \cap U_I \neq \varnothing$ and $|U1|<|U2|$, i.e. the more members of the group U_I have expressed an interest in a given article the better. The later ordering relation can be incorporated into the suggested ranking method.

An important characteristic of the method is that it does not require explicit representation of the Web objects, due to the fact that it exploits "membership" relations. The set of objects A_u are identified based on their relevance to the context "interesting to the user u", rather than on specific syntactic properties of their representations. Therefore it can cover objects behind the conventional search forms, such as pdf files, images, music files, and compressed archives. In many cases the user is not certain of what information exactly to look for and needs to learn more about the content of the information space. In such cases browsing a collection of documents generated on the base of the current context can be a good navigational strategy. Thus this framework supports information retrieval based on contextual browsing, where user $u \in U_I$ can navigate through the matching collection of articles A_J.

4 Related Works and Conclusion

The Web is probably the richest information repository in human history, but it is usually hard and time consuming to find desired information there. The low precision of the web search engines due to the lack of contextual knowledge makes it difficult to find relevant information. The focus of the current efforts of the Web research community is mainly on optimizing the search, assuming active users vs. passive information.

Recently there has been much interest in supporting web users through collecting web pages related to a particular topic (Brin & Page 98), (Chakrabarti et al. 99), (Mukherjea 00). These approaches aimed at topic specific resource discovery typically exploit connectivity for topic identification but not community identification. Community identification does not play any significant roles in these methods and therefore user search experience within a community is ignored. Some systems such as (Kumar et al. 99) do exploit the experience of other web surfers to derive clustered topical interests but the focus is on organizing surfing history in coherent topics for later use. The problem of identifying community structure on the Web was addressed in (Kumar et al. 99). However, the approach employed for community identification is based on analysis of the Web graph structure and is not explicitly related to resource discovery. In collaborative filtering systems (see Balabanovich & Shoham 97) items are recommended on the basis of user similarity rather than

object similarity. Each target user is associated with a set of nearest neighbor users (by comparing their profiles) who act as 'recommendation partners'. These systems are aimed at recommending items from a fixed topic/database. In contrast, our approach is aimed at large scale resource discovery based on derived topics reflecting similarity of interests among users. A derived benefit of such an approach is localizing the search within an individual topic of interest. Categories and formal concept analysis (Carpineto & Romano 96), (Wille 82), modeling and using contexts (Dichev et al. 01), (Lawrence 00), (Glover et al. 99) have been studied for a long time, motivated by the need for a formalization of the notions of concept and context. A major practical issue is the level at which contexts are defined and analyzed. The context information used in Inquirus 2 metasearch engine (see Glover et al. 99) is in the form of category of the desired document. The context is used to select the search engines, to modify queries and to select the ranking strategy. Our framework is close in spirit to the application of Galois' concept lattices (Carpineto & Romano 96), but the grouping of web objects into classes is based on dynamic descriptors associated with web users.

In this paper we have presented a novel framework for information retrieval on the web. The basic assumption is that the results of a search would be more relevant to a given user when provided within the context of semantically related objects marked as "interesting" by their peers. In addition, a contextual structure would help users in getting better insight about the scope of their search, localizing the search, reducing the amount of time for deciding on the relevance of the hits of a search, comparing the hits to objects selected by their peers, optimizing the search strategy, etc. An additional advantage of the presented approach is that the topical clustering can cover objects behind the conventional search forms including non-indexed web objects, such as pdf files, images, music files, and compressed archives. By partitioning web users into groups it would be possible to make useful predictions about some other shared features and patterns of users' behavior and derive some correlating properties regarding the web information space. Moreover, the identification of significant groups of users with similar interests can help producers of information to reach interested consumers in a timely manner.

Constructivist Use of Interactive Digital Video: Encouraging Students to Apply the Principles of Educational Psychology to a Web-Based Interactive Teaching Exercise

Keith Dils, King's College, USA

Constructivist teacher educators can introduce preservice education students with the experience of applying the principles of educational psychology to real-life situations by providing a technology-aided project. Just such a project was undertaken when preservice education students were provided with a desktop computer with digital video editing software and a digital video camera. The students proceeded to investigate (through classroom discussions and a review of the literature) the value of the principles of educational psychology. They then constructed their own understanding of how the lessons from the literature could be "brought to life" by writing, producing, and acting in teaching scenarios that were then converted to web-based interactive digital video teaching exercises. For these teaching exercise scenarios, students provided a brief "stem" video clip demonstrating a teaching situation. Typical teacher reactions to the situation (representing different applications of various psychological principles) were then provided with prompts asking the user to select the best teacher response. In the process of constructing this web-based interactive digital video teaching exercise, it was intended that students construct their own knowledge of the benefits of applying the principles of educational psychology. The resulting project was then placed on the Internet so that other preservice, and inservice, teachers could benefit from these exercises.

Improving Collaboration in Web-based Distance Higher Education Using Synchronous Technologies

Abstract: This paper describes the development of an online course in Microelectronics by implementing live sessions and online discussions. The main goal of this implementation is to increase the learning process efficiency by fostering the collaboration between the instructor and the students as well as between the students. The pilot run shows that following this approach the average final mark increases while the average completion time decreases resulting in a higher student's level of knowledge.

1. Introduction

The course was initially implemented in an asynchronous way using the Core Module of LOTUS Learning Space 4.01 (LLS) environment and was run for two academic years in the Department of Electronics, University "Politehnica" of Bucharest. The text-based course material was reorganized in a larger number of chapters in order to better keep trace of the students' assessment. Some chapters have laboratory work that was implemented in an online manner by means of web-based interfaces that were designed for all the simulation tools used within the lab. These interfaces allow a student to launch remotely a job using a low cost Pentium based computer.

2. Synchronous implementation

The decision of combining asynchronous with synchronous activities within a web-based distance course was taken after the first two years of running the pilot in which we saw a major increase of the laboratory completion time and, more important, a decrease of the average final mark compared with the period in which the course was taught in a face-to-face manner.

Using the Collaboration Module of LLS we implemented live sessions as well as online discussions within the course. The live sessions are facilitated by an instructor, and require all students to be logged on during a time period determined by the instructor. In a live session, instructors presents to students text and graphics on a Whiteboard, real-time applications that appears in a window on each student's screen and/or ad hoc classroom questions that each student can see on the screen. Online discussions allow real-time interaction between course participants. This way design projects and theoretical problems can be discussed without any delays. At the beginning of the course these facility is frequently used by students for getting known each other. Online discussions do not require all course participants to be logged on the same time.

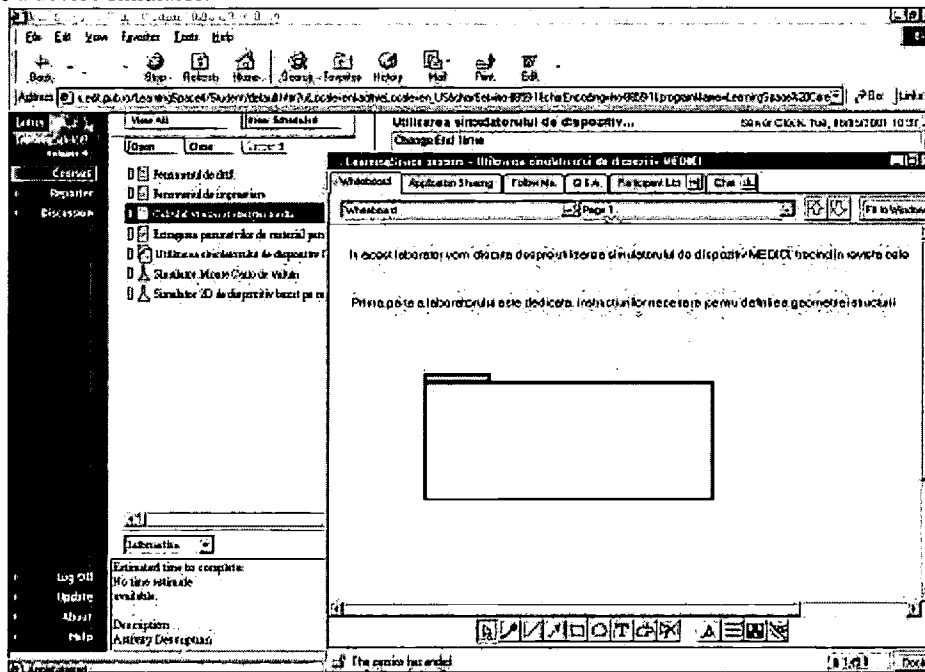
Figure 1 presents a live session in which the instructor uses the Whiteboard facility showing the students how to use a device simulator.


Figure 1: Screen snapshot of a whiteboard session

3. Conclusions

The implementation of synchronous activities within a web-based course allows a better interaction between the students and between the students and the instructor resulting in better grades and shorter completion time. The pilot run shows an increase of the average final mark compared with the last academic year with 9.7% while the average completion time decreases with 19.3%.

Optimizing Web Pages for Instruction

Timothy Dirks
Institute of Computer Technology
589 W. Fremont Ave.
Sunnyvale, CA 94087
tdirks@ict.org

Abstract: Through a hands-on demonstration and discussion, this brief session will cover the basics of web page design and creation and explore further ways to ensure a worthwhile Internet experience. Included will be at least ten important and very useful tips and tricks about web development and web page optimizing techniques that successful web designers use when creating instructional-informational web pages for readability and functionality. Specific suggestions will be demonstrated for image optimization and suitable use of graphics, the implementation of tables and the target tag, the appropriate use of background images and colors, the necessity of a clear navigational layout, and techniques for search engine optimization, debugging, and proper monitor display. The level of instruction will not be highly technical, but appropriate for general audiences. From novice to expert, attendees will discover ways to use the Internet to enhance a Web-based, online curriculum.

Summary: Ten Important Optimizing Techniques for Web Page Development

The following summarizes, in outline form, the 10 web page design and creation tips that will be briefly discussed in the short paper session:

1. Optimization of Graphics – why optimize?
2. Other Image Issues – Do's and Don'ts
3. Tables Issues
4. Text Issues
5. Use of Background Images/Colors
6. Links - Use Targets
7. Layout and Navigation
8. Titles and Search Engines
9. Debugging

Questions to Ask About the Effectiveness of One's Own Web site(s)?

1. Can users find what they are looking for - easily and quickly?
2. Is content useful, informative, fresh, updated regularly?
3. Is the content structured specifically for the Internet experience?
4. What is its purpose? ($, informational, or ego-focused)
5. Are graphics fast-loading and appropriate?
6. Is the 'look and feel' visually attractive?
7. What are the possible sources of frustration?
8. Would users want to come back?
CAUTION: You only have about 7 seconds to get a user's attention!!

Learning Objectives

Participants should come away with an enhanced understanding of web design and development, new skills, and knowledge of several outstanding Web-based resources and tools at their disposal.

Online Access

A similar presentation, given by the same author, was delivered at the National Education Computing Conference (NECC) in Chicago, IL in June of 2001. The Powerpoint presentation may still be accessed by visiting: http://www.eboard.com/. Type 'necc-2001' (don't include quote marks, case-sensitive) into the "Enter an e-Board" text box, and then click on the hyper-link to access the page with the Powerpoint attachment (approx. 1MB).

Presenter Information

The presenter, Tim Dirks is the Manager of Online Courses and Training for the non-profit Institute of Computer Technology in Sunnyvale, California. He has over 20 years experience in the areas of teaching, counseling, and technology. His areas of expertise include the integration of applications into classroom curriculum, technology in education curriculum, and Web site development. Currently, he is the manager and online curriculum developer (for an instructional technology certificate program for K-12 teachers with three major university partners – see http://www.ict.org/onlinehome.html for additional information), web site manager and author (of an award-winning site on Hollywood films, http://www.filmsite.org/), and technology trainer (classroom-based and online with the Institute of Computer Technology, http://www.ict.org/).

Prior to joining the Institute of Computer Technology, he was the Public Programs Manager at the Tech Museum in San Jose. He has a Masters Degree in Religion from Yale University, a Masters Degree in Education from Stanford University, and a California Life Teaching Credential.

If they ask you to put your course online over the weekend, tell them to take a hike

Dr. Patricia Stevens, Jackie Dobrovolny, Sandy Kent, Kerri Shulman

Abstract: This presentation focuses on the development of an online, graduate course entitled Marriage and Family Therapy. This course was a traditional, face-to-face, class, offered by an urban university. The professor who teaches this course worked with three graduate students during the Fall, 2000 semester to design and develop the online version of this course, which she then taught during both the Spring and Summer 2001 semesters. In addition to describing the development process, this article summarizes lessons learned and keys to successful online graduate instruction.

The Marriage and Family Therapy course is an introductory theory class in marriage and family counseling. It requires students to shift their worldview from linear to systemic thinking. The objectives of this course are to: (1) introduce the student to an understanding about relational and systems paradigms; (2) introduce the major systems theories; (3) expose the student to family life-cycle development, healthy family functioning, diversity, and family-of-origin issues; (3) examine the roles of marriage and family counselors in a variety of practice settings; (4) observe various theories in use; (5) examine professional issues such as training, supervision, and ethical concerns; and (6) integrate theoretical concepts using the student's family of origin.

In the traditional, face-to-face class, the professor provided an overview of the major theoretical orientations in systems therapy. In written assignments, as well as in small group discussions, students examined their own family dynamics to identify personal issues that might hinder or assist their ability to work with clients. To understand the theoretical constructs of different counseling theories, students used examples from their own family history and watched videos of experts applying different theories. They also worked in small groups to analyze several different cases from several different theoretical perspectives. Additional assignments included a current research issues paper, a midterm, and a final examination.

There were two major reasons for developing an online version of the Marriage and Family Therapy course. First, the online course needed to provide students in rural areas the opportunity to participate in the program without having to travel long distances. Second, the course is an introductory course taught by several professors in the counseling department. The online course had to be structured so that these various faculty members could easily teach the online version of the course.

The challenge in the design of the online course was to maintain the integrity and instructional quality of the traditional, face-to-face course. It was especially challenging to create the discussion segments of the course that relate to the student's own family. We used the eCollege^SM course management software to develop this course, which resides on the eCollege server. The specific eCollege features we used were the Webliography^SM, Document-sharing, the Journal, and the Threaded Discussion.

The Webliography and Document-sharing features allowed students, the professor, and the teaching assistant to share course related resources. The Webliography^SM contained links to the Internet. Students, the professor, and the teaching assistant can all add relevant information to the

Webliography. One of the assignments was for students to add five new relevant websites during the duration of the course. In addition to the URL, students provided a brief description of the site and rated its usefulness on a five point Likert scale. The Document Sharing feature allows students, the professor, and the teaching assistant to share word processing documents, images, spreadsheets, etc. The professor posted sample assignments in the Document Sharing section of the course to help students understand specific assignments and to provide alternative ideas for completing each assignment. Students shared their papers with each other by posting both drafts and final papers in Document Sharing (Lamb & Smith, 2000).

The family of origin analysis was one of the major assignments in the Marriage and Family Therapy course. This was often a difficult assignment for students due to the personal nature of the questions and sometimes the emotional reaction to addressing these issues. The eCollege Journal feature allowed students to share their family origin assignment with the professor, who could add comments and responses to the student's journal entries. Students could choose to share their journal entries with other students or with just the professor.

The Threaded Discussion feature allows students to post responses to a discussion question and respond to the comments posted by other students, the professor, and the teaching assistant. The online Marriage and Family course used this feature several times during the semester to help students manipulate the course content, thereby making it personally meaningful, and to explore alternative ideas and perspectives. The threaded discussions were also an opportunity for students to interact and communicate with the professor. This student/faculty interaction is a critical aspect of quality online instruction (Graham, Cagiltay, Lim, Craner, & Duffy, 2001; Shank, 2000).

Threaded Discussions were an integral part of the "lectures" in the online Marriage and Family Therapy course (Rohfeld & Hiemstra, 1995). Three guest lecturers, who were practicing marriage and family therapists, each lead a discussion during one week of the course. These experts provided electronic documents or journal articles, which students used to prepare for each discussion. Additionally, the professor assigned several journal articles she had published. Those articles were on the professor's professional website and students linked to each article from the course. This strategy allows other professors, who might teach this course in the future, to merely change the links thereby using their own articles or lecture notes. Videotapes, which were on reserve at the university library, were also used as a type of course lecture.

The course provided for large classes to be divided into small groups, similar to the small groups used in the traditional, face-to-face course. Each small group has its own threaded discussion where students share with each other descriptions of their family dynamics and compare and contrast their family structure, roles, rules, and issues. These small group discussions originate from each student's family of origin assignment but students may choose to not reveal in these discussions everything they included in that assignment. Each small group also has its own Document Sharing section where students can share resources with just the other students in their group.

To replace the current research issues paper, which was assigned in the traditional, face-to-face course, and to facilitate more student interaction, the professor assigned a more practical, less research oriented paper in the online course. During the first week of the Spring 2001 class, the professor asked the students to select a target population for their papers, i.e., either the general public or graduate students. The students selected the general public. Each student then selected a specific topic relevant to marriage and family counseling, researched that topic, and wrote a short paper. Using the Document Sharing feature of eCollege, students analyzed each other's papers and provided feedback and suggested revisions. Students then revised their own papers and submitted them to the professor for grading. The final papers will be posted to a public website.

Development Process

The team who developed the online Marriage and Family course consisted of the instructor, her teaching assistant, and two instructional designers from the Technology and Learning Team (see next section for more information on TLT). During the first meeting, in August of 2000, the professor explained that she had been asked to develop four online courses for the Spring 2001 semester. We decided that it was impossible to design four effective online courses in one semester, and instead agreed to design one course for the Spring semester and then design another course during the spring for the Summer semester. We also decided to design the Marriage and Family course first and we created a team agreement that outlined the roles and responsibilities of each member of the group.

Generally, we met once per week for about 1.25 hours. During our next few meetings, we evaluated different online course management software products. We selected eCollege primarily because they provide 24/7 technical support to students and professors and because it was one of the online course management products supported by our university. The next step was to convert the major components of the traditional class to an online environment. The components with which we were particularly concerned were:

- The small group discussions of the family of origin assignment

- The case study assignment where student groups review cases from several different theoretical perspectives

- Guest lecturers

- Midterm and final exams that were designed to help students prepare for the state board examination.

Another concern in the development process was how to show the videotapes the professor used in her traditional course for case study work. We considered many options for distributing the videotapes, including streaming video, digitizing the videotapes and distributing CD-ROMs, and using a distribution service to copy the videotapes and distribute them directly to students. The challenge we faced was obtaining copyright permission from the owners of the videotapes. For a variety of reasons, none of our options was successful so we temporarily sidestepped this issue for the Spring and Summer 2001 semesters by placing the videotapes on reserve in our campus Media Center.

By November, our team was ready to learn eCollege and to put content into the course shell. Three of our team members attended formal training at eCollege. The team worked together to learn the technical aspects of eCollege and to design the course to take advantage of the various eCollege features. As we added content to the course, we worked with a graphic designer, from the Technology and Learning Team (see below for more information on the Technology and Learning Team), to include visuals and the professor added copyright-free clip art. Many of the visuals were in the weekly introductions, which are short motivational documents. The teaching assistant entered over 300 test questions and reviewed the course as a student to look for inconsistencies and problems. Specifically, she was making sure potential students knew what they needed to do each week and what was expected of them. The teaching assistant repeated this formative evaluation several times during the development process.

As a team, we spent approximately 400 hours developing the online Marriage and Family Therapy course. The professor spent approximately 200 hours, her teaching assistant spent approximately 80 hours, and the two graduate students from the Technology and Learning Team spent a total of approximately 120 hours.

Technology and Learning Team (TLT)

The TLT mission is to assist the faculty in the effective use of instructional technologies. Thirteen graduate students, primarily from the Information and Learning Technology program in the School of Education, staff the TLT and each generally works 15 to 20 hours per week. There is one full-time staff member. For more information on the TLT, please see their website at www.tlt.cudenver.edu.

Lessons Learned

Student evaluations of the online Marriage and Family Therapy course taught during the Spring 2001 semester were very positive. After the fifth week of the course, students reported that they were pleased with the workload and very satisfied with the interaction with both the professor and the other students. They also reported spending an average of six hours per week working on assignments and readings for the course. Not attending a traditional class or having face-to-face interaction was not a problem for these students. Hardware/software problems and the amount of time required to complete the writing assignments were of moderate concern. As expected, convenience was the major reason for taking the online course, however, knowledge of the instructor was also an important determinant. Students were "highly satisfied" with the course as a learning experience.

At midterm, all students indicated that they were "satisfied" with the online course at that point in the semester and 66.7% reported the course sequencing and assignments were easy to understand and follow and that the pace of the course was "about right." Unfortunately, 66.7% of the students reported significant technical problems that "interfered with their learning."

At the end of ten weeks, students completed another evaluation. Generally, students continued to be positive about all aspects of the course but there was a slight drop. Anecdotally, this dissatisfaction seems to coincide with the same dissatisfaction students express in traditional, face-to-face courses as they approach the 10-12 week point in the semester.

The use of videotapes was, and continues to be, problematic. First, we were unable to obtain copyright permission for the videotapes we used in the traditional, face-to-face course or to establish a distributor for those videotapes. Some developers of online courses upload videos or copy them to CD-ROM without permission but we decided not to do this. As noted above, our temporary work-around was to put these videotapes on reserve at the university Media Center. We are currently investigating alternatives, as the online Marriage and Family course will soon include students who are outside our metropolitan area and thus, can not get to our university. Another problem with the videotapes is if we obtain the resources necessary to put the videos on the Web, our student's Internet connections may not be sufficient to support video streaming. Perhaps our next work-around is to obtain permission to copy the videotapes to CDROM and distribute those CDROMs to the students.

Selecting the best course management software is another important issue in the design of online instruction. We chose eCollege mainly because of the 24/7 technical support and the support our university provided for this product. The technical support both the professor and her students received from eCollege was excellent. Our advice to others is to test the features you need in your course, in the various course management products you consider using. Just because a course management system claims to have "chat," for example, or document sharing, does not mean that feature works as you need for it to work for your unique course design. Also consider the Internet browers and the Internet Service Providers (ISP) you and your students use. Some course management systems work better with some browers and/or some ISPs.

The experience of developing this course was an intellectually stimulating adventure for everyone on the development team. Team members provided their individual strengths to the endeavor, creating a dynamic atmosphere. The process was time consuming and demanding, but well worth the effort, as well as being an enjoyable experience.

It is important to stress, however, the intense time commitment required to develop a quality online course (Creed, 1996; Eiler, 2000; Lamb & Smith, 2000; Smith, 1997). In addition to learning the idiosyncrasies of a particular course management system, the paradigm shift is particularly difficult and it takes time to work through these new ideas. It also takes time and patience to input the course content. Finally, the delivery and implementation of an online course is very time-intensive. A high level of team interaction and support is, therefore, necessary throughout the entire course development and delivery cycle. University administrators often are not willing or able to provide the financial or time resources necessary to develop and deliver effective online instruction. When faculty are asked to develop online courses and continue with their normal workload, instructional quality may suffer, as well as faculty enthusiasm and morale.

In summary, we believe that it is imperative to have sufficient time, support, and resources to design and develop quality online university courses. Adequate time to develop the course in a thoughtful manner and to address the inevitable paradigm shift is critical. Technical training for faculty and funds for graduate assistants to help with both the development and the delivery of the course are also imperative. Finally, resources to take advantage of the electronic medium are necessary. For example, in the case of the online Marriage and Family course, we still need funding to create video case-study samples and/or to purchase the appropriate copyrights for the videotapes used in the traditional, face-to-face course.

There is no doubt that higher education must create a variety of course delivery mechanisms in order to stay competitive in the 21st century (Menninger, 2000). "Although the primary mission of the university -- the creation, preservation, integration, transmission, and application of knowledge -- are not changing, the particular realization of each of these roles is changing dramatically" (Duderstadt, 1997). We must also recognize, however, that in addition to variety, we need quality. This undoubtedly will require both university administrators and faculty to reassess many of their assumptions about the process of designing, developing, and delivering university instruction.

Biographies

Dr. Patricia Stevens (pstevens@ceo.cudenver.edu) is the Director of the Marriage and Family Training Program at the University of Colorado at Denver. She is the President of the International Association of Marriage and Family Counselors, a Clinical Member and Approved Supervisor with the American Association for Marriage and Family Therapy, and a Certified Family Therapist. Dr. Stevens is a Licensed Professional Counselor and Licensed Marriage and Family Therapist. She maintains a small private practice in Denver, CO. Dr. Stevens has written and presented extensively at the local, regional, national and international levels in the areas of marriage and family training, substance abuse, gender issues, and ethical and legal issues in marriage and family therapy. She is an approved online presenter with the State of Colorado Jurisprudence Workshop, which is required for licensure.

Jackie Dobrovolny (Jackie_Dobrovolny@ceo.cudenver.edu) is a doctoral candidate at the University of Colorado at Denver (UCD). Also at UCD, she is an instructional designer on the Technology and Learning Team and teaches instructional design for multimedia projects and project management. Jackie designed and taught an online interface design course and as an independent consultant, Jackie helps organizations decide if, when, and how to use technology-based instruction, performance support, or other performance improvement interventions. Jackie began her career in instructional technology in 1977.

Sandy Kent (Sandy_Kent@ceo.cudenver.edu) is a candidate in the Information and Learning Technologies master's degree program at the University of Colorado at Denver (UCD). She was an instructional designer on the Technology and Learning Team at UCD and currently she works at Colorado Mountain College (CMC) in Steamboat Springs, where she is a media and distance education technician. She has been with CMC since 1987.

Kerrie Shulman (Kerrie_Shulman@ceo.cudenver.edu) is a candidate in the master's degree program for Counseling Psychology at the University of Colorado at Denver (UCD). She is specializing in Marriage and Family Counseling and is currently working as a graduate/teaching assistant helping faculty develop online courses. Kerrie holds a Bachelor of Arts in psychology from the University of Colorado at Colorado Springs.

Beyond Mythology to Technology

University of North Dakota

Abstract: Making the leap to a technology-enhanced, on-line educational experience has been a four-year labor of love for the *NatureShift! Linking Learning to Life* project. What began as a Technology Innovation Challenge Grant designed to get technology and hands-on learning out to an information isolated highway of communities, schools, parks, museums, and other formal and non-formal educational settings turned into a true test of metal for learners, educators, community volunteers, and instructional designers alike. The paper will discuss lessons learned in building an educational website and tapping the talents of partners, community, and other technology projects nationally. In its past three years, the NatureShift project has taken technology training to educators, taught pre-service teachers, and built a technologically advanced web site for delivery of instructional materials, tutorials, tools, and collaboration. The project has stretched out to the rurally isolated, crossed gender and cultural learning barriers, and embedded new software products from other projects around the country into its on-line curriculum. Yet the biggest barrier the project faced has been surmounting the mythology surrounding technology. The project had to leap over the mythos and learn to use technology, not as a tool, but as a springboard for interaction and self-actuated learning.

The paper will show how the more the project tried to create an educational web site and teach educators how to use new technologies and the more the project tried to improve on the latest technology available, the farther back it fell into the self-generating myths surrounding technology. Most educators have heard the mantras: Technology IS the curriculum; Technology makes learning fun; Technology puts learners in control; Technology is easy; Technology is hard to learn; Technology makes teaching better...more efficient...more productive, ad infinitum. NatureShift studied the rocky terrain, learned many of the pitfalls first-hand, and finally made the leap to step over the cloud of "learning technology." What the project discovered was that, by itself, technology can neither do nor be any of these things. The most lasting lesson NatureShift learned was a finely-wrought skill for hiding technology within learning environments. The result: The imaginations of project educators, student teachers, and partners have opened to a new world of learning. By having instructional designers build the content to the technology and then training the content, not the technology, to educators in the field (whether pre-service or in-service, formal or informal), provided the key to good on-line curriculum and a successful method of training. The results are hinting at a dynamic link that takes place between learner, technology, and learning as soon as the technology begins to disappear.

Pedagogy The computer and the Internet have radically changed the face of traditional educational technologies and with their introduction into education these new tools have also affected what we understand about teaching and learning. The computer crept slowly into education in the mid-twentieth century, at first for machine-like conversations with humans that mimicked the lock-step robots of the assembly line, computers were for "programmed instruction"[1] (Goldsworthy 2000, Skinner 1958). Eventually, however, computing peppered the landscape of learning and tossed in its own instructional rules into the process that suggested technology could aide learners in constructing meaning from the learning process (Harper *et al.*, 2000). The recognition of ways technology gives learners control over much of the learning environment challenged the educator's traditional role. The ability of the learner to interact with the content, to reorder it, reshape it, or question it, at his or her discretion meant that educators had to revise their most core concepts of teaching, relearning how to shape an instructional experience in this new environment (NCES, 1999). This landscape required multidimensional as well as multimedia construction (Havinga 2000). Not only was a teacher faced with the challenge of framing a lesson plan according to new principles, they had to design instruction that could be delivered through this foreign medium of technology and learn new rules of engagement – to understand how students interacted with technology for learning (Elkind 2000).

The use of the new technologies in framing instruction, first the computer and later the Internet, gave the learner freedom to create personal learning goals and eventually build new learning constructs. However, these glamorous new tools quickly developed their own mythology. The computer, the digital camera, the informational technologies of the Internet solicited more interest than the work they were created to do. Learning got lost in the glamour. These new technologies also came with learning curves. Educators either embraced them as exciting challenges or evaded them as impediments to the instructional process.

---

[1] Programmed Instruction, a term referring to drill and response instructional exercises programmed into early computers with feedback stamped out on punch cards. Learners performed drills until they mastered the content. The practice was introduced to education during the 1950s when B.F. Skinner's *stimulus and response* educational theory was at its height.

NatureShift was designed to employ and infuse new technologies into its model and its methods. Its mandate to bring technology and its training to educators from the vastly different worlds of formal classroom education and informal free-choice educational settings was a monumental goal. *NatureShift* was faced with a double-edge challenge: to train educators in the use of new technologies and, at the same time, in a new model for teaching and learning with technology. What the project discovered early was that professional development for educators required debunking the technology myths that impeded learning new methods and practices.

<u>Importance of the Study</u>   New national technology standards for students and teachers coming out of ISTE[2] as well as other organizations are being accepted nationally by accreditation organizations such as NCATE[3]. These have raised the bar for pre-service teacher education and are rapidly pressuring for adoption of higher technology standards by public schools nationwide. The educational community is being asked to increase technology access and implement rigorous technology profiles throughout its schools and universities even as it struggles with implementing best approaches to training its educators. Add to the picture a technological landscape that keeps growing and changing and the importance of successful training methods becomes paramount. The *NatureShift* experience has shown that the challenge for building instruction through technology and training teachers in its use is indeed great and there is not an easy answer. Nevertheless, we have seen trends that suggest there are rules that work in this new landscape. One finding of particular note has been the discovery that difficulty with or resistance to technology could be surmounted by concentrating training and curriculum not on use of technology but on accomplishing tasks that are known. By modeling technology use, empowering teacher-learners to put hands on the technology, and integrating the technology with meaningful tasks clearly worked during training and on the web sites.

<u>The *NatureShift* Challenge</u>
The *NatureShift* project has 10 pilot site partners who implement the *NatureShift* "Exploration Model"[4] using curricular content from five cross-disciplinary education modules. Five pilot sites are formal school environments, and five are informal (or free-choice) educational environments (parks, libraries, and museums). The project provides professional development in the model and the technologies to educators at all sites. At the start of the project, *NS* educators approached professional development using known methods of training. Those methods included trainer-to-trainee instruction and hands-on activities to learn the technologies (computer hardware, educational software, scanners, QTVR production, and video camera). Teachers were given specific tasks to learn the technologies and then specific tasks to learn the ingredients of the model, all new content for teachers to learn but doing so using instructional practices that were very familiar. This approach quickly introduced educators to new technology. Teachers learned to use the video camera and they were thrilled. Sometimes they learned effective strategies to integrate the camera into their instruction. The same for learning the computer and other new technologies. Practice in creating technology-enhanced instruction that followed the precepts of the *NS* model met with the same results. Teachers learned to set-up a lesson by engaging students with an authentic situation or *Task*. They built *Web Adventures* so their students could learn how to research using the Internet. They loved learning to construct Real World Adventures that put meaning into students' understandings. They learned to design multimedia projects or portfolios that taught their students to construct meaning from their learning. Yet, after every *NS* site training or conference workshop, participants failed to retain most of the knowledge they had gained. Worse yet, trainees had more problems when they returned to their sites. Either the technology failed or they could not remember how it worked, and they had no time to redesign curriculum or even a lesson plan that incorporated new technology. If they did not get enough training at the workshop, the technology did not get used.

By the start of the grant's third year, the project was faced with a dilemma. Staff was modeling new technologies. They were modeling innovative teaching and learning strategies. Yet, knowledge was not being retained. Teachers did not remember the technology at follow-up workshops, nor were they demonstrating any ability to transfer knowledge gained to new situations. At partner workshop after workshop, the same questions and issues arose. "Technology is too hard to learn.... It always breaks down.... I don't have time in my day to do all this creative planning... I can't teach students to use a technology I don't understand... I don't know what I'm supposed to do with this technology."[5]

<u>Lessons Learned</u>   In year three of the grant, the project changed course. *NatureShift* sponsors several workshops throughout the year, including two professional development workshops for partners. Each workshop and training includes surveys and self-assessments for participants to evaluate their learning. Although a formal statistical analysis of data will not be completed for another year, an anecdotal review of participant comments, taken in fall, 1999 revealed a common response. Participants were asking for *application* training. They wanted to know *how* to apply the *NatureShift* model, not how to use technology to implement the model. In response, the project tested a new training approach during its January 2000 workshop.

Partners were given the task to create the web pages that would represent their work on the *NatureShift* web site. Only 10 percent of partners knew anything about creating web pages. They had not retained lessons in how to capture images and most had not learned to use photo manipulation software. They were not promised any training in technology but a voluntary technology lab

[4] *NatureShift Exploration Model* - A four-part teaching and learning model that includes: 1. An engagement in the form of an authentic task, 2. A Web Adventure (research on-line), 3. A Real-World Adventure (explore learning in one's own world, and 4. A Project (multimedia-based summative presentation that captures the learning by the learner).
[5] Compiled data from *NS* Summer Institute and Winter Workshop "Exit Questionnaires," 1998-2000.

was put at their disposal for practicing any of the technologies they wished to learn. Ninety percent of workshop participants availed themselves of the technology lab. Evaluation comments at the close of the workshop revealed nearly 95% satisfaction with the workshop. Several evaluation comments clearly indicated educators felt they learned a great deal of technology as well as a new appreciation for web based instruction. Yet, no targeted technology training had been used during the workshop! Participant knowledge of technology was addressed on an individual basis during production.

The positive results of the Winter Workshop provided insight in designing the weeklong Summer Institute of July, 2000. Although not yet tabulated, cursory results from the Institute clearly indicate that using project-based instruction is much better at overcoming the technology learning curve than drilling in skills or putting technology in an educator's face and hoping they will overcome their preconceptions about it. At the Institute, partners were asked to design a *NatureShift* Exploration that would meet a curriculum need in their classroom. They were told their Exploration would have to be evaluated and would go up on the *NatureShift* web site. Again, there was no focus on learning technology, although new technology instruction was offered in audio production, video production, Inspiration software, and digital cameras. Teachers had to use cameras to record events at the Institute. They had to use Inspiration to present their curriculum concept, and they had to learn how to work in a networked environment on the computer. They were given plenty of time to work on their tasks. The results were more stunning. When partners returned home, they remembered how to logon to the *NS* server and transfer files. They complained when they did not have the latest technology because they already had plans for its use. Half of the partners had begun and even finished their *NS* project the following fall before staff had inquired into their progress. The basis of the *NatureShift* model is to build critical thinking and engage learners in problem-solving and inquiry-learning. It outlines a method for teaching that, when used for professional development has begun to prove its worth. The true test came when partners were asked to present their *NS* work and the ways they had found the project to be helpful. Presentations ranged from Powerpoint to posterboard. In each case, a clear confidence and appreciation of technology was evident. Projects reflected the clear value and place that technology would hold in their lifelong learning

Evaluation Methods   The sources of data for this study include evaluations completed by partners, outside workshop participants, and pre-service teacher candidates enrolled in the *NatureShift* elementary education technology course at the University of North Dakota. Except for outside workshop participants, teacher candidates and partners all completed post evaluations of each training session. In addition, anecdotal data was collected at every course. Evaluation and survey instruments have not been validated, but were created by the project internal evaluators and have been consistently applied during the life of the project. The project's external evaluators will conduct statistical analysis of the data. Each pilot site educator is currently required to create a complete *NatureShift* Exploration, including all pedagogical stages of the model. During the final year of the project, educators will be required to conduct an evaluated test of their *NatureShift* Exploration in one of their classes or with selected students. The Exploration model requires students to process what they have learned and thought in a summative project. The student projects from an educator's Exploration will be evaluated for evidence of knowledge acquired and critical thinking. Evaluations will consist of a teacher assessment rubric, student assessment rubric and evaluator assessment of project content. The external evaluation team will provide the rubrics. The team will also evaluate student projects for evidence of critical thinking and knowledge acquisition. If partner educators have acquired skills with technology and grasped an understanding of how students learn by using different technologies, their Exploration projects will reveal the clearest evidence of that knowledge.

Summary
The myths of technology create strong impediments to understanding it. What are some of the typical myths that crop up and blur our vision? "Technology is fun! Students will be engaged just because we use it. Technology IS the curriculum. Technology is too difficult to learn. Technology is easy. Creative planning for technology takes a long time. Technology makes teaching better, more productive. Technology always breaks down." (*NatureShift* Project, Annual Reports of Progress). In some instances any one of these myths might be true. Yet it is the resulting attitude that colors our approach to learning. What *NatureShift* discovered is that educators come to a workshop with their myths embedded deeply to remain even after training has taught them differently. The most effective method the project has found to overcome the mountain of resistance or misconception is to remove the mountain from view. Give the learner the task of putting one foot in front of the other and the mountain is easily crossed because attention is diverted to territory that is understood. Give teachers an instructional task and they will learn technology like they learned to write on the blackboard, without little thought of the chalk in their hand.

Usability Test of the PIC Website

Introduction

Over the past ten years, the field of education has experienced an incredible shift in focus in regards to the way information is accessed by and presented to both teachers and students. Computers in classrooms, educational software, and the Internet have become popular choices as educational and reference tools both for educators and students rather than simply diversions. Digital libraries, virtual museums, and the concept of "distance learning" continue to evolve as educational resources, fueled by demand from educators and students as well as policy makers. While these advances have greatly increased the number of resources available to users, much work remains to be done as to the effectiveness of these resources when used in a "live" environment.

The Plant Information Center (PIC) discussed in this paper is a web-based learning center that references a digital repository of botanical specimens (images) and botany-related information. As an educational tool, PIC extends beyond the boundaries of a traditional library through a series of applications that support interactive learning, communication with botanical experts, and a channel for contributing resources and knowledge to PIC's information store.

PIC is a partnership of the North Carolina Botanical Garden, the University of North Carolina (UNC) Herbarium, the UNC School of Information and Library Science (SILS), the McDougle Middle School, and the Orange County Public Library of North Carolina. PIC is a web-based educational initiative that provides integrated mechanisms for botanical study by unifying numerous resources and permitting access from multiple entry points. The goal of this interface is to provide a useful and meaningful tool for teachers and students in regard to the North Carolina Science Curriculum (Greenberg 2001). (http://www.dpi.state.nc.us/curriculum/science/strands 68.htm). This paper focuses on a study of the top-level navigation as it relates to overall usability of the Plant Identification Center's (PIC) website (http://www.ibiblio.org/pic) for middle school students. In particular, this study has aided in determining whether or not the design of the site provides intuitive access for the user to the site's tools.

Background

While there has been substantial research involving children's learning processes (most notably Piaget and Inhelder 1969), it was not until the 1990s that research was done on the specific information needs of children, or how they access this information (Hirsch 1998; Large, Beheshti, Moukdad 1998; and Fidel et al 1999). Studies regarding children's information needs, most recently Large & Beheshti (1999) shed light on the issue of how new technology either enhances information-seeking behavior or detracts from it (Large & Beheshti 1999). Other studies, less recent but equally important, by Carol Collier Kuhlthau (1988), V.A.Walter (1994), M. Gross (1995), and P. Solomon (1993) address the types of information needs of children. Most of this research deals with how children determine the relevance of information obtained through an electronic medium when faced with an imposed query; it also deals with their searching patterns (browsing) in respect to the Internet as a whole, not necessarily within an individual site.

Additional studies by C.L Barry (1994), J.S. Watson (1998), and C. Cool (1997) address the ways that students determine the relevance of information and the medium in which it is presented (text vs. digital). Finally and most extensively, much research has been done on the searching patterns of children (S.G. Hirsh, 1996; Schacter, Chung, G.K.W.K., & Dorr, 1998; Marchionini, 1989, 1995; Borgman, Hirsh, Walker, Gallagher, 1995; Large, Beheshti, Breuleux, 1998; and Bilal, 1999). Most of the recent work has focused primarily on electronically based information.

There has also been research done to determine the effective information architecture with regard to website usability (Gullikson, Blades, Bragdon, McKibbon, Sparling, Toms 1999). This research concluded that navigational aids play a crucial role in the effectiveness of a website, and emphasized the significance of these tools in users' overall satisfaction with the site. The research validates design conventions (Yale Style Manual, Web Developers' Virtual Library) that suggest an effectively designed website balances the number of initial options a user has and the depth of the site itself. An informal standard of two mouse-clicks to reach the desired information or goal is regarded as optimal from system design. Formally, the practice of studying and improving usability rests on using measurable data to gauge interfaces along several core points. Furthermore, usability literature encourages involving users in the design process and promotes an iterative design process that allows the product to evolve through early testing on real users (Nielsen 1999, Beyer & Holzblatt 1997).

There are several methods of assessing and improving the usability of an interface. In this project, we first performed a heuristic evaluation of the site. Using guidelines and heuristics from the Yale Style Manual and from Jacob Nielsen, we critiqued the site and identified possible problem areas. We then developed a formal usability test in order to measure our hypothesis against specific criteria on subjects from the target audience.

Interface description

The PIC website provides access to a variety of information sources, some of them advanced and complex botany tools; the structure of PIC is also rather complex. This interface was designed for use by middle school students, ranging in age from 11-15 years, for use in the science classroom. There are six main sections or tools available at the PIC website, as follows: Tree Identification Keys ("Plant Keys"), NC Trees, Plant Search (access into BOTNET database), Glossary, Frequently Asked Questions ("Ask the Expert"), and Links (to external relevant sites). These six main pages, along with the home page, compose the top-level structure of the site. These main pages share the same graphic layout and links to each appear in navigation bars (both along the top of the page and in the side bar) on each of the other main pages, with one exception. The Search page looks different, and although this page may be accessed from any other main page within PIC, it provides direct access only to the PIC home page. Some of these main pages, such as NC Trees, Ask an Expert and the Glossary, lead users to tools that are clearly within the framework of PIC. Other tools, such as the Tree Identification Keys and the Plant Search, lead to external resources. Furthermore, several of these sections (Glossary and Plant Keys) have several subsections included within them. These issues will be discussed further in later sections.

Critique of Existing Site

The PIC site presents an enormous amount of information as well as some sophisticated research tools , such as the BOTNET database. Especially for novice users, the site's organization and navigational aids will be fundamental to its successful and satisfying use. The PIC homepage provides explanations of each tool, as well as several links to each (a top navigation bar, a side navigation bar, as well as textual links in the descriptions). It is easy to get to any of the tools from the homepage. Also, the descriptions presented on this page are aimed at students in tone and language.

We identified the following points as possible breakdowns in the functional design of the site:

- Within particular tools, the site fails to give users a cue as to where they are in the site and how to easily return to the homepage or to another tool.
- Although offering quality information, the site's vocabulary within tools may be too difficult for more inexperienced botanists and students.
- The site lacks "graphic identity." The continuity of PIC breaks down once a user enters any of the specific tools.
- There are several areas, specifically the Dictionary and the BOTNET search results page, that fail to chunk information well.

Overall, the PIC site has some strong points; the homepage is designed with the student audience in mind and provides good cues for navigation. However, this careful attention to the site's audience falls away within the individual tools. These tools were originally designed for professional botanists, and younger students or novice users may have trouble navigating through them.

Usability Test Methodology

The test group consisted of eight students from a botany "cluster" at MacDougle Middle School, five males and three females. All students were 11-12 years of age. One student was in the sixth grade, the rest were seventh graders. All of the seventh graders had received basic classroom instruction in botany prior to participating in the study.

Specifically, this usability test sought to answer three questions pertaining to top-level navigation of the PIC website, as follows:
1. Can users identify the correct tool to use for a given task?
2. How efficiently can users locate information within a tool to correctly answer the given question?
3. Can users find and interpret the site's information to correctly answer the given question?

Students participating in this study had previously collected, pressed, mounted, identified, and researched a plant specimen using traditional methods. Students used the tools available on the PIC web site to validate their research regarding identification of the specimens. This usability test focused on how well test subjects completed twelve benchmark tasks associated with the system categories and the functions present in each. Two questions (or tasks) were assigned that related to each of the six categories of the PIC interface.

A 100% success rate in completion of these 12 tasks would have been ideal; however, a more realistic standard of success was based on a percentage of success relative to a passing grade in the science class (>68%). An effectiveness criterion was gauged by counting the number of mouse-clicks each task requires. While users may have taken different paths to access a particular tool, the efficiency of site navigation was determined by comparing the mouse-clicks used to reach a

particular tool with the shortest possible path. Additionally, each user was encouraged to "think aloud" while performing each task in order to illuminate the rationale behind each of the user's decision.

Volunteers were recruited and trained to act as proctors during the test so that each individual test subject would be paired with a proctor. On the day of the test, each proctor was provided with: one pre-test survey, one post-test survey, one task worksheet, a tape recorder with tape, a pencil for the test subject, paper and pen for proctor notes. Proctors set up testing stations at terminals around the computer lab.

When the test subjects arrived they were paired with proctors. Test subjects were reminded that the purpose of the study was to gauge the usability of the PIC website rather than the individual subject's personal competency in completing the given tasks. At this time, test subjects had in their possession plant specimens used in conjunction with the task worksheet.

Subjects first completed the pre-test survey. Subjects were then allowed five minutes to read over the PIC homepage and browse the site. At the end of these five minutes, the proctor started the tape recorder and asked the subject to begin working on the task worksheet. Subjects were allowed forty minutes to complete the task worksheet.

As the subjects progressed through the given tasks, proctors encouraged the subjects to think aloud and recorded the number of mouse-clicks used to find an answer to each question on the task list. If a test subject became "lost" in the site and was unable to reorient him or herself, the proctor made a note of this situation and pointed the subject back to the PIC homepage. Likewise, if a subject made various attempts and was unable to find an answer to a particular question, the proctor made a note and asked the subject to move on to the next question. Test subjects were encouraged to find answers to the questions on the site rather than relying on prior knowledge. If a test subject knew the answer to a question already, the proctor encouraged the subject to find the place in the website where this information was documented.

When the test subject completed the task worksheet, the proctor stopped the tape recorder. The test subject then completed the post-test survey.

Results

For analysis, we coded each question as "answered correctly? (y/n)," "correct tool used? (y/n)," and "number of mouse-clicks." We used these data to answer our original three questions. We coded all unanswered questions as "no" in both the "answered correctly" and "correct tool used" field.

Can users identify the correct tool to use for a given task?
We used proctor notes as well as audiotapes to decide if test subjects had identified and reached the correct tool for each question.

% Questions for which Test Subject used Correct Tool (TS = test subject)

TS1	TS2	TS3	TS4	TS5	TS6	TS7	TS8	Group
64	86	79	50	43	79	71	50	65

% Students that used correct tool for individual question (Q = question)

Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11	Q12	Q13	Q14
75	75	75	75	63	63	63	88	75	63	63	63	25	50

According to our standard of success (>68%), only half of the test group was able to successfully identify and/or locate the correct tool for each question. The fact that test subjects were in many cases able to provide the correct answer to the question despite failing to use the correct tool may mean that subjects were relying on prior knowledge or that subjects were able to glean answers from other areas of the PIC site. Overall, our data shows that the tool's descriptions on the homepage and the navigation bar's cues do not offer enough information for middle school users to intuitively assess which tool they need. Subjects had a tendency to either browse from tool to tool or to repeatedly return to the tool they found most familiar or easy (commonly the NC Trees page).

How efficiently can users locate information within a tool to correctly answer the given question?
We used proctor notes to find the number of mouse-clicks used to answer each question. Proctors also noted when test subjects had to scroll down, although this information is not reflected in the table below.

Average Mouse-clicks per Question compared to shortest possible path:
(Q = question, A = average of group, SP = shortest path)

	Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11	Q12	Q13	Q14
A	7	8	8	8	16	16	6	9	3	3	7	3	4	6
SP	3	3	3	3	5	5	2	2	2	2	2	1	2	2

It should be noted that question five, which scored an average of sixteen mouse-clicks, involved using the Keys tool. Use of this tool involves answering a series of questions on successive pages; therefore the shortest path through the Keys to an answer may involve anywhere from three so seven clicks. Question six involved NC Trees, which should have been accessed through a shortest path of only three clicks to any particular tree. It is somewhat unclear, from our data, whether test subjects had difficulty in initially identifying NC Trees as the correct tool to use, or whether the high average of mouse-clicks for this questions reflects the fact that test subjects needed to back out of the Keys tool screen by screen since there is no direct link back to the homepage from within the tool.

Also, some of the tools require quite a bit of scrolling in order to reach the desired information. For example, both the dictionary and the NC Trees tools present long, alphabetically organized lists; these two tools would benefit greatly from alphabetical links at the top, allowing the user to jump directly to the desired section.

Overall, the number of mouse-clicks used to answer each question was higher than we had hoped. Averages declined toward then end of the task list; this may indicate that users were becoming more familiar with the site as they progressed through the tasks. More likely, the lower averages at the test's end mean that only the more efficient users had time enough to reach the questions at the end of the test.

Can users find and interpret the site's information to correctly answer the given question?
We used completed task worksheets, as well as proctor notes and audiotapes, to decide whether or not the test subject had correctly answered each question.

% Questions answered correctly (TS = test subject)

TS1	TS2	TS3	TS4	TS5	TS6	TS7	TS8	Group
71	93	79	57	79	93	86	93	81

According to our previously stated standard of >68% indicating success, all but one of our test subjects successfully completed the task list. As a whole, the test group averaged 81%.

% Subjects that answered individual question correctly (Q = question)

Q1	Q2	Q3	Q4	Q5	Q6	Q7	Q8	Q9	Q10	Q11	Q12	Q13	Q14
88	88	88	75	100	88	88	100	88	88	75	75	38	50

There is a significant drop in correct answers toward the task list's end, probably because most of the test subjects ran out of time before completing the task list. For the most part, if a test subject answered a question, they answered it correctly. That is, we did not see many incorrect answers; instead we saw questions that had been skipped entirely, abandoned due to frustration or confusion, or simply not reached due to time constraints.

While all but one test subject was successful in answering the questions according to our >68% standard, we found it interesting that not a single test subject was able to answer all fourteen questions. Trial runs through the task list by a proctor who had no previous experience with the site took about twenty-five minutes; test subjects were given forty minutes to complete the task worksheet. This indicates to us that the benchmark tasks took far longer for the test subjects to complete than we had anticipated.

Summary and Recommendations
Overall, we found that while the test subjects were able to answer questions by using the site, they were not efficient in finding their answers or overly successful in identifying and locating the proper tool. The post-test survey posed open-ended questions to test subjects . The answers to Question 2, "What did you dislike most about the site?" offer some illuminating information, as follows:
- "It was not well put together in the sense that you had to 'guess' if you didn't know much about trees."
- "Not enough pictures. The terms should be explained a bit better when trying to identify a plant."
- "a little too much information"

From these answers, it seems clear that the test subjects did not find the site intuitive overall. Audiotapes also reveal that many of the subjects struggled with vocabulary on the site and would have benefited either from more pictures, more explicit instructions, or more ready access to the glossary/dictionary.

Several subjects expressed confusion in reading results on the BOTNET Search page. There is quite a bit of information presented on this page, and although the page currently uses a table and different fonts to set apart various pieces of information, the overall effect is overwhelming especially for novice botanists since records appear to run together. The page could be presented in strips of alternating color to distinguish records (gray/white/gray/white for example). Also, there is a Search box on the homepage that acts as a shortcut to the BOTNET search; our users tended to interpret this box as a search function for the PIC site in general rather than the BOTNET database. This search box should be either removed from the homepage or labeled explicitly as a shortcut to the BOTNET tool.

The site provides many ways to access tools from the homepage, but it does not provide adequate navigational aids for returning to the homepage or for moving directly to another tool. For example, once inside the Plant Keys tool, it is necessary to "Back" through all of the questions answered in order to reach a place where other tools are accessible. Also, although the "Plant Information Center" graphic at the top left of each main page is a link to the homepage; this is not obvious enough to most users. The site would benefit greatly from a static navigation bar that appeared either at the top or on the left side of every screen. Furthermore, there should be a clear cue to the user indicating where they are in the site at any point. This could be accomplished through a breadcrumb trail at the top of each page listing the path that user took to get there (for example, "Home → Glossary → Dictionary" where each of these is a link to that section).

The site presents an enormous amount of information; sometimes information is repeated in multiple sections, which may result in confusion for the users. Specifically, we found six distinct glossaries/dictionaries on the site. There are three sections within the Glossary tool alone, none of which seem especially intuitive for novice botanists. The Student botanical dictionary is not comprehensive enough to be fully useful for students; also, the wording in these definitions does not seem very different from the wording in the full dictionary. The full dictionary is certainly comprehensive, but is difficult to navigate since it requires so much scrolling. The full dictionary would benefit greatly from a navigational bar of alphabet links at the top, with corresponding "back to top" links at the beginning of each letter section.

There are many areas of the site in which the wording or vocabulary is too complex for young or novice users. For example, once in the Plant Identification Keys tool, users need to know the definitions to botany terms in order to answer progress through the tool. Although there is a glossary included in this tool, we feel it would be especially useful for users if alternate text could be incorporated into these pages to provide "look-ahead" definitions. Also, although one of the aims of the designers was to familiarize students with using professional research tools, we feel that users in this age group would benefit from more explicit, simplified instructions as to how the tools work.

PIC has great potential to be a valuable and fun learning tool for young botanists. It is encouraging that students were able to find information in the site, despite often failing to identify the correct tool to use. Ultimately, though, we feel that if students become confused or frustrated in their search for information they are unlikely to return to the site in the future. This test revealed several aspects of the PIC interface that interfere with its success as an educational tool. These results on are being incorporated into the next iteration of design on the PIC website. We have illustrated here that usability testing offers a means of gathering measurable data to support principles of interface design and learning theory. By using as iterative design cycle to address the issues discovered in testing, PIC designers can improve the interface in order to benefit the students who will be using it. As digital libraries and electronic resources grow in popularity and pervasiveness the need for systematic usability testing and iterative design cycles also grows. Resources such as PIC have the potential to give students an educational experience that would be hard to replicate without the computer and the Internet, but in the end these tools are only truly valuable if students are able to interact with them in the intended way and master their use.

Footpaths in the Stuff Swamp

Jon Dron (University of Brighton, UK)
Chris Boyne (University of Brighton, UK)
Richard Mitchell (Inferdata Corporation, US)

Abstract

In this paper we consider stigmergy (loosely, the effect of communication through the environment) in relation to the Internet, especially with regard to Web-based learning. We begin by examining ways in which stigmergy occurs on the Web, before going on to describe its use in the construction of our continually evolving system, CoFIND (Collaborative Filter In N Dimensions). CoFIND's purpose is to replace the role of a traditional teacher in structuring and selecting learning resources. It attempts to achieve this through a process of stigmergy and natural selection, leading to a degree of self-organisation brought about through the independent actions and interactions of its individual users. We discuss some of the issues raised and attempt to explain some of its success as well as account for its failings.

Stigmergy

Stigmergy is a word coined by Grassé to refer to systems such as those employed by termites when building mounds (Heylighen, 1999). Termites build mounds start by dropping mud randomly in a given area. The presence of a mud heap encourages other termites to drop their lumps of mud nearby, with larger mounds being more attractive than smaller ones. Adjacent mounds therefore tend to grow towards each other, so forming arch structures. Stigmergy plays a role in many self-organised systems. It explains the formation of ant-trails, for example. If an ant finds food, it leaves a trail of pheromones on its way back to the nest. When other ants encounter this trail, they are inclined to follow it. If they too find food, they too leave a trail of pheromones back to the nest. As more ants find food, so the scent grows stronger. Eventually the food runs out, no more ants leave a pheromone trail and the scent dissipates. The ant trail ceases to be. Stigmergy also plays a major role in human dealings. This can for example be seen in the spontaneous formation of footpaths in a forest, recessions caused by fluctuations in stock prices and the large crowds that gather round smaller crowds in a street (an effect well utilised by professional buskers). A number of simple individual acts which affect the environment in turn affect other people, directly or indirectly. Coordinated behaviour arises as a result of indirect communication processes.

Stigmergy and the search for useful Web pages

The Web is composed of a vast number of individuals interacting with Web sites and each other. Much of this interaction is recorded, which suggests the possibility that something akin to footpaths in a forest could form, although many of those records tend to be hidden in individual server logs. Crawford characterises the Web not as a super-highway but as " a swamp, albeit a swamp with many remarkable hillocks of well-organized, first-rate data and information." (Crawford, 1999). If some sense or pattern could be discerned within the stuff swamp, a system of footpaths leading to useful hillocks, then navigating the Web would be a simpler affair. There are two clear potential approaches to the building of such footpaths: by design, or by stigmergy.

Footpaths by design

Yahoo represents the pinnacle of achievement in the creation of footpaths by design. Its large group of researchers trawls through thousands of web sites every day, weeding out the poor and ill-conceived, categorising and organising the gems that they find. Despite a bizarre classification scheme which puts *Education* next to

Entertainment, Arts and Humanities next to *Reference* which in turn sits next to *Regional* (Hudon, 2000), Yahoo's power is that it is organised by beings who understand meaning in a human context. This distinguishes it from the various web crawlers whose algorithms mechanically extract some kind of meaning from the content of what they are indexing. There are disadvantages with designing footpaths, a big one being that an individual's view or that of a small group will not necessarily coincide with that of the general population of users. Even where categories are agreed upon, unless the community of researchers has a similar set of interests and goals to those of the users of the system, relevance may be low. Because of this, a niche market has developed for more specialised directories or subject gateways, created by groups of like-minded researchers with an interest in a given field. Educational technologists might use The World Wide Web Virtual Library of Education (http://tecfa.unige.ch/info-edu-comp.html) or the TIP database (http://www.gwu.edu/~tip/) for example.

Footpaths by emergence

Recent generations of Web search engines, such as Clever (http://www.almaden.ibm.com/cs/k53/clever.html), Alta Vista's Raging (http://www.raging.com), and Google (http://www.google.com) make explicit use of "footprints" in the form of what Kleinberg (1999) describes at Latent Human Annotation. Such systems iteratively mine the Web for clusters, based on an analysis of in-degree and out-degree in hubs and authorities. Implicit recommendations based on what is effectively a form of citation (links imply approval) are condensed and purified, resulting in emergent patterns indicating popular and probably relevant sites of interest. A similar idea underlies the seminal PHOAKS (People Helping One Another Know Stuff, http://www.phoaks.com), which parses newsgroup messages for URLs, then bases its categorisations on topics and themes which relate to them. The quantity of citations in a relevant category provides the rating of a resource as useful or not.

Stigmergy is exploited by the family of systems generally referred to as recommender systems, collaborative filters or social filters. PHOAKS and Google are both examples of implicit recommender systems, which take a form of existing behaviour and extrapolate or infer preferences from what people are already doing. Amazon takes a similar approach when recommending books based on matching your purchases with those of others. The other main class of recommender system is the explicit variety, exemplified by Firefly (Resnick & Varian, 1997). Here, users are actively polled for their opinions on items such as films, books or Web sites, and their opinions are matched with those of other users to provide recommendations. By taking explicit recommendations, areas of uncertainty found in implicit systems are removed. In an implicit system, backlinks to Web sites may well be used in unexpected contexts which do not indicate a genuine recommendation, such as "this a dreadful site." Similarly, Amazon may often be used to purchase books as gifts and thus implicit recommendations might not reflect a person's own taste. However, if the user has explicitly rated a set of books then we can assume likes and dislikes with a high degree of confidence. The disadvantage of explicit recommendations is the demand that they make on users, leading to the cold-start phenomenon: if there are no ratings, the system is useless, as there will be nothing to match one user with the next. Early users will thus achieve disappointing results and (in a negative feedback reaction) will cease to use the system, which will therefore never grow. None-the-less, collaborative filters show interesting stigmergic patterns. Imagine a greatly simplified system with only two matched users. If user Adam recommends books A, B, C and D, Bob recommends books B, C, D and E, because their ratings intersect each will be recommended to read a book which they have not already read. Assuming that each likes the book that has been recommended, then they in turn will recommend them, leading to a stigmergic reaction. Without any intentional act of communication, an organised cluster will have developed.

Stigmergic communities

Community interactions, both synchronous and asynchronous, can provide some indication of the paths their users are taking. For example, it is easy to spot more popular newsgroups by the number of postings. Like crowds that gather around a busker in the street, the greater the size of the crowd the more likely it is that others will join it. More subtly, there are often clues which may be gleaned from the subject lines and hierarchical thread patterns themselves. For example, flames tend to follow recognisable patterns and word usage which will either lead others to read those threads or (perhaps more often) to avoid them. Similarly in Chat rooms, people tend to be drawn to areas where there is the highest activity. Once there, quantity of words is often a broad indicator of the quality of a given discussion. Short, social messages may indicate less depth than longer, involved messages. There is therefore a stigmergic form of self-organisation that inhabits even the least structured forms of

discussion. However, its operation is typically crude and undiscerning. Only the broadest of patterns may be visible and, as a form of self-organisation, it is no smarter than the rule which makes a group of birds nest together.

Enhancing stigmergy to structure communication

Stigmergy is exploited by a number of communication systems to achieve subtler and easier forms of organisation than would be achievable by their more primitive counterparts. A superb example of such a system is ChatCircles (Donath et al, 1999). In this system, each participant is represented by a circle. The more a person participates, the larger the circle grows, shrinking with time like the pheromone trails left by ants. It is only possible to "hear" people (see what it is that they are typing) by moving your own circle close to them. Thus, drawn by larger circles and larger groups, clusters of activity form naturally as a result of participation in the process. Two cues are available to the user, the size of the circles (indicating activity) and the number of circles in a cluster (indicating levels of participation and interest). Neither cue is the result of an explicit attempt to communicate with other users; they are simply the result of rational behaviours within the system.

Odigo (http://www.odigo.com) takes another approach, a synchronous chat system that centres discussions around web pages and web sites. Visitors to particular pages can discuss shared interests or the contents of those pages. Users can discover "What's Hot Now" identifying those pages that are most in use by Odigo users in real time. This feature enhances the users' ability to identify clusters and areas of interest. Popular sites draw more users, which makes them more popular and so the self-reinforcing circle continues. A related approach is taken by uTOK (http://www.utok.com), which allows asynchronous interactions through the ability to leave notes relating to a given site. As the user browses the web, the small uTOK panel indicates whether any messages relating to that site have been left by other users. The value of a site is indicated by the number of interactions, with users being drawn to sites with larger discussions. uTOK combines this with a voting mechanism for notes that have been left, which gives some indication of the quality of a discussion as well as the quantity of contributions. This multi-dimensional approach allows for richer forms of stigmergy than are afforded by, say, simple clustering alone. Through the application of simple local rules, complex patterns that convey sophisticated information to users of such systems evolve and develop. uTOK takes this evolutionary metaphor to its logical conclusion, as low -rated messages are removed from the system. Thus, both the structure and content of a given cluster of knowledge are determined by individual local interactions.

CoFIND

Over the past three years we have been developing a Web-based system known as CoFIND (Collaborative Filter In N Dimensions, first reported in Dron et al, 1999) which seeks to organise itself through the combined individual actions of its users. In essence, CoFIND is a self-organised database of resources, akin to a subject gateway, with a small, relevant body of resources created and found collaboratively by its users. It is written using Microsoft's ASP with a database backend.

CoFIND utilises evolution, in a Darwinian sense. Through a process of voting, resources (mostly Web sites) compete by moving up or down lists of returned results. The landscape on which they compete is variegated, with individual niches determined by the use of *qualities*, the things that users value in a resource. Typical qualities might be "useful," "amusing," or "good for beginners." A differently ordered list of resources would be returned by users seeking *useful* resources than by those seeking *amusing* resources. Like resources, qualities compete, changing size and moving up or down the list according to how frequently they are selected and how often they are used to vote for resources. If they are not much used, they will become "extinct". Users also decide upon binary categories for the resources, characterised in CoFIND as *topics*. As resources, topics and qualities are created by the users themselves; the system orders itself and is regulated according to the needs of its participants.

CoFIND is designed to be used by a single cohort of adult learners with similar learning goals starting at a similar state of knowledge. If there is too much disparity between the needs of the users, then whatever shapes and patterns emerge will be chaotic. As Darwin recognised, evolution and adaptation works most effectively in small, parcelled populations such as those found on islands. Large populations with high levels of connectivity result

in most significant changes and mutations being cancelled out by a process of dilution and competition. By limiting the participants to a small and focussed cohort, CoFIND results in highly focussed subject gateways.

The intention behind CoFIND is to create a kind of group intelligence that takes on some of the roles of a teacher. One of these roles is to select and recommend source material and texts for students to read, matched to the needs of those students. Through the use of qualities to rate resources and topics to categorise them, students are able to achieve this goal themselves, without central guidance. We have achieved a measure of success in this goal (Dron et al, 1999, Dron et al, 2000). However, a number of obstacles still remain, most notable of which are those of encouraging sufficient participation to overcome cold-start problems, and of achieving meaningfully self-organised results. Lately, we have been attempting to partially address these problems by developing CoFIND along more stigmergic lines, allowing richer patterns to develop than are possible through evolution alone.

Stigmergy and CoFIND

The first place we sought to introduce stigmergy was in the selection of topics, a solution that arose as a result identifying the wickedness of the problem of generating collaborative paths. We wished not only for users to be able to select appropriate resources for their learning needs, but (as a teacher would do) to select them in an appropriate order. However, the dependency of one topic on another, and the need to understand one resource before embarking on the next is an intractable problem. In most teaching there is a narrative thrust. The appropriate order in which tasks should be attempted is dependent on what has come before and what comes after. It would not be appropriate to average-out, concatenate, or otherwise join sets of elements from one path with those of another, any more than it would make sense in most novels to jumble up the order of the chapters. The meaning of a set of resources is intimately connected to the order in which they appear. Our solution was not to create a single path by combining others, but to attempt to shape the route through a subject area in real time, to collaboratively beat out the path through the topics as we go.

Stigmergy and topics

Topics are generated by the users of a CoFIND system. They may be entered by any user into one of four distinct, but undifferentiated, screen areas. This number was decided on purely pragmatic grounds, calculated according to how many words could be squeezed onto one average 800x600 screen and the assumption that an appropriate number of topics in any sector would be around seven, which is approximately the number of items that can easily be assimilated at a glance (Miller, 1956). Within a given area, topics are in competition with each other. Every time a topic is selected, it gains emphasis by getting larger, whilst other topics in the same area get smaller. The algorithm is balanced so that this change is not too dramatic, allowing for a certain amount of stickiness before topics start to fade away.

Figure 1 shows a use of CoFIND within a traditionally taught classroom setting.

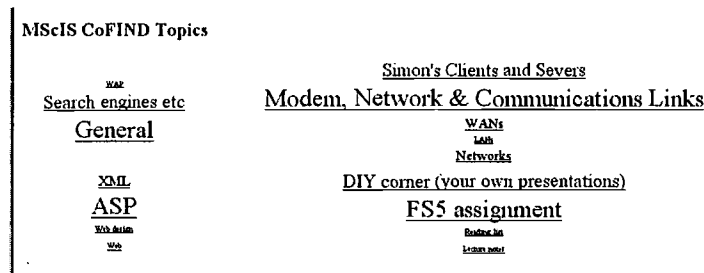

Figure 1: Simon's Clients and Severs

The prominent topics are mostly closely related to the development of the course at the time of this snapshot, with a project on ASP and a strong interest in XML in personal projects, for example. *Simon's Clients and Severs* [sic], however, is an anomaly. It was claimed to be a mistake by the student who added the topic, caused by a

350

misunderstanding of how to add some of his own work to the system. In fact, this is probably untrue, because the student repeatedly clicked the topic label over a period of a few minutes immediately after adding it, thereby increasing its relative size and prominence. It is (even when spelt correctly) a topic of only marginal interest in the context of the course. Despite this, the topic got to be quite popular, visited by twelve different students over two months. This compares with only ten visitors over a similar period to *ASP*, a topic which was being covered in class and thus of greater intrinsic interest. It is thus tempting to conclude that usage was being driven by stigmergy, kick-started by the student who added the topic in the first place.

Stigmergy and qualities

The second explicit use of stigmergy in CoFIND lies in the quality selection mechanism. Like topics, quality labels vary in size according to usage. For a quality, the size of its label is related to the number of times it has been used to rate resources. In addition, qualities are displayed in an order which is determined by an algorithm which primarily considers the of number of times they are selected, tempered by the number of times they are used to rate resources, and a novelty rating which decays rapidly as they age. It is thus quite common in the early stages of quality evolution to find smaller labels closer to the top of the list than larger ones, as shown in figure 2.

[Add new quality]
Figure 2: Stigmergy and qualities

Stigmergy in CoFIND is intended to enhance and emphasise patterns of behaviour. By providing different cues to the user, a more complex set of interactions can be elicited. The size of the quality indicates the relative number of explicitly rated resources which it will lead to, whilst position is an indicator of the relative perceived usefulness of the quality, gleaned largely from implicit usage statistics- users click the qualities which they believe will be more useful.

Users are encouraged to select a quality by its position and/or by its size. This process typically results in those qualities at the top of the list also having the largest labels as, once selected, a given quality will then be used to rate resources. The fact that this synchronisation does not occur straight away introduces a latency which magnifies the overall stigmergic effect, following a pattern like that of Senge's Beer Game (Senge, 1993). In the Beer Game, retailer, wholesaler and manufacturer are caught up in a vicious cycle of supply and demand which arises from the latencies within the system. Retailers, responding to a consistent slight increase in demand for a certain brand of beer, increase their orders from the wholesalers. The wholesalers increase orders from the brewer. Because of inherent latencies, partly due to delivery cycles and partly due to how long it takes to brew beer, orders are not immediately met, so everyone perceives increased demand and an inability to meet it. To compensate, the retailers increase orders to cope with the backlog, the wholesalers follow suit a little while later, the brewer brews more beer to cope. These effects are magnified as they rise through the system. By the time the backlogs of orders are met, all players in the system have a massive over-stocking of beer, orders are cancelled and everyone suffers accordingly. Within CoFIND, the analogous positive feedback loop is actually beneficial, leading to increased polarisation of the use of qualities, hence to a richer structure.

Discussion

The effect of stigmergy in CoFIND is used to create structure in a set of resources. By encouraging positive feedback loops, clustering occurs more readily than were the system simply to make use of qualities and ratings to decide which resources are valuable.

Our intention is to replace one role of the teacher with a collaborative group mind, a function that, by our own criteria, CoFIND is performing effectively. There is doubt, however, that this group mind can match that of even

the dullest of professors. Whilst it is true that in every one of the ten or so instances of CoFIND so far implemented students at all levels have found and rated a set of resources far better than those already discovered by the teacher alone, there are problems with the ways in which structure has developed. The example of *Simon's Clients and Severs* is a good illustration of how the system may easily be subverted by a determined anarchist or self-publicist. It would be easy enough to programmatically prevent such an occurrence in future, but the fact that the ploy was successful shows that stigmergy can as easily lead to useless or even harmful categorisations as to those which have pedagogic benefits.

Another unresolved issue lies in the related problems of overcoming resistance to using the system and the cold-start phenomenon. The former problem is partly one of interface design, an issue that is slowly being dealt with. However, it is also related to the latter problem, as the system is only useful once there are many resources, topics, qualities and ratings. Although the use of qualities should help to more effectively discern useful resources, the overhead in providing ratings for more than one quality makes the start even colder than that experienced by most other collaborative filters.

CoFIND's problems are exacerbated by the fact that the system is currently only being tested within a conventional University teaching environment. This means that the students always have alternative sources of knowledge to CoFIND, that they are motivated by the need to pass examinations rather than to learn about a given topic, and that there is a limit to the time they can allocate to what is perceived as a fairly peripheral activity. It is significant that the most prolific use of the system so far has been when it is used to provide formative peer assessment of the students' own web pages. Like any computer system, it does not exist in isolation and, as an adjunct to existing working systems, offers insufficient extra value to encourage widespread successful use.

In conclusion

We have begun to show the potential for stigmergic systems in structuring a web-based learning environment and identified some techniques for providing richness in that structure. Although we have identified some fruitful directions, the potential is still waiting to be fully exploited. Part of the reason for this lies in failure to consider the system as a whole, partly in the inherent flaws in collaborative filtering technologies. It is, however, apparent that the Web gives enormous potential for the development of group minds, composed of yet distinct from their constituent individuals and, given time and appropriate environments, that these minds may one day rival those of traditional teachers as a means of creating, distilling, structuring and disseminating knowledge.

Student and teacher collaboration in the Virtual High School

Bruce Droste, Virtual High School, USA ; Augusta MacAusland, Marlboro Graduate Center & Virtual High School, USA ; Ruth Adams, Shrewsbury High School, USA

The Virtual High School (VHS) is a consortium of high schools that offers network-based courses (NetCourses) taught by consortium teachers for students in consortium schools. Each school contributes at least one teacher, who teaches a VHS course in place of teaching a section of a regular course at school. Teachers in the VHS pool, with the help of experienced facilitators, design and offer NetCourses over the Internet. Each school in the cooperative can enroll 20 students in these NetCourses for each section of a teacher's time (i.e., one netcourse) that it contributes to the pool. Each VHS school also provides a part-time coordinator who acts as liaison among students, the VHS teachers, and the central VHS administrative staff.

In September 1997 the Virtual High School offered Internet-based courses for the first time to about 500 students in 27 schools in 10 states. In May 2001, after eight semesters of operation, VHS offered over 150 different courses to over 3,000 students in 300 schools located in 32 states and 12 foreign countries. The number of students enrolled and the average number of students per netcourse have been steadily increasing.

Statistics show that over 80% of the schools participating in VHS have enrollments of fewer than 1,500 students. Half of these schools have fewer than 800 students. As VHS has developed, some of these small schools have come up with creative ways to get involved in VHS, and VHS has supported them in order to make their participation possible. In some cases whole districts and geographic regions have organized into "sub-cooperatives," pooling their local resources to take advantage of VHS courses. For instance, four very small schools decided to join together to support the training of one teacher who will offer one VHS NetCourse next year. According to the reciprocal VHS formula, they will then distribute the 20 available student seats in VHS among the four schools. The bottom line is that instead of schools finding an expensive solution, or no solution at all, to the challenges that many schools face in meeting the demands for course offerings, they are able to work with VHS to develop creative solutions – all without hiring new staff or adding a new building.

To supplement its ongoing evaluation based on surveys and site visits, VHS in 1999 commissioned its third-party evaluator SRI International to collect data on the quality of a sample of the courses that were taught during the first two years of VHS's operations. (School principals and others at participating VHS schools had already reported that they believed the courses to be of high quality.) SRI convened a panel of six content area experts (which, as a group, had extensive secondary-level teaching experience, as well as state and national experience in the development and application of standards for curriculum, instruction, and assessment) to assist in establishing standards for NetCourses and to conduct course reviews. SRI collected 24 reviews for the 12 courses (2 reviews for each course) and synthesized the results. The study concluded that VHS courses provide students with high-quality curriculum content. The experts rated 11 of 12 courses at least "satisfactory" and more than half of the courses reviewed was rated as "high quality." The reviewers rated the area of curriculum content especially high for the large majority of the courses reviewed. These findings indicate that VHS's emphasis on multiple, interweaving quality control mechanisms is paying of and that students are being offered courses whose content is of high quality.

Vermont Governor Howard Dean: This is a model for what all high schools .. .. ought to be doing, especially small schools. Leland and Gray now has an opportunity to have a curriculum as good as any high school in the state, and the very best high schools anywhere in the country. This is a school of 240 kids and they don't have to take a back seat to any other high school in the country no matter what their resources are, This is an extraordinary project.

For additional information about the Virtual High School, including its current course offerings, visit the VHS web site at http://vhs.concord.org.

Portraying the Evolution of a Web-based Nursing Course Through the Eyes of an Educational Technologist

Jill Ducey, The University of Kansas Medical Center, USA

Our Educational Technology staff at The University of Kansas Medical Center works in a partnership with faculty members and clinicians to administer their classes on the Internet as web enhanced or as web based courses. Some faculty resist utilizing the Internet to teach a course. The purpose of our department is to curtail some of the reluctance they may feel about teaching a course online. An optimal faculty-technologist relationship can combine to create an intuitive web based learning environment. Depicted in my poster session is the first online course that my client and I developed. In the beginning my client had little experience with computer technology but was open to new possibilities. The first year the course had fifteen total modules, eleven taught in a traditional classroom and four taught online. The following year the course was taught entirely online. Over the last four years the course has seen the addition of a new discussion board, a task based icon system, and an orientation video. This poster session will illustrate the collaborative teamwork that morphed a traditional course into a cutting edge web based course.

NEW TRENDS IN WEB COMMUNICATION TECHNOLOGY:
WEBCASTING

This paper examines a brief but rich history of Internet webcasting first born as a

"push" technology that did not succeed. Later, webcasting was reborn as a phoenix in the

flame of streaming video and audio. Now, it develops practical applications that are of interest

for both individual and corporate consumers.

An archeologist of the Internet will find that most of the sites related to webcasting are

dated 1997-98. Webcasting appeared in 1997 as the automated delivery of personalized and

up-to-date information. Those were the glorious days of the Internet. The World Wide Web

broke into the Internet mainstream just two years earlier and immediately brought the issue of

information overload. The browser's technique of information retrieval demonstrated serious

weaknesses from the very beginning. The Internet could be compared with the Library of

Congress, with all the books scattered and visitors walking around and painfully trying to find

a page with the information they needed. That's why after two years of the WWW experience,

an idea came to apply the TV programming and broadcasting model to the Internet.

"Push" technology represented the first wave of webcasting and *Newsweek* advertised

it as a fundamental innovation that would alter the fate of the Internet. This was a new model

of delivery of information across the WWW designed for the individual customers as well as

corporate users. While the previous model was based on "pulling" the information from the

Internet, the new one promised to "push," or to deliver condensed and processed information

directly to the user's desktop via pre-selected channels. "Push" technology had enough public

exposure and venture capital but survived only in corporate intranets. Facing the dilemma

whether to search the WWW or to search hard drives overloaded with pushed content,

consumers decided to stay with the old browser technology of retrieving information. The

prophets of "push" technology also made a mistake by tying up their fates with the advent of the broadband Internet connection era. When it did not arrive on schedule, the credibility of "push" technology was seriously undermined.

In 1999-2000, webcasting was reborn in the streaming video and audio technology. Streaming implies real-time transmission of encoded video and audio over the Internet to multiple recipients. Instead of promising again an overnight revolution in WWW technology, webcasting is now focusing on practical issues that can be solved under the existing condition of modem ISP. DSL, cable modems, satellites, wireless technology, and bandwidth connection are the options under development. Webcasting insistently tries to return the consumer's trust by promoting real life projects. One of them is to bring local TV programming via webcasting to small rural and underserved communities. Webcasting is also used to promote public safety and security purposes. Another direction is radio broadcasting which is extremely successful. Further, webcasting is used for internal corporate tasks. Finally, new webcasting software and hardware is aggressively developed.

The "push" technology has been a battlefield between major players. Currently, we are witnessing a new approach where major players are united and cooperate within International Webcasting Association. Webcasting has survived in an attempt to become a viable alternative to cable and satellite television providers. After the days of the WWW "gold rush," a slow but steady time of meticulous explorations and work has begun.

Brewing ALE's: Creating Authentic Learning Environments

R. T. Jim Eales
Interaction Design Centre, CSIS Department
University of Limerick, Limerick, Ireland.
jim.eales@ul.ie

Abstract: Making education more authentic is an important issue, and we believe the Internet can play a vital role in this aim. In this paper, we outline our research into developing Authentic Learning Environments (ALE's). We use our three level model of authentic learning to describe our practical investigations into this area in a university setting. We also highlight what we consider to be important design challenges for the future development of ALE's.

Introduction

The Internet and World Wide Web are playing an increasingly important role in higher education. Students now often ask "are your lecture notes available on the web?" The course website has become an integral part of the educational landscape for many courses. However, the World Wide Web has the potential to be much more than a passive information delivery system. In a previous publication (Eales & Byrd 1997), we argued that the Internet and the WWW could provide the opportunity for students to metaphorically break out of the classroom and to virtually deschool society. Our vehicle for virtually deschooling is the Authentic Learning Environment (ALE). An authentic learning environment seeks to support authentic learning by utilising a networked technical system allied to appropriate authentic learning activities. Our previous paper was largely theoretical, although we did offer a number of tentative design suggestions for systems to support authentic learning. One of the few perks of being involved in education is that it is possible to conduct educational "experiments" using our own courses and students. In this paper, we report on our practical attempts to create an authentic learning environment. Our experiments, not surprisingly, produced a wealth of interesting findings in a number of different areas. In this paper we focus specifically on the issues relating to authentic learning. We begin our discussion by outlining our original argument and attempting to further define and explain authentic learning.

Virtually Deschooling Society

At WebNet '97 in Toronto, Canada, we presented a paper entitled *"Virtually Deschooling Society: Authentic collaborative learning via the Internet"*. In this paper we argued that technology had made little impact on educational practices in the past, but that the Internet had the potential to offer something very different. It could allow the student to break out of the classroom and the possibility of virtually deschooling society. We drew on Illich's (1973) radical ideas on deschooling (learning without schools) and attempted to link them to more modern theories of situated learning and authentic activities. The notion of authentic learning is closely linked to social theories of learning, situated learning and the idea of communities of practice. A community of practice is "a set of relations among persons, activity, and world, over time and in relation with other tangential and overlapping communities of practice" and "participation in the cultural practice in which any knowledge exists is an epistemological principle of learning" (p. 98) (Lave & Wenger 1991). Seely Brown, Collins and Duguid (1989) argue that much of what goes on in schools is inauthentic and suggest that we should focus more on authentic activities. Educational institutions are, of course, also communities of practice with their own authentic practices. The problem is that educational institutions achieve credibility only if their explicit practices are of value outside of the institution. Skills, abilities or knowledge that only have value or meaning within the walls of educational institutions are considered to be inauthentic and of little value. Resnick (1987) suggests that there are four broad characteristics of mental activity used outside of school that stand in marked contrast to mental activities developed in schools:
1. Individual cognition in school versus shared cognition outside school.
2. Pure mentation in school versus tool manipulation outside school.
3. Symbol manipulation in school versus contextualized reasoning outside school.
4. Generalized learning in school versus situation-specific competencies outside school.

As Illich (1973) warned, "education becomes unworldly and the world becomes non-educational" (p.31). This danger is the motivation for authentic learning environments.

Authenticity, in its broadest sense, is an extremely complex philosophical concept. We intend to adopt a working definition of authentic learning as the development of skills and understanding that has relevance and value outside of educational institutions and particularly in the workplace. In an educational context, we use the term authentic to refer to learning that, in some way, reaches outside of the school community and culture.

A Model of Authentic Learning

In order to get a better understanding of the various ways in which an ALE might support authentic learning we have developed a three level model (fig. 1). We felt that the term authentic learning was being used in a number of different ways. We wanted some way of distinguishing between the different forms of authentic learning and in particular focusing on what we term level III authenticity, engagement with authentic cultures.

Level I - *Engagement with authentic information.* One of the great values of the Internet, and in particular the World Wide Web, is that it brings the learner face to face (via a fairly standard interface) with an ever expanding universe of local and global digital information.

Level II - *Engagement with authentic tools and simulation.* Some aspects of the "real world" can never be experienced in a direct sense. Simulation can be of immense educational value n these cases. Authentic simulation for educational purposes has exploited a number of different media and focused on a wide range of skills (see Vanderbilt 1990).

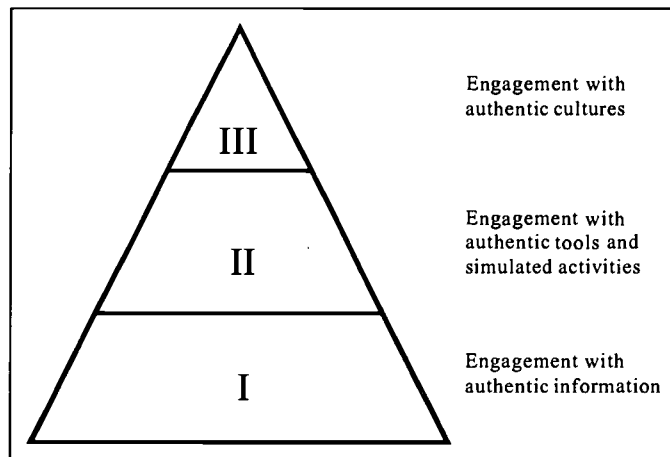
Level III - *Engagement with authentic cultures.* This is the level which we believe is of major significance, particularly in terms of the potential educational contribution of the Internet. Our focus in this paper is on the role of the expert participant. Other roles for authentic contributors include that of the mentor (see O'Neill 1998).


Figure 1: Three level model of authenticity

Investigation -The Context

The basis for our "experiments" was a third year undergraduate course module (class) in Computer Supported Cooperative Work (CSCW) in the department of Computer Science and Information Systems at the University of Luton, England. This module ran in 1999 and in 2000 and had 35 students on each occasion. The field of CSCW is concerned with the study of group activities and the design of computer-based technologies to support cooperative work (sometimes referred to as groupware). A particular problem in CSCW education, is that most students have limited or restricted previous experience of computer-mediated group activities. This is especially a problem at undergraduate level. Without this personal experience there is a danger that the learning will be overly theoretical and detached from the learner and most probably lacking in interest. As this CSCW module

was essentially part of an Information Systems course our focus was mainly on the use of CSCW systems rather than their technical implementation, although we did consider some design issues. An important part of understanding CSCW is appreciating the subtleties of group activities and group dynamics mediated by technology (see Grudin 1994). Such issues as how do groups structure large collaborative information spaces, or how do individuals deal with event awareness in a constantly changing group workspace, require a large active workspace to provide a realistic experience. Complex computer-mediated social interaction issues are particularly hard for computing students to appreciate without first-hand experience. Our solution, which seemed appropriate, was to use a CSCW system to provide a hopefully authentic CSCW experience to underpin the teaching of CSCW theory. The use and development of the shared workspace became an integral part of the learning experience for this module

The basic course structure for a module consists of 2 hours per week for lectures and 2 hours per week for tutorials or practicals spread over one semester (approximately 14 weeks). The technical system described in this paper, was intended to replace the tutorial/practical element of the module. The lectures continued as usual. Assessment carried the following weighting: 50% final examination, 25% for a group assignment and 25% for participation in the collaborative workspace. One of the advantages of our particular situation was that the student's personal experience of the shared workspace was sufficient justification for using a CSCW system as part of the course. Having taken the decision to use the system it then seemed appropriate to seek to use it to investigate novel ways of supporting learning.

An important part of our investigation was the involvement of an authentic "expert". The expert was importantly not an academic but a practising researcher in CSCW, based at a major government research establishment in Australia. She was a representative of a culture of CSCW users and also of CSCW system developers.

The System

The software used was the Basic Support for Cooperative Work (BSCW) system (Bentley et al., 1997) developed at the German National IT Research Center (GMD) (http://bscw.gmd.de/). The software can be used for free on the servers at the GMD or can be downloaded for running on one's own server. BSCW is essentially an asynchronous shared workspace system. Access to a group workspace requires only a standard web browser. The system supports a variety of information-sharing activities including structured discussions, uploading and downloading of documents and links to websites. BSCW also incorporates authentication of group members, different access rights and event icons to indicate when objects have been added, changed, read etc. Participation in a BSCW workspace is restricted to registered members, and each registered user has a unique user name and password. The BSCW system was originally created as primarily a business tool but is being increasingly used for educational purposes (Appelt and Mambrey 1999). For us the system had a number of distinct advantages. It was easy to set up (we used the servers in Germany), it offered web-based access, was content-free, flexible and reasonably easy to use, in effect, an educational technology test bed.

Findings

One of the advantages of using a collaborative workspace system for these investigations is that all of the online interaction was captured in the workspace and was available for later analysis. Extracts (indented text) used in this paper are taken directly from the discussions in the shared workspaces. A short questionnaire was also administered to the student group at the beginning of the module

Level I Authenticity – Engagement with Authentic Information

The students were unfamiliar with the area of CSCW and had only limited experience of groupware systems. At level 1 we used the system to provide important online papers in the area and links to significant and interesting CSCW websites. This is very similar to a standard course website. BSCW, however, allows the students to actively participate in the collaborative development of this information space by adding links to websites they have discovered or by uploading relevant documents. The workspace was also useful for distributing course administrative information.

Level II Authenticity – Engagement with Authentic Tools and Simulated Activities

Our main use of the BSCW system was to support asynchronous threaded discussions about various issues in CSCW and to encourage the students to reflect on their use of the system. The educational value of asynchronous computer-mediated conferencing systems has been well documented (for example, Harasim 1990). We considered that these online discussions were not only educationally valuable but that they also simulated the kind of online discussions that might take place in a workplace. Such discussions have to have topics to fuel them. The main topics for our discussions were the BSCW system itself and the various social and technical issues that emerged during its use over time. As the sheer volume of information in the workspace increased various "secondary" phenomena occurred, such as the problem of workspace organisation, workspace event overload and group friction followed by the establishment of group norms. The students often expressed their frustration with these issues, but from an educational perspective these were valuable authentic CSCW experiences that are difficult to adequately describe theoretically and also difficult to simulate. For many of the students the shared workspace experience became more than just an educational activity, it developed into a genuine online community (Preece 2000) that stimulated their interest and motivated them to participate further.

At this level, the system was being used both as a simulator of workplace groupware use and as an experimental educational environment. These dual functions often lead to confusion, not least for the lecturer. What role should I play? I originally seeded various discussions but tried to stay in the background as much as possible. I later felt compelled to become more involved and play a more active part in trying to direct the learning. This is a "problem" perhaps peculiar to teaching CSCW, where the simulated authentic activity and the collaborative learning are so closely related. The system was also used to support small group (4 or 5 members) projects. Each small group created an online folder only accessible by group members. Some of the groups preferred to work offline and only submit their final report online while other groups took advantage of the system to exchange resources and versions of their reports. We would argue that the use of the shared workspace system proved very successful at level II of our model. The system supported educationally valuable and challenging activities while at the same providing first-hand experience of fundamental CSCW issues.

Schooling Bites Back!

Having tried to escape from schooling and to create a more authentic environment we found that schooling in the form of one of its most enduring myths "everything can be graded" blighted our activities. In previous course modules, where participation in a shared workspace was voluntary, student use had been somewhat limited. We decided from the outset that the extrinsic motivation of 25% of the final grade for participation was a necessary evil. Ideally we would hope that student reaction would be of this form:

"Finally I think I would have contributed whether or not there was a grade involved, simply because it has been fun to use a new system like this!!"

However the more common student feedback was:

"There is no way I would have participated in BSCW if there was no grade attached to it. I find it takes too long wading through all the various folders and discussions that are going on, by the time I finish doing that I don't feel like replying to anything. The sole reason for my participation is the GRADE."

I announced at the beginning of the course that there would be a grade for participation in the workspace and then rather naively hoped that the students would put the matter to the backs of their minds and just get on with participating. However, the issue of what constituted the right kind of participation was a recurring topic of discussion. Some students even virtually followed me around the workspace, reasoning that if they contributed to a discussion I had contributed to, their contribution would be sure to be noticed. Student behaviour at times resembled pigeons pecking at seed in a Skinner box.

Design Challenge – Authentic Assessment

Part of the student anxiety about assessment was no doubt caused by the fact that it was a new type of assessment for them. I wanted to motivate activity rather than simply assess some deliverable. I wanted to reward the quality of participation as well as quantity. Providing a set of clear marking criteria at the outset could have no doubt reduced the general level of student anxiety, but it does seem

to be inherently difficult to grade activities like participation in discussions. Assessment is possibly the most inauthentic practice in educational institutions. This is not to say however, that assessment does not take place in the workplace or in other areas of life. How can we assess in a more authentic way, or better still, how can we instil intrinsic motivation without assessment?

Level III Authenticity – Interaction with Authentic Culture

[Education] "cannot be a closed system that shelters a well-engineered but self-contained learning process. On the contrary, it must aim to offer dense connections to outside its setting" (p. 275).

Etienne Wenger (1998)

We considered the level III activities to be the most important and perhaps the most novel part of our educational experiment. The major advantage of creating an asynchronous educational online workspace with universal (web-based) access is that people can participate from anywhere in the world. The key ingredient at this level was the expert. We saw the expert as above all a representative of an authentic (CSCW) culture, a community of practice of users and of developers. In this capacity she could provide a valuable authentic correcting and modifying influence on the development of our culture represented in the shared workspace. There is a very real danger that in a university, Level I and II "authentic" learning will mutate into an inauthentic set of practices. At a more basic level our expert also played the role of the outsider, as she pointed out "In this situation, I'm really the only outsider". For the students there is no doubt that she also represented the exotic. For some strange reason young people in England are intrigued by anything Australian. The principal activity of the expert was to join in the various online discussions, most of them relating to CSCW. In particular, there was an "ask Kylie" folder that functioned rather like an asynchronous meeting room.

The observations and comments of the expert had a significant influence on the discussions and practices of the shared workspace. For example, acting on her suggestions, we set-up an introductions folder where everyone was encouraged to write a little bit about themselves and their background. We also started signing our comments in discussions rather than just relying on our somewhat obscure user names. Later influence in the workspace was somewhat overshadowed by an embodied visit from the expert.

Whose Culture is it, Anyway?

The impact of the "authentic" is a valuable resource. Our virtual expert had a significant influence on the activities and learning in the module. However, we would have liked to maximise or magnify her influence. One of the main problems seemed to be that she had to come to terms with our culture. In many ways the shared workspace became an extension of the module and of the university. The workspace existed only online, its physical location was actually in Germany, but the culture undoubtedly represented Luton. Our expert expressed confusion about various aspects of the workspace culture.

"...yes, it is a bit strange participating in BSCW discussions from such a long way away. It's not so much the distance but because of the distance, I don't know the people who are contributing, nor how to interpret what I read."

I set up the workspace; many of the participants knew each other off line; membership was restricted to module members who were motivated by a good grade. Such factors tend to naturally influence the fundamental character or culture of the online community and make it difficult for an outsider to have an impact. It seems we had broken out of the classroom only to take the classroom with us.

Design Challenge - Virtual Legitimate Peripheral Participation

How can we maximise the level III impact of our expert without significantly increasing the amount of time and effort required from her. Clearly her influence was constrained by numerous factors including the activities of the workspace, her role, the influence of assessment and the existing bonds between members of the module. The expert also had to enter the shared workspace without her cultural trappings, her specialised language, her artefacts, her common knowledge and beliefs. Lave and Wenger (1991) described how newcomers became part of a community of practice as "legitimate peripheral participation". What we ideally need in an authentic learning environment is for the students to enter the culture of the expert rather than the expert to enter the culture of the students, a kind of virtual legitimate peripheral participation. We are not suggesting that this would be "true" legitimate peripheral participation, but we are suggesting that this could be a valuable and authentic educational

experience. One way of achieving this would be to give students restricted access to the shared workspace of a workplace. (The research centre where our expert was based also used the BSCW system on occasions.) In this situation the expert could become a guide or interpreter for the group. Perhaps students could even perform some useful function such as test subjects.

Conclusions

In this paper we have outlined our experiences and theories focused on the idea of developing authentic learning environments. We have only just begun, and there are many technical and educational problems to be solved. We are motivated however, by two powerful convictions. Learning should be more authentic and the Internet is potentially an extremely valuable tool for supporting authentic learning.

Abstract: One computer classrooms have become the bain of numerous educators since the first computer was placed in the first classroom. Away from all the other computers, sitting quietly in the corner collecting dust. Yet the classroom environment is slowly changing and evolving to include ... a Web-enhanced one computer classroom. The Web-enhanced one computer classroom is a useful environment, once the seeds of disparity are overcome.

Introduction

Since Vannevar Bush (1945) first imagined the creation of an intelligent machine that could hold all of the knowledge in the world and the machine could learn from trying to duplicate a human's mental process in an artificial manner, man has been moving steadily towards the Information Age. With the rise of the World Wide Web's existence, and open access for use by the general public in the early 1990s, the information that is accessible by a computer has become insurmountable. Even as early as 1980, Seymour Papert suggested the existence of a simplistic computer that would offer easy access and learning opportunities to the learning environment.

> I believe that the computer presence will enable us to so modify the learning environment outside the classrooms that much if not all the knowledge schools presently try to teach with such pain and expense and such limited success will be learned, as the child learns to talk, painlessly, successfully, and without organized instruction. (Papert, 1980, p. 9)

With such prophesies as these, the technologies have led us towards the dawning of the new Information Age, where anything is possible. The one significant difference between the technology and its appropriate and successful use within a learning environment is the influence of the instructor; only the instructors has the subject matter expertise and the instructional design skills to appropriately and successfully integrate the technologies available today. After all, "Computers are not an end in themselves. The goal of technology integration into the classroom and curriculum is not to expose students to computers and the Internet. Technology, by definition, is a tool" (Dockterman, 1998, p. 21). Perhaps the most difficult aspect to help educators realize is that technology is just a tool, just as a pencil or paper or a chalkboard have been touted as revolutionizing elements within a classroom environment, so shall the computer. Yet a one computer classroom is the environment that many educators find themselves in these days, with Web access an element that must be further discussed.

Why the One Computer Classroom?

The drive to place computers in every single classroom has become a driving force over the previous eight year period. Numerous levels of the community heard the need and the desire for computers in the classroom and a push began to entrench the hardware in the schools to enhance the learning environment. The hardware is advancing by leaps and bounds, but what of the professional development opportunities that must follow the hardware? Educators must have the time and opportunity to delve into the numerous capabilities of a Web-enhanced computer that sits on their desk. There are so many possibilities for a one computer classroom that it is astounding. Yet three overriding themes concerning a one computer classroom have been designated.

What Can an Instructor Accomplish With Just One Computer?

A computer can help an educator accomplish numerous aspects of the professional day's events. One computer in a classroom environment can be a tool that not only enhances the educator's daily chores, but also enhances the learning environment. Dockterman (1998) offers at least four elements that are generated by the computer in the classroom educational environment.

- One computer for personal productivity
- One computer as a presentation tool
- One computer and interactive group software
- One computer as a learning station (Dockterman, 1998, p. 23)

The educator has the opportunity to enhance personal productivity of tasks such as student attendance and digital gradesheet software. Further, the educator has the ability to hook the computer up to a television set as a presentation tool, or load the computer with Web-enhanced interactive group software to enhance active learning environments that could also enhance the computer as a Web-enhanced learning station. Only the creativity and opportunity for professional development opportunities that enhance the educator's creativity will further the integration of technology within the learning environment. However, time must be set aside for the educator's specific professional development opportunities to encourage the integration of the technological endeavors into the curriculum; time is one element of which all educators find lacking and this must no longer be the situation if educators are to enhance not only their technological skills but also the learning environment for their students.

Conclusion

As with all innovative and creative possibilities, a risk must be taken in order to learn and improve upon the opportunities for the learning environment. After all, "The goal is to support an underlying educational purpose. And that underlying purpose and understanding will remain with the students regardless of what happens to the technology" (Dockterman, 1998, p. 22). Creating a successful learning environment is the focus of every professional educator, and all tools must be appropriately used towards the accomplishment of the lesson objectives. The use of a Web-enhanced one computer classroom is merely one way to reach these goals.

Web Access@Fresno State: A Plan for Implementing Web Accessibility at California State University, Fresno

Candace Egan, California State University, Fresno, USA

The release of the Rehabilitation Act's section 508 standards for electronic and information technology in December 2000 has served as a catalyst for university Web accessibility efforts. At California State University, Fresno a work group was formed in November 2000 to lead its Web accessibility activities. The key question of the group was how to implement Web accessibility. Development of an implementation plan was seen as the core component necessary to guide the campus in its Web accessibility activities. The Draft Interim Web Accessibility Plan is an attempt to provide a comprehensive planning document that will guide Fresno State for the next two to three years. This poster presentation provides an overview of Fresno State's plan and planning process. The lessons learned from Fresno's experience will be presented along with the key planning questions that should be considered by university's developing an accessibility policy and plan.

Using Checklists for Large Scale Website Audits

NSW Australia
johne@testingcentre.com

Justin Bicknell
Access Testing Centre
112 Alexander St Crows Nest 2065
NSW Australia

This paper describes the methodology for a comparative audit of 108 websites under the jurisdiction of an Australian State Government using a checklist to evaluate usability criteria. The objective of the review, conducted by Access Testing Centre (ATC), was to evaluate and compare the 108 websites against a variety of specified conformance and usability criteria, in order for the client to identify and promote best practice and uniformity.

To compare the websites against a range of usability criteria, ATC developed a unique testing instrument that took the form of a checklist, which identified key areas of strength and weakness in each site from a sample of key pages. It was developed using a seven-point rating scale incorporating a range of usability criteria drawn from conformance specified by the client, W3C guidelines and usability heuristics.

The main benefit of developing and implementing a checklist to evaluate the websites was the creation of an accurate method for analysing a large sample of websites while minimising the time usability experts spent on the task.

Employing Internet2 Technology to Enable Collaborative Research and Distributed Training in Complex Multi-Operation Settings

Abstract: The United States Air Force is positioned to take full advantage of Internet2 technologies. This paper summarizes the Air Force's Distributed Mission Training Research Network (DMT-Rnet), an Internet2 based network for collaborative research and training via distributed PC-based systems. This network creates complex environments for multi-operator training and performance research. An initial phase of this project utilizes the dynamic distributed decision making network (DDDnet) as the platform. DDD simulations require important team-oriented cognitive processes such as communication and coordination, resource allocation and sharing, and decision making. Observers at each of the distributed locations rates performance using web-based tools that allow immediate data pooling, analysis, and feedback, within 10 minutes after data input was complete.

Introduction

The United States Air Force is positioned to take full advantage of Internet2 (I-2). Emerging capabilities from I-2 technologies are already enabling huge advancements in Internet-based training and performance-based research. Current Internet-based technologies have limitations that restrict progress such as severely limited bandwidth, reliability issues, latency, interruptions and security issues. These barriers can be minimized with I-2, due to much greater bandwidth and efficiency. This brings about new opportunities in collaborative research and training.

Just a cursory look at speeds alone is impressive. An OC-48 connection on one of the main backbones of I-2 runs at 2.4 gigabits per second, which is about 45,000 times faster than what people typically have to endure on a 56K modem. New options such as multicasting, tele-immersion, virtual laboratories, digital libraries, and distributed learning added to the mix create an Internet that can be used for much more than ever envisioned.

Here at the Information Systems Training Research Branch, Brooks AFB, researchers are involved in two major programs grounded in I-2 technology. One example of this is focused on investigations and enhancement of operational expert training through an internet-based research base to enhance Distributed Mission Training (DMT). The DMT-Rnet project will establish an I-2 based network for collaborative research and training via distributed PC-based systems. Another area of research that is growing exponentially is the Advanced Distributed Learning (ADL) project, an "umbrella" topic of research which integrates numerous multidiscipline projects. Both DMT and ADL projects are national in scope.

In this paper we describe the first phase of a DMT-Rnet collaborative research program in which we are leveraging emerging I-2 capabilities to connect distributed PC-based simulation systems and create complex environments for multi-operator training and performance research. The USAF DMT project relies on a network of highly realistic battle simulators that allow expert operators to train in a virtual battlespace across a highly secure and classified communication network. In contrast, the DMT-Rnet project will develop less expensive PC-based systems that can run in unclassified mode on Internet2. This allows the PCs to be distributed and deployed as training systems in almost any setting. It also allows University-based research to occur, using these simulation systems that reflect essential components of operator expertise. In fact, multiple Universities can and have been networked to enable real-time multidisciplinary collaborative research.

An initial phase of this project utilizes the dynamic distributed decision making (DDD) team-in-the-loop simulation environment (Hess, MacMillan, Elliott, & Schiflett, 1999; Kleinman and Serfaty 1989) as the first platform for this work. DDD simulations require important team-oriented cognitive processes such as communication and coordination, resource allocation and sharing, and decision making. Other systems have also been developed within this program, and each provides an integrated, internet-enabled, collaborative training space that supports three integrated capabilities: distributed team performance; distributed assessment; and distributed training (Elliott, Chaiken, Stoyen, Petrov, & Riddle, 2000; Schiflett & Elliott, 2000). For example, another internet-based platform based on AWACS WD functions is a java-based architecture composed of a federation of "intelligent" agents. These agents generate and execute scenario function, data collection, decision support, and can emulate WD roles within the scenario. That allows participants to play with or against agent-based simulated friendly and/or enemy forces. It can also execute scenarios in all-agent mode, providing what-if analyses of different scenario characterstics (e.g. amount, location of assets and targets).

For this particular effort, we developed an internet-based version of the DDD, the DDD Network (DDDnet), which allows players in distributed locations to connect and perform a distributed mission in real time. Preliminary tests of the DDDnet were successful. Participants from four Command and Control research groups (e.g. Brooks AFB, TX; U of South Florida, U of Central Florida, and Aptima HQ in Boston, MA) were connected and performed in a team-on-teams Command and Control battlespace scenario. The DDDnet achieved and maintained a synchronized connection involving all 16 participants. Simultaneously, observers at each location rated performance using web-based tools that allowed immediate data pooling, analysis, and feedback, within 10 minutes after data input was complete.

The DDDnet is a internet-ready version of a Linux-based collaborative gaming space that connects players to each other and to others, such as observers, confederates, trainers, or researchers. In the DDDnet observers at any location in the network are able to observe the scenario play in real time. They can view the screen display and electronic communications of any player, and communicate to one another via email or voice. In addition, the DDDnet can connect players to one another for interactive mission planning, debriefings and after-action reviews. Other internet-based systems have also been developed for specific training and research functions, within the scope of the DDD-Rnet project.

Researchers using these internet-based systems will be able to access detailed performance and team processes during the mission planning, mission execution, and during the mission debriefing phases of performance. An integral part of the DDD Rnet is a suite of team performance and process measures that provide feedback and evaluation metrics for team performance. These measures are available from three sources: the DDD simulation data output, observation-based input provided by distributed observers, and reports provided by the participants. They can be targeted at four levels: individual performance; team performance, and system-level team-on-team performance, and mission outcomes. The DDD-based performance measures focus on mission outcomes related to capture of effectiveness, timeliness, efficiency, speed, and latency of particular events embedded within a scenario. The DDD can collect and provide feedback on many of these measures in real time, throughout the performance of a scenario. Others are captured immediately afterward through web-based data collection and distribution systems.

Issues

DMT enables highly realistic mission rehearsal based on networks of high-fidelity simulations that immerse the personnel in virtual battlespace scenarios. These simulators are highly realistic, in terms of equipment characteristics and procedures used in an operational setting. They look and function just like the "real thing". In fact, some of these systems are fully functional as operating USAF systems—the main difference being the added capacity to connect and operate within a simulation network. Because these simulations strive for maximum

realism, they must run in classified mode within its own dedicated network, thus restricting data analysis and publication. Further, systems such as these are extremely expensive, difficult to deploy and utilize in field settings, and less available for use, relative to PC-based systems.

In contrast, DMT-Rnet systems will enable systematic investigations in unclassified mode and establish the infrastructure to conduct multi-level investigations of operational performance using less costly PC-based systems. These systems can be readily deployed to operational field settings and enable cost-effective distributed training wherever internet access is available.

DMT-Rnet systems will not be total replications of operational systems. Instead, these synthetic team task sytems will capture the cognitive and task demands of most interest to trainers and researchers (Elliott, Dalrymple, Regian., & Schiflett, 2001). For example, a PC-based system may simplify the "button pressing" procedures required in an actual operational system and instead focus on display characteristics, decision making processes, tactics, strategies, and/or teamwork functions. Convincing arguments have been stated for the relevance of systems which are based on psychological fidelity, and the absolute need for internal validity for the advancement of scientific knowledge (Berkowitz & Donnerstein, 1982; Cook & Campbell, 1979; Mook, 1983). The DDDnet was developed to represent the underlying cognitive and decision making task demands of Airborne Warning and Control System (AWACS) Weapons Director Teams, based on multiple investigations of cognitive and functional aspects of this performance domain (Coovert, et al., 1999).

Another benefit of this type of a synthetic task environment is the variety of subjects that can participate in the research. High fidelity simulators are so close to reality that they necessitate expert operators as subjects. There is a shortage of personnel in the Air Force in general, and particularly for high-expertise tactical operators. The operational Air Force simply can't spare these people for all of its research issues, regardless of potential payoff from these investigations. Systems such as the DDDnet can use naive subjects and train them quickly to use the system, thus allowing skill acquisition to focus on underlying tactics, strategies, teamwork, or other training/research objectives. This saves another commitment of operational personnel for the Air Force as well as money, both of which are in short supply. It also allows researchers to study knowledge-based skill acquisition processes and interventions (e.g., training content and delivery; distribution and display of information; coaching and decision support capabilities).

The issue of knowledge aquisition is important when working with training objectives that are remotely administered and scored, for example Advanced Distributed Learning (ADL). To achieve optimal content and delivery, we must use cognitive principles to identify specific knowledge structures required to coordinate, interpret, and predict the activities of others. This is fundamental to measure and enhance individual and team situational awareness. We must measure, from a functional cognitive perspective how often people should update their knowledge, by what method, how it should be shared in a team.

Performance feedback is another critical objective in this project. Targeted feedback is necessary for progress and quality of training. Distance training makes this a little more difficult, but with the right steps it can be accomplished. Here, we focus on embedded measure of awareness and performance, online feedback, web-based collection, and rapid delivery of performance feedback to facilitate debriefing. The same technologies that enable the DMT-Rnet missions can be used to provide performance feedback.

Method

The AWACS DDD-Net was recently implemented and demonstrated, allowing distributed simulations over the Internet. Aptima, a small research corporation, worked with faculty and staff at the University of Central Florida (and associated Institute for Simulation Technologies [UCF/IST]), the University of South Florida, and researchers located at Brooks Air Force Base to test the feasibility of the project (Entin, Serfaty, Elliott, & Schiflett, 2001). It linked the different locations, allowed multi-role missions, data collection, and feedback. Different parts of the network included Internet2 connections for improved speed and performance. At the same time, we investigated the manner by which the subjects shared and sequenced information and resources.

The network presented a prepared scenario, with objectives laid out. People in the different roles had individual taskings as well as an overall mission goal. The software presented them a map with their unit information displayed. They controlled the movement and action of the units assigned to them. Teammates shared the information regarding position and movement of relevant friendly and hostile forces. Resources were reallocated between teammates as necessary for optimization, or even between different site nodes of the network.

For example, someone connected at a node in the University of South Florida can send a message to the person playing the role of the Joint Forces Air Component Commander (JFACC) at a node at Brooks Air Force Base requesting control of a KC-135 (refueling tanker). The JFACC can then switch control of the KC-135 to his naval counterpart working from the University of South Florida.

Information was shared much like resources. An example is someone playing the role of Intelligence, Surveillance and Reconnaissance (ISR) operators. This person has control of various information gathering tools, such as Predators UAVs (Uninhabited Aerial Vehicles). They send out these Predators to find specific targets or locations. Once found, the ISR team sends this information to the appropriate person needing that information. It can be sent to everyone in his or her particular site, or to other individuals require that specific piece of information.

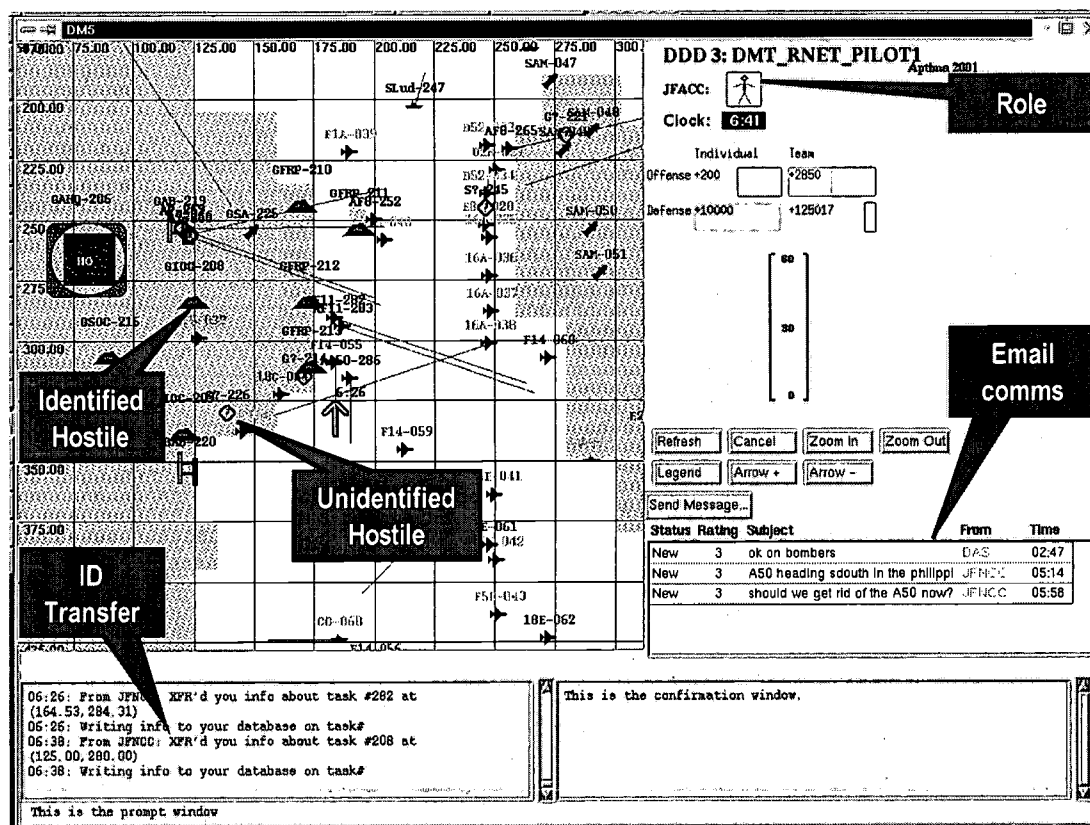
Communication and resource allocation within and between the different sites is closely monitored and analyzed, and will reap enormous amounts of useful information on command, control, and communications process measures.


Figure 2. DMT-RNet Screen from distributed scenario execution involving four nodes

Summary

Brooks Air Force Base has teamed up with a small business (Aptima), the University of Central Florida, and the University of South Florida to create the DDDnet, a command and control training and research system using PC-based systems networked by a mixture of current Internet and I-2 connections. The DDDnet is a low physical fidelity system focusing on the cognitive tasks and decision making processes involved in command and control rather than realistic replication of operational weapon systems.

The DDDnet will be part of the larger DMT-Rnet, which is envisioned as a research and training network that presents mission-type scenarios ranging in complexity from very simple to highly realistic battle scenarios which could challenge operational experts. Classified information is not involved, making it possible to utilize I-2 technology to maximize performance. DMT-Rnet systems trade off total realism to attain advantages of much lower cost, transportability, and features valued by trainers and researchers. These features include quick and easy scenario generation, online performance feedback, tutoring mechanisms, and the ability to manipulate, control and/or configure task demand, display characteristics, and other functional aspects of the system.

Multiple operators collaborate in the presented scenarios, and are given different levels of resources and information. They must work together, implementing the most efficient methods of sharing these resources to accomplish the mission. Assessment and feedback are integrated into the program. These platforms are analogues of actual operational systems, based on cognitive task analyses conducted during system development. They will enable distributed and multidiscipline research to present new information on individual, team, and system performance. They will also serve as cost-effective systems that can easily be deployed to any site having access to the internet. Results will benefit the Air Force specifically, and will also generalize to other similar performance domains requiring collaborative real time problem solving and crisis management teams.

Abstract: This paper describes developments in the use of the World Wide Web and e-learning at Southern Cross University over the last 10 years. It then looks ahead at opportunities and challenges that are likely to be faced during the next 10 years.

Southern Cross University was an early adopter of the World Wide Web having a server up in 1992 and a University Home Page in early 1993. While limited use of student email groups had occurred prior to the Web it was the Web's point-and-click and graphic capabilities that really launched the current phase of interest in e-learning.

Between 1995 and 1997 there was limited experimentation with individual, Web-based units and Web-mounted course resources. In 1998 special funding provided by the University Executive allowed for full design and development of sufficient units to support the commencement of online delivery of two degree programs. In addition, the online course management software/hardware solution LearningSpace was adopted. Unfortunately it proved unsuitable for the Southern Cross University environment and was replaced by Blackboard CourseInfo that was phased in during 2000.

In 2001 and beyond the University faces a wide ranging series of challenges and opportunities, many of which will have to be successfully addressed if the overall development of e-learning is to be consolidated and become a sustainable, mainstream University activity.

Early Technical Developments and Explorations (1992-1994)

The early technical development and rapid technical evolution of the World Wide Web (the Web) is well documented in books by both the co-developers Tim Burners-Lee and Robert Cailliau (Burners-Lee (1999), and Gillies & Cailliau (2000)). Up until the end of 1993 the use of the Web was largely confined to the global high energy physics community where it was used for the exchange of documents related to collaborative projects. In addition to these engineers and physicists some university computer department staff and a few developers were also experimenting with the Web. Towards the end of 1993 there were still only a few hundred servers worldwide and Web (Port 80 http) traffic measured only around 1% of the NSF backbone traffic (Connolly, 2000).

Southern Cross University (SCU) was an early adopter of Web technology with a trial Web server being downloaded from CERN and operating in the Computing Centre in late 1992. This Web server was the second in Australia and within the first 100 to be set up globally (Hill, 2000).

In 1993 the Web was demonstrated at a number of SCU seminars and its potential to displace an existing gopher-based campus wide information system was discussed. Furthermore the possibility that the Web could function as an innovative educational technology was also recognised by some staff. The release of the Mosaic browser for all common platforms in late 1993 made the Web even more attractive than it had been when only line mode text browsers had been available.

In May 1994 the Web moved into the wider community with the heavily oversubscribed First International World Wide Web conference organised by Robert Cailliau and held at CERN research facilities in Geneva (http://www94.web.cern.ch/WWW94/). This ground breaking conference was followed in October by a second conference, aptly titled "Mosiac and the Web", held in Chicago and organised by NCSA

(http://archive.ncsa.uiuc.edu/SDG/IT94/IT94Info.html/), and the International World Wide Web Conference series was established (see IW3C2, 2001).

In late 1994 two Southern Cross academics hatched the idea of staging a national Australian Web conference. Subsequently in April 1995 the first AusWeb conference was held at Ballina in NSW. The series is now entering its 8th year and has established itself as Australia's National Web Conference (AusWeb, 2001). It was recently granted the status of an Endorsed Regional Web Conference by the IW3C2.

Early Web-based courseware development initiatives (1995-1997)

In 1995 a number of proposals were developed and circulated for new course development and delivery systems. These included a "Network Learning" model and a model for "Telecommunications-based Education". Each of these proposals sought to integrate the Web onto existing traditional forms of course delivery (Chua, Debreceny and Ellis (1995), Debreceny, Ellis and Chua (1995), Ellis (1995 a & b), Ellis, Debreceny and Hayden (1995)).

These proposals sought to create new pedagogical formats that incorporated the unique features of the rapidly evolving Web technologies (eg Java applets, animation, streaming video and audio etc) as well as providing improved information organisation/representation and more efficient distribution systems. They also sought to challenge the need to differentiate between on-campus and off-campus (external or distance education) students and to provide equitable communication and collaboration opportunities for all students regardless of their geographic location or study pattern (full or part-time).

In 1996 the School of Social and Workplace Development offered a fully online post-graduate unit in Futures Studies. This was an exercise in top-down curriculum design with all study materials, interactions and assessment being handled online via the Web and email. Full details of the unit are provided in Ellis, Wildman and O'Reilly (1996). In 1997 the materials for a further 10 post-graduate units were moved online using existing materials already produced in traditional paper-based distance education format but adding a discussion listserv and additional hypertext reference lists. This could be characterised as a bottom-up approach to curriculum design. Staff in other Schools e.g. Commerce and Management, and Exercise and Sports Science also began to offer some course materials online using the bottom-up approach.

At this time the University funded a three year Technology in Learning and Teaching (TiLT) project whose brief was to encourage and support development and use of information technologies in the learning, teaching and other scholarly activities of the University. TiLT assisted in development of Web-based courseware and associated technologies and support systems, provided limited training and development programs for staff, including an online self-paced Web development course undertaken, at least in part, by over 140 staff.

It would be reasonable to conclude that at the end of 1997 the average features and functionality of Southern Cross Web-based online units were comparable to the median of sites described in an extensive survey carried out by Mioduser et.al.(1999), that is, they were not outstanding and indeed most of them lagged behind expectations and the advanced capabilities of the available development systems. In order to stimulate more sophisticated and more extensive unit development lobbying began for special funding. At the same time, educational designers were employed within the Teaching and Learning Centre to provide academic support in creative pedagogical design for the new learning environment.

Full-scale Web-based courseware development (1998-2000)

Late in the second half of 1998 the University Executive took the decision to allocate specific innovations and development funding to two major projects that would develop and deliver two entire degree courses online: A Bachelor of Social Science and an Associate Degree in Paralegal Studies.

The first stage of development of each course commenced in the second half of 1998. A project management methodology was employed to facilitate the integration of discipline expertise, educational design, technology and learner support components. In the School of Social and Workplace Development this involved a multidisciplinary team working to prepare 5 units for delivery in first semester 1999. In the same timeframe the School of Law and Justice targeted the development of 2 units. Each School prepared a detailed project plan

involving development, delivery and evaluation stages under which extra new units would be brought online each semester until the academic program structure was complete.

In order to gain consistency and efficiency the formal decision was made by both Project Boards to adopt LearningSpace (http://www.lotus.com/home.nsf/welcome/learnspace) as the course delivery shell. This decision was taken quickly without completing a detailed evaluation of the product but more or less going on the reputation of the company behind the product. IBM/Lotus LearningSpace is part of the Lotus Notes suite of products and enables users to access their materials, collaborate with peers, work off-line (using proprietary client software) and submit certain types of assessment. As a regional University working with a limited telecommunications infrastructure, one of the key features which initially attracted SCU to LearningSpace was its capability for users to work with the full study package entirely offline, logging on briefly to communicate and receive updates to the teaching resources.

Whilst the underlying structure of the LearningSpace system obviously suited its corporate origins, it did not translate at all well to the SCU academic/student environment. Busy academics with no Lotus Notes experience found the product difficult to use, the issue of client installation and use proved problematic (Patterson, Ellis and Brice, 2000) and student support needs became excessive. As a result of all these factors in December 1999, the University's Executive accepted the internally published evaluation report (Hayden, Saenger and Parry, 1999) and recommendations of a special working party that the University migrate to Blackboard's CourseInfo, now simply termed Blackboard (http://blackboard.com). The transition was slated to occur in the 2000 calendar with all support for existing LearningSpace materials being phased out by 2001.

Adopting Blackboard CourseInfo has also allowed the concept of a personalised Web page homebase (or "portal") for students to be realised. All students at the University, regardless of whether they are engaged in online units or not, can now log in to their own Web portal called "MySCU", and from there access a range of intranet services; a calendar and tasks area, links to their units, as well as links to the Library, Computing, and other student services currently available. This personalised portal is a synthesis of the functionality of the Blackboard CourseInfo application and the student intranet resources and services.

Support and training for staff in using Blackboard CourseInfo was an important priority. Whilst the application is an easy-to-use, intuitive program, staff are encouraged to take advantage of the short orientation/training sessions held regularly throughout the year. An email helplink and Web site resource provide follow-on support. Students are being supported in accessing and working in their Blackboard CourseInfo environment by online help, phone and email services. Consultation on pedagogical design is accessed by teaching staff via the Teaching and Learning Centre's program of individual, group and institution-wide support services.

In first semester of 2000 nearly 100 individual units had an online dimension to their delivery, from supplementary resources and interactivity to full Web-based delivery online. In addition, about half as many again were in the process of development for delivery in 2001. By the end of 2000 the transition from LearningSpace to Blackboard had successfully been completed and at the commencement of 2001 over 150 units were on offer with a variety on online functions embedded.

The Future: Consolidation (2001 and Beyond)

Oliver (2001) proposes that four major areas of concern that need to be addressed if the adoption and sustained use of online learning in Higher Education in Australia is to be successful. The areas he considers important are: the establishment of cost effective practices; the achievement and maintenance of quality in online learning delivery; ensuring access and equity in delivery of programs; and establishing practices which can enable online learning to be sustained and to grow as a mainstream activity in university teaching and learning. Oliver goes on to note that "while these issues are suggested as discrete entities, it is recognized that there is considerable overlap in the influencing factors and in the strategies and processes by which they can be overcome".

While the Southern Cross experience to date supports Oliver's proposals it also provides a more detailed break down of the major areas of concern into a larger number of specific issues and gives some indication of the basic problems that need to be addressed and the opportunties that are available. These include:

? **Developing new approaches to online pedagogy and assessment.** Recent Australian research (Alexander & McKenzie, 1998) highlights the disjunction between expectations of students and staff, and their actual experiences with technology . The significantly improved attitudes of students to their learning (16% intended

improvement; 62.7% actual improvement), was sadly not matched by improved quality of learning (87% intended improvement; 37% actual improvement). The enthusiasm of students and staff to new opportunities promised by elearning opportunities were not fulfilled. On closer analysis the single major cause of this shortfall was that assessment processes were not changed to better suit, or indeed take account of, the unique context of learning as supported by networked computer technology (Alexander and McKenzie, 1998: 234).

It is important to consider the methods of assessment that apply in a range of discipline areas and are supported by both the capabilities of the technology and the staff. The e-learning environment has extended the range of skills to be assessed for example information literacy skills, publishing works online, participation in a range of discussion formats, multimedia simulations, web page design, collaborative and peer-reviewed tasks. Opportunities for new assessment methods are also afforded, e.g. MCQs, timed online exams, international collaboration, group projects, peer- and self-assessment with rapid feedback (O'Reilly and Morgan, 1999).

In this richly abundant and democratically delivered context of digital information, plagiarism is emerging as an important issue associated with assessment. Clearly, if students do not feel that the tasks they are required to undertake in the course of their studies are meaningful, fair and authentic, they may be more inclined to take a strategic approach. This approach to learning can range from lawful practices such as using tactics to impress tutors, through to dishonest practices such as cheating, simply to perform prescribed tasks and achieve the necessary grades. Assignments which address the plagiarism question through a need for authentic and sustained engagement over the study period and allow students to demonstrate their learning in the most relevant format are all now possible, and challenge existing teaching and learning practices across disciplines.

? **Student preparedness/IT literacy and support.** The e-learning environment places new demands on students. In the past the University has offered a Success in Tertiary Education (SITE) program. It now is preparing to offer something that focuses on success or readiness for elearning. Newton and Ledgerwood (2001) demonstrate the need to take an holistic approach to student support. They illustrate how a student intranet site can be used to provide links to counselling services, financial services and other support agencies that can all contribute to a student success in their studies.

? **Access.** The University currently operates a relatively small modem bank at its main campus and even smaller numbers of modems at several of its regional study centres. These have been heavily congested for a number of years. As a result of the rapid uptake of Internet access into Australian homes, business and community venues (e.g. libraries) the university has moved to recommending that students, particularly those studying units with a substantial online component, should take steps to gain independent ISP access via either home and/or their workplace. Thus what only a few years ago loomed as a large and expensive problem for the university has, for the time being, faded away as relatively cheap dial-in access (up to 56Kbps) which has become universally available. However, on the horizon looms the issue of broadband access. Currently costing 5 or more times the monthly cost of dial-in access, and not being universally available, it seems the issues of access will soon be back on the University's agenda. The access speed of students is intimately linked to course design and media richness, and what can or cannot be feasibly and practically delivered at various connection speeds. Rather than bandwith limitations disappearing in the near future (as predicted by some writers e.g. Downes (2000)), it may be that the digital divide between those who have and don't have connectivity is mirrored in another division – this time a bi-modal distribution based on those with high or low bandwidth access.

There is also increasing pressure from staff, particularly those teaching online, to have broadband access away from their offices (at home or on the road) to allow more flexible work practices. The challenge for staff will be to convince management that this is an opportunity cost that is worth incurring.

? **Equity.** At Southern Cross University, units which require connection to the Internet in order to satisfy requirements remain in the minority and are frequently optional rather than core compulsory elements of courses. Compulsory online units will only be accepted by current students in courses where the Internet authentically represents the working environment, for example in disciplines such as information technology, multimedia and management. While students continue to have an option to study in traditional on-campus or off-campus modes, the additional costs of study online are not a barrier, but a choice.

In the case of online study, efforts are made at SCU to ensure compliance with the guidelines for Web accessibility. Being an "equity" institution, a strong awareness exists to consider screen design and printable pages as well as ensuring alternatives are available to students for communication and interaction.

? **Timely resource development and reusable learning objects.** Another exciting challenge with e-learning is that of developing material that is up to date and maintaining its currency. In the case where online material dates much faster than print materials, SCU often explicitly requires students to develop good information management skills and might also request permission from students to reuse the data they generate, for future cohorts. This helps staff to keep up to date as well as effectively expanding their teaching resource base.

Opportunities are also more available for developing just-in-time training and performance support. E-learning systems mean that education and training no longer needs to be the front-end-loaded model. Subjects in applied areas such as research in natural medicine are continuously revised through dynamic student input together with additional knowledge-building by academic coordinators. Staff development is also timely and responsive.

? **Staff development for e-learning.** This is a key challenge if long term, sustainable change is to achieved. Strategies need to be developed, adopted and funded. Ellis (1999) and Ellis and Phelps (2000a and b) outline what can be achieved by a structured and multi-pronged approach to staff development and support. Moving into the e-learning enviroment is a chance to either de-skill staff, by having the new work done for them, or re-skilling staff by providing them with the training and tools to work in this new environment.

At present Southern Cross is undergoing a major re-structuring of its administrative and support services. This review will include the issue of how staff development can best be provided and will address the need for not just initial training in new areas but also for ongoing support and training, as upgrades, new software and hardware become available. Hopefully these activites will be regarded as productivity investments not just costs (Ellis, Debreceny and O'Reilly, 1998).

? **Administrative and other system readiness.** The maximum benefits of developing a technologically advanced e-learning system will only be achieved if related systems are also updated and integrated. At Southern Cross University students can already obtain examination results via the Web and work is in progress with a new student administration system which will address issues like online enrolments and financial payments, direct student acesss to, and control of, personal information etc. The University's student portal system, "MySCU" is used to encourage students to customise their own online site. At this time, six other Australian universities have also invested in developing similar facilities.

? **Technical support and the scalability of support.** There needs to be major 'behind the scenes' planning and funding if increased demands on IT infrastructure and associated support services, such as help desks, are to be able to smoothly and seamlessly handle increases in demand generated by expanding e-learning activities.

? **New technologies, new work practices.** Perhaps the most difficult issue to predict is just how far and how fast innovations in e-learning environment will move in the next few years and what demands such moves will place on existing resources and established practices. Whatever the pace, the adoption of appropriate change management strategies will be central to the success of any enterprise-wide adoption of this new learning and teaching environment.

Concluding Remarks

We have described the developments experienced at Southern Cross University from early adoption of the World Wide Web to its move into the e-learning environment. The current task, which will probably extend over the next decade, is to consolidate e-learning provision as a mainstream activity, to make it a part of everyday university culture and to make sure that it can be sustained without the need for special funding.

The establishment of cost effective practices will include the reuse of learning objects and the integration of teaching approaches with streamlined information management systems that are easily (Web) accessible by both students and teaching staff. The achievement and maintenance of quality in e-learning will need to be supported by the continued employment of some specialist educational design staff and the adoption of a multi-disciplinary staff development action learning approach to course design.

To date moving the online components of teaching and learning into mainstream adoption has been specifically enabled through the benefits of a scalable product such as Blackboard Courselnfo. Design for optimal Web accessibility has included considerations of regional infrastructure, equity characteristics of our student group, extended student support services and customisable portal features.

Change management continues to require a multi-pronged approach to staff development, administration and policy development being accomplished through a dynamic and diverse range of activities. The next 10 years of online teaching and learning at Southern Cross University promises to bring students increasingly together in an online/e-learning environment, and to generate active learning outcomes and provide peer support irrespective of geographic location or enrolment pattern (full or part -time).

Abstract: In 1996 the Virtual University (VU) started as an online learning project at the University of Hagen with a few courses and a small number of users. Today the Virtual University has grown into a large learning platform with a student community of more than 10,000 and more than 200 learning events online. This paper describes some of the experiences made with development and use of the Virtual University, and in particular outlines the variety of effects on all areas of the university. Not only has the learning environment and process of students changed dramatically, but faculty, administrative staff, and technical support personnel have experienced fundamental challenges and reorganizations.
The virtual university is leading towards a major quality improvement in open and distance education. Many papers describe technical, didactical or legal aspects: this one aims at giving an insight into the complex impact on the whole organization.

Paper Outline

This paper describes how a research initiative, the Virtual University project, grew into a project that changed the appearance and the processes of a whole large organization, the University of Hagen. The paper presents a short review of how the project developed, and then explains how the different user groups were affected by the new teaching and learning paradigm. Finally, some necessary further developments are outlined.

1. A brief review

As life-long learning is getting more and more essential in professional life, learning via Intranet and Internet is becoming more an more popular and successful and distance learning is getting more important. The University of Hagen has an experience and a tradition of distance education since more than 20 years. Therefore, it was a logical consequence to use the Internet for learning and teaching purposes. The benefits of distance education, time - and location independence and the advantages of the Internet (fast information, easy communication and co-operation possibilities) were combined in the project Virtual University, Germany's first university to offer all its services in the internet. The Virtual University (VU) is a model for a modern education system.

The project is experimenting with and evaluating different forms of teaching and learning in the Internet. When the project started a suitable software platform was not available for our purposes, so a platform was built based on Internet technologies and a commercial database system. It is a virtual university system that integrates all functions of a university into a complete, homogeneous, extensible system with an easy to use and intuitive student-centered user-interface. The project started with only a few courses of electrical engineering and computer science, however, courses and events from all department were moved to the system over time. For instance, after the first year more than half of the courses came from humanities. This clearly contradicts the original assumption that web-based learning would be accepted easily by the technical departments and their students, but would be accepted very slowly in non-technical departments. Currently, more than 10.000 students are using the Virtual University of Hagen. Since the beginning of the Virtual University more than 200 virtual learning events took place. The

experiences are positive throughout.

The functional structure of the Virtual University was surprisingly stable over the last five years. Even though the graphical appearance was reworked completely, the organization of the information space did not change at all. Of course, the technical infrastructure has been continuously improved. The most important and critical extensions of the systems over time were tools for the staff and for administrators. This is an ongoing effort to improve efficiency and usability, especially for non-technical personnel.

The home page of the Virtual University offers the following functions:
education - for participation in courses, seminars, practical training and exercises; *news* - a campus wide blackboard containing all sorts of up-to-date information relevant to the users of the Virtual University; *office* - the component including administrative functions; *research* - offers access to all research-related activities in the university; *cafeteria* - a forum for social contacts between students; *library* - offers access to both traditional and digital libraries , *information* - provides general information about the university; *shop* - offers all material that can be purchased from the university

2. Impacts on Learning, Teaching and Management

2.1 Impacts on Learning

The experiences made with all types of teaching events (courses, seminars, exercises, practical training, etc.) were absolutely positive. For instance, a user survey in 1999 showed, that the intensity of the contacts in virtual seminars is substantially higher than in conventional seminars, also the readiness to form working and learning groups. Most students expressed the opinion that the discussion quality is higher than in conventional seminars. The majority of the students scored the offer of online-seminars with "very useful" (Mittrach 1999).

Another aspect is the dropout rate, always a problem in open and distance teaching. The drop out rate in the virtual seminars was significantly less than in conventional seminars.
What are the reasons for such improvements?

2.1.1 Communication and interaction

The students in a distance teaching environment essentially work by themselves, except for the very rare events where group work on the campus is required. This easily leads to a feeling of isolation, emotional distance and helplessness. Hence, it does not come as a surprise that the major impact of the Virtual University derives from the communication and cooperation features it includes and stresses. Where the students feel connected, they have a much lower tendency of just giving up and leaving, which, in other words, explains the better success rate in the Virtual University.

In the Virtual University communication and interaction possibilities are connected with teaching and information material everywhere. At any point inside the learning material students are able to enter a discussion group, to write an email, check the newsgroup, even to start a video conference (if available, but most students prefer text-based communication). Technical possibilities are interlinked and presented in a user-friendly way. Students are now able to search in the library, to do online exercises (e.g. compiling programs, fill-in text, simulate processes, etc.), to track the status of their corrected tasks (sent in, in progress, corrected, and finally the results), to archive their results and, very important, to communicate with each other and with the teacher.

Our experiences show that the majority of the students prefer asynchronous communication media like email and news, because of their time and place independence. The favored synchronous communication tools are text-based tools like chat. Videoconferences are mainly used for consultation-hours and oral examinations.

2.1.2 Tutoring and Student Support

Nobody should be left alone with a problem in the VU. Suitable communication partners can be found in the information area (common information), in the teaching materials or in the newsgroups. It is essential to support all kind of contacts: between students, between students and their teachers, and between students and organizational staff.

Newsgroups and email were not a novelty at the University of Hagen. These tools have been used some time before the VU. However, a new quality was reached through the Virtual University by the fact that communication became *context-oriented*, available in all situations and at all times. Students do not need to change between different tools, websites, etc.: all functions required are presented in a context-oriented way in one learning environment. Moreover, various mixtures of digital communication became a central medium for certain teaching events like seminars.

2.1.3 Topicality

It turns out that the Virtual University contributes to more up-to-date and consistent information and documents for students. Prior to the VU a lot of redundant and sometimes even contradictory information was available, course material contained errors and was not always up to date. Now information could be delivered just in time, mistakes can be corrected instantaneously, and difficult issues can be explained with additional information given in an ad-hoc way.

Students reacted soon to these dynamic possibilities of the VU: they show up, if mistakes are found and issues are explained poorly.

2.1.4 Applicability

Students have now the ability to learn directly on-the-job, to take part in cooperative processes, to initiate and to work in virtual teams. They learn to organize themselves and to produce high quality solutions within a group. The direct access to different information resources is a great support for our students and prepares them for typical work-environments in industry. Especially our working students (80% of all students) have a direct advantage of these experiences.

2.1.5 Innovation

The communication and interaction possibilities and the integrated technical features create new forms of teaching methods. Not only practical training, but also online exercises, virtual laboratories, interactive training (fig. 1) and virtual seminars now are common in the VU. Students evaluate the interactive elements as a great support for understanding complex topics. Among these interactive elements are virtual laboratories, simulations, style checking and compiling programs in exercise environments, graphical exercises etc. The following two examples illustrate some of the new learning methods which are typical for the VU.

2.1.5.1 Example 1: *Real systems in the virtual laboratory*

In this new environment we can run practical training from the distance even for systems only available at central locations. An example is a robotics practical training: the user writes the control software for the robot, then transmits it to the robot in the central lab, where the robot executes the commands it receives. The user can closely watch the robot's behavior via video, and can thus see and hear what happens, instead of just getting feedback data from a simulation system.

This kind of learning and experimenting from the distance also is of special interest for continuing education, technology transfer and industry cooperation.

2.1.5.2 Example 2: *Virtual seminars*

The virtual seminar has already been mentioned several times in this paper. It is one of the didactically challenging teaching events at the Virtual University, as seminars have traditionally been defined as teaching events with teacher and learners present in one location, and nobody ever tried to do seminars at a distance. Virtual seminars are very popular among students.

The Internet services used for such a seminar are email, ftp, news, chat, audio- and video conferencing. Services are specifically combined for different seminar phases. There are also mixed forms between virtual and conventional seminars, e. g. only certain seminar phases are assisted by Internet-based tools

The virtual seminar allows a well-structured teaching process using online as well as off-line communication tools which support the student's learning success. Seminars get a new quality: In contrast to conventional seminars a continuing learning process is triggered, and the discussions taking place in the Internet are much more structured and disciplined than in conventional seminars (Feldmann 1999).

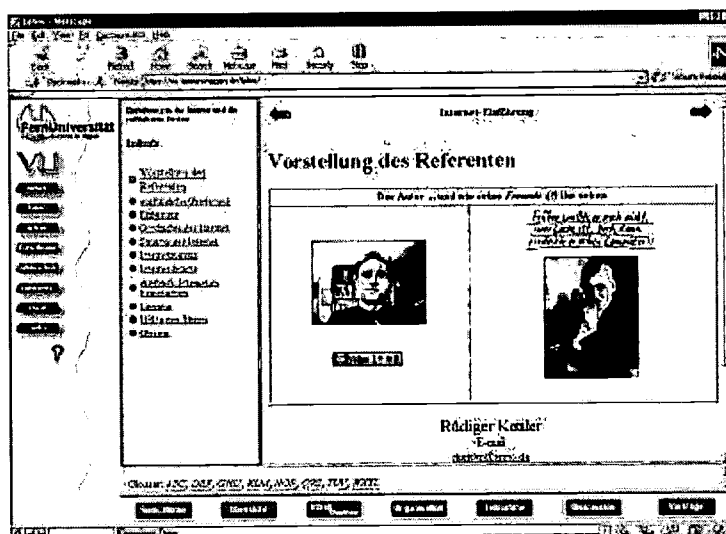
Internet based communication tools enable and motivate very active communication, co-operation and discussion processes. People really interact as opposed to the typical traditional "listen and then (maybe) ask a question" behavior. The forming of groups and learning together in the net are new and highly valuable experiences for the students.


Fig. 1: A student's contribution

2.2 Impacts on Teaching

Most papers on virtual universities focus exclusively on the students. Let's have a look at the teachers. If done wisely, teachers benefit from a VU approach; if done naively, teachers may easily get drowned in communication, email, etc. At the University of Hagen teachers are professors, research assistants, mentors in the study centers and tutors (whose task is to correct student exercises).

No need to say that the success of a VU approach completely depends on the positive attitude and active participation of the teaching staff – but important to note, that this is the major hurdle in real-life when it comes to implement a VU! It is easy to get enthusiastic students, but a completely different job to motivate the staff.

For the teachers everyday life changes in the VU. More and more, the teacher gets to support the student's learning process, to organize learning, to act as a guide, instead of delivering information.

Not too many of our teachers liked the idea of changing their everyday life, but experience showed that their prejudices (e.g. to get too many emails or to have problems with the technology) were not confirmed once they kept to certain rules. This, however, required some creativity and much patience on the part of the VU developers.

Let us highlight some of the major changes experienced by the staff:

2.2.1 Communication and Interaction

The easy availability of Internet-based communication media made people assume, that students will use these tools in such a frequency and in such numbers that teachers would be overloaded with masses of questions, requests and comments. If not done properly, this of course may be the case, but if the philosophy is to imitate the students' behavior on the campus, then something different will happen: students start to organize themselves in the newsgroups instead of going for the teacher all the time. The reason is that the teacher is not always available, will take some time for a reaction, but other students are always out there and somebody is always ready to jump in. Thus, the teacher can concentrate on the issues that produce serious problems for students, and can sometimes lead

the discussion where necessary. It is essential for the teachers to organize and if necessary to delegate communication processes (e.g. generating FAQ, editing drafts for common questions, organize cooperative work).

2.2.2 Tutoring and support

As mentioned before, teachers worry about the changes in their daily work. To support our teaching staff, we implemented (and are still implementing) a variety of different tools, such as emailing to different user groups, a campus-wide easy to use blackboard, the automatic generation of newsgroups for new learning events, and so called "teaching assistants", software packages that help to set up, structure and run complete courses or seminars. Shortly the teachers learned about the major benefits in their daily work:

- students have rather good contact to tutors, they know their students much better than before
- continuous communication between the students and the teacher throughout the courses, so it is now possible to track the learning process and to intervene on time before a student drops out or fails an exam. Homework is much better than before, even better than homework typically is at a campus university.
- discussing questions and problems is time - and cost-effective
- building of learning and working groups is possible, students support each other instead of looking for help from the teacher
- it is possible to find overlaps in the student's topics and to provide hyperlinks to each other's contribution
- if classroom phases are integrated in a course, these can be used for discussions on a rather homogeneous starting basis. Furthermore, the time needed to get to know each other is shorter than in conventional courses

2.2.3 Topicality

The topicality of documents is one of the main advantages of web based teaching material. Instead of writing one document and then sending it to the students, there is now a continuos process of correcting, adding information, and updating information. Students now expect up-to-date material.

The fear teachers have is that it is too much work to update data in different systems and to archive different versions of one course (students must have the chance to be examined according the version of a course they were enrolled in, even if this version is an older one). However, with the appropriate data management system and integrated version management these processes can be supported in a very user-friendly way.

Another important support feature is to install easy to use upload possibilities and a clear navigation structure for the existing material (authors and teachers are not always the same persons).

2.2.4 Applicability

Applicable contents are a quality requirement for a university with more than 80% working students. The Internet is a highly usable instrument to collect and present applicable contents. Searching, retrieval and publishing is a lot of easier for the teachers using modern technology. Most of our teachers using the VU were inspired by the new publishing possibilities, even though they had to spend some hours in creating web content. To support the teachers, the VU developer group provided their experience through hotlines, tutorials, etc. This support was essential for a positive motivation of the teachers.

2.2.5 A Word about Innovation

Innovation is a coin with two sides. On the one side there is the potential to simplify daily work by the use of innovative technology, on the other side are the people - responsible for the use of innovative tools but feeling uncertain in this new world - and thus tend to keep to traditional patterns.

Our teacher interface, personal assistance and the demands of our students helped them to see the benefits, to improve the daily work and - as a result - to convince colleagues to participate in the VU.

2.3 Impact on Management

The third group concerned of the VU is the university management. The management's responsibility is usually the enrolment process, administration of students data, student information, billing, etc. – shortly all organizational tasks around the study. In the beginning of the project nobody inside the management realized the Virtual University platform with it's few users and they even don't want to recognize it. Now, five years later, a lot has changed for managers and their staff.

To deny an increasing number of students and their demands was not possible. More and more students started to study virtually, and surprisingly more and more tutors and teachers used the system to support their work, and even the management staff utilized the system to search for information, to get an overview about the latest news, to announce new information for the students, etc. In the second year, the VU caused several problems: More and more students wanted to download their courses directly through the web, with the consequence to find new billing processes for them. They demanded electronic enrolment and more electronic course material.

Furthermore the stock increased, thus data transfer had to be automated. Teacher and tutors refused to feed in their data in different systems, so a synchronization of VU and organizational systems became necessary.

The general management of the university realized the potential of virtual teaching. In 1997 they started to promote the system in the different organizational areas. By the help of additional money for extensions of the VU, for electronic study material and other improvements around the virtual teaching and learning area the ground for further developments was ready.

2.3.1 Computer Center

The largest visible impact is the delivery of the whole system to the university's computer center, because it is not possible to run a system with more than 10000 users as a research prototype with only a few persons. To become the delivery successful many changes and improvements had to be implemented. E.g. the database (Sybase) had to be changed to the official university's database, an Oracle database. Passwords and the whole VU stock has been transferred to the computer center's database.

2.3.2 Printing and Shipping Department

The delivery of the study material will change in the future, more and more students download their material, the shipping of documents will decrease in the long last. Therefore the tasks of the shipping department are changing, not all people are liking such developments. Instead of producing paper material the shipping of CDs with large data, videos and audio data will increase. The production process of paper teaching material had to be synchronized with the electronic material, to avoid irregular contents. A professional content management system could be a possible solution for this problem.

2.3.3 Study center

The study centers modify from an university bureau with several administration and support facilities towards modern communication and support centers, serving the students the necessary technical equipment and support in using the VU. The external tutors in the study center itself use the VU as a tool to administrate their own teaching events (e.g. exercises) and to inform about the current courses and about the students enrolled in this courses.

3. Preview

The transfer of the software platform to the university computer center could not be the last thing to be done. The increasing number of users and new technological developments require new and better tools for the VU. The most important running improvements are the following:

- **Tutor support tools:**
  The existing tools should be extended with better possibilities to manage News, Emails, cooperative workspaces. New workflow components could ease the daily work of the teachers.

- **Communication and interaction:**
  Integrated instant messaging and a pool of available communication profiles should support the important communication and interaction processes.
- **Data management:**
  This component is essential for a smooth and secure handling of the complex universities data stock.
  Furthermore a professional content management is necessary to optimize the process of editing and publishing learning materials in different systems.
  Another aspect is the congruent data management, which is currently in progress with a new developed core data base for all organizational data concerning the different courses.

4. Summary

The Virtual University project was a real success in the sense that it developed from a research initiative into a comprehensive change of the whole university.

Students, teachers, and administrative staff have contributed to this transformation. A major driving force, though, were the students: once the project was under way, the number of participating students increased fast, as did their requirements, so that the development could hardly be stopped or neglected.

The large number of participating students finally forced the university to accept the project developments as a general service and to move the infrastructure and the support services from the project into the university computing center. The consequences for the university organization were underestimated at first, but the problems were solved as more and more persons accepted the approach.

The overwhelming success of the project triggered the foundation of two start-ups which make the know-how of the Virtual University developers available to industry.

The students feel that the quality of their studies has substantially increased, the teaching staff is finally getting used to the new form of teaching, computing center and study centers are catching up with their new role and change of daily work.

The main lesson we learnt is that, in order to get this kind of project accepted, all user groups must be involved at the earliest possible time. This includes administration, which is often overlooked, as many processes and tasks change in a fundamental way on the road to a virtual university.

Steps towards the Design of Attractive Virtual Spaces for Tele-Learning

Marion R Finley, Jr., Yuki Sogabe
Multimedia Laboratory
Asahi University

{finley, ysogabe}@alice.asahi-u.ac.jp

Abstract: An approach to the design of so-called *attractive* virtual spaces in the context of tele-learning is proposed. Initial formal definitions of the concepts of virtual (communications) spaces and *attractive* are outlined and steps towards the construction of such spaces are given.

Introduction

The work in progress reported in this paper is a continuation of previous work on the construction and testing of virtual communications spaces for use in creating *attractive* Internet/Web-based environments for tele-learning (Sogabe, Mase, and Finley 2000). In this paper, an attempt is made to relate the spaces created, or, more precisely, the underlying Internet/Web-based systems that support these spaces, to critical human factors, such as willingness-to-pay, (user) satisfaction, and the like expressed as utility functions (Akimaru, Yamori, and Finley 99) (Yamori 99). Once again, the M^2COTS ("mass-market components off-the-shelf") approach (Sterling *et al* 99) is favored: as much as possible, standard, easily available, off-the-shelf equipment will be used for the experimental tests. The fundamental objective is to find useful design criteria for building tele-learning environments that will prove attractive to students and effectively assist in the recruiting of new student clientele (Finley 99). Currently emerging multimedia wireless and other wireless technologies such as Bluetooth (Miller & Bisdikian 2001) are expected to play a significant role in this work. For present purposes, the objective cited above is broken down into several basic steps: First of all, an attempt is made to develop a formal definition of the concepts of virtual space and of *attractive*. Then, these two will be juxtaposed to give an initial definition of *attractive virtual space*. Next, an initial design procedures for attractive virtual spaces will be suggested.

Initial Design Procedure for Attractive Virtual Space

The term virtual space has seen many uses and the authors have been inspired by such as Jensen (Jensen 99) and (Fernandez et al 2001). At this point, the definition is still incomplete, but essentially a virtual space, or more accurately, a virtual communications space, is a kind of topological space whose points will be users or internal network nodes and in which subspaces or manifolds will correspond to user communities, that is, aggregates of users, for example, as the members of an Internet-based discussion group. Neighborhoods, a fundamental topological concept, will correspond to the set of local devices surrounding the user, for example those linked by the Bluetooth technology or by a wireless LAN. These spaces have some continuous aspects, for example, the time axis or other dimensions corresponding to (digitized forms of) analogue phenomena in the real world and may be viewed from several points of view: the user's perceptions thereof, the designer's intentions, and the physical support. Of course, the user's perceptions should correspond to the designer's intentions and the physical support should realize these intentions. A formal framework for these concepts is currently being elaborated. As for the concept of *attractive*, intuitively this simply means "capable of attracting, intriguing, and holding the interest of members of a target population, that is, the potential candidates for using a given service." What constitutes *attractive* is a subject unto itself, but, via polling and interviews, the authors hope to be able to derive the major characteristics of a potentially attractive virtual space. Some simple examples involve properties that may be expressed as utility functions such as willingness-to-pay, user satisfaction, and the

like. If one takes, the virtual spaces that are effectively defined by cellphones among a population of teenagers (some of the most avid of cellphone users in Japan), one sees a number of properties that make those spaces attractive: immediacy of access, relative privacy, access anywhere, anytime, compactness of the physical devices themselves, the low cost of e-mail (as opposed to voice conversations), and other such attractive properties. Once identified such desirable properties, utility functions relating these properties to critical system parameters may be constructed. Such functions then may be optimized using genetic algorithms or other techniques (Finley 2000).

From the preceeding, the elements of a design procedure may be given. First, one identifies the various factors of conceivable interest to the target population, for example, such things as willingness-to-pay, general user satisfaction, user preference for such and such a feature, etc. These may be tested using polling techniques among the target population. Next, these factors may be related to certain critical system parameters, such as bandwidth, delays, screen definition, and the like, again using polling among the target user population. This will give rise to empirically derived utility functions which now may be optimized by techniques such as genetic algorithms. Thus, one would obtain a function, say, W, with

$$W = f(p_1, p_2, \ldots, p_n)$$

where the p_i are the system parameters of interest. Now, using an optimizining procedure, the values of p_1, $p_2, \ldots, p_n$ that yield an optimal value of W may be found. The system then should be designed to conform to these values. Prototypes may be constructed to verify these results, which may, in fact, yield only an initial value which may then be refined by further adjustment of the p_i. At this time, tests are being conducted to determine essential factors for tele-learning environments. The results of these tests will be reported in future publications. Initial tests suggest that sometimes one single, simple factor might suffice for the systme to qualify as *attractive*.

Understanding Computer Ethics

Under grants from the National Science Foundation, Educational Media Resources -- a nonprofit company -- has created an interactive multimedia CD-ROM on computer ethics. (The result of this work, a CD-ROM/book entitled Understanding Computer Ethics, will be published later this year by Prentice Hall.)

This paper, delivered by Dr. John Fodor (creator and author of UCE), will examine the topic of computer ethics as it relates to network environments. It will include the following areas:

Introduction to the field of computer ethics,
Origins of computer ethics,
Various definitions of computer ethics,
Approaches to computer ethics,
Significant ethical issues in network environments, and
Resources for further understandings.

Introduction to the field of computer ethics
The paper will start with an examination of the learning objectives that will result from the reading. In short, these include:

a. a basic understanding of this new field called computer ethics (a.k.a. technology ethics and information ethics),
b. familiarization with basic terms and concepts in computer ethics, and
c. acquisition of appropriate skills to anticipate and/or handle computer ethics problems when they emerge.

In keeping with this introduction, a fundamental distinction will be drawn among the various levels of computer ethics: Pop, Para, and Professional (i.e. the various ways in which one can be "doing" computer ethics).

A final point of the introduction is to review the practical reasons to justify the study of computer ethics. One of the most obvious practical reasons is the financial loss resulting from breaches in computer security, computer privacy, ownership of intellectual property, and professional responsibility.

Origins of computer ethics
Next, video clips will be shown of several historic figures in computer ethics. These include Walter Maner (who coined the term "computer ethics"), Donn Parker (who wrote the first codes of ethics for the ACM), and Deborah Johnson (who wrote the first book on computer ethics).

Various definitions of computer ethic

Since computer ethics is a relatively new field, there are various definitions that are being advanced. The paper will examine some of these definitions and it will draw some relationships among them. For example, the paper will review James Moor's definition that computer ethics is the "analysis of the nature and social impact of computing" and "the formulation and justification of policies regarding the use of computing technology".

Approaches to computer ethics

Many valid approaches are available to study computer ethics, these include: Computer Science, Sociology, Psychology, Philosophy, Law, and Public Policy. The paper will briefly point out these approaches, and comment on them.

Significant ethical issues in network environments

Several important issues will be raised. Questions and answers will be provided on such topics as:

Privacy -

a. An examination of the Principles of Fair Information Practice,

b. Potential harms that need to be minimized when gathering personal data,

c. Considerations that are necessary to meet reasonable expectations of privacy,

d. Various rules of conduct for persons involved in the design, development, operation, or maintenance of any system of records,

e. Administrative, technical, and physical safeguards that should be taken to insure the security and confidentiality of institutional records.

Security -

a. Various ways in which computers are involved with crimes, and precautions which can be taken against each of them,

b. An examination of human behavior as it relates to security-relevant expectations,

c. Gaps in computer security and how they may be filled,

d. Vulnerabilities that are posed by administrators who lack sufficient knowledge to modify their systems.

Ownership of Intellectual Property -

a. Differences between trademark, copyright, and patent infringements by users on your system.

b. Institutional policies for protecting intellectual property by computer users,

c. Administrative safeguards that protect intellectual property rights,

Throughout the paper case studies will be used to illustrate better the concepts raised.

Evaluation/Performance Measurement & Assessment

Outcome Based Evaluation for on-line activities

This paper will examine Outcome Based Evaluation, as a measurement of performance and assessment for on-line activities. Outcome based evaluation, OBE, is the measurement of results. The types of evaluation examined herein will include specific on-line activities that involve demonstrations of skill; acquisition of knowledge; and changes of attitude or behavior for on-line users/participants. (Principles discussed in this paper can be applied to any project that has outcome goals.)

In addition to describing what outcome based evaluation is, this paper will review how outcome measurement differs from traditional methods of evaluating and reporting, why institutions should measure outcomes, and how to perform an OBE. The paper will examine the Government Performance and Results Act of 1993, which requires documentation of results of certain grant activities. Finally, sample questions and templates for outcome based evaluation will be provided, and resources for additional information of OBE will be given.

What is outcome evaluation?

Most evaluation tools fail to determine the impact of the products, programs or services they provide on those who use them, because they do not take as their focus the results, or outcomes, of the initiative. There is increasingly a convergence of thought among decision makers that institutions must begin to reshape their services and products by focusing more effectively on outcomes.

The IMLS defines outcomes as benefits to people: specifically, achievements or changes in skill, knowledge, attitude, behavior, condition, or life status for program participants. Any project, therefore, intended to create these kinds of benefits has outcome goals. Outcome based evaluation, OBE, is the measurement of results. It identifies observations that can credibly demonstrate changes. It systematically collects information about these indicators, and uses that information to show the extent to which a program achieved its goals. (OBE measurements differ in some ways from traditional methods of evaluating and reporting.)

Why focus on OBE?

Institutions spend billions of dollars each year to create programs and services. In order to understand the social and economic impact of these programs and services, it is essential to have a testing instrument that will accurately test for outcomes. Unfortunately, many individuals and organizations are not provided with adequate frameworks or tools to measure their efforts.

In other cases, such as government policies, certain institutions -- like museums and libraries -- are required by law to test for outcomes. For example, congress requires IMLS to document results of grant activities each year to meet the requirements of the Government Performance and Results Act of 1993. OBE reports show how effectively their grants make contributions to museum and library audiences.

The need for OBE in institutional and government settings, translates well to efforts on-line. Whether one is creating an on-line course, resource materials, or an e-commerce site; knowing the outcomes of the program and services will help to improve the contents and delivery.

Structuring an OBE
Creating an object based evaluation requires:

> Realistic and measurable outcomes
> Organizational capacities to implement and manage the evaluation

Outcomes that are related to activities
Goals that are realistic
Specifying program outcomes
Developing measurable indicators
Identifying data sources and data collection methods
Analyzing and reporting findings
Using outcome information

When creating a good evaluation instrument, it is important to begin with clear goals and objectives. These objectives should describe the change that is expected from the program. Outcome based goals and objectives are usually:

Specific - written to point the way to action.
Attainable - to increase the probability for success.
Quantified - to specify how much change is desired.
Measurable - to assess progress toward change.
Targeted - to identify who should change.
Time Specific - to tell when the objective is to be reached.

Goals and objectives that come as close as possible to fitting this profile are important because OBE focuses upon how well a program reaches its goals. And, the point of a quality evaluation is to make this focus as systematic as possible.

An evaluation matrix will be provided to help individuals create an OBE standard for themselves. The matrix helps to envision a wider range of data collection methods. Various collection methods will be reviewed in order to help create an OBE to meet various on-line interventions. These include:

Anecdotal Record Form
Formative Review
Implementation Review
Questionnaires
User Interface Rating Form

Outcome based evaluation does not invalidate other approaches. Instead, it augments them. OBE supersedes less formal modes of evaluation by cutting directly to the question of effectiveness. "In the end, however, only a demonstrably positive and intended outcome is sufficient." [All citations are included in paper.]

Specific on-line cases are given as examples to illustrate each of the points made above.

SONUS: SOFTWARE FOR DEVELOPING SKILLS IN ACCENTUATION

LIC. MARTÍN FONTECILLA DELGADILLO
ARTS DEPARTMENT/ TEC DE MONTERREY (MÉXICO, 2001)
ADDRESS: P. Del Acueducto 172-B3 Int. 8. Villas de la Hacienda. Atizapán CP: 54500
TEL: (5)58-87-54-91   e-mail: mfonteci@campus.cem.itesm.mx

Sonus is a design software created to develop basic skills in accentuation used in Spanish words. It is divided into four parts, each one of them develops an specific skill. Each part contains three main processes: *diagnosis, study or review and evaluatio.* Nowadays, Sonus is used for more than three thousand users such as professors, office workers and students, inside the Sistema Tecnológico as well as other places.

1 Introduction

Sonus is a program designed to practice and improve basic skills of accentuation. Among these skills are: dividing syllables, identify accented syllables, classification of words and application of the accent rules.

Each one of these parts is divided into three basic activities:

a.-   Diagnosis
b.-   Study and review
c.-   Evaluations

When these four skills are developed the student will surely know how to write correctly Spanish words.

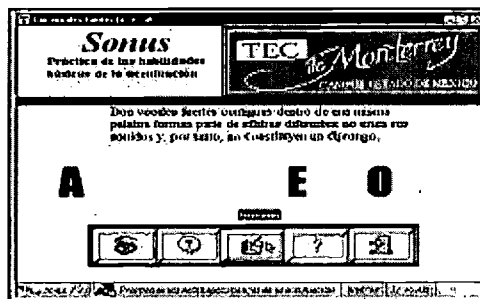
2 Diagnosis

As a first step diagnosis evaluates how much the student knows about each one of the four skills. This evaluation is important because:

1)   Gives the students quantitative information about each one of the skills, for example, number of correct and wrong answers, distribution of them in specific groups, etc.
2)   Gives the students information about which topics has the major mistakes and must be reviewed.
3)   Prepares students to know their weakness and anticipate the results, so they can reach higher grades in the exams.

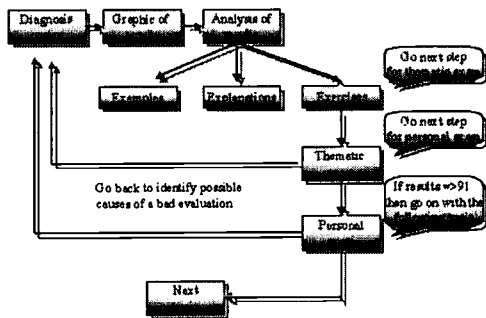
The next graphic shows the students the different alternatives to start working at Sonus and other important information needed in this program.

To enter the first activity click on "Diagnosis" and immediately you will see a window where all instructions are given.
This activity gets through three important stages: review (shown in the last drawing), results and mistakes analysis graphics. Review is composed of 50 vocables which are selected from a group of 1500 words (so each review session is different from the other), in which the student should do different exercises such as dividing into syllables, identifying accented syllables or stressing different words. Once review is done, Sonus will display a graphic indicating number of right and wrong answers, types of mistakes distributed in order of importance, and final grade, as shown:
These graphics will give the student a general view of their mistakes. This diagnosis ends with a mistake analysis which helps the students compare their given answers to the correct ones. Moreover, the student has the chance to start studying just by choosing the suggested icon.

3 Review
Review comes after diagnosis. It might be selected from the main menu as shown in the following drawing:
The main purpose of this activity is to study the topics in where the student have shown weakness in their knowledge. This activity is important because:
1) Offers the student the essential knowledge to understand the selected review topics.
2) Improve a specific skill by practicing and continuos feedback.
There are three steps to follow in the review process: exemplification, explanation, and practice. (In the following drawing an example of one of the review topics, stressed vowels, is shown. Each one of the steps is represented in the icons below:


On the supplied examples the student can work with a variety of words, in which different rules and principles are presented and must be learned by practicing and by reading the explanation. Even tough these are short they offer the necessary information so that the students can improve the specific skills. Finally, the students must practice the acquire knowledge either by separating words like in the diagnosis part or by games such as: Hangman. While practicing the students will receive immediate feedback indicating the correct answer when needed. After this, a grade indicating how much they control the topic will be displayed. This activity is very important, because if a grade upper than 91 is not obtained, the student can not go on with the corresponding evaluation.

4 Evaluations
In this activity the results of evaluations and grades are formal and helps the instructor and the student evaluate the progress in an specific skill. There are two different types of exams: thematic and personal. The thematic exam is a general review about the acquire knowledge and it consists of 30 vocables in which the student must divide syllables, identify the accented syllable, classify and apply the accent rules. On the other hand, the personal exams have the purpose of reviewing the mistakes made by the students during the diagnosis and review sessions, and give them a formal grade. An important point is that this evaluation is personal because it focus on the mistakes made by and only by the student. At the end, the average of the personal and thematic exams will be immediately kept at the student record.

5 The sequence of activities
The Sonus previously mentioned activities form the basic structure of it. Nevertheless it is not possible to do every topic at the same time. The student must start with the easier topics and finish with the difficult ones because it is necessary to have good knowledge about each of them to move forward. The requirements needed to access the advanced topics are:
1) Solve diagnosis and review exercises with an average grade upper than 90, which will immediately open the thematic exams.
2) Solve the thematic exams with an average grade upper than 90, which immediately will open the personal exams.
3) Solve the personal exams with an average grade upper than 90, which immediately open the next topic exercises.
In each activity, if the student does not reach the required grade, he/she must go back to the diagnosis exercises of the specific topic to start all over again. These requirements are explained in the following diagram:


Sonus contains other important characteristics (not illustrated at this moment), which are: sound and on-line help. Sound is an important element in this program, because the student can identify, just by listening, different types of pronunciation. Sonus contains 500 different types of voices and pronunciations related to this skill. On the other hand, the on-line help carry the student through the program easily so that he/she will not be distracted in their learning process.

6 Sonus Results

Since 1998, Sonus has been used in different campus of the Tec de Monterrey like: Ciudad de México, Hidalgo, Querétaro, Irapuato, Guadalajara y Estado de México as part of some classes such as: Spanish Writing, Advanced Writing, Reading and Writing, Speech, all at college level. Results obtained with Sonus are shown in the graphic below:

Graphic: Development of dividing syllables skill (Semester 9801). Diagnosgtic Review
This graphic shows how 110 students increased their average from 84 to 96 during 10 diagnosis activities. Pointing this out, students who improved their grades throughout written reports also have shown an improvement in their skills. This software let the instructor focus his attention on research more than reviewing and feedback activities.

Sonus is not only for students, but also for training purposes to all personnel and the teacher's staff. Another benefit is this software can be installed in the teacher's laptops so they can practice on it during their free hours. Their progress has been similar to the student one; the following graphic explained the above situation:

Graphic: Development of dividing syllables skill (February 1998). Diagnosgtic Review
This graphic shows the fulfillment of a group formed by teachers and office workers who started with a diagnosis average of 73 lesser than the student's average which was 84. Otherwise, this group progress was greater than the student's group because after ten diagnosis activities they got an average of 95.

During a third experience with Sonus with a group of 28 students from a public high school on April 20, 21 and 22 of 1999; the skill tested with diagnosis and review activities was dividing into syllables. This group first average was 60.28 shown in the graphic below:

Revisiones Diagnósticas
As in the first results, the second review average was almost the same, but as it was moving forward, the average got higher, almost close to 90. The difference between the second and the third average was that the students realized that they needed to study their weakness, they did so and as a result of that their score was improved. After this, the students attitude toward their mistakes was positive so each time they made mistakes, they went back and study them. So this is why their final average was almost 90. Now, as we can se this improvement has not been only quantitative but qualitative. The following graphics shows this fact:

Revisiones Diagnósticas
(Note: Sílaba simple = simple syllable; Diptongo = Diphthonge; V Fuertes = strongs; Hache = h; Adiptongo = Adiphthonge)

This graphic represents mistakes made during the diagnosis by seven of the 28 students. In their first session these students made 139 mistakes, specifically in the skills of adiphthong and accented vowels (93), however by fifth session the related amount of mistakes reduced evidently (12). This means that among all the different skills those were easily understood. On the other hand some skills like the diphthong and the use of the "h", are extremely difficult to understand and correct, as it is shown in the graphic. This is why the instructor must pay special attention to those students who have difficulty in these skills.

To conclude we would like to point out that during the next months we will be checking the results of the courses given this semester to students and professors; however, we can see that they tend to improve as we have seen during this presentation.

XML-Based Automatic Web Presentation Generation

Flavius Frasincar, Geert-Jan Houben
Department of Computer Science
Eindhoven University of Technology
Eindhoven, the Netherlands
{flaviusf, houben}@win.tue.nl

Abstract: This paper presents a method that automates hypermedia presentation generation on the Web. The method is based on RMM (Relationship Management Methodology) for aspects of hypermedia design. It distinguishes between the logical representation of the data and its actual presentation. Using new emerging Web technologies like XML (Extensible Markup Language) and XSLT (XML Stylesheet Language Transformation), we have implemented a prototype to experiment with the proposed method. Data filters written in XSLT prove to facilitate the multi-phase hypermedia presentation generation method.

Introduction

World Wide Web (WWW) is the most important platform for information exchange between Internet users. As a result there is an increasing need for methodologies that support the design of Web-based Information Systems (WIS) (Isakowitz et al., 1998a). We consider WIS that integrate heterogeneous data sources, such as XML repositories, relational and object-oriented data bases etc. A user asks a query to such a system and as a result a presentation is generated (De Bra & Houben, 2000). The main focus of this paper is the question how to automate the process of generating such hypermedia presentations.

Several hypermedia design methodologies are available, like RMM (Relationship Management Methodology) (Isakowitz et al., 1995) and OOHDM (Object Oriented Hypermedia Design Methodology) (Schwabe et al., 1996). The design method that we use here applies the core of RMM for reasons of its simplicity and its E-R (Entity-Relationship) foundation. Extending the well-accepted E-R model to model information domains, and subsequently adding navigation structures to it, proves to be a solid ground on which to base the automatic generation of hypermedia presentations.

Before we discuss the prototype implementation, we shortly mention the key concept (both in RMM and our specific design method) of 'slice', which is used to denote meaningful presentation units. A slice groups together attributes and possibly other slices. In order to have a uniform approach to slice hierarchies (Isakowitz et al., 1998b) we consider primitive slices to be attributes. Each slice belongs to an entity but it can contain also slices belonging to different entities: in this case, the relationships between entities which make such an embedding possible are indicated. If the relationships are one-many an access structure (index, tour, and indexed guided tour) is associated to the slice nesting. Many-many relationships (from the E-R model) are decomposed in two one-many relationships. There are two types of slice relationships: aggregation (presented above) and reference (hyperlinks between slices). For a particular application, the application model describes all slices and their relationships (Isakowitz et al., 1998b), thus specifying the hypermedia aspects of the application. Due to the fact that each slice is owned by an entity and encapsulates some of the entity's attributes we can view the application model as an extension of the E-R model, and thus as an important step in the design process of the hypermedia presentation.

Method and Tools

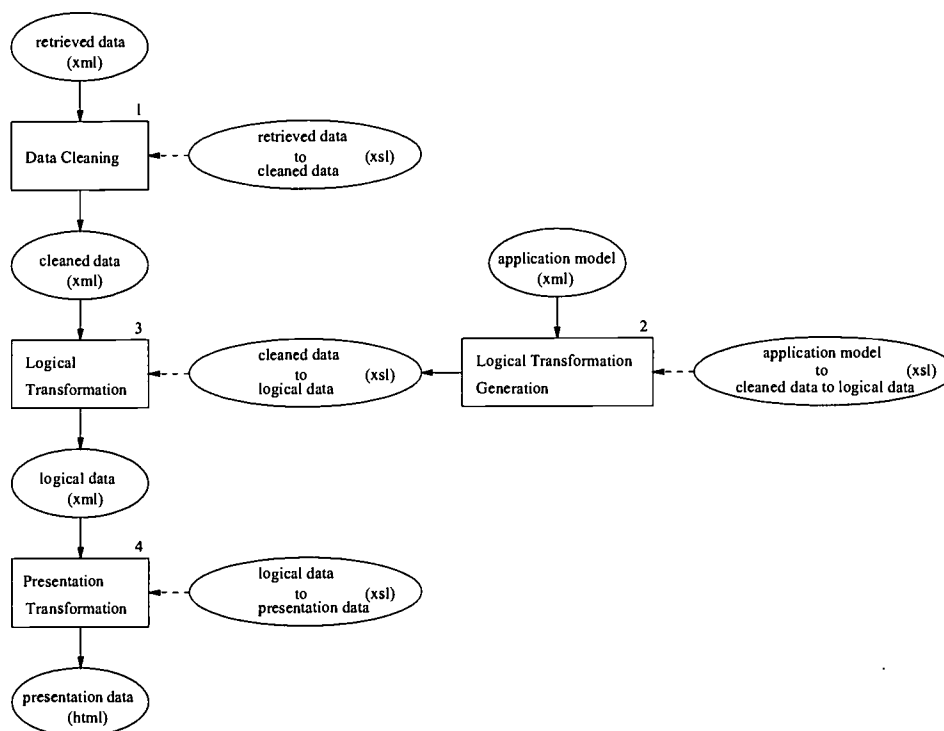
The presentation generation method is based on four steps which are depicted in (Fig. 1). In the first step, Data Cleaning, the data retrieved from the Data Retrieval module is adjusted to the specific format for E-R model instances. For each application, there is an application model which describes the slice relationship model on top of the considered domain model. In the next step, Logical Transformation Generation, a transformation engine is produced based on the specific application model. This transformation engine is used by the following step, Logical Transformation, to package the retrieved data instances into slices. The final step, Presentation Transformation, generates a presentation, e.g. in HTML, from the slice packaged data.


Figure 1: Method

The artifact of each step is a valid XML (Extensible Markup Language) (W3C XML Working Group, 2000, Bradley, 2000) file, that is a file that complies to a prescribed DTD (Document Type Definition) file. For the Logical Transformation Generation step an XSL (XML Stylesheet Language) (W3C XSL Working Group, 2000, Bradley, 2000) file is produced which is also an XML document. At the core of each step there is an XSL file which describes to an XSLT (XSL Transformation) processor how to convert the input XML file to the desired output XML file.

In order to experiment with the proposed method a demo was developed. The domain model of this application is based on the data provided by the Web site of the Rijksmuseum in Amsterdam. The prototype uses annotated Rembrandt paintings to exemplify the clair-obscur painting technique. As a software tool, the XSLT processor Xalan, provided by the Apache XML Project (Xalan Apache XML Project, 2000), is used. The next sections illustrate the different steps of the method for this demo application. Due to space limitations we can only show small excerpts of the software.

Data Retrieval

The demo considers one particular query, a restriction that doesn't affect the purpose of the presented method to show how to dynamically generate hypermedia presentations on the Web. The user asks a query to

the system, a query which is expressed (in the current implementation) in SQL. The results of the query are encapsulated in an XML file which has three components: entity instances, attribute instances, and relationship instances. (Example 1) presents a small excerpt from the DTD used to describe the retrieved data and (Example 2) provides a piece of the retrieved data as an XML fragment.

Example 1 (Data.dtd)

```
<!ELEMENT attribute-instance (#PCDATA)>
<!ATTLIST attribute-instance attribute-id CDATA #REQUIRED>
```

Example 2 (Data.xml)

```
<attribute-instance attribute-id="attribute.technique.name">
<![CDATA[clair-obscur]]>
</attribute-instance>
```

Data Cleaning

The Data Cleaning step bridges the gap from the XML data representing the SQL output to XML data representing an E-R model instance. The transformation stylesheet of this step captures the domain knowledge to fill the missing data. Relationship names are added to the retrieved data and the inverse of the relationship instances is built (since they were not originally included in the data retrieved). (Example 3) gives a flavor of the XSL file that specifies the above transformations.

Example 3 (DataCleaning.xsl)

```
<xsl:when test="@relationship-id='painting-technique'">
    <xsl:attribute name="relationship-id">relationship.exemplifies</xsl:attribute>
</xsl:when>
```

Application Model

The application model is used to describe at the logical level the hypermedia aspects of the application (lsakowitz et al., 1998b). At this logical level, the slice types are identified. By slice type we mean a full specification of the elements (slices and/or attributes) contained in the slice, and reference relationships to other slices. In the introduction section we explained that the application model is an extension of an E-R model. (Fig. 2) presents the E-R model of the demo application. Note that we model pictures as URLs (Uniform Resource Locator), so all the attributes are of type text (string).
Figure 2: E-R model

(Fig. 3) gives the application model design for the application. There are two (non-primitive) slices, both of them called *main* that belong to two different entities, *technique* and *painting* respectively. The starting point of the presentation, that is *technique.main* (the '.' denotes the ownership relation between slices and entities), is indicated in bold font. *technique.main* encapsulates the *name* and *description* attributes from *technique* and an index structure of hyperlinks. Each of these hyperlinks has as an anchor the picture's *name* attribute and as target the slice *painting.main*. The slice *painting.main* is composed of three attributes of painting: *picture*, *name*, and *year*, and the attribute *name* of the associated painter. The entity relationships *exemplified_by* and *painted_by* are used to specify (at instance level) which attributes (instances) belonging to different entities are (logically) grouped together in the presentation.
Figure 3: Application model

We encode slices as XML elements that can contain text (the so-called empty slice) (Isakowitz et al., 1998b), slice references, hyperlinks, index, and guided tours (Example 4). (Example 5) presents a small piece of the application model which illustrates the use of slice references in slice definitions.

Example 4 (Application.dtd)

```
<!ELEMENT slice (text | (slice-ref|hyperlink|index|guided-tour)*)>
<!ATTLIST slice id ID #REQUIRED>
```

Example 5 (Application.xml)

```
<slice id="slice.painting.main">
    <slice-ref idref="attribute.painter.name"
                relationship-ref="relationship.painted_by"/>
...
</slice>
```

Logical Transformation Generation

The Logical Transformation Generation step is responsible for building the main presentation transformation engine, that is the engine that packages the retrieved data instances into slices. It is implemented as an XSL stylesheet that generates another stylesheet (Lemmens & Houben, 2001). The input of this step is the application model encoded as explained in the previous section in an XML file. Knowing the type description of each slice, a stylesheet is generated that will transform data at instance level. An excerpt of the stylesheet implemented for this step is presented in (Example 6).

Example 6 (LogicalTransformationGeneration.xsl)

```
<xsl:stylesheet xmlns:xsl="http://www.w3.org/1999/XSL/Transform"
                xmlns:axsl="http://www.w3.org/1999/XSL/TransformAlias"
                version="1.0">
<xsl:template match="/">
    <axsl:stylesheet version="1.0">
    <axsl:template match="/">
    <xsl:element name="results">
        ...
        <xsl:apply-templates select="//slice-ref" mode="ROOT"/>
    </xsl:element>
    </axsl:template>
    </axsl:stylesheet>
</xsl:template>
...
</xsl:stylesheet>
```

One can observe that there are two namespaces defined for stylesheets, one for the current one and one for the output. For each slice reference a template is called in the mode *ROOT*, which generates an element of type *slice-instance* at the top level. Once a slice instance is encoded each reference to another slice (in its body)

is replaced by a *slice-instance-ref* which points to one of the top level slice instances. The main slice type (the starting point of the presentation) is populated by all the instances of the entity that owns that slice. In case that a relationship is involved, only those entity instances that are related to the current entity instance via a relationship are considered. For attributes or slices that belong to the current entity instance the population is obvious, as the current entity instance is used.

Logical Transformation

The Logical Transformation step packages the data instances into slices (it provides instances of slice types based on the retrieved data). The stylesheet that performs this transformation was automatically generated by the previous step. The input of this step is an XML file containing the cleaned data, and the output is another XML file that describes the grouping of the input data into slices. (Example 7) illustrates how to retrieve attribute values from the input data.

Example 7 (LogicalTransformation.xsl)

```
<text>
    <axsl:value-of select="attribute-instance[@attribute-id='attribute.painting.name']"/>
</text>
```

Presentation Transformation

The Presentation Transformation step builds a Web presentation file. We used HTML for the code generator, but it can be any other hypermedia format supported by the Web. The presentation code generator is based on a stylesheet that takes as input the slice packaged data (the output of the previous step) and converts it to a HTML file, ready to be presented on a Web browser (like Internet Explorer or Netscape Navigator). (Example 8) indicates that for each *slice-instance* an HTML table is generated. For each *slice-instance-ref* a row is built in the table. (Fig. 4) illustrates the HTML representation of the *painting.main* slice instantiated with a painting by Rembrandt.

Example 8 (PresentationTransformation.xsl)

```
<xsl:template match="slice-instance">
    <TABLE>
        <xsl:apply-templates select="*"/>
    </TABLE>
</xsl:template>
```

Self Portrait as the Apostle St Paul
1661
Rembrandt Harmensz. van Rijn
Figure 4: HTML presentation

In collaboration with CWI, Amsterdam, an interface between the output of Logical Transformation and Cuypers presentation system (van Ossenbruggen et al., 2001) will enable the generation of a different, more customized presentation in SMIL (Synchronized Multimedia Integration Language) format.

Hera Architecture

The experiences with this specific prototype are exploited in the Hera project (Houben, 2000), a research project that investigates hypermedia systems able to automatically generate presentations from ad hoc queries on heterogeneous data sources. Based on the principle of separation of concerns we distinguish two components in the Hera system: data retrieval and data presentation. Data retrieval is responsible for the integration (wrapping and mediation) of the different data input sources. It processes the input query and gathers the retrieved data. Data presentation builds a logical view of the data to be presented (it includes all the steps presented in this paper except for the last one) and outputs the (final) presentation (the last step of the proposed method).

Conclusions

In this paper we have considered an automatic presentation generation method based on four steps, and we have illustrated experiences from a prototype based on this method. Throughout the entire process implemented in the prototype the data is encoded in XML which proves to be an ideal format to store this structured data. We have shown how this XML data is managed in the generation process: for each step a data filter is written in XSLT, a standard supported by W3C for XML transformations. These data filters prove to fit well in our multi-phase presentation generation.

In the future we will extend this prototype (and apply it to different applications) in order to investigate: the extension of the system to multiple queries (based on slices), the impact of having different attributes types (besides text) on the presentation generation, different back-ends for the final presentation, and slices-on-demand (slices that are provided on demand, from a query, by a servlet).

A multimedia collaborative learning environment: a visit to Allsorts Virtual Primary School

Fiona French, University of North London, UK; Ruth Wood, Kingston University, UK; Ian Cumpson, Univesity of Greenwich, UK

In this session, we will showcase the recently developed prototype of a multimedia collaborative learning environment - Allsorts Virtual Primary School - and we will present our evaluation of the prototype. One of the main aims of collaborative learning is to encourage debate and thereby facilitate a deeper processing of the subject matter by the participating students. In order for this debate to be structured and meaningful, there needs to be both shared knowledge and a shared sense of purpose amongst participants. This project is founded on the premise that a tutor-modeled multimedia virtual reality can help contextualise information and provide a highly memorable experience for users, by using multisensory representations that mirror the real world. We anticipate the session to be of interest to teachers, staff developers, researchers and multimedia designers.

A Multimedia KANJI Dictionary with Hand-writing Recognition for Students of Japanese as a Foreign Language

Shinichi FUJITA, Kazuto YAMADA, ChunChen Lin, Seinosuke NARITA
Waseda University
3-4-1, Okubo, Shinjuku-ku
Tokyo, Japan
fujita@narita.elec.waseda.ac.jp

Abstract: Dictionaries are essential for language education. Kanji is much more difficult to look up in dictionaries than English or most other languages. In a Kanji dictionary, one usually utilizes the "stroke count" or "pronunciation" or "radical" (root) to look up a Kanji character. However, an unknown Kanji character is too difficult for Japanese beginners to look up, as they do not know its stroke count or pronunciation or radical. Some Kanji search systems utilizing hand-written recognition on PDAs or in other electronic forms may be found, but they are all designed for Japanese and the result depends greatly on the stroke order of the input data. Kanji characters are complex and it is difficult for Kanji beginners to write an unknown Kanji with the correct stroke order. No system could be found that allowed Japanese beginners to look up a Kanji easily. We have developed a multimedia Kanji dictionary with a search method that is friendly to Japanese beginners, utilizing hand-written recognition. Our dictionary can also show "mnemonics" in addition to the information found in a conventional dictionary. We have tested this system and obtained good results.

1. Introduction

It is much harder for Japanese beginners to use a Kanji dictionary than for English beginners to look up a word in an English dictionary. An English word can be found using knowledge of the 26 letters of the English alphabet and their order. However, to search for a Kanji character in a dictionary is not as simple. There are three keys for looking up a Kanji character. These are "reading", "number of strokes", and "radical (root)"; they are all too hard for Japanese beginners to know.

This paper proposes a multimedia dictionary suitable for Japanese beginners, by utilizing handwriting recognition. Microsoft IME (included in Japanese versions of Microsoft Windows operating system) has a function similar to our goal. A search for an unknown Kanji is initiated by dragging the mouse. However, it is dependent on the stroke order. For example, many foreigners recognize the character "口" (a mouth) as square at first glance, yet it takes 3 strokes when written correctly, and Microsoft IME cannot show the correct Kanji if it was written as one stroke. Other systems used on PDAs localized to Japanese have the same weakness.

There are some online systems available for looking up unfamiliar Kanji characters but we cannot find any system that is friendly to absolute beginners.

2. A picture of our system

Kanji   Button to show stroke animation

Radical   Stroke count   Infoation of the Kanji
Kanji. The system shows "Reading" (On-reading and Kun-reading), "stroke count", "mnemonic", "stroke order animation", and "example usage".

3. Test use and its result

This system has been developed for self-learning. We obtained an evaluation from twelve foreign students at Waseda University. The foreign students used this system freely for about 20 minutes. We obtained an evaluation by means of a five-level questionnaire. The results were as follows:

Question	Avarage
Q1. Is this system useful for looking up Kanji?	3.75
Q2. Is this retrieval system easy?	4.17
Q3. Is this dictionary system useful for mastering Kanji?	3.67
Q4. Do you want to use this dictionary in the future?	3.67
Q5. Please evaluate this multimedia Kanji dictionary system.	3.50

Question 6. What are the good points and the bad points of this dictionary system?

Good Points	Bad Points
Many methods of searching Pronunciations available Easy to use Nice to see Searching by handwriting is useful Showing examples by sentences not by words	Too slow for looking up Sometimes I cannot get what I wrote 303 Kanji is not enough Difficult to write Kanji with a mouse

4. References

While some argue that distance learning has been in existence since Biblical times (Gabrielle, 1997), it first gained notoriety in 1969 with correspondence courses offered at the British Open University. Since then, courses have been delivered via television, radio, and every other medium imaginable. Today with the advent of the Internet, institutions and organizations are putting their courses online at unprecedented rates. In today's era of web-based instruction in education and training, course management systems (CMS), also called learning management systems, can enhance or hinder the teaching/ learning experience. Organizations are increasingly evaluating CMS software for specifications and pricing when making purchasing decisions. This is problematic because 1) CMS technology changes frequently 2) organizations do not often know what specifications are needed, and 3) existing comparisons are often outdated.

This study examined existing literature to create a list of specifications that should be considered when making decisions about CMS. These specifications included approximately one hundred components comparing course learning tools, course collaboration tools, course development/ authoring tools, and course management tools. The specifications arose not only from literature about CMS products, but also from research on web-based learning.

In addition to the specification analysis, among four of the products, costs were compared (as of July 2001). Dialogue and follow-up with the CMS vendors provided clarification and further insight concerning product development and issues. Based on this careful analysis, the Florida Department of Revenue recommended one of the products compared.

To clarify, this study is not intended to provide a specific recommendation for a CMS product. Instead, it is intended to show which variables should be taken into account when making such decisions. The technology is a tool for achieving whatever tasks are proposed; therefore specifications are necessary considerations before determining which tool best suits the needs of the organization.

Background

Traditional classrooms have used the objectivist approach to learning based on Skinner's theory of transfer of knowledge from the instructor to the learner (Hazari, 1998). Recently there has been an epistemological shift rejecting traditional approaches about learning in favor of constructivist and similar beliefs. Web-based learning is best suited to the constructivist approach. Learning has traditionally been defined as an observable change in behavior. However, this definition is inadequate because in addition to examining learner performance, we must also look at the social and cultural context in which learning occurs as well as the tools that learners utilize to construct meaning (Jonassen 2000, Wenger 1998).

There have been tremendous shifts in pedagogical paradigms to a learner-centered environment that includes authentic instruction and flourishing communities of practice. Integrating activity theory with ecological psychology, Jonassen (2000) defines meaningful learning as, "a willful, intentional, active, conscious, constructive, and socially mediated practice that includes reciprocal intention   action—reflection activities". After articulating an intention and acting on it, people then learn from reflecting on their actions in terms of their intentions. These points are critical when taking into account an environment that not only benefits the educational system but also must enhance the teaching/learning process.

Integrating Sound Instructional Design to CMS Products

Extensive research has shown that the integration of sound instructional design and motivational strategies enhance learning and performance (Song and Keller, 2001). Keller (1999) presents three challenges with web-based instruction: (1) learning environment design, (2) student support, and (3) the development and support of students' self-motivation.

The first challenge, learning environment design, deals specifically with features that should be considered when choosing a course management system. This is where the design should allow ample opportunities for interactivity, practice, and feedback. Learning environments that simulate the actual process in as realistic a manner as possible are preferable. Some CMS products excel in this area while others fall short. In the most basic form of communication in this context and others, there is a sender, receiver, and message. "If this message is intended as instruction, then besides student, teacher, and content, we must also consider the environment in which this educational communication occurs -- an environment that benefits the educational system in some ways and constrains it in others" (Berge 2000). The goal of a CMS product should be to benefit the learning environment. Specifications that should be considered include interface issues, interactivity, synchronous and asynchronous discussion options, and virtual document libraries.

One factor that has consistently been significant in research on distance learning is the need for interactivity with learning environment design. Since the advent of the Internet, capabilities for rich interaction have grown at previously unimaginable rates. However, simply because the capability exists does not mean that it is being integrated in an instructionally sound manner. Sometimes in a web-based environment, designers incorporate animation and exercises through products such as Authorware that serve more to show the abilities of the designers and the technology rather than to present challenging, engaging, and enriching activities that help develop necessary skills. Web-based learning has the inherent ability to allow learners to work at their own pace and their own convenience. It also has the ability to provide these rich opportunities with task related simulations, practice, and customized feedback. It is the designer's responsibility to ensure that these capabilities are integrated to their full potential while effectively enhancing the learning process. CMS products that allow streaming video and multimedia capability, customizable navigation buttons, and rich but customizable templates are best suited for these interactive elements. This includes the need for access to the code so instructional web designers can fully customize the products to best suit the needs of the learning environment. Therefore, though most products do not allow for this, access to the code is imperative.

Likewise, the second challenge of learner support is critical. Studies are increasingly addressing the issue of social and cultural context in distance learning environments where student isolation and attrition have always been issues. Florida State University's use of a mentor-supported system through the 2+2 program (Hayes 2000) has shown immense promise in increasing completion rates from the traditionally less than 50% level to greater than 90%. Particularly with web-based instruction, it is important to consider the ratio of students to the instructor or tutor. It is not feasible to provide a course without support that must include issues of technology in this context. Some CMS products provide a rich context for learner support, including the capabilities of online mentors, live chat, and opportunities for learner collaboration.

Finally, the challenge of developing and supporting students' self-motivation has been addressed. Recently there has been promising research with regard to how to decrease student dropout rates, particularly through student support and motivation. Visser (1998) used motivational messages to establish a personal connection with students, increasing their confidence in the ability to complete the course while also increasing their satisfaction through the exchanges. Her study showed an increase in retention rates to 70-80%. The study also showed that there was a significant difference whether the messages were customized or sent en masse. This research is promising because while Visser used the postal system to deliver the messages, some CMS products enable automatic email reminders and customized messages to address this issue. Other issues of self-efficacy and self-regulation with regard to CMS products include allowing students to access their own grades, to track their progress, and to have the capability for integrated online notes.

In conclusion, this paper examined a number of instructional design considerations as they relate to course management systems. These considerations include the incorporation of sound instructional design to encourage active learning, opportunities for practice with immediate feedback, and rich dialogue between instructors, learners, and outside experts. From the perspective of interface, the importance of the opportunity to customize all features of the course management system was addressed. Learning environment design issues such as this are critical to enhancing learning, performance, and retention in web-based environments. Finally, the integration of learner support and the ability to enhance student self-regulation and self-efficacy was discussed in the context of CMS. These findings shed light on what specifications should be addressed when considering CMS products.

Motivation and Distance Learning

Donna Gabrielle, Florida State University, USA

There has been an epistemological shift rejecting traditional approaches about learning in favor of constructivist and similar beliefs. As this study shows, the shift is especially evident in distance education. Applying Keller's ARCS model, my research focused on what specific kinds of feedback, evaluation, and practice are most effective (or appropriate) to enhancing motivation in a technology-mediated environment. Satisfaction levels with online learning were also examined. This initial collection of quantitative data (including open-ended questions) via questionnaires revealed several patterns that led to follow-up and collection of qualitative data. The qualitative information was coded in terms of frustration, motivation, interactivity, and transfer of skills. The results confirmed that when online learners are motivated or respond positively to the online training, they perceive that there is a greater transfer of skills to their jobs. Likewise, when learners lack the confidence to succeed in an online course, the end result is frustration with little or no transfer of skills. The intention was to shed light on how people responded to the online training, both positively and negatively. Some of the most revealing information came from those learners who were frustrated with the experience. Motivational tactics are essential to the success of technology-mediated courses.

What we Learned from A User Survey: Selected Results for Digital Television and Internet Planning

Larrie E. Gale, Brigham Young University, USA

A survey conducted by Brigham Young University's nationwide channel, BYU-TV, discovered substantial interest in taking distance learning courses offered over that channel and through internet communication. The group responding was somewhat older, more female and more professional than what was expected. Survey research using both the web and mail-out surveys require attention to detail and more steps in the questionnaire creation process.

TEACHER PROFESSIONAL DEVELOPMENT BY MEANS OF INTERACTIVE VIDEO-CASE STUDIES: WHAT RESEARCH QUESTIONS SHOULD WE FOCUS ON?

Alvaro H GALVIS, D.Ed.
alvaro@concord.org
The Concord Consortium,
Concord, MA

ABSTRACT

The Internet has created many opportunities for lifelong learning. It opens a worldwide window for students, parents, educators and workers. However, for solving the problem of keeping large numbers of educators up to date in their field, giving everyone Internet access is not sufficient. Relevant educational programs must be provided – programs that are closely integrated with the educational setting and that address major challenges. One such challenge stems from the necessity to adhere to national and regional standards in different content fields. Educators are required to keep pace with advances in their disciplines, while improving their performance by integrating desirable content, processes, and technology into standards-based curricular materials.

School districts face a critical challenge in providing their educators with pertinent and significant professional development opportunities. Summer courses, weekly or biweekly seminars, and participation in conferences can provide such opportunities for many teachers, but conventional face-to-face professional development programs cannot meet the demand for continuing education of all teachers. Information and communication technologies have created new means for sharing information and experiences, as well as for building learning communities of teachers, administrators and teacher professional developers. But despite networked schools districts, cheaper Internet costs, and more computer literate teachers, there is still no systematic means of providing interactive professional development.

The Seeing Math Telecommunications Project[1] offers a strategic response to this problem by adding value to an existing offering. Seeing Math focuses on helping math teachers become acquainted with the NCTM 2000 standards by offering them the opportunity to reflect and construct knowledge around interactive video case studies that are explored online. Video clips and support materials, flexibly structured as a series of individual "chapters," are used to show experienced math teachers constructively interacting with their students in normal classroom settings. Threaded asynchronous discussions help the participants to analyze and build knowledge around each case study.

---

[1] See http://www.concord.org projects: The Seeing Math Telecommunications Project

Local implementation and community sharing of experiences help to foster systemic change in the participating school districts. As the leader of this initiative, the Concord Consortium is conducting research concerning this new, highly interactive online learning environment.

The arrival of this new kind of open-ended, powerful learning environment poses new questions for research into teacher professional development. What should be the focus of the research? Is it simply a matter of comparing this new highly interactive video case study approach (and whatever variations we may choose to make to it) to more conventional treatments on basis of effectiveness and cost? Or does the use of the new technology really raise new questions, and offer an opportunity for more systemic educational change? These and other provocative questions will be addressed in the format of a free-ranging discussion group.

ABCs and XML: How Semiotic Search Engines Can Mine "Diamonds" of Information on the Internet

Joseph Giarratano
The University of Houston-Clear Lake

Ruth Gannon Cook
The University of Houston-Clear Lake

Abstract:
XML is demonstrating that the evolution from HTML to XML allows semiotic tools to be included in software program designs. This can dramatically change the nature of Internet programming because the use of symbols, graphic objects, audio, proxemics, or virtual reality programs, will introduce nonlinear dynamics to mediate with HTML and cognition. Metaphoric programming, a symbolic method of delivery of information has not been used with HTML. But research has shown that cultural content from symbols demonstrates the rich meaning and communication cultural systems. Instead of Boolean searches currently used by most search engines on the Internet, an XML-based semiotic search engine could allow for semiotic searches to build upon those cultural systems by including symbol searches and bring a whole new dimension to knowledge acquisition through the Internet.

From the Phoenician merchants' recordings of commodities five thousand years ago emerged text and printed cuneiform tablets. Guttenberg's printing press gave serfs access to information and communication. Twentieth century radio, movies, and television brought a new awareness and ability to communicate to people all over the world. Over the last thirty years computers have integrated all these prior media forms and introduced a global interactivity. The newest innovation, XML, integrates all of those communication forms into a virtual realm that can include semiotic representations to help acquire and share communication and information in a number of ways.

XML is demonstrating that the evolution from HTML to XML will change Internet programming by allowing semiotic tools to be included in software program designs. This can dramatically change the nature of Internet programming because the use of symbols, graphic objects, audio, proxemics, or virtual reality programs, will introduce nonlinear dynamics to mediate with HTML and cognition. The results of the synthesis will be a new dimension of meaning conveyance in communication.

Currently HTML provides tags to define the parameters of coding, what coding will be placed on a webpage, as well as where and how that coding will be placed on a webpage. The advantages of XML over HTML are demonstrated when XML's coding provides for more than the basic coding provisions of content positioning. XML has the ability to distinguish and incorporate semiotic representations into its program and hence provides a new dimension of recognition in software programming.

XML allows tags to be defined for a webpage document that can created to be read in ways unprecedented in other software languages like HTML. For example, XML can incorporate symbols or even musical signs as part of the data definition. The XML tags can also be created to direct the program to analyzed data, sent data to a database, put data in a spreadsheet, etc.

Semiotics is the study of patterned human communication behavior, including auditory/vocabulary, facial expressions, body talk, touch (proxemics), signs, and symbols (Webster, 1989). As sociocultural tools, the signs and symbols, etc., included in semiotics, take on enriched meaning, affecting the functions of human consciousness as well as their environment. Ultimately, everyday language and discourse come under the scrutiny of this discipline since it becomes a metalinguistic descriptor of ordinary communication (Dant, 1991). Ordinary language identifies and uses written material and verbiage to communicate and express meaning. Language also uses these "tools" to construct meaning and, in some psychological schools of thought, i.e., the structuralist school of thought, these tools are analyzed in order to study the social context of language in a meaningful way.

Levi-Strauss took this analysis one step further, incorporating more intimate terminology. He stated "kinship terms are elements of meaning...(however) they acquire meaning only if they are integrated into systems (1970)." He posited that if forms are recognized as the same for both ancient and modern minds, as the study of the symbolic functions indicates, the unconscious structure underlying customs and institutions need to be studied to "obtain a principle of valid interpretation" generically applicable across cultures (Dant, 1991). There are semioticians who research the "insignificant" semiotics of every day symbolic representations that are laden with meaning and social significance (1991). These "insignificant" phenomena often contain inspired rich meanings that fill in the gaps of information and help define cultural, and, in particular, sociocultural, trends (GannonCook, 1998; Wertsch, 1985).

The semiotic aspect of XML is a quantum leap beyond HTML that is limited to text because with XML's ability to recognize these symbols, the software program takes a big step beyond basic program commands. What this means to the field of programming and Computer Science is that a whole new synthesis of communication tools is now possible. The communication bar is raised because XML reduces the need for extraneous programming.

In the field of semiotics, "metaphoric programming" is simply a symbolic method of delivery of information. But research has shown that "a cultural content emerges (from symbols) in the development of cultural systems (del Rio & Alvarez, 1995). Instead of Boolean searches currently used by most search engines on the Internet, an XML-based semiotic search engine could allow for semiotic searches. For example, searches could be conducted for specified data, inscriptions, and even music symbols. This would enable searches to be much more intuitive, and could distill searches to hone in on more appropriate and condensed search results. XML could offer an alternative to the current information inundation that engulfs Boolean searchers and provide electronic parceling of data in ways that have not been available until its inception. Tools like XML that mediate between human consciousness and computers could provide a safety zone where new blueprints could be drawn for both. Symbols and metaphors that render the process of meaning possible could be particularly useful.

There is an old adage that "the one thing we can always count on is change." While we know change will occur, we still hold on to memories and bits of nostalgia that give meaning to our lives. In the past, books conveyed information with text and pictures; television conveyed text, pictures, and sounds; and computers combined books & media with sound and real-time interactive communication. The promise of XML is not just to win the search engine hunt for information, but to win the hunt with the trophy of meaningful and relevant results.

Teacher Candidates and Mentor Educators: Integrating Aspects of a World Wide Web Site into a Developing Lesson Plan

Ruth Gannon-Cook, University of Houston at Clear Lake, USA ; Caroline M. Crawford, University of Houston at Clear Lake, USA

The World Wide Web (Web) holds numerous possibilities for all learning environments, from the very young to the older learner. Teacher candidates and mentor educators focus their expertise upon the design and development of lesson plans that are appropriate for their classroom learning environments. Through the introduction of technology, namely the World Wide Web, educators are having a philosophical shift in thinking take place. The teacher candidates and mentor educators have emphasized the successful and appropriate integration of designing and developing World Wide Web sites into their lesson plans. The educator has the opportunity to not only design and develop their own Web sites but, once the learners are sufficiently experienced at the Web site development, they may begin development of Web-based aspects that will enhance the active learning environment and the emphasis upon higher order thinking skills.

Constructivism in Web Based Learning Revisited: Explorers with a Machete in a Hypermedia Rain Forest

Abstract: Nowadays, e-learning is booming: thousands of online courses and dozens of universities online. However... Quantity has little to do with "real innovation". In very rare occasions, online courses and teaching institutions are breaking with the rules of the Gutenberg Galaxy. They are designed on a linear basis, and based on conventional text. What if we try to put state-of-the-art technology aside for a while? What if we try to think exclusively in terms of cognitive efficacy? Then we will be able to create non-dependent on technology models for teaching online. We've done so, and developed our *"Full-Hypermedia Educational Systems Development Model"*, which intends to take full advantage (in terms of cognition and learning) of non-linear navigable structures and multimedia. We want to have our students exploring a rich, hypermedia environment. We want them to face the problem of finding their own way in the middle of (only apparent) chaos.

Introduction: Fun Fairs and Real Rain Forests

Nowadays, Internet is packed with good online courses. Thousands of them. Some include additional navigational aids, interactive exercises, simulations and links to other websites of interest; the best even add tests and a virtual notepad and student tracking facilities. Probably they will do wide use of e-mail and discussion forums. But in the end the structure is always the same: linear. There are plenty of examples of very good courses that lack one only thing: breaking with the traditions of Gutenberg Galaxy.

Most of the courses one comes across in the Web are, in some way, like fun fair's stalls: a very restricted and controlled environment where the student has no option but clicking now and then the "next page button". They are just a "safe" imitation of "real" hypermedia. All in all, perhaps it's about time to take advantage of the cognitive potentials of exploratory navigation in hypermedia networks. In practice, we mean, not only in theory. That was our aim when we begun to develop our *"Full-Hypermedia Educational Systems Development Model"* (FHESDM).

We situate the learner in a real rain forest (not a jungle: it makes no sense to build completely chaotic systems), instead of a fake. We want him to struggle in order to find a way. His way. We want to transform navigation (though it may sound bizarre) into a problematic situation. One the kind Jean Piaget proposes as generators of new cognitive structures development. Our aim? To make students construct their own knowledge. But not from social interaction and collaborative learning, the nowadays most common implementation of constructivist principles in Internet. That's undoubtedly a very good philosophy but... we felt like trying another approach. We wanted to focus in cognitive constructivism, based on the "blind" exploration of a rich hypermedia domain.

Imagine an explorer that, with a machete in his hand, wanders around an unknown for him rain forest. No map. Just never-ending vegetation. Obviously, while he walks he'll begin to build a mental map (a deformed one, for sure) of the place: rivers, openings, trees types, animals,... will allow the explorer to imagine a structure of the place, based on his own and personal way of moving and on the "designed in advance" structure of the rain forest (remember: our course won't be chaotic, being its structure very carefully thought). When eventually he gets a high enough hill, he'll be able to watch the whole rain forest, and realize the mistakes in his mental map. He'll locate the places he knows yet, and then will locate new ones. But above all he will have the chance to discover the real relationships between the locations. After all this "correcting work", he'll go down again, and have the chance to pay more attention to specific details, his knowledge of the information space completed now.

After the whole process, something is for sure: our explorer has got to know the rain forest very well.

Making Your Way in the Middle of the Woods

As we've mentioned previously, our model is based on constructivist principles (see Larios 98). Specifically:

- Subjectivity of the learning process: The student must explore the system according to his own interests. That way he will construct his own mental schema. The differential feature in our model (right the opposite to other approaches, like that of Ausubel and Novak's (Novak 01)) is that we'll provide no map to the brave explorer: he must recreate the structure from scratch. He must navigate the structure "from inside" before contemplating the whole view.
- This "blind exploration" will involve a problematic situation for the student, who, by solving it, will advance his "knowledge creating process" (assimilation and accommodation).

But constructivism isn't the only milestone of our model. We've adopted (and adapted) some aspects of Ausubel's Significant Learning Theory (Ausubel 68) too. For instance, the information structure of the courses will present first the most general ideas, providing more details as the learner moves on to deeper levels in the structure. We'll also use the idea that any new knowledge to be learnt must be attached to previous known concepts, already in the student's cognitive structures.

Some way, we want to offer the user a rich context where to play his own and personalized role (see Ascott 99), developing his own cognitive structures and augmenting, at the same time, the "incidental knowledge" (Lee 99). Our aim is to get it without eliminating narrative (Laurillard 98) and without making "cognitive overload" explode (see Plowman 99 and Lee 99). In this section we'll refer to the "Structural Dimension of Hypermedia", specifically: those aspects related to the information structure and the navigation structure. In a sense, we'll be trying to convey Structural Knowledge to the learner.

Thus, the structure of the system must be designed with an only purpose in mind: conveying a structure of knowledge. Certainly, our approach inherits the philosophy of Novak's Concept Maps (Novak 01), differing from them in two basic aspects: we propose a more methodical (and somewhat rigid) design of the network (in order to minimize the problems described in the previous paragraph), and we avoid showing an "aerial view" of the system to the student. If learning by discovery and exploration is a milestone in our model, the aid of a map from the very beginning may encourage an exploration of the woods as a whole, not of every tree and its relationship with the rest. We want an inmersive course, no a landscape to explore.

We begin the design by creating a hierarchy of layers, in which any node is a summary of all the nodes that "hang" on it. That way, penetrating into the lower layers in the hierarchy means to obtain more details of previously revised concepts (remember Ausubel's proposals). On the other hand, going back towards the root of the hierarchy allows the student to see the knowledge space from a more holistic point of view.

Once we have developed a hierarchical space of contents, it's about time to establish the necessary relationships between pairs or pages (or, more generally, nodes). In an effort to keep a sense of modularity in the course, during these first steps in the design process we'll limit to set links between nodes situated in the

same sublayer, i.e., nodes sharing the same father. That way we'll be creating small navigational subspaces, whose "gate" will be the father node.

Up to now, the proposed model looks fine, but there is little special, little different on it. This is a most suitable time to introduce a new element in our model: the "contract" concept. Thanks to it, we'll be able to superimpose several navigation structures upon an only information structure, allowing for a more customizable way of navigating through the system without using Intelligent Tutoring Systems (i.e., without taking the control out from the hands of the student, a fundamental constructivist idea).

Actually, contracts are a concept inherited from the Object Oriented Design and Programming world. For us, contracts will be the different sets of links a node can show to the student, depending on the path followed to get there. That way, an only node of contents can be inserted into several navigation structures, that's to say, into several ways of conceiving the knowledge space, all in the same hypermedia system (Fig. 1).
Figure 1: Node with two contracts.

So Blue the Rivers, so Green the Trees

Other important kind of knowledge a course has to convey is Declarative Knowledge. The nowadays way of doing so online, most of the times, is by means of text and graphics. We intend to situate our learner in the middle of a colorful rain forest. We'll try to take full advantage of multimedia, in order to complement exploratory learning. It's what we call the "Exposition Dimension" of hypermedia.

We like to consider multimedia as the third dimension of hypermedia: a set of vectors, each associated to a node in the two-dimensional network.

A vector represents the amount of multimedia information displayed by a node, and, of course, the way in which that information is displayed. We'll dedicate the rest of this section to justify and describe the way in which our FHESDM copes with this vectors, intending always to keep on the track of constructivism and cognitive efficacy: what we have so called the "docuscheme", a cognitively sound model to present education oriented multimedia information.

Reading on a screen is annoying and frustrating. People read on books and magazines, but nobody would be willing to read on a TV set, for instance. Screens are the land of pictures and animations, not of written words.

Let's use pictures then but... what kind of pictures? Well, static ones, preferably (animated pictures are too "volatile"), and shocking to the perceptive system of the student (this will encourage attention and retention, as mentioned by (Trumbo 98)). Any other feature? Yes, indeed. It seems interesting to provide a summary of the node's contents: let's employ an only picture then, captivating and eye-catching to the student, but at the same time behaving as a big and high level scheme of the node's contents. An "advance organizer", in Ausubel's terminology.

And then... What else? We want to convey contents, not just a scheme of the contents. We need a way to put a large amount of information inside our fashionable node. One interesting possibility is audio. Audio is always a powerful communication resource (see McKillop 98). What's more: by introducing oral narration in

our system, we are combining static picture with documentaries' principles. We are getting closer to the concept of "Docuscheme", now.

In order to get even closer, and to increase in an ultimate way the "information capacity" of our node, we could think of explaining every concept in the scheme by means of some kind of video, animation or whatever multimedia element the designer considers appropriate.

So now we have a big, colorful graphical scheme, explained by means of audio and acting as an umbrella that covers an enormous amount of multimedia information. It sounds fine: a node as catching as a documentary and as accurate as a textbook. It only lacks a few complementary elements more.

First, accessing the information in a node in a film-like way (not in vain we are trying to imitate television documentaries in some way), i.e., from the beginning to the end without interruptions, may be fine for the first viewing, but not for the next visits to the node. Consequently, each part or the scheme must be accessible separately, once the student is inside the node.

Second, perhaps we mustn't eliminate completely the text. Perhaps reading a textual version of the contents after viewing the full multimedia presentation may be a great opportunity for the student to analyze in full detail the information, to impose the student's information acquisition pace on the prefixed pace of video and audio. We must admit the text back in our system then, but only as a secondary element, a post-viewing resource.

Making the Most of Your Machete

Daily life in the rain forest is no at all contemplative. On the contrary, you must be continuously moving, and doing and achieving in order to survive. Well, our situation is somewhat better but... we shouldn't forget "surviving by doing", anyway. In this case, learning by doing. ¡We need to include opportunities for strong interaction in our web courses! Our model still lacks the third kind of knowledge: Procedural Knowledge.

"Learning by doing" complements the "learning by exploring" and the "learning by watching" approaches used up to now (see Scott 00). And the most common way to implement learning by doing in an online system is interactivity. But we mean real, full interactivity, not just navigating. What's more, we propose to separate very clearly interactive activities from the rest, more passive ones. That way, we reduce fragmentation, as we are not interrupting expositions of declarative knowledge.

In order to satisfy the interactivity (more precisely, the "separated interactivity") requirements of the course, we have created the concept of "satellite". Satellites are complementary nodes that "orbit around" a declarative node (see the reason for their name?). Every satellite contains an interactive activity of any kind (exercises, tests, simulations, real examples, study cases...) (Fig.2).
Figure 2: A node and its satellites.

Any question about the design of satellites? Oh, fine. Unfortunately, we don't have any answer. Each satellite depends strongly on the declarative contents it intends to complement, the available resources, the designer's objectives, etc. Anyway, if you want a hint, we recommend not to display the satellite in the same

window you are displaying the declarative node, but in a smaller, detached one: that way the context in which the activity is being realized will be before the eyes of the student constantly.

Welcome to Our Virtual Rain Forest

Though our intention was to develop a model beyond temporary technology restrictions, it seems somewhat important to introduce a real implementation of the model, in order to show that we are describing a feasible way of creating online courses, that creating that sort of rain forest is not a dream. We'll explain the technological items we are using for the time being, but keeping always in mind that, in all probability, they'll change very often in the future.

The aim of our implementation is to develop a core of navigational aids easily adaptable to any set of HTML documents. That way, once you have the contents of the course (a set of multimedia web pages), you just need to superimpose on them the core of tools previously developed to have the system running.

These tools have been built using typical Internet programming resources: DHTML for the user interface, Java Servlets for navigation control and user tracking, and XML for data representation (Fig. 3).
Figure 3: Nowadays implementation of the model.

This is a graceful way to implement the Structural Dimension. What about the Exposition Dimension? We are currently evaluating some options. Specifically, we are considering Java Applets, XML (SMIL, more specifically) with DHTML, and Macromedia Director or Flash. Though there is no definitive conclusion yet, for the time being we are using Macromedia software. The reason for this can be summed up with an only word: simplicity. The design process our model involves is rather complex, and it doesn't seem a good idea to increase the complexity even more.

There is also the problem of bandwidth. Although it's increasing very quickly, this remains the main obstacle to take full advantage of docuscheme principles over Internet. In the meanwhile, vector's graphics and streaming techniques are a good option.

Anyway, we are looking for a personalized solution, as we don't think appropriate to depend on proprietary applications. Specifically, we are trying to combine Java applets with SMIL data representation, in order to create our perfectly customized "docuscheme's viewer".

Conclusions and Future Work

When we begun our research a few years ago, we undertook two premises: first, we intended to obtain something not depending on temporary technology; second, we wished to "make the difference significant", paraphrasing the famous "The Non-Significant Difference Phenomenon" website.

We accomplished the first by developing an abstract model. In our opinion, that's the only way to walk ahead technology, and not always behind. If we concentrate exclusively on applying the state-of-the-art technology, we'll never be able to move fast enough: technology will always be faster, and bringing some kind of stability to online learning will always be a dream impossible to get into practice. Abstract models, based on pedagogical and cognitive principles, give us the chance to "take over control" of the situation. We'll ask technology for what we need, not the opposite.

The second premise is reflected in the kind of model we have created. If we put real technology aside, at least for a while, we can think in a "riskier" way. We can think of instructional systems' features different from the habitual. In a word, we can work with features that help us to transform the use of online learning into a really significant difference. We've tried to reach that point breaking with linearity and text, and making extensive use of exploration and multimedia. In a word: developing our own way of applying constructivist principles to Web Based Learning.

And next? A mountain of research and development is still to be done. The path is long, and we've just begun to walk. From an abstract point of view, we are eager to keep on improving our model, realizing new experiments, and making up new ways to obtain full advantage of the Web. And what about a more technological point of view? Well, the design process in our model, as it has been described here, involves a very complicated sequence of stages, and requires an immense amount of work. So we are planning the development of a software tool specially thought to make design work far easier and convenient, eliminating routine tasks and facilitating collaborative design.

Abstract: The paper discusses user-centered approach to adaptive Web-based tutoring in 2 aspects: construction of psychological profile of the user and adaptive interface design. The development is based on the concept of user model that is a formal description of user's characteristics such as left/right hemisphere asymmetry, perso nal features, preferences, cognitive style. This user model is initially obtained through the preliminary testing by special intelligent software environment TRIVIUM which contains special knowledge base for psychological assessment. Information in this model is applied for defining a particular educational program for each user and specialized interface design.

Keywords: User model, adaptive hypermedia, web-based tutoring, distance learning, human-computer interaction

Introduction

The paper discusses psychological aspects of the user-oriented interface design and a research framework for acquisition of user models in a form suitable for later automated use in adaptive applications, including distance learning systems on the Internet. The study of user modeling for a wide range of is continued in the current paper towards the practical estimation of psychological and other numerical parameters, with which a program with adaptive interface could automatically adjust itself to formally measured characteristics of its user.

Available literature on user modeling (see [Self, 1974; Self, 1994; Stefanuk, 1976; Wagner, 1992] for few though representative examples) reveals two opposite approaches to account for user's peculiarities in human-computer interaction (HCI). First, one would try to describe «analytically» possible groups of users of a given computer/software environment and to map explicitly their essential characteristics to the appropriate tunable interface parameters. Second, one would treat the problem in a manner similar to machine learning, neural networks etc., when a program automatically adapts to its dynamically changing environment through a kind of feedback loop. The latter, «empirical» approach may be considered as dominating nowadays in view of rapidly developing multi-agent technologies and distributed computing. It is evident that for multi-agent systems, where the program–program interaction is as important as the program–user one, such empirical modeling of «environment» is preferable.

We may give the following definition to the concept of user model: notions of the system about the user, that are based on a priory information and direct interaction between the user and system. This model presents a formal description of user's characteristics such as left/right hemisphere asymmetry, personal features, preferences, cognitive style. Usually the main attention is given to professional preparation of the user and level of his computer competence but humanitarian aspects are not taken into consideration. However, taking into consideration both psychological and professional user's peculiarities allows to minimize intellectual efforts of the user necessary for understanding system's actions in the process of exploitation and reactions on it.

TRIVIUM (first version was developed by Voinov [Gavrilova, Averbukh, Voinov, 1996]) is a tool that was implemented for acquiring user models. Its present version was developed jointly with Timothey Geleverya in the Intelligent Systems Laboratory of the Institute for High Performance Computing and Databases (http://www.csa.ru/ailab). It puts stress on psychological parameters of user model as the most important among those affecting HCI.

Psychological factors

One can group factors, which affect the user's productivity, into several classes. Within each class only those factors, which allow for a more or less formal estimation, are emphasized. They can be classified differently by different authors. For example, one could emphasize two dominant (though probably overlapping) strata: emotionally-communicative and cognitive ones.

The first stratum deals with the area of interaction between the user and the computer and comprises the problems of *perception, understanding, clarity, usability, handiness* together with some other features. The problem is how to gain the user's sympathy and confidence, taking into account the temper and intelligent peculiarities. In this way, [Kearsley, 1997] stresses the problem of *anxiety* in educational systems, which can be an inhibiting factor in learning and therefore has received considerable attention. It is closely related to *arousal, attention* and *motivation* as well as the entire topic of emotions.

Anxiety can be reduced in an instructional context by:
* Instructions that minimize stress and prepare individual;
* Increased use of positive feedback during a task;
* Reduced opportunities for failure in a task.

The *cognitive* stratum comprises deeper problems related to human mind and memory. Often novices feel the cognitive dissonance between his/her expectations and the interface layout and behavior.

An extremely important factor is *personal cognitive style* [Witkin, Goodenough, 1981], which considerably influences the problem solving way. Kearsley [Kearsley, 1997] lists a number of cognitive styles that have been identified and studied over the years. Such characteristics of individual cognitive styles may be assessed and taken into consideration: field independence, scanning, leveling versus sharpening, reflection, conceptual differentiation.

A similar taxonomy may be introduced among characteristic styles of learning. Theoretically, *cognitive and learning* styles could be used to predict what kind of instructional strategies or methods would be most effective for a given individual and learning task.

The style of logical mentality or deductive/inductive strategies is also important. In case of deduction users perform their cognitive activity via top-down strategy from the higher level of abstraction to more detailed schema. On the contrary, in case of induction the users ascend from the unconnected elementary concepts to meta-concepts. Cognitive modelling should also take into consideration the role of cerebral asymmetry. The left hemisphere forms a model in which the elements and their organization are analytical, sequential and "discrete". On the other hand, the right hemisphere cognitive style is holistic, Gestalt, analogous and mosaic. There is a vast continuum of intermediate RH/LH positions; nevertheless, most users can be subdivided into two correspondingly separated groups characterizing their cognitive and psycho-physiological type that is relevant for expert operational activity, choice of reasoning and processing strategies.

The battery of tests implemented in TRIVIUM includes inventories on major part of the mentioned above parameters, including metaphoric thinking, syllogistic reasoning, different kinds of classifications and sorting, linguistic and reflective abilities.

Special Software Environment to Acquire User Models

TRIVIUM – is an intelligent software system for multi-factor quiz's data interpretation. It can work with all types of question-answer tests. TRIVIUM allows to present respondent's verbal portrait and profile according to the test results. It includes the following components (Figure 1):
1. Respondent's workplace. It has simple interface, because it is intended for non-programmer users.
2. Psychologist-expert's workplace presents interactive program that functions in 3 modes:
- test development – psychologist is able to define a list of questions, variants of answers, list of scales that characterize test result and scheme of their calculation. The scheme of calculation is a table that defines conformity between the answer on each question and scales. At a choice of concrete variant of the answer all the scales on which it (variant of the answer) influences and also their increments are determined under this table.
- Editing of knowledge base of the rules for test results interpretation.
- Statistical data processing. Psychologist is able to get personal data for each respondent (name, gender, date of birth, time of testing), all his answers, set of calculated scale values and their verbal interpretation. Expert is able to enter comments for each respondent in this mode.
3. Information base containing rules for tests' results interpretation, quizzes' base, respondents' tests, personal data, users' profiles.
4. Fuzzy inference engine for automatic verbal interpretation of tests' and quizzes' results using rules, defined by psychologists-experts.
Figure 1.

Quizzes' results are analysed according to the following scheme.

Testing
↓
Factors in "raw values" (numerical values)
↓
Factors expressed in linguistic variables
↓
Entrance vector of factors
↓
Analysis of the entrance vector of factors in the inference engine
↓
Output vector of factors
↓
Translation of the linguistic variable of each factor into its verbal (textual) expression
↓
Text construction of the verbal portrait in dependence on availability of the groups joining the factors on semantic commonness

There are a lot of factors that influence upon the choice of special educational program for the user therefore to find an optimal one it is necessary to carry out a full psychological investigation of the user to get his psychological portrait, to provide comparison of his psychological peculiarities and educational program. For example, profound learning of the material would be difficult for the "novice" and he should be presented only part of the course with basic quest ions. If the user has some preliminary knowledge of the subject domain but wants to define some questions more precisely he should be given part of the material he is interested in. And the whole learning material should presented to the "professional". Therefore for correct defining of the user portrait it is necessary to use a balanced test system but not a single test.

At present Trivium tests' base includes the following quizzes:
1. 16 PF (Personality Factors) Cattell test that assesses the level of 16 personality traits in individuals 16 years and above.
    A reserved vs. outgoing
    B concrete thinking vs. abstract thinking
    C emotionally less stable vs. emotionally stable
    E accommodating vs. assertive
    F sober vs. enthusiastic
    G flexible vs. conscientious
    H shy vs. venturesome
    I tough-minded vs. tender-minded
    L trusting vs. sceptical
    M pragmatic vs. unconventional
    N forthright vs. astute
    O self-assured vs. apprehensive
    Q1 conservative vs. experimenting
    Q2 group-dependent vs. self-sufficient
    Q3 spontaneous vs. controlled
    Q4 relaxed vs. tense
    It measures levels of dominance, abstract thinking, anxiety, independence and control.
2. Test on locus control.
3. Personal scale of anxiety demonstration. It allows to assess common level of a person's anxiety. This assessment may be used for the construction of

the so called "short-term" interface.

4. Callerman-Pluchek test.

User model is formed on the basis of these tests results. Screen forms are presented on the figures 2-4.

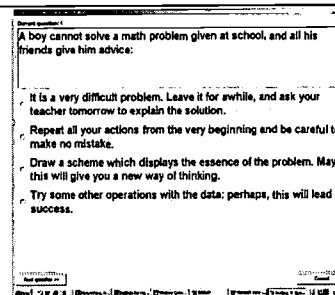
In this framework a special program was realised that can assess user attention. It allows to assess 2 parameters of the user - attention volume and concentration. Methodology that is put into the basis of testing is called "Proof test". The user is given 10 rows each one consisting of 20 letters and he has to pick out a letter in each row that coincides with the first letter within 30 seconds. As a result he is given a verbal and numerical assessment that is put into the user model. Knowledge of the user model parameters allows to choose corresponding interface for him. For example, if the user is scattered he should be given more help, the forms of interface objects should be changed.
Figure 2.
Figure 3.


Figure 4.

System is prototyped in the framework of: Python scripting language, Tcl/Tk/Tix GUI toolkit, FuzzyCLIPS inference engine, original data processing library. It runs both under Unix and Win32 (Windows 95 and NT). Taking into consideration user's peculiarities the software developers may enhance usability, handiness and efficiency of interfaces.

Discussion

The work is now in progress. The approach and software described in this paper may be implemented for the design and building of adaptive interfaces embedded in different HCI applications. Taking into consideration user's peculiarities the software developers may enhance usability, handiness and efficiency of interfaces. A series of experiments for mapping of UM parameters onto interface parameters are now under examination using TRIVIUM environment. For further automation and adjustment of the resulting user models a set of specially designed intelligent *agents* is being developed aimed at controlling and monitoring users' activity during their active work or learning sessions. Variable parameters of the interface may be the following: form of presentation and format of input and output data, dialogue type, level of messages of auxiliary character, automatically set up parameters, set of necessary auxiliary commands.

Preferred method for navigation is a very important characteristic for the system design. For example, users who rated themselves as having difficulty navigating to specific areas were expected to benefit from a menu-based interface. Menu-based interfaces require less mental demand than other types of interfaces. Users who rated themselves as having no difficulty navigating through the system and wanted to quickly navigate were expected to benefit from an interface where menus could be skipped and shortcut keys could be used [Bushey, Mauney, Deelman, 1999].

Abstract: In this paper we evaluate educational software, available in the market, designed for the purpose of teaching programming that addresses mainly beginners and intermediate students. The evaluation is conducted on the basis of an evaluation model built in University of Macedonia, Greece in the context of project "Odysseia" that is mainly designed to introduce computer and network technologies into the everyday school practice, especially in secondary education. The paper discusses briefly the project and introduces the educational software that was evaluated. Next, it presents the evaluation method and the processing of the data and finally reports some conclusions derived from the evaluation.

Introduction

The number of products from the educational software industry has significantly increased the last decade. The reason for that increase is closely related to the basic policy assumption that educational system should serve the overall target of 'information society for all' (see CEC 2000). Schools should prepare students to use actively new information and communication technologies (ICTs) taking advantage of the life-learning process that these technologies support. As a result in most countries all curriculums are under continuous development adopting ICTs in teaching and learning. In Greece the national curriculum is currently under reform, especially in secondary education, attempting to follow educational and technological advances. A number of projects come with this reform. One of the biggest in that respect is 'Odysseia' Program, which is part of the Ministry of National Education and Religious Affairs' Operational Program 'Educational and Initial Vocational Training' and is implemented by the Directorate of Studies for Secondary Education, the Directorate of the Community Support Framework, the Pedagogical Institute and the Computer Technology Institute, which are underwriting the design and technical support and monitoring the implementation of the 19 Projects that make up the Program. It is a dynamic, action-oriented program designed to cultivate and develop the faculty of critical

thinking and to change the practices of teaching, learning and communication in Greek schools through the use of computer and network technologies in secondary education. These Projects are designed to introduce computer and network technologies into the everyday school practice of more than 370 secondary schools in Greece in every subject on the standard curriculum, in order to create a substantial number of school communities which have incorporated these technologies as an integral part of their daily teaching and learning practice. Project E42 is a particularly important facet of the overall endeavor to inspire in teachers a positive attitude towards the use of the new technologies, while at the same time educating teachers to become capable users of these technologies. The proposed training programs are addressed to teachers of all school subjects, not only computer science. The special one-year post-graduate training programs carried out in the modern Instructor Training Units at selected Greek universities are training a nucleus of 100 selected teacher/educators who will thus be able to provide in-school training for their approximately 6000 colleagues in the Odysseia schools. In that respect the University of Macedonia in Thessaloniki runs the action "EPENDISI" which not only aims to train secondary schoolteachers but also to build a database that contains information and resources on several evaluated educational software available in the market on almost all secondary school subjects (www.ithaca.uom). The evaluation of the software is conducted on the basis of an evaluation model built in University of Macedonia, that examines both social and practical acceptability of educational software (see Georgiadou & Economides 2000). This paper will present the evaluation results on eight online educational software designed for the purpose of teaching programming that address mainly beginners and intermediate students. In the following section, we briefly present each one of the programming software.

On-line Programming Software Presentation

An Introduction to MSW Logo: www.southwest.com.au/~jfuller/logotut/menu.htm
It is a thorough tutorial concerning the programming language MSW Logo. It covers basic programming aspects such as simple commands, the repeat command, functions, variables and some additional features. It includes instructions and suggestions for teachers and additional links concerning Logo.

How C Programming Works: www.howstuffworks.com/c.htm
This is a tool for Web authoring and it is compatible with any browser. Works with self-contained page sets instead of separate pages, offering an easy to use, fast environment to edit sites. It includes tables, maps, frame sets, slides, forms, windows opening, style-sheets and more - all in WYSIWYG.

Introduction to C Programming I: www.cit.ac.nz/smac/cprogram/cstart.htm, http://www.studyweb.com/
This is an in depth tutorial covering the C programming language. It assumes little or no knowledge of the C language, but does assume some knowledge of programming in general. It includes interactive multiple-choice exercises that can help the students to study and understand the issues presented.

Introduction to C Programming II: devcentral.iftech.com/learning/tutorials/c-cpp/c/
This series contains a set of tutorials that help one to learn about the C programming language, which start with the assumption that the user know a procedural language like Pascal or Fortran already, and simply want to map that knowledge to C. These tutorials introduce the user to C by showing him/her how Pascal maps to it. It also introduces several concepts not found in Pascal. Most of these new concepts deal with pointers. Readers coming from a Fortran, Cobol, BASIC, etc. background should find that the Pascal code is easy to read.

Logo: library.thinkquest.org/18446/eintro.shtml
It is a tutorial that concerns the Logo programming language. It includes 10 lessons with the basic aspects of programming, such as simple commands, the repeat command, functions, etc. It also includes examples and exercises that can be modified by the students.

LOGO Programming: members.aol.com/mckoss/logo.htm, http://www.studyweb.com/
This is an online small tutorial for learning LOGO a child's programming language. This tutorial is designed for an adult to assist the child with the learning process.

Pascal Programming v2.1: www.mgu.bg/manuals/pascal/default.htm, www.cit.ac.nz/smac/pascal/default.htm
This is an online courseware for beginning Pascal programming. It starts with a discussion of variables and ends
with an online interactive test. Every subject contains exercises that can be done interactively.

rLogo: www.embry.com/rLogo
rLogo is an easy to learn programming language designed for the World Wide Web. It is based on the Logo
programming language.

Evaluation

Evaluation Method

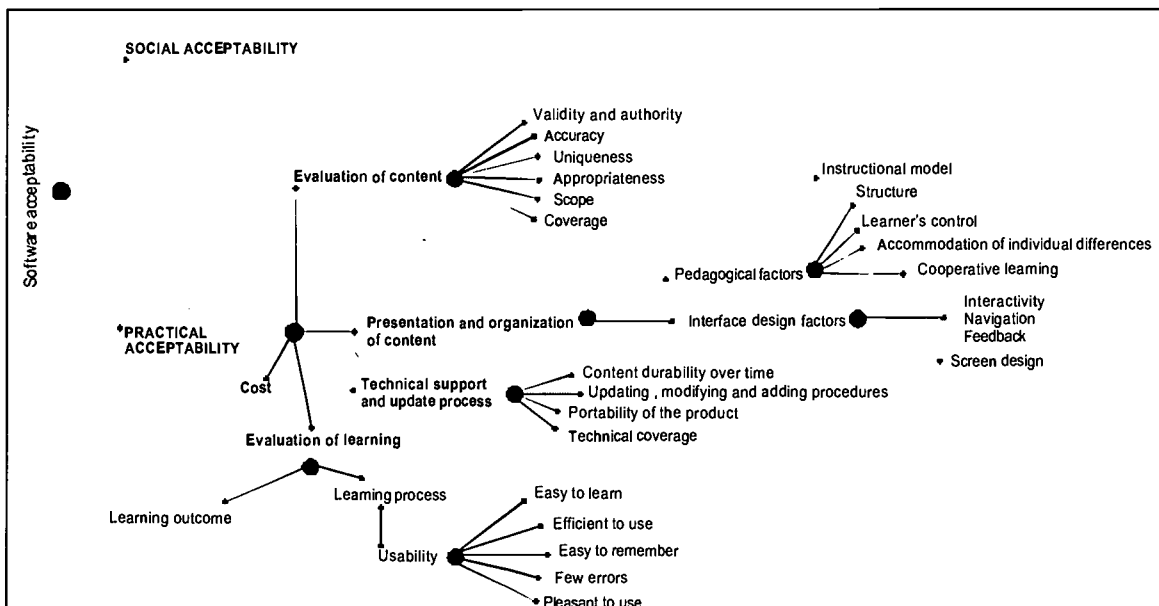
For the purpose of the evaluation of educational software a framework has been designed based on the
integration of a number of important issues emerged from research on instructional design and system
evaluation the past fifteen years, and which should be considered from designers and evaluators of hypermedia
courseware. The framework is concerned with both social and practical acceptability of educational software,
based on Nielsen's idea that "the overall acceptability of a computer system is a combination of its social and
practical acceptability" (Nielsen 1990). The term social acceptability is related with the social basis of an
educational system. In cases when the basis is teacher-centered, then the software that provides high levels of
learner control is possibly socially unacceptable and vice versa. Given that a piece of educational software is
socially acceptable, its practical acceptability is examined through the evaluation of the following sectors:
Content, Presentation and Organization of the Content, Technical Support and Update Process, and finally, the
Evaluation of Learning. All sectors are equally important, as educational software has to be simultaneously
pedagogically and technically sound. Moreover, each sector includes a number of criteria, which should be meet
in a satisfactory level, in order to characterize a piece of educational software of high quality. Furthermore, cost-
effectiveness is always being examined when similar products seem to have the same educational value. The
following figure (Fig. 1) presents all factors included in the framework only in a diagram due to the lack of space.
However, all the details about it can be found in "Evaluation Factors of Educational Software" (Georgiadou &
Economides 2000).


Figure 1. Diagram of the Evaluation Framework

All the above issues were used as a basis for the development of evaluation instruments mainly in the form of a suitability scale questionnaire and the evaluation was conducted from a team of researchers on educational technology in the University of Macedonia. The items included in the questionnaire were fixed alternative, with six-point scaled format from 'strongly disagree' (1) to 'strongly agree' (5) including a 'non-applicable' point (0). Some example items follow that are concerned with the Interactivity – Navigation – Feedback sector, included in Interface Design Factors (see Tessmer, Jonassen, & Caverly 1989).

1. The system has help key to get procedural information	0 1 2 3 4 5
2. The system has answer key for answering a question	0 1 2 3 4 5
3. The system has glossary key for seeing the definition of any term	0 1 2 3 4 5

Data Processing

The evaluation was conducted for each one of the titles mentioned above and then the sum of the scores of all items for every title was compared with the scores of the other titles. However, not only the overall sum was examined but also the sum for any given sector in practical acceptability i.e. Content, Presentation and Organization of the Content, Technical Support and Update Process and finally, the Evaluation of Learning. This approach was chosen in order to ensure the case when a title is pedagogically sound but lacks in terms of interface design and vice versa. The following table (Tab. 1) presents the results of the evaluation in percentage mode where 100% corresponds to the maximum value. Despite that every factor and sub-factors were examined separately during the evaluation process, the table presents principally the results of the main factors in order to allow easy interpretation. For example, the Interface Design Factors included in the 'Presentation and Organization of the Content' sector integrate Interactivity-Navigation-Feedback and Screen Design parameters as shown in (Fig. 1). However, (Tab.1) gives a single percentage for Interface Design. Also, it has to be mentioned that with regards to the evaluation of learning, Table 1 is concerned only with the Learning Process, i.e. Usability Evaluation and not with the Learning Outcomes which are typically evaluated with performance tests or assignments used to judge the quality and the quantity of learning as resulted scores are typically interval or ratio values (or can be transformed as such) so that powerful inferential statistical analysis can be employed to make generalizations about uniform impact.

		Percentage of social acceptability	Overall percentage of practical acceptability	Evaluation of each sector involved in Practical acceptability				
				Content	Presentation and Organization of the Content		Technical support & Update Process	Usability
					Pedagogical Factors	Interface Design Factors		
1	An Introduction to MSW Logo	80%	73%	86%	56%	66%	67%	90%
2	How C Programming Works	80%	70%	85%	62%	63%	50%	88%
3	Introduction to C Programming I	80%	79%	90%	72%	74%	70%	90%
4	Introduction to C Programming II	90%	67%	80%	65%	59%	51%	78%
5	Logo	90%	77%	86%	66%	73%	68%	92%
6	LOGO Programming	80%	65%	75%	62%	53%	63%	72%
7	Pascal Programming v2.1	80%	78%	93%	70%	72%	62%	92%
8	rLogo	80%	65%	86%	61%	55%	47%	78%

Table 1. Results of the Evaluation in a Percentage Mode

Discussion

This section is concerned with the conclusions derived from the processing of the data, during the evaluation of the software. It is obvious that all the software that has been evaluated has achieved satisfactory gradation in both Social Acceptance and Content Evaluation fields. On the contrary, the majority of the software presents the poorest performance on the 'Presentation and Organization of the Content' field that include Pedagogical and Interface Design factors and in turn the latter include screen design and interactivity-navigation-feedback parameters as shown in (Fig. 1). This difference shows that authors and producers of educational software often still focus on issues related with the validity and authority of the content in expense to issues related with interface design, despite the fact that hypermedia systems provide the necessary technology for highly interactive and potentially adaptive learning environments. Reigeluth and Curtis argued in 1987 that "the failure of so many instructional programs and materials has often been the result of an emphasis solely on content, with little regard for principles of instructional design to produce effective, efficient, and appealing instruction" (Reigeluth & Curtis 1987). The evaluation results show that their argument is still valid; fourteen years after.

Moreover, only four out of eight software examined contain exercises: How C Programming works, Introduction to C Programming I, Introduction to C Programming II, and Pascal Programming v2.1, and from these only two titles support interactive exercises with the appropriate feedback: Introduction to C Programming I and Pascal Programming v2.1. The other titles are limited strictly to simple examples that enhance the understanding but do not support collaboration or interactivity. In addition, it was also noticed that most of the examined software do not take into account the diversity that characterizes most of the students, like different previous experience in some learning fields, motivation, ability of assimilation, etc. With regards to Screen Design, all titles exhibit the information using basically text, images and graphics and not any other screen elements that could motivate the learner and assist him/her in retaining and recalling the information (i.e. video, animation etc.). Only Logo use some moving images as presentation means. Regarding the 'Technical Support' field almost half of the software has inadequate technical support from the designers or the corresponding company. Even fewer software companies offer additional instructions or suggestions for the teacher or even some kind of relative documentation on the potential of the software and teaching scenarios. Information about the hardware and software needed is often limited and inadequate. Additionally, we have concluded that the titles exhibit a lack in information concerning the last update or the frequency in which the site was renewed.

It is generally accepted that the Usability field has achieved relatively high scores in almost all of the cases. Usability is usually associated with five parameters (see Nielsen 1990): (1) Easy to learn: The user can quickly get some work done with the system, (2) Efficient to use: Once the user has learnt the system, a high level of productivity is possible, (3) Easy to remember: The casual user is able to return to using the system after some period without having to learn everything all over, (4) Few errors: Users do not make many errors during the use of the system or if they do so they can easily recover them, (5) Pleasant to use: Users are subjectively satisfied by using the system; they like it. All the environments examined were easy to use and the navigation procedures were simple in understanding even for the moderate student.

Finally, the best scores in all fields were exhibit by "Introduction to C Programming I" that is an in depth tutorial covering the C programming language. It assumes little or no knowledge of the C language, but does assume some knowledge of programming in general. It includes interactive multiple-choice exercises that can help the students to study and understand the issues presented.

However, as an overall conclusion we could say that despite the plethora of educational software available in the market the need for continuous research on evaluation methods and techniques is profound, as educational software has to be pedagogically and technically sound, in order to contribute meaningfully in the improvement of the learning experience. And above all designers and evaluators should always be aware that if educational hypermedia is not well designed, they will create psychological problems for users, such as memory overload and divided attention, or they will fail to suit the variety of ways that people work together or alone (see Preece 1993).

Abstract: Nowadays economic logic has changed and has imposed a set of new rules. Those who play by the new rules will prosper; those who ignore them will not thrive in a competitive word. In fact traditional organisational forms and their vertical structures tend to be slow in developing and implementing decisions and less facilitative of innovation. Due to this many management gurus have argued that current models of organizational structure fail to meet the challenges of the information age. Indeed, some commentators claim that the age of traditional organisational is over. They assert that traditional hierarchy outlived its usefulness and new organisational models needed and that IT lies at the heart of these new models for next century. The purpose of this paper is to evaluate the Internet impacts on organisational structures and identify new emerging forms of organisations in the light of IT advances.

Introduction

To evaluate how organisations change Brown and Eisenhardt (1998) consider two theories. One perspective is a Darwinian view, in other word, a process of how living thing grow, adapt, and change. This is *Evolutionary Theory* that describes the process of gradual change across time through variation, selection, and preservation. This theory gives a passive role rather than an active role to organizations. The organisational growth model that has been introduced by Greiner is an evolutionary model. The second and newer perspective is *Complexity Theory.* This theory emphasizes the emergence of surprising called adaptive systems. According to complexity theory, adaptation is most effective in systems that are only partially connected. According to this theory after an unknown period of time a significant event occurs that create a pervasive changes in all aspects of human life. The time of occurrence of such event called Bifurcation Point. Looking backward, when we look in history we can identify many of these bifurcation points, for example, electricity in its time was a bifurcation point. In our age The Internet can be seen as a new bifurcation point.

Internet is a pervasive phenomenon and it is commonly believed hat the Internet and its inherent distributed capabilities that lead to decentralized views. They have had profound effects on organisational structure, because organisations can gain enormous location flexibility in various activities. Nowadays the Internet has overcome distance and organisations now have to deal with different combinations of physical and electronic spaces and places. The challenge for companies in information markets is the shift from physical to electronic infrastructures.

Many factors are driving change -or maybe it is better to say impose change- but as Byrne (2000) report, none is more important than the rise of Internet technologies. According to Johnson (2000) the Internet is going to mature faster than any other development seen to date. He claims, in a traditional organisation, CEO has used information as a power device. In the 21st century Corporation, continuous link between customer, knowledge workers, suppliers and so on is necessary. In such a setting the free flow of information is inevitable. With the Internet everyone can participate, regardless of size and circumstance (Bulloch, 2001).

Using the Internet offers opportunities for reducing operating cost levels and enhancing services (Venkatraman, 2000). It also provides opportunities for leveraging divers sources of expertise within and across organisational boundaries (Venkatraman and Henderson, 1998).

The growth of Internet-based business is truly meteoric (Mahadevan, 2000). A recent report in Purchasing magazine stated that 81% of purchasing professionals use the Internet in their job. That's up from 73 percent in 1998, and represents an incredible increase from 1997, when just 45% of buyers utilized the Web (Johnson, 2000). Ford and General Motors have announced that they will do all procurement over the Web within a year.

(Bulloch, 2001) reports, four years ago, according to a recent CFIB survey, only 30% of firms with 5099 employees were using the Internet to do business. Today that number is 85%. And it is no surprise that 82% of these firms are using the Internet for email, 46% own a Web site, 23% are buying online and 17% are selling online. Some researchers (Teo, et al. 2000) claim, the advent of Internet has increased the importance of IT and opened new opportunities that can dramatically alter way a firm compete, for example Intranet and extranets have enabled firms to reduce costs and streamline business operations.

(Ross, 1999) reports the Poster Gallery in Albuquerque, N.M. sells just about every poster in print, using volume orders to secure discounts from vendors. " In our first year we sold $4000," says Robert Farley, the owner. Two years later, " we're doing about $300000, 99.9% of it on the Internet."
In contrast, Simon (2000) declares that loyalty may be less on the Internet than in traditional organisations. In spite of great advantage, the Internet's effect on centralisation will not be as strong as one might expect, but there is evidence to support both points of view. One of major criticisms of the Internet is that it does not lend itself to a centrally managed environment (Smith, 1999).

Traditional Forms:

In summary, looking backward, four organizational models have been introduced for prescribing how to design an organization to achieve alignment among the various component within the organization and its environment. The models are discussed briefly below:

The Bureaucratic Hierarchy. In bureaucratic organization, authority hierarchy is well defined, duties of employees are clear (division of labor). Organisation characterized by high formalization and employment decisions based on merit .The strength of this model lies in its standardization of activities and doing them in a highly efficient manner (Robbins, 1987). Its two major weakness are too emphasis on specialization leads to subunit conflicts.

The Entrepreneurial Organisation. In contrary of bureaucratic firm, an entrepreneurial firm always looking for innovation, and continually searching for the risky environments (Mintzberg, 1983). The key to success in entrepreneurial organizations is real-time, organization-wide information sharing, and collaboration throughout the organization (Applegate, 1994).

The Matrix Organisation: In effort to minimize environmental complexity, in 1960s, researchers introduced the matrix model. This model characterized by using specialists from various departments to collaborate as a team(s). In contrast with its primary objects, the matrix failed to create a suitable climate throughout the organization. Its various information channels result overlapping authority and power struggles (Robbins, 1987; Applegate, 1994).

The Adhocacy :In dynamic and complex environment, there is a need to sophisticated innovation. Mintzberg (1983) suggest the adhocracy as a final solution, and characterized it as a "highly organic structure, with little formalization of behavior, high horizontal job specialization based on formal training. According to Robbins (1987), adhocracy is a kind of organization with low vertical differentiation, low formalization, decentralization and great flexibility.

Emerging forms: Characteristics and Imperatives

Many studies have been devoted to find characteristics of emerging forms of organizational structures (Miles and Snow, 1992; Klenke, 1994; Applegate, 1994; Chesbtough and Teece, 1996; Hagl III, 1996; Kelly, 1997; Lee, 1997; Li, 1997; Brown and Eisenhardt, 1998; Hitt and Keats, 1998; Venkatraman, 2000 and 1994; Mahadevan, 2000; Symon, 2000; Black and Edwards, 2000; Byrne, 2000; Eisenstat). It is obvious that mentioning all the related studies are far beyond the scope of this paper, however, I will try to evaluate briefly the main ideas of above papers.

A number of terms have been used to describe the organizational form of the future. (Chesbrough & Teece ,1996), Hagel & Armstrang (1997) and Chutchian (1999) called it *Virtual Corporation.* Other names including: *Plug –And –Play Company* (Cairncross, 2000), *Network Organisation* (Black and Edwards, 2000; Byrne, 2000), *Web Company* (Hagel III, 1996), *Knowledge-Creating Company* (Nonaka & Takeuchi, 1995), *Opportunity Based Design* (Eisentat et al. 2001). Despite the different names, all the new forms emphasize on similar

drivers: globalisation (Chesbrough & Teece, 1996, Hitt & Keats, 1998; Symon, 2000; Raynor, 2000) the move to an information economy (Venkatraman, 1994 & 1997; Bjorn & Turner, 1994), flexible environment (Boddy & Buchanan, 1986; Kelly, 1997), to be entrepreneurial and to be responsive to markets (Eisenstat et al., 2001), and customer orientation (venkatraman, 1994 & 2000).

Some commentators identified "technology " as an "imperative" that determine structural characteristics such as span of control, and centralisation of authority (Klenke, 1994). Bjorn (1994) recognise technology as an "enabler", however he argue that it is not technology itself that should be the primary focal point of organisational transformation. It is obvious that IT has had a profound impact on business and organisational structure (Venkatraman, 1994; Miles & Snow, 1992; Li, 1997), and it seems, this trend will continue at faster pace. Particularly, the role of IT to the change in organisational routines, and its potential as a main source of organisational innovation must be emphasized (Venkatraman, 1994, Li & Williams, 2000).

Generally, researchers have argue that in the light of IT advances, organisations have been moved away from centrally coordinated, multi-level hierarchies towards a more flat and flexible structures (Boddy & Buchanan, 1986; Boddy & Gunson, 1996; Li, 1997; Hitt & Keats, 1998; Byrne, 2000). In other words, because vertical structures tend to be slow in developing and implementing decisions and less facilitative on innovation, hierarchical organisational structures are replaced by more horizontal structures (Klenke, 1994). Coordination, in traditional structures, usually was achieved through establishing standards, developing plans and schedules, but a horizontal structure will use more formal integrating mechanisms (Hitt & Keats, 1998).

Today organisations confront a set of new imperatives that have changed the nature of competition. The new situation, need new rules. Successful organisations in 21st firstly must identified new imperatives and then build a proper organisational structure to cope with them. New imperatives can be posed as follows:

Globalisation: Drucker points out that one of the big headaches for companies in the new century will be globalisation (Raynor, 2000). Globalisation has largely been due to worldwide economic development and the opening of domestic markets to foreign firms. A recent survey showed that approximately 50% of small businesses in the US. Were operating in international markets, up from 20% in the early 1990s(Hitt & Keats, 1998). Advanced information technology has overcome the geographical distance (Li & Williams, 1999). In fact all the players in recent years have close ties with each other, but this ties are all electronic (Chutchian, 1999).

Entrepreneurship and Innovation: Traditional business typically concentrate on opportunities they can pursue by them, by contrast, new organisation must encourage their people to look for a richer multiplicity of opportunities, including those that business can't seize alone. Kelly (1997) alleges that one of the main source of wealth in new situation flows directly from innovation. Some researchers claim that innovation is the first rule in globalises economy ((Hitt & Keats, 1998). Companies in Internet Age, require organizing efforts that move beyond efficiency and control to ones that emphasize the ability to take advantage of opportunities (Black & Edwards, 2000).

Customer or service orientation: Customers in new landscape are informed and knowledgeable. Venkatraman & Henderson (1998) and Schacklett (2000), assert that, emergence of electronic customer communities, is one of the most profound aspect of advanced IT. They also argue, in the industrial economy consumers could not be effectively linked together across time and space. Nowadays, using the Internet customers can remotely experience products and services. To be more precise, electronic communities signal a power shift from manufacturers to customers. According to Byrne (2000), future company will tailor its products to each individual by turning customers into partners and giving them the technology to design and demand exactly what they want. He also avers, the real power of IT results from its potential to Tran formative change, and much of that will involve the company's relationship with its customers.

Flexibility: Flexibility is a vital characteristic. Firms must be flexible to manage unpredictable change in their environments. This feature, will able companies to deal with enhanced competition, and rapidly react to competitors. Hitt and Keats (1998), claim success in the 21st century organisation will depend first on building strategic flexibility. As noted earlier Implementing a horizontal structure can also enhance organisational flexibility.

Cost Reduction: In the light of IT advances, over half of web purchasers' view three or more sites before they purchase, consequently, Simon (2000), predicts, price will be even a bigger factor in new landscape. Using IT in many virtual companies have had a dramatic effects on cost reduction. A typical bank transaction costs $1.25 when handled by a teller, 54 cents when done by phone, but the same transaction processed over the Internet costs 2 cents! In some cases a Net-based catalogue system reduced procurement costs to one-twentieth (Byrne, 2000). Roughly 65 % of IT managers believe the Internet technology has reduced costs in their organisations, and 55 % say it has increased revenue (Wikon, 1999). A major impact of the Internet and its inherent distributed capabilities, says Mahadevan (2000), is dramatic reduction in search costs for both the buyers and the sellers

Outsourcing: while moving manufacturing offshore is nothing new to many corporations, Brenner (2000) report, still a significant percentage of corporate purchasing cost is focused on outsourced services from third-

party vendors. Nike creates a global network of organisations to produce athletic shoes instead of keeping all the work inside the organisation (Miles & Snow, 1992). Waters (2000), reports the strong global economy will expand demand for U.S. goods and services. But the domestic labour force will be unable to produce these for a competitive price. Some companies, are finding that they can cut costs and leverage the most out of their staff and budgets if they partner with other companies that specialize in particular areas that they can't do or as efficiently themselves (Chutchian, 1999. Ford Motor Company has process links with Goodyear Tire that allow it to exploit concurrent engineering and reduce the time of new product introduction. The potential benefits are that each partner can leverage the competencies in the extended network without resorting to the costly options of vertical integration. (Vekatraman, 1994). According to Wilson (1999), 53% of IT managers say they are outsourcing at least some of the development of their Internet/Intranet projects.

Improving Quality: As noted earlier, with using the Internet, customers are informed, so corporations must rely on the quality of their product than on the strength of their brand (Hagel III & Armstrong, 1997). There are some evidence that using advanced IT offers opportunities for reducing operational cost levels and /or improving products and services (Vekatraman, 2000).

Cooperation through IT: New situations create a need to "Digitisation", which means simply removing human minds and hands from an organisation's must routine tasks and replacing them with computer and networks (Byrne, 2000). Unlike traditional organisations that most interaction occurs within business units, in a virtual corporation people from a variety of units are worked together (Eisenstat et al., 2001). Recent advances in collaborative software; Internet/intranet technologies and personal desktop video conferencing have facilitated the use of external experts (Hitt & Keats, 1998). Management must encourage collaboration and coordination.

Developing human capital: Human capital has been and will continue to be, the most important asset of every organisation. Management, increasingly, need for knowledge workers and found out that; working in the competitive world is a war. A war for talent; it is a war for three types of resources- financial, human and technology (Venkatraman, 2000). According to InternetWeek's survey, more than 60 percent of IT departments were experiencing a shortage of skilled workers in those fields. According to Li (1997), around half of GNPs of industrialised countries are made up of information contents and it is estimated that around half of the workforce in all these economies are information workers.

Collaboration Through Online Personal Learning

David Gibson
National Institute for Community Innovations
Montpelier, Vermont
United States
dgibsonvismt.org

Abstract: This paper discusses the online Personal Learning Planner project underway at the National Institute for Community Innovations, and presents some of the details of the theory and thinking that is guiding the development. The web-based software is part of work by the National Institute for Community Innovations (NICI at http://nici-mc2.org) to develop tools for enhancing preservice education and supporting increased use of technology, especially in Professional Development Schools.

Introduction

The online Personal Learning Planner builds a human and machine web-based assistant site that is based on a theory of dialog recently articulated by myself and Anne Friedrichs (Friedrichs, 2000; Friedrchs and Gibson, 2001). The theory of collaborative interaction for learning is consistent with several writers concerned with authenticity, use of technology to create problem-centered learning teams, representation of complex dynamics in educational settings, and online learning. (Carroll, 2000; Gibson, 1999; Gibson & Clarke, 2000; Newmann & Wehlage, 1995; Stiggins, 1997; Wiggins, 1989, NSDC, 2001).

Friedrichs (2000) discusses four distinct dialogue stages that manifest themselves in the Personal Learning Planning process:

1. Sharing Experience: Listening to own and others' inner speech and natural attitude about a skill or concept.
2. Expressing and Examining Diverse Concepts: Recognizing conflicts; analyzing old and new concepts, models and beliefs; working in one's zone of proximal development.
3. Articulatiing Applications and Understandings: Practicing new skills; combining old and new concepts; using others' ideas, using scaffolds to renegotiate understandings.
4. Communicating New Powers and Creations: Celebrating effects of critical analysis

The online Personal Learning Planner (PLP) provides a structure within an online working space with private and public access controlled by the learner to enable the above framework to work among a learner and any group of people serving as critical friends and advisors to the learner. With funding from the U.S. Department of Education under the "Preparing Tomorrow's Teachers to Use Technology" program (http://www.ed.gov/teachtech/). NICI has developed the first version of the PLP as a "critical friends" online space for future teachers who are assembling portfolios of evidence that they meet the standards required for a teaching license. The PLP is designed to assist learners through the processes of:

Self-assessment of strengths, interests and aspirations
Planning preservice education learning goals and projects
Linking goals and projects to valued outcome standards
Creating original work and sharing the work with others
Receiving high quality feedback for the improvement of their work
Documenting and validating the achievement of learning goals
Assisting in the selection and preparation of exhibits of learning

Future plans for the PLP include many other learner groups such as K12 students and teachers, trainer-of-trainers programs, leadership programs, and groups as learners, for example, school-based action research teams using the site to develop collaborative products and seeking advice from remote experts to shape and validate the group's work.

Groundwork and Rationale

The lineage of the online Personal Learning Planner comes from two sources. One source is a bold move by a local secondary school community in Montpelier, Vermont that in 1993 placed "individualized educational plans for every student" in their long-term strategic plan. This led, in 1995, to the creation and implementation of a school-wide program to place personal learning at the center of a continuous conversation involving all students, their parents or guardians, and caring adults in a school. Support for the school-based development came from the University of Vermont. As well, the writings of researchers and theorists such as Bentley (1999), Moffat (1998), Friedrichs (2000), Gibson (1999 & 2000), influenced the effort. In addition, early in its development, the concept of the Montpelier "PLP" was picked up by the Regional Laboratory at Brown University, and combined with similar movements and interests in Rhode Island, Maine, Massachusetts and other New England states. In Maine, for example, the concept of personal learning took on a primary role in that state's exciting new proposal for the reform of secondary schools. In other work of the Lab, the theme of personalization became a crucial feature of the secondary reform network in the region, and was tied to the principles of "Breaking Ranks," the reform monograph of the National Association of Secondary School Principals. Thus, the concept of personalization of learning as essential to educational reform is well-founded in theory as well as practice.

The other source is the pioneering work of the WEB Project, which makes available web-tools and networked communities for original student work to be shared and critiqued online. The WEB Project successfully brings together working professionals and classroom teachers in support of the improvement of student work by focusing high quality feedback to a learner based on their articulated intentions for their work. The secrets of success of the project are probably many, but it is worth pointing out the learner-centered nature of the online dialogs and the singular focus on creation of original work. Also, the entire sequence of activity in the project only begins if and when a student shares a work-in-progress and asks for specific feedback. These qualities of learner-centeredness, creativity, self-initiative and intellectual focus have been carried forward into the web-based PLP.

The rationale for building a web-based tool focused on the improvement of preservice teacher work has two parts. First, there is a need for feedback to come from a diverse audience, yet preservice and induction programs sometimes have limited resources and structures that produce scant feedback to aspiring teachers. As a result, an aspiring teacher's work evolves in isolation, perpetuating the general conditions of teaching present in most schools today. A web-based professional network can help overcome isolation, but even more important, it can provide the future teacher with high quality information that might not otherwise be available. The advantages of "anytime, anyplace" access to experts is an obvious benefit of a web-tool.

The second rationale is that there is a need for effective documentation of learning beyond paper and pencil formats. Ideally, documentation should be a record of the decisions as well as the validation of the work produced. In small personalized programs, preservice teachers benefit from many interviews and observation/feedback sessions related to their work, but in many programs, that experience is limited to the last few months of preparation. An online personal learning planner can help create a longitudinal multimedia record of growth and change in an aspiring teacher's skills and capabilities

The sources of inspiration and rationale led us to ask "What does preservice teacher work look like?" "What would happen if we could build a site for the improvement of a future teacher's work?" "Could the principles of personalization and helpful feedback in a professional network assist teacher education programs?" The online Personal Learning Plan is a way to pose answers to these kinds of questions.

Critical Components in the Online Personal Learning Plan

One of the first questions often raised is whether online learning of any kind can truly be personal. Isn't person-to-person the most *personal* way to learn? In fact, isn't online work one of the most *impersonal* kinds of interaction there is between humans? I don't wish to argue these points here. Online learning is here to stay. It brings remote resources to the desktop anytime, anyplace. Yes, it is in its infancy. Yes, it lacks many important features needed for rich human communication, but so does writing, film, video, and even talking. Using new communication tools in learning is a matter of integration and balance and its effectiveness depends mightily on the attributes of both the learner and teacher. In spite of these challenges, online learning is growing and evolving at a rapid pace.

The Online PLP promotes a uniquely learner-centered approach to the challenge of integration and balance of technology in learning. The following basic assumptions guide the thinking behind the NICI - PLP.

Face-to-Face as a Foundation of Learning

The online world is an extension of human contact. The Online PLP doesn't and cannot replace face-to-face contact needed for learning; it extends, deepens and enhances personal contact.

Three bases for planning and action for learning

The purposes of learning can be categorized by three domains:
Institutional priorities – our shared community goals
Professional priorities – our scholarly traditions and expectations
Personal priorities – our source of deep meaning

The Learning Cycle

The Online PLP can be a powerful extension and helpmate in the "action research" process of planning, doing, reflecting and consolidating knowledge.

Focus on the learner's work

The learner's productivity and self-efficacy is the ultimate goal of the Online PLP. Work samples are the critical source for evidence of learning, the documentation of progress, and the verification that high standards have been achieved.

Self-Direction and Making Meaning

Learners produce better and are more highly motivated the more they have decision-making power over their learning. Learners gain from posing questions to advisors, and from knowing about, developing and using a variety of learning assets - their strengths, interests, aspirations, community and personal resources. All learning is a matter of making personal meaning out of the alternatives presented in experience.

Flexible Thinking Tools

Learners gain from scaffolding and assistance in stages and types of thinking, for example, divergent thinking, using multiple frameworks and perspectives, and so forth.

Structure and Roles

The online Personal Learning Planner allows all media formats and a multiplicity of linkages among learning goals, projects, and the evidence of attainment of standards of performance. Distinct from electronic portfolios that concentrate on the presentation and storage of completed work, the PLP concentrates on the improvement of work and the documentation of change of work over time.

Three user levels and a server administrator level are provided. Users levels include the Learner, Advisors, and a Program Administrator. The learner is in charge of their PLP. They create or choose goals, link them to standards or other external sources, create work that stands in relationship to the goals, make decisions on when both goals and work will be shared with advisors, and decide when work and goals are to be archived into permanent storage. Learners can make digital collections from their body of completed work. Each collection is presented as a self-contained website in which each work can independently attach reflections, summative evaluation, and new context-setting narrative and graphics.

Advisors are associated with one or more learners. When a learner's goal or work is being shared for

critique and feedback, the Advisor can discuss, offer direct edits or validate the goal or work as adequate for its purpose. For example, a goal might be validated as appropriate to completion of a secondary teaching license in science; a piece of work might be validated as evidence of achieving a standard of performance linked to one or more goals. The validation process can be formalized with rubrics or left as narrative, and any rubric can be associated with any piece of work's link as evidence. When a group of advisors scores a work using a common rubric, a summative rubric can be built upon completion of the work.

The Program Administrator can review all Learners and Advisor records, add and delete Learners and Advisors, set defaults on the number of advisors that need to agree in order for validatio n to be complete, create rubrics, create and edit standards, and make other selections associated with program management. The Server Administrator controls the hardware and communication decisions needed for site maintenance and archiving.

PLP as a Team Tool

The use of the PLP as a team tool assumes that agency for a group operates much like it does for an individual, once internal communication and trust within the group has been developed. Outside reviewers can be invited to become project advisors. The PLP allows anonymous or "tagged" contributions by group members to facilitate both group and individual accountability. As a collaborative tool, the PLP facilitates building a group's history as well as a collection of validated work products.

Self- Assembling Texts & Courses of Study

David Gibson
National Institute for Community Innovations
Montpelier, Vermont
United States
dgibsonvismt.org

Abstract: This paper describes the development of an interoperable meta-database system - a system of applications using metadata - that is intended to facilitate learner-centered collaboration, access to learning resources, and the fitness of channels of information to the emerging needs of learners at both individual and group levels. The new web-based educational database applications are preparing to use the concepts of self-assembly to treat digital media paths as a new form of "texts and courses" in education.

Introduction

New media = new modes of thinking. New tools for thinking and expressing have a profound effect on learning. They don't just change how we access information. New tools change the very modalities, scope and depth of how we see and interact with the world. For example, because MTV music videos led to television and print ad commercials with documentary-like, visual flashes of information; textual narratives of the past have given way to film-like story lines. Because online "chat rooms" led to new forms of "talking" with several people at once and asynchronous "listservs" and "threaded discussions" led to group archives, the concept of classroom dialog is evolving. Being able to see the 3-dimensional structure of a storm leads to new insights into the complex dynamics involved. And math classes with computer simulations and modeling are a different breed than math classes with only a pencil or chalkboard for representation. These are examples of how new media changes thinking as well as ways of working.

Learning through texts and courses is evolving to take advantage of new media and the globally connected web of experts, knowledge and tools. "Texts" now mean rich digital media streams; "courses" mean episodes and series of engagements spread across space and time. In both texts and courses, the static pre-planned paths and chapters of the past are giving way to more flexible ways of putting materials together for learning. This paper begins to discuss the application of the concept of self-assembly in a new web-based educational database application that treats digital media paths as a new form of "texts and courses" in education.

Self-Assembly

The word phrase "self-assembly" refers to something that is capable of putting itself together. The phrase also brings up images of self-organization, pulling oneself up by the bootstraps, spontaneous generation, and evolution - "something" coming from "nothing." How do these processes work and what might they mean for educational texts and curriculum?

Processes of self-organization are prevalent in both materials sciences and artificial intelligence research today. In materials science, self-assembly most often refers to the three-dimensional conformation of materials brought about by catalytic agents or processes; for example, through evaporation and vibration. (AMP, 1998 & 2000; Discover, 1998; Ingber, 1998) Engineers who previously thought in Cartesian, gears-and-straight-line terms are finding the mixture of biology and hardware and software to be liberating. (Petit, 1998)

In artificial intelligence (AI) research, self-assembly approaches include using "neural networks," "genetic algorithms" and "genetic programming" as the catalytic agents and processes (Engel, 2000; Sette,

Boullart & Van Langenhove, 1997). In the world of information and AI, as the conformational role expands to mean interacting-bodies of information, the complexity expands to n-dimensions, in configurations sometimes referred to as "landscapes" where "fitness" processes occur. The brain science and evolutionary metaphors in AI begin to give us clues as to why we might want to pay attention to self-assembly of texts and courses. The AI approaches have been characterized as:

- convenient for the implementation of model-based control strategies (Kulkarni, Tambe & Dahule, 1999)
- producing good results when a search field is too large to use conventional search or optimization techniques, and possessing an ability to undertake searches with few presumptions about the outcome (von Rönik, 1997)
- Useful when the complexity of a process is very high and no mathematical function is known to exist that represents the whole process; and where there are multiple objectives for optimization (Sette, Boullart & Van Langenhove, 1997)

We explore here two extensions of these kind of core ideas for a web-based set of educational applications. We envision "texts" (meaning any digital multimedia format used in teaching – digital video, audio, texts, pictures, tactile computer interfaces such as steering wheels, ramps and pulleys) and "courses of study" (meaning a planned and coordinated sequence of learning episodes) that can put themselves together. Some concepts helpful for the discussion:

- **Elements and Paths** – multimedia granules or chunks of information connected in a web of relationships through one or more "story lines." Elements can be singular or organized into complexes via subpaths. A path refers to a longer line of thinking/representation that organizes several elements or complexes. An element is a thing; a path is a relationship.

- **Fitness functions** – defined in part by the strengths, interests and aspirations of a learner, and in part by the professional and organizational goals in the learner's contexts. Fitness occurs when the learner's profile meets the structure of information and an exchange of resources occurs that is mutually beneficial to the learner and the world of knowledge.

- **Recombination** – mixing up elements of information and presenting new cross-fertilized ways of seeing and thinking about those chunks.

- **Feed Forward & Feedback Paths and Loops** – linear and nonlinear connections among the elements, which can have positive and negative influence on other element complexes as they form internal and external relationships.

A metaphor for the connections is a "loop," "trail" or "path" model of cross-referenced materials. For example, let's use three separate four-element paths to illustrate (Figure 1). In the first path, four multimedia elements (text, sound, video, jpg, etc) are associated with a theme such as "teaching civil rights in a high school history class." One of the elements is a video clip of "Martin Luther King" and is also found on a second path having to do with speeches of political leaders in the early 20th century after World War II. That path intersects with a third path that contains other post-war elements of culture and society.

The 1960's student protests against the Viet Nam war

Post-WW2 culture and society

Martin Luther King

The Civil Rights Act

Speeches of 20th C

Teaching civil rights in a high school history class

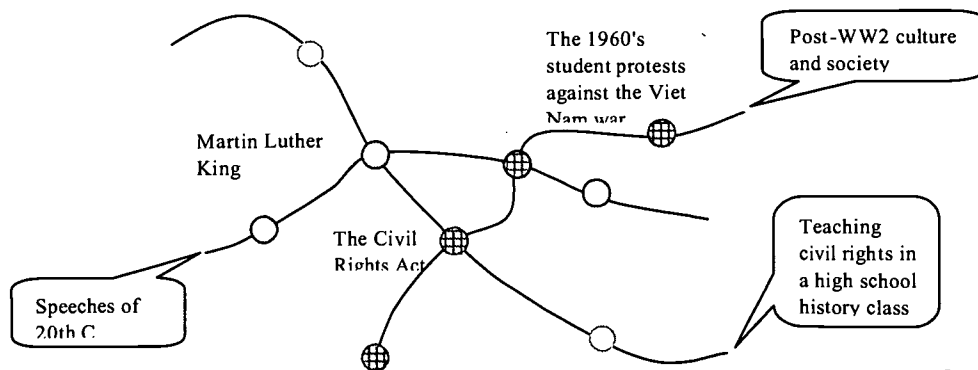
440


Figure 1. A path model of cross-referenced materials

The media chunks represented by element points in the web of relationships are small self-contained, self-running, self-explanatory chunks of digital information with metadata that assists in the formation of the paths. Possibilities for the metadata include

- "Audience" with qualifiers for age, grade level or level of expertise
- "Discipline" making an association with the media chunk for application within a specific field of knowledge. (e.g. the "I Have a Dream" speech as part of fields such as Political Science, Television & Media, or African American Studies)
- "Theme or Big Idea" taking the expert consensus on the major ideas of the related discipline and relating those to the elements (e.g. the King speech as Oratory, Documentary, Facing Historical Oppression).
- "Teaching points" with subject-object-predicate structures such as "galvanized public opinion about rights," "influenced the media and arts," or "led to campus riots." The teaching points might be story summaries among many that are subsets of the discipline using that element.
- "Story Line" a framework for basic narrative flow, e.g. beginning, middle, end, flashback series, historical, working backwards from high point, theme and variations, metaphoric comparisons, struggle of opposites, montage, etc.
- "Position" information in terms of outline or story line hierarchy such as "overview," "descriptive detail," "justification," "opposing view to x," etc.
- "Order or precedence" using historical, logical, causal, etc.

The paths connecting elements are multicausal (complex nonlinear) relationships with bidirectional capabilities. One element can have a positive influence on the next element or group of elements at one point in time, and have a negative influence at another point in time. As well, within each element there can be a complex crossing of directionality (e.g. playing different influence roles in two different paths at the same time). The agent will have to maintain simultaneous contradictory channels in an evolving configuration of relationships. "Meaning" within the channels will come at least partially from a model of the path as a whole, and in some instances, from "crosstalk" or superposition of wave functions within the element or a subpath itself.

The weights in the valuation structure of the model of the learner will play a role in defining the paths and determining the distances between elements on different paths. The natural language-like structures of the metadata will constitute a fuzzy model of the world that has two perspectives: the "model of the learner" perspective and the "model of the field of knowledge" (the combined weighted paths of the participating experts' models of the field of knowledge). When these two perspectives meet each other, there is a kind of tug of war between the learner's interests and ideas with those of the field, leading to the idea of "fitness" of the two perspectives or landscapes for each other. (see Csikszentmihalyi, 1996)

Fitness functions in the context of texts and courses will refer to the evolving configurations of strengths, interests and aspirations of a learner, as well as the professional and organizational goals in the learner's contexts. Both direct and implied collection & analysis methods will create the functions. For example, a direct collection method might be a survey of the learner, a personal profile, a test, or an interview. Implied collection methods might include tracking a learner's searches, uses of resources, and public communications with experts and others.

The self-assembling text will need to be able to build a model of the learner and adjusts its model over time to fit the changing configurations of the learner. In short, it needs to involve an adaptive agent that represents the learner in the web space and interact with other adaptive agents representing the knowledge structures in the web space. Valuation functions with weighted sums, as used in Arthur Samuel's checkers game player (1959) may provide the kind of thinking needed to construct the agents.

With the idea of recombination, we get both abundance and new connections. Abundance is needed to generate alternatives and new connections are needed to store memories of the past and to measure the distance of those to future connections.

Self- Assembling Texts

We are using the word "text" to mean a rich digital media stream utilizing all forms of storytelling, film and video, reading, audio, visualization and so forth.

Several scaffolds, narratives, streams of thought, outlines and story line formats at various "sizes and shapes" (determined for example by time to display and read/view, number of elements, and message complexity) will provide seed structures for the self assembly of texts. Time scales might range from 5 to 15 minute episodes to several hours, as in a miniseries, that would take several days to experience, but that could be approached in convenient samples of time. The number of elements might range from 3 or 4 (each of which may involve several media subelements and last from 30 seconds to 2 or 3 minutes) to several hundred or thousand per story line. Message complexity may have both intensive and extensive dimensions. Intensively, the level of complexity refers to the detail, depth of coverage and the vertically integrative scope of the topic within one or more representation hierarchies (as in part to whole relationships). Extensively, the level of complexity refers to the "same level" or peer-to-peer scope of relationships involved in the story line (as in whole to whole relationships). The complexity levels may be defined in terms of the numbers of elements, connectors, loops, and intersections both internally and externally that constitute a particular weighted path for the current purposes of a story line.

The seed structure of the self-assembling text implies that we need to create a new form of metadata that sits at a higher level of abstraction utilizing lower level metatagged media elements as pieces. For example, given a topic such as "stream biology" there may be many "introductory" sequences, which are differentiated to suit "body messages" of "macroinvertebrates", "energy production", or "city and recreational planning."

Production of the metadata structure of the story lines can at first come from existing texts, films and other media productions, but the ideal system will then evolve with new paths being added by knowledge-producing learners and experts.

Self- Assembling Courses of Study

The old structure of schooling was dominated by courses of study that had been created by a single teacher. The courses were designed to move a group of learners from some level of knowledge and ability to another, coordinated primarily through common texts, exercises and tests held at common meeting times.

The new structure of learning made possible by "anytime, anywhere" telecommunication networks and new media allows a natural emergence of a course of study. The course of study arises out of the interactions and dialog among a learner's expressions of interest, strengths and aspirations, a peer and expert community that shares interests as well as guides the learner, and the wider world of expertise systems.

As new courses develop, old educational functions take on new meaning. For example, "registration" will be accomplished through searches, self-assessment, and asking questions. "Forming goals" for the course will occur within a dialog with scaffolded self-guidance and with advisors and other learners. "Monitoring progress" will occur through learner and advisor talks, draft works and the feedback process, and ongoing assessment. "Completion and validation" of course and program attainment will follow how a work becomes evidence. Paths and subpaths will link up into book-length units. Role of human mediation w/agents and texts will become an integrated support system for the learner.

In the Personal Learning Planner (PLP), recently created by the National Institute for Community Innovations, a number of online structures are moving into place to take advantage of the self-assembly of texts and courses. Performances are moved outside of classrooms and focused on evidence of a small number of important standards. Common stable scoring guides with examples of work are provided across a boundary-free professional landscape. Managing multiple non-linear pathways of choice by learners and advisor groups and individuals is supported.

Gilbert's Usability Monitor (GUM)

Juan E. Gilbert[1]
Auburn University
Computer Science & Software Engineering
107 Dunstan Hall
Auburn, AL 36849 USA
gilbert@eng.auburn.edu

Abstract: With the continued growth of the World Wide Web, the task of determining interface usability has become much more complicated. The days of focus groups and usability studies are becoming more difficult as applications are being ported to the Web. Today's user base spreads across culture, age, gender and professional boundaries. Conducting a usability study has never been more difficult. This paper introduces Gilbert's Usability Monitor (GUM). GUM is a new form of usability that addresses interfaces that have a volatile user base, such as Web based applications.

Introduction

There are several different methods that determine usability. Usability methods can be categorized as inquiry, inspection or testing methods. Inquiry methods include surveys, questionnaires, interviews, focus groups and field observations (Hom 1996). Inspection methods include heuristic evaluations (Nielsen 1992), cognitive walkthroughs (Rowley 1992 & Wharton 1994), structured observations (Lund 1985), user modeling (Gong 1994) and Pluralistic Walkthroughs (Hom 1996). Popular testing methods involve Think Aloud Protocols, Question Asking Protocols (Hom 1996) and Remote Testing (Hartson 1996). These methods generally require additional usability experts, test users, expensive equipment or inconvenient time commitments. For these reasons, interface designers will often skip or reduce usability testing. Gilbert's Usability Monitor (GUM) offers an alternative to these approaches that eliminates the additional usability experts, expensive equipment, test users and inconvenient time commitments.

GUM is a hybrid usability method that combines techniques from prototyping and remote testing (Hartson 1996). The prototyping technique that GUM is modeled after is the reusable or evolutionary prototyping method (Hom 1996). This method involves the design of a functional prototype that contains part or all of the completed product. The prototype may undergo several modifications before the final version has been created, which will be a product of the original prototype. GUM combines the prototyping strategy with remote testing. GUM gathers data about the user's interactions remotely over the network as the user is using the interface. GUM automatically evaluates the user's interaction in real time. GUM creates a model of the interface with respect to how the designer intends the interface will be used. The interface's usability will be evaluated against this model in real time with real users. GUM is based upon the premise that **an interface is not usable, unless it is used by a real user according to the designer's original design.** It is possible for a designer to design an interface to be used in a specific manner, yet the users use the interface in a different way. This interface is usable according to the user's satisfaction, but not with respect to the interface's original design. The designer can adopt the user's view of the system, which will make the system usable by this definition. Usability can be measured with respect to effectiveness, efficiency and satisfaction (Frøkjær 2000). GUM measures effectiveness and efficiency, but not satisfaction.

Monitoring Usability

The goal of GUM's design phase is to create a model of how the interface is to be used. This model will be created according to the designer's intent on how users will make use of the interface, i.e. an interaction model. The interaction model is created after the development has been completed and before

the product is released. The designer creates the interaction model by example use. In other words, the designer uses the application as he/she expects users to use the application. While the designer is using the application, GUM is recording each move that is being made. This process records how the designer expects the interface to be used by real users. The output of this process is an interface interaction model, which is stored in a server side database for use during the evaluation phase.

The evaluation phase of GUM introduces the concept of rapid prototyping. GUM uses a form of reusable or evolutionary prototyping where the prototype is a working model. The designer will make changes to the working model based upon real time user interactions. Each user's interactions will be compared to the interaction model. The designer will make changes to the interface based upon feedback from the usability monitor.

The usability monitor runs periodically and searches the database for usability contradictions. Usability contradictions occur when the interface is being used in a manner that conflicts with the interface interaction model. If a contradiction is found, the usability monitor will send an email notification to the designer stating that a contradiction has occurred. Upon receipt of the email message, the designer will make the appropriate modifications. The modifications may require interface changes or changes to the interface interaction model.

Conclusion

GUM is under development and requires future experimentation with new and existing Web sites. GUM provides an effective means of measuring usability remotely. GUM defines usability with respect to the designer's original intent on how the interface is to be used. This usability measurement can provide feedback to the designer when their original design is being violated. GUM provides the designer with the absolute facts, which in turn, give the designer the opportunity to improve the interface before users are completely turned away or accept how the interface is being used. GUM does not replace the other usability testing methods, it simply improves upon them and gives the designer another testing option.

Abstract: Web based instruction is growing at an incredible rate. Teachers, instructors, trainers and several others are putting their instructional content online. The format, style and media types vary from instructor to instructor. In essence web based instruction is being done by an unknown number of people in an unknown number of ways using different media types and platforms. In this paper, an instruction repository will be introduced that has the ability to unite all web based instruction under one umbrella. The media types, platforms, instructors and formats will remain independent. The repository creates a new learning architecture for web based instruction.

Introduction

The web has been heavily populated with instruction. There is an unknown number of instructional lessons on the web. Finding useful instruction on the web is a very difficult task. This task creates the need for an unifying repository. The creation of such a repository would facilitate ease of search, reuse and universal access. This learning architecture would create a new model of instruction. In the traditional classroom, there exists a one-to-many instructor-student model. There is one instructor teaching many students. In a tutoring environment, there exists a one-to-one instructor-student model. Implementing this new learning architecture, the instructional model will be changed to a many-to-one instructor-student model (Gilbert 1999). This repository of instruction will provide each student with many instructors facilitating a many-to-one instructional model. In this instructional model, the major task is matching students to instructors that accommodate their learning style (Dunn 1978). In the sections that follow, the architecture for a distributed instruction repository will be discussed.

Repository Model

The internet consists of several domain name servers. Each domain name server contains a list of domain names, i.e.: www.eng.auburn.edu , and a corresponding IP address. When a browser connects to the web, it will ask a domain name server for an IP address before it is connected to the requested web site. This model can be adopted to define a learning architecture that consists of an instruction repository with domain names and instructional meta data.

In the instruction repository, instructors/teachers can submit queries that will yield a domain name. The domain name will correspond to an instructional lesson on the web. This function is similar to the domain name service, but it also models credit card processing on the web. For example, most electronic commerce sites buy or lease merchant services from a merchant service provider. The merchant service provider gives the store owner access to their credit card processing server. The store owner submits a query to the credit card processing server and the server returns a response code. The response code

informs the store owner of an acceptance or rejection of the credit card transaction. By combining the credit card processing model and the domain name service model, a new learning architecture can be implemented. This new learning architecture is the Domain Instruction Server (DIS) environment.

Domain Instruction Server (DIS)

The Domain Instruction Server (DIS) is a repository consisting of web deliverable instructional lessons. The sequential organization of a collection of instructional lessons defines a course. Instructional lessons are created by an instructor and placed on a web server. The web server may belong to their college, school, company; internet service provider or it may be their own personal machine. In any case, the web server is world accessible and it contains their instructional lessons. Each instructional lesson has several common attributes. These attributes can be viewed as instructional meta data.

The instructional meta data associated with each instructional lesson is uniquely identified by a location attribute. The location attribute is a web address that points to the first page of the instructional lesson. For example, if an instructor creates a web based course that consists of 30 instructional lessons. Each instructional lesson will have a first page. This first page will have a corresponding web address. This web address will be stored as part of the meta data for each instructional lesson. All subsequent pages that follow the first page will be linked from the first page. A few of the other meta data attributes are:

- Lesson Name
- Instructor's Contact Information (name, email, etc.)
- Instruction Method-Media (i.e. Visual, Audio, Video)
- End Of Lesson Quiz Location
- Lowest Passing Score
- Assistant(s) Contact Information (i.e. Graders)
- General Description

These attributes are common across all instructional lessons stored within the repository. By collecting several instructional lessons from several instructors the repository creates a high level view for each course as seen in figure 1.
Figure 1: High level view

In figure 1, there are three instructors teaching the same course. This course is composed of five lessons and fifteen different instructional lessons. Each row in figure 1 corresponds to a lesson, i.e. an entry on a syllabus. The columns under each instructor represent an individual course taught by the above instructor.

Each instructor teaches the same course using a different media type or style. Each rectangle in figure 1 is an instructional lesson consisting of all the meta data mentioned above. Figure 1 is a high level view of the DIS organization. The lower level architecture is discussed next.

DIS Architecture

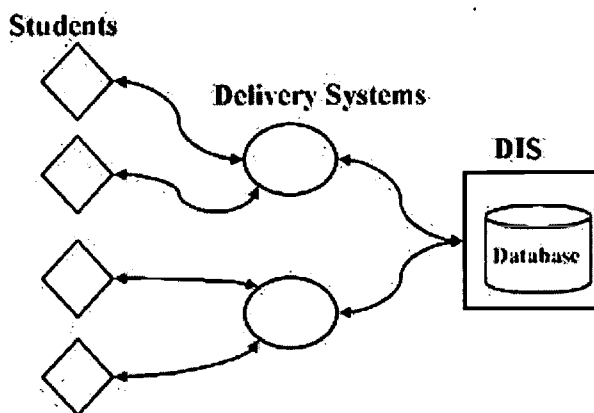
The architecture that supports the DIS environment is very flexible. The primary objective in defining the architecture is to obtain total flexibility with respect to varying platforms across various implementations. This architecture must be platform independent, universally accessible and easy to use. With these requirements in mind, the architecture in figure 2 was defined.


Figure 2: DIS Architecture

In figure 2, there are three layers. The first layer consists of the students. These are designated by the diamonds. The students are using a web browser to connect to the second layer. The second layer is composed of multiple delivery systems.

Delivery systems are the middleware that provide instructor flexibility for their instructional lesson selection process. Within the DIS architecture, there exists the concept of instruction method selection. As described by figure 1, the DIS contains several instructional lessons. These instructional lessons have to be selected for use. The process of selecting an instructional lesson for use is called "instruction method selection" (Gilbert 2000) Within instruction method selection the tasks of how, when and which instructional lesson to select must be addressed. For example, in figure 1 there are three different instructors teaching the same course consisting of five different instructional lessons. The first instructor may choose to use instructional lesson number 2 before instructional lesson number 1. In this case, the sequence of the instructional lessons for the first instructor would be 2, 1, 3, 4 and 5. The other instructors will sequence their units as 1, 2, 3, 4 and 5. This difference in instructional lesson sequencing an be facilitated through the use of two different delivery systems. Each delivery system uses the same repository to select instructional lessons, yet the order in which the instructional lessons are selected differs. Delivery systems may also vary on how and when to select an instructional lesson.

Instructional lessons are generally selected after one instructional lesson has been completed. This process is common between all delivery systems. In general, each instructional lesson contains an evaluation measure. Typically, the evaluation measure is in the form of a quiz. Based upon the student's performance on the instructional lesson's quiz, the next instructional lesson can be selected. Gilbert (2000) used case-based reasoning (Kolodner 1993) as the instruction method selection technique. For example, when a student completed an instructional lesson, the student was given a quiz. If the student scored 80% or better on the quiz, the next logical instructional lesson was selected using the same instructor's method. The 80% can be viewed as an instruction method selection threshold. If the student scored below 80%, the student was forced to retake the lesson using a different instruction method. The instruction method was selected by treating the student's quiz as a case which was compared to other quiz cases. If there was a match, then the student was assigned an instructional lesson based upon a previously observed quiz case.

Gilbert's method of instruction selection was implemented using one specific delivery system. It is possible to implement other methods. For example, it is possible to implement a delivery system that uses neural networks to perform instruction method selection when students perform below 75% on an instructional lesson's quiz. Also, delivery systems can vary across user interfaces. The user interface for each delivery system could be different. Delivery systems consist of at least four major components.

- Instructional lesson sequencing.
- Instruction method selection threshold.
- Instruction method selection technique.
- User interface.

It is possible that delivery systems may consist of more components, but the four listed above are a minimum.

The DIS environment may be composed of more than one server. Figure 2 illustrates an implementation with one server. Figure 3 show a possible configuration that contains more than one server. Figure 3's implementation models the domain name server implementation. There may be multiple servers, but each server contains the same information. In figures 2 and 3, each server contains a database. This database is the repository that contains all of the meta data for each instructional lesson. Instructional lessons are added to the database by the instructors. Instructors must subscribe to the DIS service. This is accomplished by filling out a form on one of the servers that is part of the system. Once an instructor subscribes, they will have the ability to register their instructional lessons. Registration is accomplished by putting your instructional lessons' meta data into the database by using the forms. After the instructor and their instructional lessons are added to the database, the instructor can start using a delivery system. All delivery systems communicate with the server using the same communication protocol.
Figure 3: Multiple Servers Architecture

Delivery systems submit queries to the DIS using the HTTP form POST protocol. The most common query will be a request for a list of instructional lessons associated with a course. The first step to submitting a query is the creation of a form in html code. In most cases, the form will consists of hidden fields with specified values. Figure 4 gives an example of a query that requests a list of all the instructional lessons for an Algebra II course. The html code in figure 4 contains several hidden form attributes. For example, the R_URL attribute contains the web address of where to send the results of this query. The results of this query will be sent using the HTTP form POST method as well.

```
<FORM ACTION="https://.../dis" METHOD="POST">
<INPUT type="hidden" name="R_URL" value="https://.../script">
<input type="hidden" name="Login" value="Your-DIS-ID">
<input type="hidden" name="Course" value="Algebra II">
<input type="hidden" name="Query" value="List_All_IU">
</FORM>
```

Figure 4: Sample query from a delivery system

In other words, the delivery system will post a message to a server within the DIS environment. The server will read the form attributes and execute the corresponding query. The results will be written to the user's browser and immediately posted to the web address in the R_URL field. The Course, Login and Query attributes are very straight forward. These attributes correspond to the course being taught, the instructor's login and the query that is to be executed. This simple query is a small example of how the delivery system communicates with the server(s) within the DIS environment.

Conclusion

The DIS environment defines a learning architecture for web based instruction. The DIS environment is designed to work with schools, universities, industry, individuals, etc. DIS serves the purpose of adding a new instructional, many-to-one instructor-student model for web based instruction. This new model of instruction will link students to instructors that before now, may have been impossible to learn from. This will be extremely useful for rural school systems that are experiencing teacher shortages. With the increase of instruction on the web, DIS provides an interface for instructors to find existing lessons under a common interface. This will increase the use and reuse of instructional lessons on the web. Learning architectures for web based instruction should facilitate ease of search, use, reuse and adaptability. The DIS architecture is designed to accomplish all of those features.

Abstract: Which educational objectives can be achieved and what kind of problems do educators and students encounter using wireless laptops connected to the Internet in the classroom? This paper describes and presents the results of an in-depth study on the introduction of laptops in academic education at the Free University of Brussels, Belgium. By means of participant observations, questionnaires and interviews we analysed the (changes in) classroom practices and the diversified use of wireless notebook computers in nine different disciplines (humanities and exact sciences).

Introduction

Numerous institutions incorporated laptop programmes in their educational settings. Each of these different approaches yielded positive outcomes (Rockman et.al., 1997; Studenten Service Centrum, 2000). Nevertheless, few evaluations have been made on the introduction of *wireless* laptop computers. Going wireless with notebooks in the classroom provides educators and students new perspectives: ease of movement, flexibility, convenience, cost effectiveness and time saving (Skelton, 2001).

The Free University of Brussels intends to equip all its students with wireless laptop computers. First, the university initiated a pilot project "Learning by Doing - Interactive Education in the Wireless Laptop Class". During one semester small scaled experiments were conducted, thoroughly described and evaluated.
The specific concerns are:
* The use of new didactical approaches supported by ICT
* Development of a supportive model for educators (both technical and pedagogical)
* Sensibilisation of other, not participating educators
* Finding more precise answers to students' need for (laptop) computers

A classroom was equipped with wireless access to the Internet and computer projection devices. The pilot year implementation involved 10 educators from different faculties, selected on the basis of their project proposal. The groups of students were not larger than 40 students (max. 2 students per laptop). Some of them were familiar with innovative technologies, others had never been in touch with new educational methods. Every participating educator was assigned a notebook computer. Prior to the start of the pilot project in the second semester of the academic year 2000-2001, three introductory sessions were held with all the instructors, the project leader, the technical support staff and the researchers.
It was decided to use block scheduling for 37 sessions. The domains covered were: Theory of Architecture, Research in Criminology, French, History, Survey Research, Toxicology, Mathematics, International Law and Maritime Law.

Research methodology

Multiple research methods were used to assess this pilot project: a questionnaire was administered to all the participating students (N= 133), we did in-depth interviews with 2 complete student groups (N=13) and made participant observations (22) . Only open-ended questions were used in the survey.
Besides items such as computer use (in classrooms), ICT needs and knowledge, the survey assessed students' attitudes toward educational innovations and more specifically to the wireless laptop pilot project.

1

The observations took place with the aid of a structured observation list. During the course of our research we obtained other – more informal - information from instructors and project collaborators. Also, educators were required to keep teaching journals.

Findings

The classroom practices varied quite considerably across the involved in the laptop program, related to the educators' technology capabilities, preparation, and specific curriculum. Some educators experimented with teaching strategies that differ from their traditional approaches. The wireless laptop program seemed to encourage both process and product oriented education, (multiple) task based, and individualised instruction. It enabled student centred learning. Project or problem based education is one of the possible implementation strategies for the future. According to our observations, the wireless laptop class offers the following possibilities to teaching and learning processes:
- Instruction (e.g. different phases in data-analysis using SPSS)
- Presentation and demonstration
    - o By the educator (e.g. explain or show topics about Maritime Law)
    - o By the student (e.g. presentation of a piece of work on Nazism)
- Drill and practice/exercises (e.g. solving integrals by means of a learning environment, downloading French newspaper articles to analyse parts of speeches)
- Self study (e.g. International Law – consulting, summarising and learning online international reports about refugees)
- Simulation (e.g. Java-applets showing the function of neurotransmitters)
- Communication (e.g. apply newsgroups for online discussions on architecture, send tasks to educator by e-mail, formulate feedback to the instructor in French)

Of course, variation of these approaches is recommended.

Students and educators reported a significant enhancement of communication, collaboration and interaction in the classroom due to the specific characteristics of the wireless laptops: unwired laptops can be rotated, moved and transported easily. The experimental use regularly led to inter- en intragroup interactions. Consequently, the observations showed improvements in motivation, attitude and attention (significantly higher at the start of each laptop activity). Few educators encountered hard- or software problems. Most of the time, all network facilities became available without any problems. Constraints included: limited battery power time, touch pads, smaller keyboard, expensive learning tool, expected health problems (eyes, wrist, bad position).

In fact, only slight differences between a regular notebook class and the unwired version were found. The wireless aspect mainly benefits the freedom of movement, which makes class organisation more flexible.

More comprehensive information will be presented on the Webnet 2001 Conference.

Conclusion and perspectives

The aim of the current study was to identify which educational objectives can be achieved and what kind of problems educators and students encounter using wireless laptops connected to the Internet in the classroom. Technology such as the unwired notebooks can play multiple roles and lead to innovative uses. An overall satisfaction was observed. Therefore, the wireless laptop project will be continued and scaled up next year with a doubled number of participants and expansion to the different campuses of the Free University of Brussels and Vesalius College.

A Study of the Influences and Barriers to Professional Use of Information and Communication Technology: Teachers vs. Private Sector Employees

Katie Goeman, Free University of Brussels, Belgium ; Johan van Braak, Free University of Brussels, Belgium

This paper discusses the use of Information and Communication Technology (ICT) among teachers and private sector employees. Various social, psychological and technical aspects were identified as possible determinants of ICT use: innovativeness, i.e. the willingness to adopt new methods and ideas; computer attitudes; perceived organizational barriers; and computer attributes. In January/February 2001, questionnaires were administered to 384 professional ICT users. By means of linear regression modeling, it was demonstrated that computer attributes were the strongest predictor for professional ICT use. The second best predictor was the hindering effect of perceived computer barriers. This poster session will display the development of the research instruments, as well as presentation of the main results.

Computer and Information Literacy (CIL) and Netest
Three Years Later

Stacie Gomm
CIL Director
Utah State University
stacieg@cc.usu.edu

Donald H. Cooley
Computer Science Department
Utah State University
cooley@don.cs.usu.edu

Abstract: Computer and Information Literacy (CIL) has been implemented as a graduation requirement at Utah State University for three years. Based on faculty input, six competency areas were defined and tests were developed to evaluate students' ability in each area. Students are required to demonstrate proficiency in each area to satisfy the CIL requirement. In order to facilitate this requirement, specific testing software had to be developed. This software (Netest) is now being used to administer and deliver CIL tests. It is also being used by several departments to administer and deliver course specific tests.

Computer and Information Literacy Defined

The environment in which students learn has significantly changed in the last decade. The ability to use computers to access and present information is now an important basic skill. In 1995, the Utah State Board of Regents, Utah's governing board for higher education, mandated general education articulation between all schools in the system. Part of this articulation involved a uniform requirement for competency in the areas of computer-based information access and manipulation. This articulation process developed what is now termed the computer and information literacy (CIL) requirement. While the basic skills or competencies embodied in this requirement are uniform throughout the State, there is variation in the manner in which these competencies are assessed. In some cases competency it is shown by passing a specific class, and in other cases by passing test s. At USU for uniformity and consistency, this requirement can only be met by passing six computer-based examinations; one for each of the six competencies. These competencies are: Computer Ethics, E-mail, Operating Systems, Document Processing, Information Resources and Spreadsheets. Initially, based on a campus-wide survey, specific skills were outlined in each area and then tests were developed to assess these skills. Students must score 70% on each exam in order to satisfy the CIL requirement.

The CIL requirement has been in place and implemented for three years. It has been a significant undertaking in terms of time, people and financial investment. We have learned much from this experience and are constantly improving our processes.

In the Beginning

In 1994, Utah State University formed a CIL committee consisting of at least one faculty representative from each college. After a campus-wide survey, this committee established the six competencies and tests for each competency. It was decided students could take these tests until 70% competency was shown and would do so during their Freshman year. It was a great idea, but making it happen was the real challenge.

With funding from the central administration a dedicated CIL testing facility was established. With NSF and FIPSE funding, a computer-based testing system was developed to store student data, individual tests, to administer the tests, correct and score the tests, and gather statistics for each test and test question. Early on, it was decided to use the Internet as the means to deliver tests to students.

The Birth of Netest

NSF and FIPSE grants assisted in funding the initial development of the testing system called Netest. Student programmers, supervised by faculty, were hired to develop software modules to meet the various functional requirements for Netest. Because of the diversity of competencies, two types of tests were needed. The first type, what is now called a concept-based test, simply requires that the student show that they have mastery of the concepts underlying the competency by answering a specific set of questions. This type of test is similar to those often delivered by computer-based testing systems. It involves a mix of true/false, multiple choice, matching, sequencing, fill-in-the-blank(s), and essay questions. One of the strengths of Netest is the variety of question categories available for such tests.

The delivery system for the second test category was more challenging to develop. In truth, most of the CIL competencies can only be shown by performing specific tasks. For example, document processing competency is best assessed by requiring the student to perform specific tasks on a document, not answer a series of multiple choice questions about such tasks. For Netest, such tests are called performance-based tests. In this case, Netest delivers two files to the student. One file consists of the operations to be performed, and the other file in the initial state for the test, e.g. an initial document. According to the instructions in the first file, the student modifies the initial state file. When completed, Netest transfers the modified file to the server and removes both files from the client.

While tests can be delivered over the Internet, security is maintained by requiring any such test to be unlocked before it can be taken. In the unlocking process, Netest randomly selects from a database of choices for questions (concept) or task/initial state files (performance) to generate a test for a specific student. Since the unlocking process is controlled, and the tests are administered in a specific lab, security is maintained.

In addition to delivering tests and managing test and student databases, Netest has an extensive capability for test development and editing. Any instructor with a Netest account can develop a test and have it delivered and administered by Netest.

An important capability of any computer-based testing system is that of gathering statistics. Among the statistics gathered are information about each individual test (how many times it was passed the first time, the second time, etc.) and each individual test question (how many times each question was answered correct, incorrect or skipped.) These statistics may indicate a poorly written question, or perhaps one where the given answer was incorrect. Using this information the instructor can make changes and improvements to their test.

Netest is controlled through three user interfaces, i.e., Manager, Instructor and Student. Managers can add, edit or delete Managers, Instructors and Students. They can unlock specific tests at the request of an instructor or student (depending on protocol). Instructors can develop, change and delete tests they "own". They can also manually grade performance tests and update a student's test score. Students can take tests and view their personal statistics.

The Netest paradigm is also useful in other testing environments. Netest includes a model of a "class". A class is made up of students. Tests belong to classes. When a student views his/her statistics, the test scores are shown for the classes in which the student is enrolled. This allows tests to be developed for several classes with students only able to access the information belonging to their classes.

Netest Today

Because of the flexibility of Netest and the fact that it is able to run on the Internet, other areas of the university have become interested in using this product. Netest is now being used to administer tests for the CIL requirement as well as the History CLEP test and several other Business, Computer Science and Agriculture tests.

Although, there are many testing programs available today, Netest is unique since it includes performance based testing capabilities. This type of test must be hand graded at this time, but we are working to develop an algorithm to automate the grading of performance-based tests.

CIL was driving force for the development of Netest. For three years changes were made in Netest because of the dynamic nature of CIL. That has not changed. Programmers are still employed to make revisions as necessary, but now CIL is not the driving force; the many courses using Netest to administer their exams are suggesting changes, usually beginning with the statement, "Wouldn't it be great if Netest could ...." Based on the past, we anticipate that Netest will continue to change and evolve.

Details of CIL

For CIL testing a secure testing environment was needed. For this purpose, the CIL testing lab was constructed, consisting of 24 Pentium based computers using the Windows 98 operating system. The software on these machines include the Corel Suite and Office 2000. Each computer has access to the Internet and the University VMS system. The lab is staffed with consultants who unlock tests and answer CIL related questions, and technicians who set up student accounts and maintain the computers in the lab. The lab is open from 8:00 a.m.- 8:00 p.m. Monday through Friday and 12:30 p.m. – 4:30 p.m. on Saturday.

To fill the gap between what was required to pass the CIL tests and what students actually can do, on-line, interactive teaching tutorials were created for many of the tests. Macromedia's Authorware was used to develop and deliver these tutorials. Each tutorial included a practice CIL test so students can pretest their skill level. These practice tests are self-checked by students. If students need more explanation as they practice, they can refer back to the tutorial by clicking on a button in the practice section. This button returns them to the tutorial section explaining the skill they are asked to show. This allows students to acquire and assess all of the skills needed to pass the CIL tests before they actually take the tests.

Additionally, short courses were designed to provide a live instructor to teach students the specific CIL skills. These courses provide instruction as well as practice for each test. They are taught once a week and one competency is taught per week. Any student registered to take the CIL exams may attend the short courses.

The full CIL requirement is outlined on the USU CIL Web Page (http://cilserver.ser.usu.edu/) as well as procedures for taking each CIL test. This web page links to the teaching modules and other relevant information. Students can study this information from anywhere and then come into the lab to take the tests. The lab is used to ensure test security.

Utah State University has several extension sites throughout the state. Some of them are more than 200 miles away. Students who attend USU at one of these sites also need to take the CIL tests. Since the Internet is the means where these tests are given, it is simple to have these sites implement procedures to give the CIL tests through the Netest system.

CIL – Three Years Running

In the three years since its inception, over 7,000 students have taken one or more of the CIL tests. Both the CIL requirement, and Netest are dynamic, and undergoing assessment and change. As part of the CIL laboratory three to four students work half-time making changes and updates to Netest. This has been an excellent opportunity for these students to gain real-world software development and engineering experience.

The following table represents passing/attempt statistics to date for the CIL tests:

	Passed First Attempt	Passed Second Attempt	Passed Third Attempt
Operating Systems	85%	79%	78%
Ethics	60%	54%	45%
Document	95%	96%	97%
Spreadsheets	95%	85%	73%
Information Resources	83%	89%	86%

Table 1: CIL Test Pass/Attempt Statistics 1998-2001

Because of the dynamic nature of any technology related skill, it is necessary to frequently assess the utility of those skills. In March of 2001, students, faculty, and advisers were surveyed concerning the current requirements, goals, and implementation of the CIL requirement.

The survey showed that faculty view the CIL requirement positively – 89% support it while only 11% oppose it. They do not think any of the current competencies are obsolete but would like to add several, including presentation software, graphics and web page development.

Academic advisors are satisfied with the CIL requirement and tests – 71% satisfied and 22% not satisfied (7% also replied N/A). They also feel the students they advise are satisfied with the requirement– 64% satisfied and 25% not satisfied (11% replied N/A).

Students were asked which of the CIL competencies were being used in their courses at USU. Most (97%) students are using E-mail, 82% are using the Internet, 82% are using Operating Systems and 68% are using Document Processing. Only 36% are using spreadsheets and only 33% reported "using" Computer Ethics. It was interesting to note that 81% of the professors are using a web page to communicate class information, thus requiring Internet usage to be an integral part of the course.

Future of Computer and Information Literacy and Netest

There are over 4000 new freshmen every year at Utah State. So far, a little less than half have taken at least one of the CIL tests. It remains a significant challenge to convince students to meet the CIL requirement early in their academic career. Part of the problem lies in the fact that some students are not aware of the requirement. Also, the fact that meeting the requirement is not tied directly to a class or classes, tends to cause students to put off meeting the requirement. In the next few years the number of students who take the CIL tests will increase more rapidly because of the "glut" of procrastinators who now need to graduate.

Netest is still changing as well as the processes involved. It has been a significant undertaking to develop the Netest program — a program which administers accounts, tests, and people, and provides global access to this system via the Internet. It is difficult to describe in a few words the capability of Netest. A demonstration is more appropriate. Netest is definitely worthy of being shared with others. Other colleges in the state of Utah are looking at the possibility of using Netest to facilitate their Computer Literacy Requirements.

As the world of computers changes so will CIL. The CIL committee meets each semester to review the competencies and to determine if additional competencies should be added and which of the current ones are obsolete. Currently, the committee is considering adding Presentations Software, Graphics – scanning and downloading/capturing, and/or Web Page Development to the CIL tests. However, adding three modules without taking away any would be significant additional burden to students. There is a possibility of having exams required for students depending on which college/department they are enrolled.

Lessons Learned

CIL is USU's first campus wide requirement assessed by a single set of tests. The normal college implementation scheme for such a requirement has been to allow departments to offer a course(s) which, if passed, meets the requirement. Maintaining content uniformity in such classes is always difficult, if not impossible. USU's approach, while we feel is more pedagogically sound, brings its own challenges. It is only because of support from the administration that classes have not been developed to meet (replace) the requirement. While there are some classes that teach to the CIL requirements, students in such classes must pass the same set of tests as those not taking a class. While the CIL requirement will evolve at USU, it is also apparent that it will likely migrate. Discussions are now underway with Public Education in Utah to make CIL or some version thereof, a requirement for all high school graduates. Hopefully, a high school based CIL requirement will also be test-based and centralized like USU's CIL requirement.

Implementation of a digital learning environment: The real results

Lisa Gommer and Gabriëlle Visser
DINKEL Institute, Educational Center
University of Twente
the Netherlands
E.M.Gommer@dinkel.utwente.nl

Abstract: At the University of Twente, a course management system called "TeleTOP" has been implemented in all faculties the last 1.5 years. The paper describes the TeleTOP-system and the implementation process. To find out how teachers use their course environments in education, an analysis was made of 60 course environments. Results show, that these course environments are mainly used for the dissemination of information and less for interactive communication. Also, course environments help students prepare for learning, orientate on course content and practice, but are rarely used for giving feedback, monitoring and assessment. In the last section, tips and recommendations are given for improving the use of course environments.

Introduction

Since the introduction of the world wide web, the web has been used in many ways to support education. The last three years, one particular use of the web has been very popular; the course management system. Different tools or platforms have been developed and implemented in universities all over the world. At the university of Twente, a choice was made for a home-made solution; the TeleTOP system. After successful use in one faculty, the university-wide implementation of TeleTOP started in the summer of 1999. Now, after 1.5 years of hard work, it is time to see what the results are.

In this article, we present the results that can be achieved with the implementation of a course management system in a relatively short period of time. Also, by taking a closer look at the first implementation results we want to research what the "real" results are; to what extent are the implemented course environment really used in education? The third and most important goal of our research is to give examples and guidelines that instructional designers and teachers can use to improve the use of course environments in education.

TeleTOP, the Course Management System of the University of Twente

As said in the introduction, TeleTOP is the course management system of the University of Twente. The goal of this system is to support and facilitate the learning process of students by supplying them with all the information they need to follow a course and with several options for communication with teachers and fellow students through the world wide web. As the University of Twente is a campus-based university, the course management system is used mainly to support on-campus learning.

TeleTOP was developed in the beginning of the year 1998 at the Faculty of Educational Technology (Tielemans & Collis, 1999). The most important demands for the system were, that it should be consistent in terms of lay-out and structure, very easy to work with for both teachers and students, accessible through the WWW without any extra system requirements and based on a database-system. According to these wishes, the development took place at the faculty of Educational Technology. Later in 1998 the Faculty started using the system in its courses.

Because of the successful implementation at the faculty of Educational technology and also because of the lack flexibility in existing systems, the university board decided in 1999 to choose TeleTOP as course management system for the entire university. In the year 2000 the university wide implementation started on a voluntary basis. All technical facilities where supplied by the university and a team of instructional designers was available for educational support, but it was up to the faculties to decide if, and to what extent, they wanted to join the TeleTOP implementation.

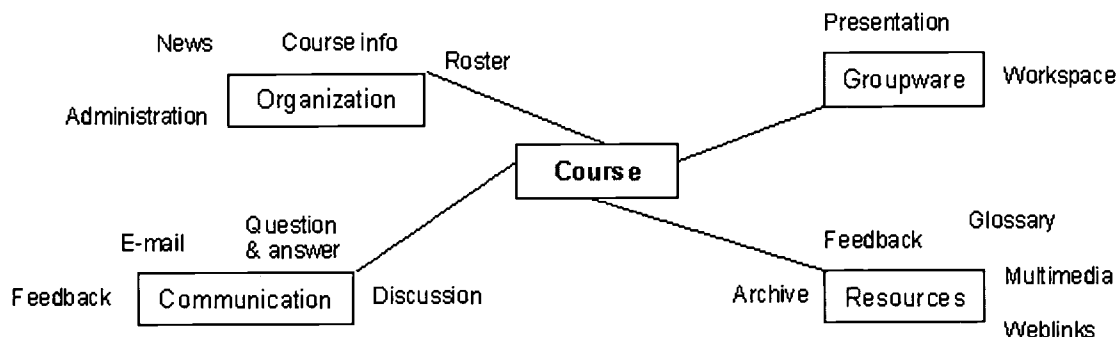
Like most course management systems, TeleTOP is a course based system. For every course, an environment can be created. The teacher can choose which functionalities he or she wants to use for his or her course. Figure 1 gives a schematic representation of the TeleTOP system.


Figure 1: Schematic representation of TeleTOP

The core of every TeleTOP environment is "The Roster" (course schedule). This roster gives the student a very clear overview of the activities and materials in the course. In each TeleTOP site, the roster consists of 3 columns that tell the student what to do *before, during and after a session* (see figure 2. The TeleTOP Roster). By clicking on a link in one of the roster cells, the student is taken to a page were he or she can find more detailed information, study materials and assignments related to that particular activity.

Figure 2: The TeleTOP Roster

Implementation strategy and results

The way TeleTOP has been implemented at the various faculties differs. In general we can distinguish three strategies used for the implementation of TeleTOP:
1. Overall strategy: TeleTOP is implemented in all study phases of the program and all teachers are expected to use TeleTOP to support their courses;
2. Phased strategy: The implementation starts in the first year of the program. Then, the system is gradually implemented into the other study-phases;
3. Pilot strategy: The faculty starts with a few pilot courses. When the pilots prove to be successful, the implementation is expanded to one of the other strategies.

The implementation strategy is not prescribed by the university board, but is chosen by the faculty itself. For each faculty an instructional designer of the DINKEL Institute is available for support during the implementation process.

As soon as the faculty board has decided to use TeleTOP in it's education and a choice for an implementation strategy is chosen, a demonstration of TeleTOP is organized for all teachers that will be involved. For the acceptance of TeleTOP by teachers it is proven to be important, that during this introduction, the faculty-director states clearly why and in what way TeleTOP will be used in the Faculty.

After this plenary demonstration, in which a quick overview is given of the TeleTOP system and it's possibilities, individual one-hour appointments are made with the teachers. These appointments can be divided in a technical instruction of TeleTOP and advice about the didactic use of the system. During this appointment the instructional designer and the teacher take a closer look at the course and decide which functionalities of TeleTOP (described in figure 1, §2.1.3) will be most suitable to support the course. After this one-hour introduction, the teacher is able to start filling the course environment with information and materials. For further support during the use of TeleTOP in their course teachers can contact the educational consultant, or take a look at the TeleTOP-supportsite (available on the WWW). This supportsite offers teachers technical as well as didactic tips for the use of TeleTOP in their course.

Right now, after 1.5 years of implementation, more than 400 courses offered at the University of Twente have been implemented into the TeleTOP system. At this moment, all faculties have decided to participate in the TeleTOP implementation process.

The Research

Looking at the sections above, one might conclude, that the implementation of the TeleTOP system has been very successful until now. In one and a half year, more than 400 courses were implemented in TeleTOP and most of the teachers and students at this university are working with the system. However, what really matters is not how many course environments have been created and how many people are involved. If we really want to know how successful the implementation was, we have to look at what is happening inside these course environments to support the learning process. To find out what the real implementation results are, these are the research questions to be answered:
a.   For which goal(s) are the course environments used?
b.   How do the course environments support the learning processes of the students?

To answer the first research question we identified which of the following three types of interactions were found in course environments;
-   Information supply; the teacher supplies the students with information. This can be textual, but also graphical information, video and audio, etc. Information supply can be divided into two sub-categories, namely:
    - *Supply of organizational information*: e.g. the course schedule tells the students when and where the classes take place.
    - *Supply of content-related information*: e.g. in the course environment, the students can find documents in which quantum-mechanics are explained.
-   Communication; the teacher communicates with students in an interactive way. This can for example be the answering of questions students send in, discussion statements, etc. Communication can be divided into two sub-categories:
    - *Organizational communication*: e.g. the student asks the teacher when the assessment will take place.
    - *Content-related communication*: e.g. the students have an online discussion about the solution of a math problem.
-   Course work; students work on products such as reports, presentation, etc, within the course environment. This last category can be divided into:
    - *Individual course work*; one student works on a product and hands it in individually.
    - *Group-based course work*; students work together as a group on a project, report or something else, supported by the course environment and hand in their product as a group.

The instrument used to answer the second question, is an existing educational model, based on *instructional functions* (Terlouw, 1997). Instructional functions describe which activities should take place in education to ensure that the desired learning processes take place.

The following main functions and sub-functions are defined:
- *Preparatory functions:* motivating, connecting to prerequisite knowledge, giving insight in learning goals, planning the learning process
- *Executive functions:* orientation on knowledge, orientation on skills and attitude, practice
- *Regulative functions:* monitoring progress and effort, feedback during practice, assessment, feedback after assessment

The instructional functions mentioned above give no information about the medium or activity in which these are fulfilled. Within a course, some of these functions will be fulfilled by the teacher (e.g. the teacher gives the students feedback on their work), some by textual materials (e.g. the book lets the student orientate on knowledge), etc. A course management system like TeleTOP in itself cannot fulfill any instructional functions. What we would like to know is which of these instructional functions are fulfilled *through* the TeleTOP course environment, using the environment as a carrier of information and tools.

Because of time constraints, it was not possible to analyze all courses in TeleTOP. For this reason, a selection procedure was made to select 15 % of the existing TeleTOP environments. 10 faculties participated in the research. From each faculty, we selected 6 sites, which brings the total number of analyzed course environments at 60 (= 15% of 400). The course environments were randomly selected on their unique course code.

Results

In table one, we see in the first column the number of course environments (n = 60) in which a certain goal was addressed. In the second column, we see the same data in percentages.

Goal	# of course environments	% of course environments
Supply of organizational information (OI)	60	100.0
Supply of content-related information (CI)	50	83.3
Organizational communication (OC)	15	25.0
Content-related communication (CC)	9	15.0
Individual course work (IW)	25	41.7
Groupbased course work (GW)	12	20.0

Table 1: Goals for using course environments

In table two, we can see how the instructional functions were fulfilled through the 60 analyzed course environments. In column one, we can see, in *what number* of sites the *sub-functions* were found. In column two, in *what percentage* of the 60 analyzed sites *at least one of the sub-functions* was addressed.

Instructional functions	# functions	% sites
Preparatory functions		
Giving insight in learning goals	37x	
Motivating	29x	
Connecting to prerequisite knowledge	15x	
Planning the learning process	12x	
Percentage of sites in which at least one of the preparatory functions was found		*81.67*
Executive functions		
Orientation on knowledge	48x	
Orientation on skills and attitude	19x	
Practicing	37x	
Percentage of sites in which at least one of the executive functions was found		*88.33*

Regulative functions		
Giving guidance / monitoring progress and effort	02x	
Feedback during practice	21x	
Assessment	03x	
Feedback after assessment	01x	
Percentage of sites in which at least one of the regulative functions was found		*20.00*

Table 2: Instructional functions fulfilled through the TeleTOP course environments

Conclusions

Looking at our research questions and the results, we can draw the following conclusions:

For which goal(s) are the course environments used?

In the course environments we analyzed, the emphasis is clearly on the dissemination of information from the teacher to the students. This information is not only organizational but also content-related. In the TeleTOP environments, teachers offer students lecture notes, articles, etc. This matches with the results of the university-wide evaluation of TeleTOP (Peters & Visser, 2001) where students indicate, that the most important benefit of TeleTOP is, that it provides access to information and study materials. In contrast to the first conclusion, not so many course environments are used to support two-way interaction between teachers and students. Content-related communication seems even more difficult to realize. This also corresponds with the results of the TeleTOP evaluation (Peters & Visser, 2001) in which teachers indicate that they do not perceive a functionality like discussion as very useful, because the discussions are seldom content-related and often not very serious. However, with this conclusion, we have to add, that there could be a lot of communication through lectures and e-mail, which is not visible in the TeleTOP environments. Finally, if a course environment is used to support course work, the emphasis is mostly on individual course work and less on group-work.

How do the course environments support the learning processes of the students?

The results show us, that TeleTOP environments are primarily used by teachers to prepare students for learning and helping them to practice and orientate on course content. More attention could be given to helping the students plan their learning and connecting to prerequisite knowledge. Remarkable is, that the amount of guidance, monitoring and feedback is still very poor. Even when students are asked to hand in course work, feedback is not often given through TeleTOP, but face to face or sometimes not at all. Finally, in almost all cases, assessment seems to take place outside of the course environments.

From this research we conclude, that although a lot of activity and dissemination of information is taking place in TeleTOP, some possibilities of the system are not (or not sufficiently) exploited yet. During the first 1.5 years of the TeleTOP implementation, teachers had to put a lot of time and effort in getting to know the system and making their paper-materials available in a digital format. An earlier evaluation study at the Faculty of Educational Technology (Collis & Messing, 2001) shows the same results. Now that this first implementation round has been done, it is time to move to a second round in which the emphasis is on didactics and online interaction. Together with educational consultants, teachers can find ways to come to a better use of their course environments.

Tips and recommendations

In order to elaborate on our conclusions, we conclude with tips and recommendations that teachers and educational designers can use to improve the use of learning environments. Although this research was fully based on the situation at the University of Twente, we feel that the tips and recommendations here could also be used at other educational institutions using a course management system to support their courses.

a.   Alternatives for content-related information: content related information in a course environment often exists of lectures, notes or articles. In addition to this, as a teacher, you can:
   *   make a link from the course environment to online scientific magazines
   *   give a list of relevant, fun and interesting websites students can use while making their assignments
   *   show examples of excellent course work from students of previous study-years

- ask students to search for content-related information and collect this in the course environment
b. To stimulate two-way communication between teacher and students, one can:
  - tell students how often you are going to answer questions that students post in the course environments, so students know when they can expect an answer or reaction
  - ask one student to fulfill the role of moderator in an online discussion or ask a student to actively stimulate the discussion by putting in statements
  - stimulate the use of discussion by putting the first items in yourself and invite students to join
  - stimulate students to ask questions, by putting a few frequently asked questions and answers from last year's group in the course environment
c. The problem with content-related communication often is, that it doesn't occur because it is a separate activity that is not integrated in the course. Some recommendations to stimulate this:
  - The teacher plays an active role in the communication
  - Clear assignments in the course environments tell the students what the topic is and what contribution is expected of them
  - Participation is assessed and rewarded
  - During the face-to-face meetings, the outcomes of the online communications are used in one of the activities
d. There are several ways to motivate students in a course environment:
  - ask students to prepare questions for the next lecture and post them in the course environment
  - give students an active role in the development of the course environment, by making them (as part of a course assignment) deliver content for the site
  - clearly state what intentions you have with the use of the course environment in the course
e. Helping students plan their learning process
  - In the course schedule, instead of only indicating when the lecture are and what assignments have to be made, also indicate how much time a student should spend on each course activity
f. The problem with feedback often is, that it is very time consuming to give written feedback to each student in a course environment. Some alternatives for face-to-face feedback:
  - provide a model-answer, so students can compare their answers to this example
  - use peer review; make students assess each other's work
  - make practice assignments optional; students who really want to practice will make the assignments and receive feedback. Students who feel they don't need the practice can skip the assignments.

Final note: To stimulate teachers to a better use of their course environments, it is essential, that practical tips and recommendations are disseminated into the faculties. Below, we list a few of the many ways to do this:
- Build a support environment in which teachers can find didactic tips and good practice examples.
- Give teachers access to the course environments of their colleagues, so they can see how other teachers fill their course environments and learn from each other's successes and failures.
- Make a list of 'example course environments' available for the whole university on a prominent place and explain to teachers why these are considered 'good examples'.
- Organize didactic workshops where teachers can work on improving their course environments with help of an educational consultant.

e-mail: cjgonza@ull.es

Abstract: Nowadays, the problem of presentation adaptation to user has been studied under the conditional text technique (ITEM/IP, C-Book, De Bra's adaptive course on Hypertext) or providing alerts about the state of a web page (ELM-ART, AST y Interbook).

In our case, we have considered the adaptation of the media (image, sound, animation and text) according to the student goals and the stored information of the student model.

In this paper, we describe the design and implementation of a generator program with dynamic update of content as a component of a ITS to diagnostic and treatment the Dyslexia in the Spanish language.

ITS design is based on Web technologies. So, we have added to the traditional model several modules that can adapt and modify dynamically the system behaviour. Therefore, we had designed and developed a generator program of presentation that handle a set of templates related to the activities that the system have to show.

1. Introduction

Web-based courses and other educational applications have been made available on the Web within the last five years. The problem is that most of them are nothing more than a network of static hypertext pages. A challenging research goal is the development of advanced Web-based educational applications that can offer some amount of adaptivity and intelligence. Adaptive and intelligent technologies usually could be further dissected into finer grain techniques and methods, which corresponds to different variations of this functionality and different ways of its implementation [1]. In this work, we will focus on the *adaptive presentation technology* (APT). APT objective is to adapt the content of an web page to the student goals, knowledge or any other information stored in the student model. The pages in the systems with adaptive presentation are not static. To each user in particular, the pages are generated adaptively or assembled from pieces.

To provide the adaptation, the techniques currently used are: "conditional text" (ITEM/IP, C-Book, De Bra's adaptive course on Hypertext), and to show "adaptive warnings messages" about the student knowledge state into a page (ELM -ART, AST). But, this techniques do not consider the media adaptation.

Our objective is to create dynamically the activities presentation that the pupil has to realise taken into account the totality of media that the system will show (sounds, images, words, sentences, explanations, feedbacks, ...), the student learning characteristics and the knowledge state. For these reason, we have follow a methodology of media and modalities adaptation to define the components of our adaptation.

We have organize this papers as follow: firstly, we describe the methodology used, then the components of the adaptation and finally, how we have modelled and developed the generator program.

2. Intelligent Multimedia Interface Design

2.1 Media and Modalities Adaptation Methodology

Intelligent Multimedia Presentation Systems (IMMPS) [2,3] has been defined as Knowledge Based Systems (KBS). IMMPS uses their knowledge base to adapt dynamically and to take design decisions on real time according on the user-computer interaction requirements. [4].

The process of adaptability is characterized with several attributes, which are not clearly delimited [5].

463

- *Determinants:* are factors that guide the adaptation process (i.e., adaptation based on the users characteristics, kinds of task or interaction, etc.);
- *Constituents:* are interaction aspects that are adapted (i.e. content, presentation primitives as interaction techniques, media or modalities);
- *Objectives:* are particular goals that guided the adaptation process (i.e. to minimize errors numbers, to optimise the efficiency and efficiency, etc.);
- *Rules:* Guides the process of instantiation of adaptation constituents according to the state of adaptation determinants.

The adaptation process is carried out trough the selection of constituents based on the determinants using the adaptation rules.

a) Determinants

In order to this methodology, for design the adaptation in our system we have categorized the determinants in two spaces:

- a) Interaction Context Space (IC)
- b) Information Space (I)

More specifically, the IC space are building with the follows determinants:

- *Student Model:* formed by a perfil (personal characteristic of student) and records (variables about the learning evolution).
- *Teaching strategies:* has the knowledge about the plan of didactic sequence, and are based on a set of rules that permit adjust the system to the student according to the learning goals.

On I space, determinant is the convenience level about media use. We have designed different modules to evaluation and treatment according to the presented problems in each dyslexia type. The follows modules were defined: syntactic, audible discrimination, levels of phonologic awareness, knowledge of letters and lexemes and suffixes. The nature of each task depend of module and stimulus presented into the module. Text can be presented as visual or audible way, with diverse styles (script, bold, ...), in a graphic way, with sounds, etc. By the other hand, graphics and animations can be presented isolated or in a time sequence joined the audio. For instance, in the case of audible discrimination module, we must use the audible media that have more incidences in the task (words, couple of words, syllables, etc.).

b) Constituents

Into this methodology, we are going to define the adaptation constituents:

- *Information presentation:* the information is presented according to the kind of dyslexia and the level of routes affectation.
- *Task simplification:* is the process where complements object are deleted, options are reduced,....
- *Visual components of presentation:* phrases, words, images and animations are presented in accordance with their level of incidence in the kind of task that the pupil has to do and/or the type of errors committed.
- *Audible components of presentation:* as the visual components, phrases, words, feedbacks and explanations are presented in relation to their level of incidence in the kind of task that the pupil has to do and/or the type of errors achieved.

c) Objectives

Our goals are:

-In technical terms:
- *Easy scalability and system reuse*
- *Decreasing computing resources cost*

For these reason, we have designed the system with a scalable architecture. So, with this architecture we can represent dynamically the media and the system can increase easily in media and stimulus with a simple addition of their references and relations in the database.

-In pedagogical terms:
- Increasing student attention and motivation.
- Encouraging the significant learning through a right combination of media and modalities

Consequently, to achieve the goals, we have defined the instruction system with a set of components. Components are several kinds of tasks and events for encourage the attention, motivation and learning process during the program execution.[6]

d) Rules

Rules define the allocation of constituents to determinants taking into account the level of satisfaction of the adaptation goals.

Some of the rules that we have defined to our system are:

- If the user has phonologic dyslexia, then show pseudo words or familiar words in the evaluation.
- If user has phonologic dyslexia, then show irregular words and introduce pseudo words or familiar words gradually into the treatment.
- If user has superficial dyslexia, then show irregular words in the evaluation.
- If user has superficial dyslexia, then show pseudo words or familiar words and introduce gradually into the treatment irregular words
- If user has superficial dyslexia then enlarge gradually words long.
- If user has superficial dyslexia then enlarge gradually words complexity.
- If user do not response in a time t to the asked interaction i, then call the attention of the pupil by a pedagogical agent or an animation.
- Be DO = { $d_{o1}, d_{o2}......, d_{o\alpha}$} the set of pictures related with the o object, if the object o is presented with the related picture d_o then the next visual presentation object must change for the next related picture $d_{x..}$
- Be IO = { $i_{o1}, i_{o2}......, i_{o\alpha}$} the set of images associated to the o object, and be $o=\{word, letter, sentence\}$, if the student has made an error related to the object o, it is presented with its associated image i_o in light up modality.
- If user has committed a error during the treatment, run the feedback using the agent, with the explanation related to error type produced
- If user makes error n times, decrease complexity task.
- If user makes error n maximum times, review the requisites previous and go to another task related of less complexity.
- If user makes a task satisfactorily, run the positive feedback using pedagogical agent and go to next task in order of complexity.
- If is the first presentation of a task, run the demonstration, merging in the time the sequence of audible and visual media with the agent execution.
- ....

In the following section, we will describe how the system has been designed and developed to realize the adaptation process of media and modalities in the multimedia interface.

2.2 System Modelling

As we have mentioned before, we have different modules of evaluation and treatment of dyslexia. A module that measure the latency time in the reading of words determines type of dyslexia presented. Then, we need determine what are the specific problems of each pupil in each type of dyslexia. For this reason, the pupil has to resolve all task proposed by the system in the evaluation for each module, according to the presented problems in each dyslexia type. Afterwards, the modules of treatment are activated in the difficulty levels that match to the problems detected in the evaluation.

Regarding to the tasks presented, our system has an inference engine responsible of monitoring the user answers to the interactions asked. According to these responses and the goals satisfaction level, the system determines the instantiation of the adaptation constituents.

But, depending on the kind of decision we have stored the rules in the interface and other in the inference engine. For instance, the inference engine determines the next task and the media (pictures, phonemes, sentences, feedbacks, etc.) that would be used in the activities presentations according to the stored data in the student model (perfil and records). These specifications are stored in the database. Interface reads these database specifications and decides when and how uses the media according to users responses in the task. Then, the basic unit of the inference module is a task. Presentations are components of a task and are the basic units for interface.

Developed prototype [7] allows the presentation adaptation of tasks to the individual characteristics of student through a program that generates dynamically activities and builds the presentation more adjustable to the learning style of the pupil.

How is produced the adaptation? In the database we have all the audible and visual media that the system can use and the relations with the contents to teach. Interface decides in each case, what and how merge the media according to the instructional objective and the data about previous learning of student.

In this sense, the system works in the following way: starting off student records, the contents that the pupil has to acquire are determined by the treatment goals to this particular student. What and how the activity will be showed to acquire the fixed objective will be determined by the student perfil.

Fundamental objects in the implementation of system are: objective, task, activity and structure.

1.- Object *objective* has instances of *task* object by an aggregation type relation (instances of the *task* exists although *objective* object has been deleted). *Objective* object allows us to know what exercises the student must do to advance in the search tree.

2.- Each instance of the object *task* will be a *task1, task2,....., taskN* object. Instances are formed by *activity* objects with a composition type relation (if *taskN* does not exist, all activities associated are deleted). An instance of task tells us about how the information is presented to the user. So, an instance has an aggregation type relation with the *structure* object.

3.- A*ctivity* object can inherit attributes of different classes of activities. Classes of activities can be: *presentation, explanation, evaluation and motivation.* Its will give rules of behaviour to the *activity.*

4.- *Structure* object is a template that indicates to multimedia interface what and how must show the media in the screen.
Figure 1. Modelling of objects

2.3 Implementation

In the implementation of prototype we have used: database tools (MySQL) merged with tools for development of courses on the Web (Macromedia Flash 5, Macromedia Dreamweaver

Ultradev 4, Coursebuilder), for the production of visual media (Macromedia Fireworks, Corel Draw, Corel Photo Paint) and finally, for the generation of the inference engine (CLIPS).

Generator program of presentations has been implemented as a set of templates linked with the database. A template shows the task structure where is determined the interaction types, containers of texts, images, sounds and animation, and input/output variables.

In synthesis, the interface is a combination of dynamic pages ASP connected to a database through ODBC where the content of a presentation is a result of a SQL sentence.

Process of communication between the inference engine and the interface is carried out by the database.
Figure 2. Architecture of System

3. Conclusions

In this paper we have described the design, modelling and implementation of an intelligent multimedia interface that can adapt media and modalities of a presentation according to the users answers.

For design the interface we have used methodologies of media and modalities adaptation. These methodologies were very useful in the stages of declaration and definition of adaptation components.

For implementation we have employed tools based on WEB. Firstly, we started to implementation with Flash 5 y Generator, but we have found problems with the integration of Microsoft Agents. For this reason, we must search others tools that permit include all of our systems components. So, we decided use Macromedia Ultradev 4 that allows us an easy integration with the database and agents as ActiveX.

Currently, we are working in the development of system, because we have implemented all evaluation modules but only one treatment module. The system will be carried to schools on September in the next course for start with the process of validation and experimentation by the psychologists, members of the group of research. At the same time, we will continue with the implementation of the rest of modules.

[i] According to Colheart's double route model, there are three kinds of dyslexia:
- o __Phonologic:__ reading is produced by the visual route and is characterized by a selective deficit with pseudo words or unfamiliar words.
- o __Superficial:__ reading always is produced by the phonologic route and is characterized by a selective deficit with irregular words, but is possible to read pseudo words and unfamiliar words. Because the reading depends on the phonologic route, the pupils have difficulties with larges and complex words.
- o __Mixed:__ there are problems regarding to the previous two subtypes of dyslexia.

Each dyslexia type can present different levels of affectation, empathising or minimizing the affectation levels in some of the problems presented. So, dyslexia types not forms groups totally closed.

Challenges of Creating an Online Doctoral Program:
Panel Discussion of the Trials and Success of the Ohio State NonTraditional Doctor of Pharmacy Program

Presenters:

Dennis Mungall, Director of Virtual Education
Cable Green, Director of Educational Technology
Barbara Skunza, Program Director

Ohio State University, College of Pharmacy
500 W 12th Ave
Columbus Ohio 43210

ABSTRACT

An increasingly large number of colleges and universities are at least exploring the feasibility of, if not rushing headfirst into, offering credit-bearing courses on the Web. As the result of the combination of several factors, colleges and universities are being confronted with the need to make significant changes in the ways in which they function academically and administratively. The increasingly diverse demographics of the student population, the evolving perceived role of education, and the escalating costs for both the institution and the student all contribute to this evolutionary pressure.

In response to these challenges, numerous schools, both in this country and internationally, are actively investigating, and implementing, non-traditional academic programs. The College of Pharmacy launched the first online degree-granting program, the NonTraditional Doctor of Pharmacy Program , at the Ohio State University in January, 2001. Although there are numerous competitive advantages to a web-based course delivery system, there are an equal number of issues that must be addressed.

This presentation explores three critical issues any program must address before launching a non-traditional online degree program: **(1)** learner orientation, **(2)** translating the techniques for facilitating and monitoring student learning that have been developed for a classroom-based delivery into a web-based environment and **(3)** integrating the new program into existing University infrastructure.

Student Orientation (Cable Green)

Cable Green is the Director of Educational Technology in the College of Pharmacy, Clinical Assistant Professor in the Division of Pharmacy Practice and Administration, and Doctoral student in the School of Journalism and Communication at The Ohio State University. He studies how collaborative teaching pedagogies and problem-solving strategies can be used in conjunction with technology to create informating on-line learning spaces. Cable is active in designing, developing, supporting and evaluating on-line distance learning programs.

Web Site: http://jac.sbs.ohio-state.edu/cable/

Abstract:

Virtual universities are changing the landscape of higher education. Without the proper student orientation to multiple online education issues, students are left with traditional tools in a non-traditional environment. Aggressive student orientation must include an introduction to technological infrastructure, pedagogical issues, communication skills, and study and time management skills for an on-line community of learners to succeed.

There are fundamental pedagogical differences between traditional and on-line classrooms. While one can argue learning online is no different than a traditional classroom, the reliance on technology for the delivery of instruction changes the process by which instruction is delivered. Therefore, the incorporation an appropriate on-line learner orientation, pedagogical methodologies and strategies in a Web-based learning environment can aid in helping both student and teacher to adapt and succeed in this new learning environment.

To meet these challenges, this part of the presentation will provide a comprehensive student orientation including an introduction to technological infrastructure, pedagogical issues, communication skills, and study and time management skills for an on-line community of learners. The student orientation includes a wealth of information the novice online learner will need to succeed including: differences between on-line and traditional classes, hardware and software specifications, Internet access, configuring software, learning Internet tool sets (i.e., E-mail, web browsers, chat, bulletin boards, etc.), hints on how to succeed with on-line courses, how to create the right on-line study environment, citing web resources, and on-line codes of conduct.

Guidelines for Developing an Online Student Orientation for a Virtual University

Establishing the objectives for a web site
- Understanding your objectives will help determine the content and organization of your web site.
- While developing your web site, keep in mind your objectives when making web design decisions.

Keep the audience in mind
- How familiar are your students with the Internet?
- Will students be accessing the web site from campus via Ethernet or from off-campus via a modem?
- What type of computers or web browsers will your students be using?

Organization
- Make your web site easy to navigate
- Organize your content into logical sections
- Create a consistent style (possibly develop a template for your web pages)
- Considering limiting the layout of your web pages to the dimensions of the average computer screen.

Weaving a Virtual Education Web: **Creation of an Online, Non Traditional Doctor of Pharmacy Program (Dennis Mungall)**

Dennis Mungall, Pharm.D. (**http://members.aol.com/thertch/resume.htm**)
is the Director of the Non Traditional Doctor of Pharmacy Program in the College of Pharmacy and Associate Professor in the Division of Pharmacy Practice and Administration at The Ohio State University. He has been actively involved testing and development of bedside medical decision tools, multimedia teaching, and clinical pharmacology training for several years.

Abstract:

The presentation will focus on the following areas: Factors to consider when weaving your virtual education program, consistency of course design, faculty course development training and responsibilities, creating the "on campus" feel , student training, recruitment and, supportive resources: residents, fellows, technology experts. Other areas to be discussed include: assuring the quality/outcome of a non-traditional Doctor of Pharmacy when compared to the residential doctor of pharmacy program, creating a clinical "toolbox" for the NTPD: transferring clinical expertise via virtual clinics and finally intellectual property issues.

1. Purpose
   a. Review online curriculum approaches currently used in pharmacy education on the web
   b. Review the implementation strategy at OSU for the online NTPD
   c. Discuss the possible outcomes of a Web based program
   d. Discuss impact on faculty, and traditional doctor of pharmacy program

2. Content Description
   a. Factors to consider when weaving your virtual education program
      - consistency of course design
      - faculty training
      - creating the "on campus" feel
   b. The Nuts and bolts of creating courseware
      - What administrative web system should I use?
      - How do I create courseware: Faculty generated? Capture live lectures, Technical team to assist development?
      - What do software system do you use for creation and Porting audio/video presentations to the web?
      - Needs assessment of faculty members
      - Training faculty to create digital presentations

   c. How do we assure the quality/outcome of a NTPD , online program is at Least the same as the on campus Pharm.D. program?

   d. Creating a clinical "toolbox" for the NTPD: transferring clinical expertise

Integrating an Online Program into existing University Infrastructure (Barbara Skunza)

Barbara Skunza is the Program Manager for the Non-Traditional PharmD program at Ohio State. She has 20 years of experience in higher education administration and recently earned her Masters Degree in Public Policy and Management (higher education).

Discussions of online programs typically focus on discussions of technology, pedagogy and learners. While important, these discussions do not take into account the underlying political, and administrative, infrastructure necessary to operate an online nontraditional degree program. Servers and bandwidth aside, programs must concern themselves with integrating all of the University services traditional programs take for granted including: marketing, registration, online applications, new committees, codes of conduct, copyright clearance, use agreements with faculty, library resource distribution, etc.

My 10 minutes will focus on how to liaison with existing infrastructure to ensure a smooth administrative transition for your online program. I will follow the process from the initial idea and planning stage all the way through to the first class completing their first term.

Idea Stage: The planning phase for a program like this is necessarily long and involved. It is imperative, at this stage, that the faculty and college community share in the vision and mission of the distance program. It is at this stage that the university support is secured, both financially and philosophically.

Building the team: Most important step. Very important that you have the expertise that you need to make the technology work for the students and the instructors; but more important that they work together well and that they all share the same vision of 'customer/client focus'.

Marketing/recruitment: Ideally there is plenty of time before the first class is expected to be enrolled to engage in a well-thought out marketing scheme. It should be clear from the planning phase what the base of applicants lie. Rather than throw out a large net, we elected to concentrate on our own state, following the mission of our university, to educate and reach out to our own citizens. This strategy has served us well, as we have a large base of alumni in the State of Ohio, who were among the initial voices expressing a desire for OSU to offer a Non-Traditional PharmD.

University Processes: Because we chose to offer this program on a different calendar schedule than the university (trimesters vs. quarters) and because we were the first to offer an academic degree using web-based coursework, we were presented with many challenging administrative tasks. Special arrangements had to be worked out with university officials concerning such issues as admissions, registration, tuition, grades among others. Once in place these processes will be routine and will serve other new distance programs in the university.

Atmosphere: The most important ingredient in the success of our program has been the commitment, excitement and visibility of the team. Because these students have so little personal contact, and little if any opportunity to visit campus, their connection, and sense of belonging, to the university comes from the people with whom they interact...the team.

Regional List Servers as a Means of Peer Support for an On-Line Learning Community

John Green
School of Information Science and Humanities
The Open Polytechnic of New Zealand
Lower Hutt, New Zealand
Grejoh@topnz.ac.nz

Abstract: A regional list server is a list server providing peer support to students living in a specific geographic region. This paper analyses the effectiveness of using regional list servers to provide peer support to an on-line learning community of 300 students already using an electronic forum to study by distance. Fifteen list servers were used for the course.

Using list servers for large numbers of students, as in distance education, creates concerns as well as benefits. If even a small number of students post messages to the list, participants may have too many messages to digest. Students in a previous study commented that they preferred to work in smaller groups. Regional list servers provided students with a more intimate experience and reduced message load. The underlying principles behind the study are discussed and an explanation is given of how the interactions on the list servers are stimulated and monitored.

Introduction

The Open Polytechnic of New Zealand is the largest provider of open and distance education in New Zealand. Most teaching is done by distance. The students described in this paper were studying the Computer Concepts paper, a compulsory paper in the National Diploma in Business course and approximately equivalent to first year degree level. Most students are adults in their late 20's to early thirties, approximately two-thirds female and mainly Pakeha (non-Maori). The Maori were the first people to settle in New Zealand. Those not of Maori descent are termed Pakeha. The majority of students on the course had little experience of using a computer for anything more than word processing. Some students used e-mail regularly but most knew how to use e-mail. Few had experience of using Internet forums, list servers or on-line chats.

The creation of a community spirit is an essential prerequisite for success when using an electronic forum (Hiltz 1998) (Anderson 1998). Without this feeling of camaraderie people feel inhibited from posting for fear of looking foolish, or from responding to postings for fear of being branded a "tall poppy" or know-it-all. Speaking up in small class or posting in a small electronic communication space seems much easier because the participants develop relationships and trust with the others in the class. In previous work with an electronic forum (Green & Eves 2001) students commented that smaller workgroups would allow them to get to know other students better. In an effort to provide this more intimate space, several regional list servers based on the regions of New Zealand were created. List servers were chosen in preference to newsgroups for ease of use and the fact that the list server used offered automatic recording of student demographics and archived messages in time sequence. A list server ensured that passive students received the messages even if they didn't participate. Participants were familiar with e-mail and did not need to acquire new skills to use the list server. Students were already using a Delphi forum (Delphi 2001) for asynchronous communication. It was hoped that the relationships and the peer support network that developed would increase the rate of participation in the Delphi forum, our virtual classroom. We were also interested to see how students would respond to the increasingly varied means of student-student communication at their disposal. A major benefit envisaged was that the smaller population would reduce the information overload that can occur in list servers with larger populations.

Method

The postings of students were monitored over a period of 17 weeks. The list server chosen was Listbot (Listbot 2001). Listbot is a free service provided by Microsoft on the Internet. The site allows the creation of list servers for either announcements (one to many) or discussion (many to many). Discussion list servers were chosen to allow those subscribed to send messages to each other. Each list server takes just a few minutes to set up, which includes selecting any information that you wish the list server to gather when students register. Each list server gathered demographic information requested by the list owner when the student subscribed. Thirteen list servers were set up based on the New Zealand regions. Two list servers based on ethnicity/language were set up with the intention of supporting those students whose second language is English in the believe that they could get additional peer support in their first language. These list servers supported Maori and Chinese students.

Students were not spread evenly across New Zealand but were concentrated in the main population centres, two thirds of which are in the North Island. The mountainous South Island, often called the Mainland has less than 1 million people. It was estimated that a group of 5 students would be able to form a viable and cohesive group. During the first two weeks of the course it was essential to support single students and encourage them to subscribe to a neighbouring list server if students numbers were low in their area. This also increased the cross fertilisation of the groups without destroying the intimate sense of the space.

Marketing the list servers

The regional list servers were marketed in our electronic forum (Delphi 2001) and by mail before the start of the course. In addition whenever communicating with students by phone, fax, e-mail, or during weekly on-line chat sessions on the forum, students were reminded of the importance of using their regional list server. The various means of communication were described to the students as follows in order to help them understand what they were to be used for.

"The forum is our electronic classroom; it is necessarily formal and tightly controlled. It is your place to ask questions, to get guidance on how to get started on a particular activity in the course and the place to find and receive answers. It is your frequently asked questions resource. It is not a place to have personal conversations."

"The on-line chat is your student common room, bar or seminar room, it is informal and uncontrolled. It is the place to meet up and talk about the course, what's on TV, to gain motivation and direction, and generally get to know your classmates. Brief personal conversations are acceptable but remember it's one-to-many, so try and follow the threads of the conversations that will be fast and furious!"

"The regional list servers are like inviting people into your home to study with you. It's quick, simple, informal and direct. The e-mail you receive will be from an individual, but everyone on the list will receive the same e-mail. It's the equivalent of a small study group without the hassles of having to travel. People on your list server may be your close or distant neighbours. We encourage you to use it to arrange social events and form face-to-face or virtual study groups."

Monitoring the List Servers

The list owner is automatically subscribed to each list server. This could potentially result in information overload for the tutor even though the tutor role in a peer support network is more for policing than for interaction. In order to control the flow of e-mail, a series of rules were set up in the tutor's e-mail client, Outlook 2000, to direct the mail to a series of folders, each named after the respective list server. To ease tutor communication with the list servers a personal distribution list was also created. This provided the students with a small intimate view of their list server, whereas the tutor had an overview of the activities taking place in every list server. The tutor could address the whole class, a regional group, or an individual. It was considered important that the data for this study was gathered automatically to enable the tutor to concentrate on the tasks of motivating and directing the students in the forum. A

weekly e-mail report from each list server informed the tutor who had subscribed or unsubscribed. E-mail from the groups was archived both on the tutor's computer and in the archives of the individual list servers.

Results

For ease of analysis four regional list servers out of the 15 were analysed. The two largest urban list servers centred on the Auckland and Wellington regions contained 23 and 31 students respectively. The two rural list servers selected were centred on the Bay of Plenty and Waikato regions and contained 7 and 9 students respectively. It should be noted that although well promoted the two list servers set up to allow ethnic students to discuss ideas in their first language were barely used. Both Maori and Chinese students participated fully in the regional list servers but ignored the option of using their first language, even with the opportunity of support by a Chinese-speaking staff member. It is thought that the ethnic servers were viewed as ghettos.

Some questions asked
1. Do students have preferred learning partners with whom they communicate on a regular basis?

Students were asked to identify themselves by posting an introduction to the list server in the first few weeks of the course to encourage interaction. In larger list servers, students had more potential partners than in smaller list servers. However the data in Fig 1 shows that in larger list servers more than 50% of students selected just two partners with whom to talk. In smaller list servers most students made contact with all the other students. Students either posted messages to everyone (shown as 'All' below) or addressed the message to a specific individual. The number of messages posted to their first and subsequent partners were summed and expressed as a percentage of the total number of subscribed students. The percentages shown would have been higher if expressed as a percentage of the active students. People talk with more people in smaller list servers than in larger list servers. Fig 2 shows how the numbers of postings to subsequent partners falls off. This suggests that when group work is done groups of three may be an appropriate size.

List Server	Number of students subscribed	Number of active students	Number of students posting to All (Average number of messages)	% with 1 partner (Average messages)	% with 2 partners	% with 3 partners	% with 4 partners	% with 5 partners
Auckland	23	20	19 (3.47)	60.9 (2.21)	52.2 (2.42)	26.1 (2.00)	26.1 (1.5)	21.7 (1.4)
Wellington	31	22	19 (3.9)	54.8 (2.24)	38.7 (1.17)	25.8 (1.38)	16.1 (2.0)	12.9 (1.0)
Bay of Plenty	7	7	7 (8.29)	85.7 (2.17)	85.7 (2.0)	85.7 (1.5)	28.6 (1.5)	28.6 (1.5)
Waikato	9	7	7 (13.43)	77.8 (4.86)	66.7 (5.67)	66.7 (5.0)	66.7 (5.0)	44.4 (5.0)

Figure 1 – A comparison of the rates of posting and the number of partners in large and small list server populations

Percentage Student Participation / number of partners
Figure 2 – A graph of the percentage of students posting against the number of partners

2. Do larger populations produce more postings per capita than smaller populations?

It might be expected that the number of interactions would be greater in a larger population due to the greater range of opinions and personalities. This does not appear to be the case (Fig 1). The Bay of Plenty and Waikato list servers received 127 and 287 postings respectively from an active student body of just 7 students each. Auckland and Wellington received only 215 and 202 messages from 20 and 22 active students respectively. Waikato students posted an average of 41 messages each, compared with Auckland's average of just 10.

3. Is there an optimum size for a list server population?

Students joined the list server for their region. This resulted in groups of different sizes because students are not distributed evenly over New Zealand. When the size of list server population is graphed against the average per capita posting for each list server over the period of study, a peak is seen around 9 participants (Fig 3). It is suggested that this figure would rise if a group functioned for a longer period of time and more people came to recognise each other as individuals. Self-disclosure, the divulging of personal information and trust are key elements in raising the level of participation. Those individuals who expressed themselves more fully had more contacts and a greater number of partners than those who merely asked for and exchanged information.

Plot of Average PCP against Group Size
Figure 3 - Graph of the average per capita posting against the list server population size, over the period of study

4. Is there a difference in use of the list servers in urban and rural areas?

In the Wellington central business district, which is compact compared to the sprawling Auckland central business district, the list servers were used to arrange face-to-face study groups that met at weekends and during lunchtimes. This was entirely due to the response of one individual to a tutor suggestion. The posting rates described above (Fig 1) were measured before these groups formed and do not account for the differences in posting. No organised groups formed in Auckland though some students did pair up occasionally. The data shows that the regional list servers were used much more in the rural areas, probably due to the distances between students.

5. Is there a relationship between the number of messages a student posts and their success on the course?

Certainly most successful students were students with postings in the high 30's. However several low posters also obtained good results in the assessment and several high posters received lower scores. It is not possible to ignore the fact that everyone received the messages whether they actively participated or not. There appeared to be no relationship between posting rate and success on the course. This seems to echo the results obtained by Poole (Poole 2000) when the number of messages read was related to success on the course. In other words some students can do things other than use the list servers to obtain the necessary feedback, for example using the forum, or be happy to work through the course materials alone.

6. Does increased peer support result in success for all on the list server?

There was no clear difference in the percentage of students on the list servers achieving A+, A or C grades and those who chose not to be on the list servers. This result appears to agree with Poole (Poole 2000) who noted that there was no direct relationship between course grade and the number of messages read in a bulletin board. A larger sample of students might show that those with an intermediate skill level of B+ or B may improve their achievement by interaction with and observation of higher scoring students.

7. *Does increased peer support result in increased retentions?*

There was no apparent difference between the retention rates of the trimester with added peer support by list server and the previous one without this support. Loss of students is almost always due to personal problems with work or home life rather than anything related to the course. Retentions are more likely to be raised by the provision of student counsellors than electronic peer support.

Conclusion

The study found that students posted more messages per capita in list servers with smaller populations. Such small populations tended to be in rural areas. The optimum size of a list server population in terms of the number of postings per student is 9 students. Students in list servers with small populations had more partners with whom they corresponded regularly than list servers with large populations. This may have been influenced by the fact that the smaller list servers were filled with rural dwellers who might be friendlier than city dwellers or simply because those in the cities preferred to use the listbot to arrange face-to-face meetings. Most of the students in the large list servers had only two partners with whom they regularly communicated. This has implications for students working on group projects.

There does not appear to be a relationship between participation in the list server and success on the course. It must also be borne in mind that being in the list server did not indicate whether a student was active in the list server or the level of that activity. Students were also able to interact in the forum. Retention rate was not affected by having peer support and was affected by more personal factors. Posting rate was considered to be an unreliable indicator of future success on the course. It must be borne in mind that everyone received the postings on the listbot regardless of their level of participation. Peer support did not influence the percentage of students achieving grades A+, A or C as there was no real difference between the numbers of students in the different grades in semesters with and without the listbot facility. A further study might demonstrate that intermediate students (B+ or B) could benefit from interaction with higher scoring students.

DISTRIBUTED LEARNING: INTRANET AND INTERNET APPLICATIONS

Elinor C. Greene, Ph.D., SPHR

ABSTRACT

At a time when learning is finally recognized as a critical component to an organization's success, manufacturing industries are facing an overwhelming challenge to increase efficiency, effectiveness, and competitiveness. Organizations are becoming more centralized, more global, and more competitive, and the traditional classroom model is rapidly losing its value and appeal. Educators and performance improvement practitioners are looking to technology as a tool for effectively growing and maintaining a skilled workforce. Increasingly, companies are using distributed learning technologies to provide timely, economical, and effective learning solutions.

INTRODUCTION

Learning has become the most important part of everyone's job. The continuously changing skill and knowledge requirements of workers create a continuous need for learning. Today's organizations require learning to be delivered faster, cheaper, and more effectively. Organizations are reexamining the entire learning process - when, how, and where learning occurs.

THE COST OF TRAINING

Most training initiatives in the manufacturing world are classroom driven, led by trainers who were not educated as educators. They deliver content that is often irrelevant, to passive and disinterested learners, on an overtime basis requiring 12 hour shifts, with little or no effective measurements [1].

The costs associated with traditional methods of training are impeding our ability to compete. In 1998, the largest U.S. companies spent over $70 billion on employee training [2]. Half of this was on travel costs, wages, and benefits for employees while in training. A substantial portion was spent on inefficient or outmoded approaches to delivering workforce education.

Perhaps the greatest single issue that impacts classroom learning is time. Most training delivered by instructors is delivered at the pace of the slowest learner in the class. At the same time, companies are applying pressure to limit the amount of time employees spend in the classroom. This dilemma, coupled with an increased demand for training, creates a need for new and innovative methods to develop and deliver more effective training.

THE CHALLENGE

Today's technology is reshaping our workplace. As job skills are becoming obsolete, tomorrow's jobs will require a whole new set of worker skills. Not only will the skills of low-skill level employees need to be strengthened, but also employees in jobs requiring high skill levels will require continuous retraining. It is only through company-wide learning systems that organizations can survive. Companies today have little choice but to become learning organizations.

THE LEARNING ORGANIZATION

The learning organization empowers people to learn as they work. It uses technology to collect, store, organize, customize, and transfer vast amounts of knowledge. The learning organization provides training that is just in time - when it's needed, where it's needed, and how it's needed.

The learning organization has four distinct characteristics:

1. It is performance-based; tied to business objectives.
2. It emphasizes skills, and how people process information.
3. It assumes learning is part of work and not separate from work.
4. It incorporates distributed learning applications.

The challenge of learning faster than one's competitors is being met through distributed learning technologies, which include the intranet, internet, computer-based training, and electronic performance support systems (EPSS).

WHAT IS DISTRIBUTED LEARNING?

Distributed learning is a system and process that optimizes learning and productivity. It considers both presentation (how information is presented to learners) and distribution (how information is delivered to learners) using a combination of technology; learning methodologies, on-line collaboration, and instructor facilitation to achieve applied learning results. Results that are not possible from traditional education are achieved in a flexible, anytime/anywhere fashion.

Whether the training is provided by CD-ROM, the internet, or the company's intranet, distributed learning provides the power to speed up learning and make knowledge more accessible and economical. Today's corporations are using distributed learning applications to train and retrain both their centrally located and globally dispersed workforces.

In a survey of 700 training professionals conducted in February by the Masie Center, 80% of respondents said that they expect the demand for Web-based training to increase in their organizations this year. By contrast, 75% said they expect more demand for CD-ROM based training, and more that 60% said they expect the same for classroom-based training [3].

Corporations are using distributed learning applications to address the following needs:

- Job skills training and retraining
- Government compliance training
- Management development and leadership training
- New product and policy information
- Employee orientation
- Product sales training
- Customer education
- Sales force automation training
- Higher education

Synchronous and Asynchronous Learning

Distributed learning applications can be either synchronous or asynchronous, and generally include a combination of both.

Synchronous learning occurs in real time. It creates a virtual classroom environment with no time delay. For example, an instructor located in Atlanta may conduct a class on Programmable Logic Controllers with students in 20 or more different locations and countries. The instructor can share applications with the students, ask and answer questions, and let a student take control of the screen or simulation software. All that is required of the students is a browser and an audio hook-up, accomplished by a telephone line. Responses to learner interactions and tests are uploaded to a central location for scoring.

Researchers have reported that there is no significant difference in the achievement of students in systematically designed virtual learning environments and the achievement of those in systematically designed face-to-face environments, based on standard performance measures [4]. And with shorter

contact times, supplemented with asynchronous technologies, synchronous learning yields superior results.

Synchronous classroom learning has been widely recognized as an effective means of teaching and learning with benefits to the learners and the organization. For example, in 1989 AT&T obtained cost figures for courses delivered via distance learning technologies such as satellite up-link and down-link technologies. The courses were systematically designed using criterion-referenced methods [note 1] (the author was involved in both designing and evaluating the impact of these courses). During that year, 3,650 students attended distance delivered sessions of the courses. Savings in airfare, lodging, and daily expenses resulted in a total cost savings for the 3,650 students of $1,825,000. These figures do not include downtime while traveling.

Asynchronous learning allows participants to learn anytime, anywhere. For instance, students may download and print articles, flowcharts, P&ID drawings, electrical diagrams, or policies and procedures from the company's intranet. Or they may download a computer-based course on Lotus notes from the company intranet. They may take the course later from their seat on a plane. Or a student may elect to take a course on Hazard Communication directly on the internet from home, at a time that is convenient. When the student takes the test or completes an assignment or exercise, the responses are uploaded to a central location for scoring. Examples of asynchronous learning include self-paced, interactive multimedia courses and electronic performance support systems (EPSS).

Self-paced, Interactive Multimedia Training

Self-paced, interactive multimedia training allows participants to learn anytime, anywhere. Students can take a course off a CD-ROM, the internet or intranet, or download and run it from a computer. Multimedia training provides a multi-sensory approach to learning through audio, video, animations, and text. Learning is active rather than passive and students have control of their own learning. Students who require more time or additional practice on a particular topic can spend the time without holding back the rest of the class. Students who grasp new topics easily move through a lesson quickly. Conditional branching, based on performance on pretests and embedded tests, allows students to effectively concentrate on what they don't know without having to relearn what they already know. Multimedia simulations allows learners to experience high-risk situations without endangering themselves, other workers, or expensive equipment.

One would expect self paced, interactive multimedia courses which have been systematically designed using criterion-referenced methods to have the same effects as face-to-face instructor led courses which have also been systematically designed. However, independent studies comparing multimedia to Instructor-led training across five industries have shown significant results in several categories including retention, learning gains, learning curve, consistency, and reductions in learning time (see figure 1).

Figure 1. Comparison of Multimedia to Instructor-Led Training

Learning Variable	Percentage Increase
Retention of Content	20 - 60% Higher
Learning Gains	56% Greater
Learning Curve	60% Faster
Consistency of Learning	50 - 60% Better
Time on Learning	38 - 70% Faster
Sources: US ARMY, WICAT, United Technologies, Federal Express, Xerox	

Electronic Performance Support Systems

The most effective learning happens when training is part of the work process. Electronic performance support systems (EPSS) provide users with the information, knowledge, and tools to perform nearly any job or task while they are performing their job. A well-designed EPSS will enable a new user to perform his or her job to specified criteria the first day on the job. EPSSs use hypertext, embedded animations, and hypermedia to enable the user to perform new or high-risk tasks, or a job/task performed infrequently, with minimal training or support from others. Short, task oriented courseware modules provide users with on-the-spot training for nearly any job-related task. EPSSs generally do not run as stand alone PC applications.

BENEFITS OF DISTRIBUTED LEARNING

Organizations that have successfully implemented distributed learning have achieved both productivity improvements and cost benefits. These organizations reported the following ten benefits:

1. Increased impact of dollars invested in training. Companies are saving money because they use fewer instructors to reach more students. They are also realizing reduced travel costs, reduced downtime, and the ability to train a dispersed workforce.
2. Consistent message. The centralization of information and databases provides improved constancy of content and delivery. Organizations can easily update and make available current information to all employees.
3. Reusable content. Companies using distributed learning technologies are finding that the content can easily be re-purposed and used across applications.
4. Safe learning environment. Virtual reality and simulation technology allows trainees to view and interact with objects that would be impractical or impossible in reality.
5. Hands on interactivity. Distributed learning technologies allow for hands-on, direct, and immediate interaction with instructors, other learners, and courseware content.
6. Just-in-time information access. Unlike traditional training, distributed learning enables students to find and use the information they need when they need it. This allows for increased flexibility for students and instructors.
7. Learner centered training. With distributed learning applications, students control their own learning. The courseware moves students to new topics, remediation, or additional practice based upon their responses.
8. Real time learning. Distributed learning allows geographically dispersed students to interact with instructors and students in virtual classrooms.
9. Easy access to remote experts. An expert in recovery boiler operations interacts with students in real time, answering their questions and collaborating with the group.
10. Fewer disruptions to work. Students participate in learning at their own convenience, without disrupting critical work activities. They also enjoy convenient scheduling for training.

SUCCESS STORIES

The decision to implement distributed learning is an important step toward becoming a learning organization. The power and flexibility of distributed learning technologies make them suitable for meeting a wide range of education and training needs. The following organizations have benefited from successful deployment of distributed learning applications.

 Buckman Laboratories received numerous awards for technology managed learning. Their distributed learning system allows employees to study at convenient times without interrupting their business and personal schedules. In addition to delivering courseware and other content, Buckman's on-line training is instructor led, which helps ensure that students are keeping up with the pace and the assignments. It includes interaction at any level the student desires: privately with the instructor, privately with one or more other students, or publicly with the entire class. The training courses encourage students/employees to collaborate on assignments.

General Motors uses an EPSS application that imparts information through formal courses and captures new knowledge which is discovered while employees work. The automaker is developing its application to run on notebook-sized PCs that the technicians wear on their belts. The technicians control the voice-driven system by speaking into microphones. They view the graphical interface on a flat-panel display mounted nearby.

Weyerhaeuser Southern Lumber and Plywood Division is using asynchronous computer-based multimedia lessons to teach operators to safely load, unload, and move railcars.

Boeing Training Centers provide simulation training for pilots and ground crew technicians via integrated CD-ROM and laser disk technology. Training modules are downloaded into the network at training centers in Seattle and Miami. Each student accesses training through a Windows-based PC.

Eli Lilly & Co. is using the Scientific Performance Improvement Network (Spin) for its Research scientists. This custom application combines threaded discussions, a directory of subject-matter experts, links to databases, and online courses.

Astra Pharmaceuticals is using distributed learning applications for training on government Regulations.

Siemens Business Communication has moved to distributed learning from face to face classroom training. The results have been a 3.7% increase in productivity for 25 full time field engineers or 25 million in savings. Siemens saved $105,000 the first week they implemented the course. As a result of using distributed learning, they saved $800,000 during the first year of full time implementation.

Target Stores uses video simulations of situations a Target employee might encounter when working the complaint desk. The employee being trained sees a video of a complaining customer, responds, and then has his or her choice of words evaluated by the system.

The Department of Defense Dependents School provides distance distributed learning to students located in 14 different countries. Through this initiative students and parents are able to communicate with teachers, participate in learning activities, and work with military and community experts.

McGill University's Mining and Metallurgical Engineering Department is using distributed learning applications to teach engineering courses to students in remote locations. Dr. Ralph Harris has successfully implemented the concept of real and metaphorical bridges for web delivery of course content and performance of exercises and activities that are only feasible in an electronic environment [5].

Georgia Institute of Technology, the University of Wisconsin, and Florida State University are three of the growing number of major universities providing distributed learning applications to remotely located students enrolled in undergraduate, graduate, and continuing education courses.

CONCLUSION

Today's companies are searching for new ways to maintain their competitiveness while reducing cost and increasing the availability of quality training to their employees. More and more companies are becoming true learning organizations by adopting distributed learning applications. Distributed learning uses technology to empower people to learn as they work, and provides training that is just in time - when it's needed, where it's needed, and how it's needed. Some of the benefits organizations have achieved include increased productivity, reduced costs, consistent message, reusable content, and fewer disruptions to work. If companies in the manufacturing industry are to remain competitive in this rapidly changing global economy, they must become learning organizations and adopt distributed learning applications to better serve their employees and their companies.

NOTES

Note 1. Criterion Referenced Instruction (CRI) is instruction which has been systematically developed to solve an identified, measurable performance problem. For each performance objective, a criterion or standard by which performance will be judged is specified. The criterion may be a time limit, an accuracy tolerance, or a proportion of correct responses. The training is built to facilitate attainment of the performance criterion and a hands-on performance test is given to measure mastery or criterion achievement.

Relational Behaviors and the Development of Cooperative Learning Groups Using Computer Conferencing: A Case Study

Joseph Gregg, Jones International University, USA

How does a collection of strangers move from being an aggregate of people to a group capable of high performance using computer-mediated communication (CMC), specifically computer conferencing, as the sole means of communication? This study will elucidate the important aspects to consider when using cooperative group instructional strategies for distance learning mediated by text-based Internet communication. Understanding the cooperative group processes when using CMC that provide for the development of successful interpersonal communication leading to close interpersonal relationships will: (1) provide information for instructional designers and instructors of online courses to guide their design and delivery efforts in terms of group composition, group activities, and facilitation strategies, and (2) guide design of better interfaces and software to enhance effective communication interaction. Attending to the demands for socially functional groups is even more crucial as the aggregate of individuals coalesces into a group and, with time, evolves into a learning community.

UNIVERSIDAD AUTONOMA METROPOLITANA

The importance of Graphic Design in the develope of an educational web site.
Experiences in the building of the site for the Postgraduated Design Program for Develope of Interactive products.

Abstract
This paper describes the experiences of a research team in Mexico City in the Public Higher Institution Universidad Autonoma Metropolitana. I'm presenting the results of a year of working in the construction of the entire site for a Postgraduated Program in Develope of Interactive products, oriented mainly to those who are involved in the areas of design, visual arts, multimedia, etc. We are trying not only to build a web site according to graphic parameters and instructional design, farther we are looking for an application program that also will be built around a strong central narrative, but typically offer more opportunities for students to pursue interesting digression from the main themes of the web site. We are planing to present information more sophisticated and in-depth than in trainig tipycally applications. We are structuring and developing not only an online course or a Postgraduated program specifically for designers, we are also trying to build a Web-based learning environment providing student with feedback, incentives and interactivity, according for what they are looking for.

I am going to describes my experiences, as a graphic designer, beeing a part of a research team in Mexico City in the Public University Universidad Autonoma Metropolitana. We now are working in the construction of the entire site for a Postgraduated Program in Develope of Interactive products, oriented mainly to those who are involved in the areas of design, visual arts, multimedia, etc. We are trying not only to build a web site according to graphic parameters and instructional design, farther we are looking for an application program that also will be built around a strong central narrative, but typically offer more opportunities for students to pursue interesting digression from the main themes of the web site. We are planing to present information more sophisticated and in-depth than in trainig tipycally applications.

We began our work by the identification of our target audience, describing main objectives and then identifying all of the content information and graphic resources we will need to collect or create to achive the goals for the Web site of the specialization in Develope of Interactive products.

Im going to present our design strategies:
The first step in designing a Web site is to make sure you have clear statement of purpose and objectives to project. Careful planning and a clear sense of purpose are the keys to sucess in building Web sites, particularly if you will be working as a part of a team to builder the site.

First of all we consider our potential users, students interested in a design specialization inside the new technologies, because we know tha it's impossible to design for an unknown person whose needs you don't uderstand. So that what we have to do is testing the designs and getting feedback from users, this is the best way to see whether the design ideas are giving users what they want from the site.

The design must allow fast access to a wide range of topics, with links to related material within the local web site and beyond on the World Wide Web. We think that graphic user interfaces were designed to give people direct control over their personal computers. Users now expect a level of design sophistication from all graphic interfaces, including web pages. The goal, we are sure, is to provide for the needs of all of the potential users, adapting Web technology to their expectations, and never requirig the rader to simply conform to an interface that puts unnecessary obtacles in their paths.

Web sites can vary enormously in their style, content, organization, and purpose, but all Web sites that are primarily designed to act as an information resources share some basic characteristics. The spatial organization of graphic and text on a Web page can engage the user with graphic impact, direct the users attention, prioritize information, and make the user's interaction with the web site more enjoyable and efficient.

Design and visual logic
Graphic design creates visual logic, an optimal balance between visual sensation and graphic or text information. Without the visual impact of shape, color, and contrast pages are often graphically boring and will not motivate the viewer to investigate their contents.. Dense text documents without the contrast and visual relief offered by graphics and careful page layout and typography are also more difficult to read, particularly on the relatively low resolution screens of current personal computers.

Visual and functional continuity in your Web site organization, graphic design, and typography are essential to convince the audience that your Web site offers then timely, accurate and useful information. A careful, systematic approach to page

design can simplify navigation, reduce errors and make it much easier for users to take full advantage of the information and features of the Web site.

We are structuring and developing not only an online course or a Postgraduated program specifically for designers, we are also trying to build a Web-based learning environment providing student with feedback, incentives and interactivity, according for what they are looking for.

Our main objectives are centered into students, but we also have a problem we are trying to teach design, with a designed interface to designers, this became great challenge. So that we are conceiving a new metaphor for the spread of innovation in teaching and learning. We use technology to help students learn.

According to those considerations we think that a site with poor visual design and low editorial standars will not inspire confidence in the users. If you want to convice your users that what you offer is accurate and reliable you will have to design your web site as carefully as you would any other type of corporate communication, with the same high editorial and design standars. This is related to the recent concept of design Estability that means: design your web site keeping the interactive elements of your site working reliably.

What you have to take on consider?
As a conclusion, I am going to resume in only 10 points the most impotant graphic standars I think you have to take on consider when you decided to build a web site in order to take advantage of the information you put on it and to promote learning:

1.- User-centered desing: create sample scenarios , design for kwon person whose needs you understand and t est your designs.
2.- Build clear navigation aids: build basic links that should be present on every page of your site, clear consistent icons and graphic identity schemes, in order to give a sense to the infomation.
3.- Give users direct accesss: provide the users with the information in the fewest possible steps, and in the shortest time.
4.- Be consistence and use simple metaphors: your interface metaphors should be simple, familiar and logic, so establish a layout grid and a style for text and graphics.
5.- Structure a basic layout: organize the information around a home page that act as an entry of the next web pages, and put in it an structure based on menus, submenus and other home pages.
6.- Design with visual logic: considering the impact of color, shape, contrast and typography you will make it much easier for users to take full advantage of the information.
7.- Understand the medium: the experience for users of Web pages is oriented into two senses: as a direct medium where pages are read online, and as a delivery medium to access information that is downloaded into text files or printed, so that your expectations about how them will use your site must be your design decisions.
8.- Try, with all graphic elements, to stablish a visual hierarchy: if you decided to take on cosider the importance of graphic design in web pages, the first step to use correct elements into your Web site is to create a strong, consistent visual hierarchy, where impotant elements are emphasized, and content is organize logically and predictably.
9.- Define a general "style": not only be careful about graphic elements you have set, consider too the editorial desing and the structure of information, handling appropiate the content on the page.
10.- Use efficiently the Worl Wide Web: graphic designs require far more communications bandwith so that try to be "in" taking full advantage of technology and improve the graphic and design elements with the use of the correct application.

Managing Distributed Personal Firewalls with Smart Data Servers

Ernst-Georg Haffner, Uwe Roth, Andreas Heuer, Thomas Engel, Christoph Meinel
Institute of Telematics
Trier
Germany
{haffner, roth, heuer, engel, meinel}@ti.fhg.de

Abstract: Modern security architectures tend to become more and more complex. Not only the chances to improve Web applications using several data channels and diverse (TCP-)ports are very promising, but also the risks for criminal attacks and an intrusion into the corporate network are increasing.

The classical solution to protect networks against criminal attacks with firewalls is problematic, though. On the one hand, attacks from the inside are hardly prevented by firewalls, on the other, mobile computing poses additional security risks to the corporate networks. Personal firewalls solve some of those problems, but their central administration is very difficult. In this paper, we will discuss a possible strategy to manage distributed personal firewalls with a central tool, the Smart Data Server.

Introduction

Today's security architectures tend to become more and more complex. There are two main reasons for this. One the one hand, modern programs and applications require an increasing amount of data exchange between networks and the information flow often goes via Internet. On the other hand, potential attackers use sophisticated tools and possess extended knowledge to compromise computer systems via online connections.

The manifold possibilities to fight against these attacks, mostly with one or more levels of firewall complexes, result in very complicated security architectures at least for greater companies. In general, firewalls operate as packet filters or application level gateways. They analyze the network traffic and allow or disallow the transfer of data on base of certain rules.

Unfortunately, most attacks against an internal network do not come from the outside, but from the inside. For this kind of attacks, firewalls are mostly useless. Additionally, mobile computing, where personal laptops are plugged into both, the corporate network and (at home) into the network of a public Internet Service Provider (ISP), poses a serious risk to the integrity of the former one: viruses, worms and all other kinds of beastware may arrive at the inner network of a company (Cohen, 1984) and (Karger, 1987).

One possible answer to the question of how to secure a corporate network in such a situation is the personal firewall. If the protection of a computer does not depend on other machines, servers or programs within the network, the mobility of the system represents no security problem any longer. Likewise, internal network attacks are secured at the last possible station: at the workstation of the employees.

Unhappily, securing a network only by personal firewalls is hardly manageable. Ensuring that all personal firewalls of a company are configured according to the security policy is very difficult. In this contribution, we will focus on solving the problem of managing what we call "Distributed Personal Firewalls" (DPF) on base of a central managing tool: the Smart Data Server (SDS).

Personal Firewalls

Before we discuss special aspects of personal firewall implementations, we will have a closer look at classical firewalls first.

Cheswick and Bellovin define the expression "firewall" in their famous book "Firewalls and Internet Security" (Cheswick & Bellovin, 1995) as "a collection of components placed between two networks that collectively have the following properties:

- All traffic from inside to outside, and vice-versa, must pass through the firewall.
- Only authorized traffic, as defined by the local security policy, will be allowed to pass.
- The firewall itself is immune to penetration."

Many of the existing firewalls are mainly packet filters. They analyze the source and target IP-address of each data packet, check its TCP port number and reject the packet if one of them is not allowed to pass. Other kinds of firewalls are the circuit-level and the application-level gateway. The former is a more elaborated and complex type of packet analyzer that works like a proxy server. Details can be found in (Cheswick & Bellovin, 1995). The latter describes a scheme for "special-purpose" gateways that allows only some applications to pass through.

Personal firewalls are programs that run on front end and client machines rather than on corporate network servers. A general description of personal firewalls and a discussion of some classical examples can be found in (Zych, 2000). In principle, personal firewalls have to manage the same security tasks as classical firewalls. Nevertheless, there are some very important advantages:

- Personal firewalls work even though the communication might be encrypted due to their location on one end of the information flow.
- They are mobile inasmuch as the machine they are running on (for instance a laptop) is mobile, too. Mobile computing requires special personal solutions due to foreign ISP's and several other non-controllable factors.
- They can take care more precisely and specifically of individual security requirements.
- The security level can be easily adjusted (mostly by the user himself/herself).
- Personal firewalls can help to solve the problem of several entry points into networks whereas centralized firewall systems can hardly manage more than very few entry points.
- The penetration of one personal firewall does not directly imply possible damage for the complete network (due to several other personal firewalls on the other workstations).
- Higher degrees of bandwidth, increasing line speeds and more complex protocols make it very difficult to secure a corporate network by a centralized firewall system.

The main disadvantages of personal firewall solutions, especially for enterprise use, are the following ones:

- In general, the user is responsible to maintain the personal firewall (even though system administrators may help in some cases and with the initial setup).
- Personal firewalls pose security risks for the corporate network due to possible false-configuration (e.g. lack of knowledge or intentional act) and a central maintenance of these systems is very complicated.
- Usually, there is no 7/24 support and supervision of personal firewalls.
- Extensive intrusion detection is very complicated because there is no central administration point.
- Administration rights of personal firewalls sometimes belong to the user of the workstation and not the company's system administrator (especially for older Windows based systems).

Nevertheless, personal firewalls or at least decentralized systems are the upcoming standard to secure complex corporate networks.

In the following, we present a possibility to overcome some of the disadvantages of personal firewalls by proposing a distributed personal firewall architecture that could be managed from a central point by the middleware of the Smart Data Server (SDS).

The Smart Data Server

The Smart Data Server (SDS) as a general framework for distributed functionality is a promising platform

to provide also advanced security needs (Roth et. al., 1999a). The SDS is able to connect different data sources and to improve information exchange. The system serves as middle tier in a three-tier architecture (Roth et. al. 1999b). It can work together with several C/S-components and -structures and is a pure Java implementation. The overall idea is to put intelligence on the server side to increase the efficiency of the communication with the clients. The information channels are scalable towards the security requirements. Especially, strongly encrypted communication between server and client is possible.

Similar approaches can be found in Satoshi Hirona's HORB, an object-oriented request-broker (HORB). The Swift Company works on a product using RMI of Java (Swift). The idea of the "Common Request Broker Architecture" (CORBA) is also related to the SDS in our context (Object Management Group). In this approach, several resources can be distributed over the network. DCOM (Brown, 1997) and Java's RMI (Sun Microsystems, 1998) are also similar to the basic ideas of the SDS.

As already stated, the SDS Java server provides several information channels with scalable security levels. The internal structure of the SDS is with three layers very strict. The layers are illustrated by figure 1.
Figure 1: The internal layer structure of the SDS

The session layer is responsible for handling client requests, checking authorization or creating time-based functions by itself. It contains the basic functionality for network-connections, session handling, protocol analyzing and other request-related functionality.

The service layer consists of a set of general usable services that is engaged by both, the function layer and the session layer modules, e.g. a data store module and the central function request broker.

Function layer modules realize the application functionality. In the context of this contribution, the security policy has to be expressed as function layer module so that the rules for the personal firewalls can be distributed to the workstations of each single user.

One special feature of the SDS can help to manage the difficulties arising from distributed security: the SDS can simply be cloned and several instances of the server communicate pretty well with each other. Additionally, functions can be distributed between those clones while they still work on the same databases. Therefore, a clone of the SDS can be placed within the demilitarized zone (DMZ) while others are placed within the inner network to arrange security and trust management tasks. Certainly, it is necessary to design the security architecture for those requirements very carefully. We will have a closer look at this point in the subsequent sections.

Managing Distributed Personal Firewalls

As we have seen already, a firewall nowadays becomes a possible congestion point due to complex protocols and increasing network throughput (Ioannidis et. al., 2000). Distributed personal firewalls that are

managed from a central server can help to map corporate security policies to the configuration of workstation firewall systems.

In the following, we will provide a possible methodology to overcome the problem of distributing security policy information to decentralized distributed personal firewalls by the use of the Smart Data Server architecture. Especially, firewall rule sets have to be transferred via secured and thus encrypted channels to the client machines. Therefore, every client machine must serve as a client for the SDS communication.

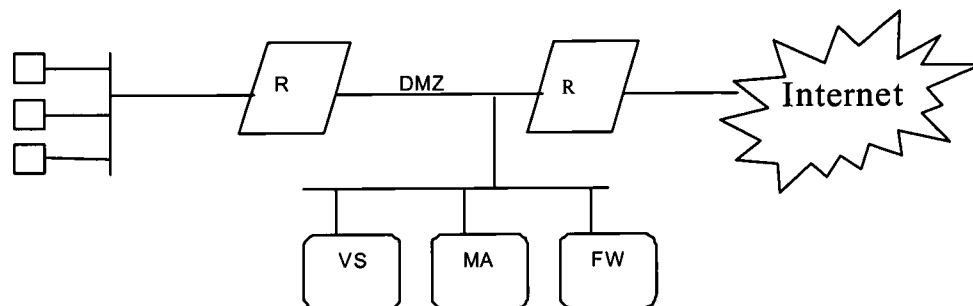
Figure 2 and figure 3 demonstrate the structural and logical task of the managed personal firewalls. While the former one shows a typical firewall architecture (FW) to protect a complex network against attacks from the outside with routers (R), virus scanners (VS), and mail analyzing tools (MA), the latter one illustrates the use of an SDS as central management server to configure distributed personal firewalls.


Figure 2: The classical Firewall architecture without use of distributed personal firewalls

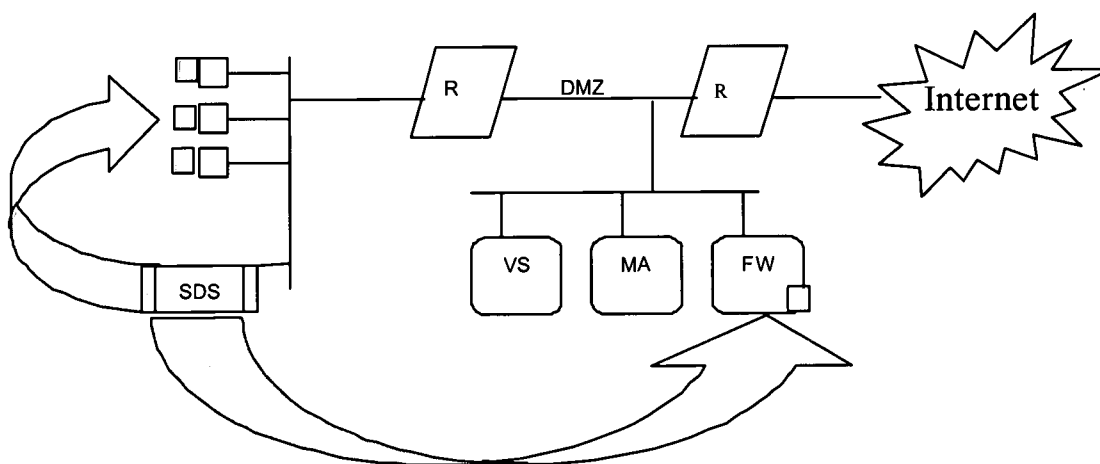
The management target is to administer not only personal firewalls on every relevant workstation but also the main (classical) firewalls that run on hosts and analyze the main traffic stream from inside out and vice versa.


Figure 3: Distributed personal firewall architecture managed by an SDS

As we have seen before, a critical point in the described methodology is the vulnerability of the SDS itself. A worst-case scenario would be an attacker (from the inside) compromising the central managing server itself and thus possibly jeopardize the integrity of the whole corporate network.

Therefore, it is advisable to – at least – "harden" the operating system platform the server is running on. Several companies offer such trusted operating systems on base of Windows-NT or UNIX systems (e.g. Argus Systems Group, Computer Associates International, Hewlett-Packard Company).

The process of distributing the security policy can then be based on concepts like the *PolicyMaker* as a general approach for trust management. It provides a formal model of trust management and a framework for the development of decentralized security features. A corporate security policy can thus be distributed from the central firewall complex to the single end points of personal firewalls. Further details of the PolicyMaker approach can be found in (Blaze et. al. 1999).

Summary and Outlook

Modern security architectures mostly operate with a central firewall solution. All traffic from the internal corporate network to the Internet and vice versa has to pass through the firewalls. Not only an increasing bandwidth cause problems to that solution, but also encrypted data transfer protocols and manifold security holes arising from mobile computing pushes other methodologies. Additionally, central security tools may cause bottlenecks and potential vulnerabilities for the whole network communication. Even though personal firewalls solve some of these difficulties, they lead to a set of additional problems, mainly administrative ones.

In this contribution, we wanted to point out the idea of distributed personal firewalls, where a central management is able to control the diverse firewalls on the end-user client machines. One possibility would be the Smart Data Server as administrating middleware that has been briefly presented. With scalable secure information channels it can serve as a central management tool for corporate and end-user personal firewalls. Then, a system like the PolicyMaker can help to administer the security tasks for the distributed firewall systems. It is important to see that the central management of distributed personal firewalls also offers new working surfaces for attackers and therefore has to be designed very carefully.

The next steps to go are the verification of the theoretical construction in practice and the evaluation of the security aspects. After this, also questions of performance and the overall efficiency of the approach have to be examined.

Abstract: During collaborative development and evaluation of a set of web-accessible shared resources for teaching introductory programming in Java by staff from several campuses and courses, a number of issues arose that reduced the effectiveness of these processes. This paper highlights the issues that occurred during development and evaluation, describes the lessons learnt, and considers ways of solving these problems for development of future resources.

The Project

The aim of this project was to develop a set of shared modular resources, accessible via the World Wide Web, intended to support the teaching of first year programming in Java in several different degree programs. It was intended that the lecturers could use these resources as they saw fit, e.g., as demonstrations during a lecture, or as exercises for students to work through during tutorials, or as additional resources for students to use at home. The resources therefore were not tied to any particular course's sequence of topics, but were intended to be stand-alone. The project group initially consisted of ten academic staff members from four campuses and three Schools within the faculty, teaching in four different degree programs.

At the commencement of the project, the project leader introduced a strategy for the design and development of the resources, together with a vision of a collaborative process for the project group. This strategy had earlier been employed for developing other resources (Ellis *et al.* 1998). The first couple of meetings were spent establishing a list of resources to be developed. These sessions included brainstorming to determine topic areas, associated and prerequisite information, and levels of difficulty within each topic (Ellis *et al.* 1999). For the development stage, the group was divided into three sub-groups, each to design and develop one resource. By the end of the first year, only part of two of the three resources had been developed. Only four group members remained. The main reason for the dwindling of the project group was lack of time for the project. All staff on the project team had high teaching and administrative loads, and none of the grant funding was for load relief for staff to work on the project. After the initial stage, project meetings became reporting and planning occasions rather than working meetings. This was partly because, since group members were on different campuses, many meetings were conducted via videoconferences. This slowed down the process of evaluation, especially development of instruments.

The Evaluation Process

The evaluation specified in the original grant application included: a survey at the beginning of semester to determine the students' knowledge and understanding of learning processes, self-directed learning, group work, and information technology including programming; measurement of students' use of, and responses to, the resources through online monitoring and questionnaires; semi-structured interviews with a focus group of students about their response to the resources; semi-structured interviews with teaching staff about their response to the resources and

their ways of using them within different teaching styles (e.g., lectures plus tutorials, problem-based learning, and distance education); and a final survey to ask students to evaluate the resources.

The ASCILITE CUTSD Project

At the end of the first year, the group applied successfully to become part of a project funded by a CUTSD (Council of University Teaching Staff Development) grant (see CUTSD 2000) obtained by ASCILITE (Australasian Society for Computers In Learning In Tertiary Education). An ASCILITE mentor was assigned to assist with the evaluation of our resources. The mentor introduced a web-based Collaborative Workspace for communication between the group members. Documents were placed into this workspace and could be accessed and amended by anyone in the group. However, many group members were too busy to experiment with using it effectively, and tended to revert to email to distribute versions of documents.

ASCILITE proposed the concept of Action Inquiry, defined in the CUTSD evaluation handbook as "the deliberate use of a plan, act, describe and review cycle for inquiry into action in a field of practice" (Phillips *et al.* 2000). This is particularly useful in educational evaluation as it offers a methodology that supports research by practitioners in the field with a particular commitment to collaborative curriculum development and evaluation work. The CUTSD project intended mentors to use an Action Inquiry cycle to support the mentees with their evaluation project. As the project was not initially grounded in Action Inquiry, the project team had to adapt it to the Action Inquiry methodology. Wadsworth (Wadsworth 1997) suggests that the investigator must spend equal time on each activity in the cycle. From an Action Inquiry perspective, the team was unable to maintain the spiral of activities that lead a systematic inquiry into practice.

Conclusion: Summary of Lessons Learnt

- The involvement in the ASCILITE project forced the completion and evaluation of several Java resources.
- The budget should have included funding for release of staff from other duties, for the development process.
- The budget should also have included an allocation of funding for evaluation, in order to establish a detailed plan and develop instruments earlier.
- It would have been useful if staff members who were involved in the project had continued to teach related courses. This would have assisted them to retain a higher level of motivation.
- Productive working meetings should have been scheduled regularly, with planning meetings less frequently.
- The development of prototypes by student groups would have provided developers with a more detailed idea of what was required, resulting in much faster completion of the resources.
- The Action Inquiry cycle is designed to evaluate a course in order to improve teaching practice, rather than to evaluate resources used to support it. The resources used in a programming course have a short life expectancy as the technology is changing rapidly. Any delays in the development of resources may result in those resources being of limited or no use. What was needed was a different evaluation methodology that enabled rapid evaluation of the resources.

Educational JavaBeans: a Requirements Driven Architecture

Jon Hall and Lucia Rapanotti
Computing Department
The Open University
Walton Hall
Milton Keynes, UK
{J.G.Hall, L.Rapanotti}@open.ac.uk

Abstract In this paper we investigate, through a case study, the development of a software architecture that is compatible with a system's high-level requirements. The case study is an example of an extended customer/supplier relationship (post-point of sale support) involved in e-Universities, this being representative of a class of enterprise without current architectural support.

In detail, we describe the relevant high-level business processes. We highlight requirements and challenges of the current business model and explore discharging and meeting them through electronic support. We propose a new blueprint architecture and argue that it is compatible with these requirements and challenges. Finally, we discuss the wider applicability of the new blueprint architecture in a wider enterprise setting.

1. Introduction

With increasing demands being made for the electronic support of distance learning and teaching, there are many reasons why an architecture for *electronic Learning and Teaching* (eLT) is important and timely:

- initiatives such as the EU Ariadne project (http://ariadne.unil.ch/) or the UK e-University (http://www.hefce.ac.uk/Pubs/default.asp) introduce new challenges for the Educational Engineer to include infrastructural electronic support for the business of learning and teaching at a distance;
- platform independent technologies are available which already go some of the way towards supporting the business model.

In fact, educational software development has never been so central to the success of a university. The UK education market is not without good electronic support; the Open University being only one of many institutions making use of information technologies in their teaching. Current development practice can, however, only be described as *ad hoc*. One of the reasons for this, we feel, is the lack of a proper foundation for the building of educational software systems. We have not yet reached a 'technological critical mass' for educational software development.

On the other hand, such a critical mass has been reached for eCommerce systems, witness the recent explosion of electronic commerce products. Technologies such as the Java 2 Enterprise Edition (J2EE) platform (Shannon et al. 2000), which includes the Enterprise JavaBeans™ (EJB) architecture, have provided the catalyst for eCommerce systems development. In this paper, we hope to go someway towards identifying the catalyst for education software development. We wish to build on the firm bases provided by EJB to extend its properties and philosophy to cover distance learning and teaching.

1.1 eLT Products, Services and Business Processes

There are strong similarities between many of the business processes of commerce operations and those within distance learning and teaching. In the most general case, both have customers; both work on a contract basis; both provide end-user support; both work through intermediaries. Moving into the electronic setting of eCommerce and eLT, we may deduce that EJB goes someway towards servicing the electronic support needs of eLT. However, with few exceptions, eCommerce has concentrated on the exchange of physical goods for which post-point of sale electronic support is unnecessary - delivery and use happen in the material rather than the

electronic world. In eLT, the commodity on offer is information employed by the end-user (potentially) every day; in this case, continued close involvement in the product is integral with its delivery and use.

Supporting (and extending) the richness of the customer/supplier dialog whilst building on previous best practice provides our motivational focus for the development of the blueprint architecture proposed in this paper, the Educational JavaBeans (EdJB) architecture. In the next section we focus on eliciting requirements for the support of the distance learning educational dialog. We begin by considering its current manifestation within the Open University, the major provider of distance education in the UK. As this is not a paper on the distance learning model *per se*, for brevity we stop short of describing the minutiae of the model, concentrating on the relevant higher-level aspects of the model.

2. Supporting Current Practice in Distance Learning

The Open University (OU) teaches, at a distance, to over 150,000 students per year. The OU teaching model - also called *supported open distance learning* - has evolved over thirty years to its current efficient and effective form. Because their use is best understood, it bases teaching on text technologies, i.e., books, electronic documents, web pages, continuous assessment and exam papers, but there is some *ad hoc* use of supporting media - such as television, audio cassettes and computer-based instruction.

The business processes underlying the OU teaching model are well defined, effective, efficient and scaleable, and so provide a rich source of dialogs between stakeholders for requirements elicitation. For the purpose of our discussion, we identify the following stakeholder groups within the OU model: *students*, *associate lecturers* (ALs, also called *tutors*), *course authoring teams*, and *student recruitment teams*.

In this section we consider, from a high-level perspective, dialogs between those stakeholders. Each dialog description is structured as follows: we describe the dialog as it exists and from this description determine minimum requirements for the EdJB architecture to be able to provide support. We then identify the 'challenges' that exist within the current model that we feel can be met by 'extended' electronic support.

Reality check: So that this paper is grounded in reality, we must consider the quality of electronic support that is currently available and sustainably available in the future. We will therefore not assume that electronic support is required as a 24/7 thing (i.e., 24 hours per day, 7 days per week), only that there will be relatively short, non-contiguous periods with the end-user in electronic contact with the supplier. Moreover, neither will we assume that the supplier can determine nor influence *a priori* the time that the end-user spends on-line. The justification for this mode of operation comes down to the fact that it is the customer who determines product use - even when that product is electronically supported. This is clearly unlikely to change.

The following section describes the dialogs that motivate the architecture. A dialog description is followed by derived requirements (labeled R<requirement number>, for reference). Then, in a box, we identify challenges, i.e., things that cannot yet be done, but with electronic support may be possible. Such challenges again source requirements, labeled as above.

2.1. Student/Student Recruitment Team Interaction: Receiving Materials

Currently, the primary delivery mode for learning materials is by paper mail at the start of the course. When necessary, a second major mailing will provide further material later on during the course. Minor mailings will then be used to inform students of errata in the course materials, should errata be brought to the course authoring teams attention during a course presentation.

Derived requirements – The architecture must:

R1   provide support for the publication and delivery of teaching materials

---

Challenge
It is important to note that, due to the present reliance on paper-like media, having the characteristic of being unchangeable when 'published', course texts remain unchanged, often for many years, even when problems with the material are known[1]. Even though every effort is made to inform students of errata, a student will often be

---

[1] Another way of seeing these characteristics is that the OU is tied to the use of media that require long 'print' runs for them to be economic. Even certain electronic media, such as CDROMs, share such characteristics.

unaware of the presence of errata, or become aware of them a long time after the error was encountered. This can have a serious and deleterious effect on the learning and teaching experience, which can contribute greatly to student (and so customer) dissatisfaction. Providing a changeable (i.e., electronic, server-side) media base can address this challenge, as long as suitable materials management, such as versioning and configuration management technologies, are also available.

Derived requirements – The architecture should:

R2	provide support for the use of changeable teaching materials as the basis of the teaching provision

2.2. Student/Tutor Interaction: Studying

Study is deadline-driven by continuous assessment components (CACs). Tutor marking of CACs provides validation and feedback on a student's learning experience. For a half credit course (one academic year's part-time study) there will be between 6 and 8 CACs; tutor marking of assessment material - closing the feedback loop between student and university - can therefore typically occur as infrequently as 5 to 7 weeks.

In addition, synchronous interactions are widely acknowledged by students and teachers alike as being very valuable. Until recently, the only means of achieving them was by telephone - with the obvious restriction on number of participants - or by personal contact - which requires travel to and, for some, an unwelcome commitment of time at some study centre. Currently, some electronic support is available, using conferencing tools such as Lyceum (Rapanotti & Hall 2000), and their use should be facilitated by the architecture.

Derived requirements –The architecture must provide support for:

R3	periodic external study validation	R4	for synchronous interactions at a distance

Challenge

Between CACs, *self*-assessment materials (SAMs) provide students with feedback on much shorter time scales– typically on a *per* subsection study basis (i.e., from minutes to hours) - answers being provided along with the teaching text. Although often enriching, such non-external validation mechanisms can also impact negatively the student experience: although success can breed success, failure on SAMs can lead to student demoralisation. Reasons for failure are twofold: the student has not understood the materials on which they are assessing themselves; there are errors in the SAMs (which unfortunately can happen). Given that external validation can be 5 to 7 weeks away, this can lead to students becoming seriously misguided before any corrective action can be taken. Currently, there is no university-wide mechanism for tutor-validation (or otherwise) of activities between CACs. What is needed is a dialog between student and tutor that has a much finer granularity than the current 5-7 weeks but which overloads neither the student nor the tutor.

Derived requirements – The architecture should:

R5	provide support for periodic external study validation at a fine granularity (i.e., *per* SAM)

2.3. Tutor/Student Interaction: Supporting a Student's Learning

Tutors are the embodiment of the university during course presentation: they provide support for learning and pastoral care to students. Tutors mark their students' scripts. They are assisted in this task by 'tutor notes' issued by course authoring teams and including solutions and a marking scheme. Tutors receive the scripts from their students at particular deadlines set by the course study calendar, and return the marked scripts to the OU headquarters for processing – registering marks and having their marking monitored – from where they are returned to the students. Script submission, marking and processing are largely text -based.

Derived requirements –The architecture must provide support for:

R6	tutor/student dialogs	R7	receiving, marking, processing and returning scripts
R8	monitoring tutor performance	R9	delivering and updating of tutor notes

Challenge

Tutors are a valuable resource for the university, not only in their role as course presenters, but in that they are customer facing. By being in contact with students possibly on a day to day basis, tutors are able to collect students' comments on course materials throughout the study period. Mechanisms exist for relaying this

information back to the course authoring teams for materials improvement, but too often are such valuable perspectives lost. The availability of a fine grain interaction mechanism could facilitate their collection and use to update course materials on an on-going basis.

Derived requirements – The architecture should:

R10 provide support for fine grain interactions between tutor and course authoring team

3. An Architecture for eLT

In this section we describe in broad terms the EdJB blueprint architecture. EdJB is a proposed extension to Enterprise JavaBeans. Its goals are:

- to leverage the technology of Enterprise JavaBeans to help the Educational Engineer;
- to provide a uniform and scalable software platform upon which the development of distance learning and teaching system development can take place;
- to provide support for the business processes of distance learning and teaching.

By being based on EJB, EdJB fosters the reuse of electronic support for programmes and courses based on the development and/or acquisition of components that can be customized, assembled and deployed in a variety of settings. At the same time:

- as does EJB, it provides a standard component architecture for building distance learning and teaching electronic support, and makes the development of eLT support applications easier allowing a concentration on the business logic of learning and teaching, rather than the low-level mechanisms for security and trust, for instance;
- it inherits from EJB desirable characteristics of electronic support, such as platform independence, that make eLT available to the whole community;
- it relies upon tried and tested technologies and includes support for legacy systems so that there is no 'ground zero' for development.

The reader should note that we do not claim in this paper to develop any radical technologies; from our perspective such radicalism is not required. Besides, as EJB gains credence as the standard platform for the development and deployment of eCommerce applications, EdJB-based systems will combine seamlessly with commercial applications. Before entering into the details of the EdJB architecture, we first identify those features of the EJB architecture upon which we will build.

3.1. The EJB Architecture

The EJB architecture, described in (Shannon et al. 2000), is an application of the 3-tier architecture. As such it separates *client view* from *business logic* from *persistent storage*; moreover, interactions between the tiers are heavily (but usefully) constrained. The EJB architecture is outlined in (Fig. 1a).

One of the strengths of the EJB architecture is that it supplies *data persistence*, *security*, and *transaction management* - low-level technologies underlying many of today's eCommerce interactions. In doing this, eCommerce application development is greatly facilitated: the eCommerce developer can focus his or her efforts on capturing relevant business logic, delegating to the EJB architecture the provision of the low-level technologies. As illustrated in (Fig. 1a), EJB containers package business logic together with services. Services offered by the EJB containers are invoked through APIs (Application Programming Interfaces) defined within the architecture. Note that EJB containers and Enterprise beans, by residing in the architecture's middle-tier, are intended to be used (and usually are) for the definition of server side logic. This is perfectly adequate for current eCommerce application where most of the computation is performed by the server, with (so-called) thin clients presenting, what are usually web based, user interfaces.

3.2 The EdJB Architecture: from Requirements to Architecture

We have already noted that eCommerce and eLT share many requirements. It follows that eLT will also require data persistence, security and transaction management as basic services. We argue, however, that eLT interactions also require a new type of service that we call, for want of a better term, *cache coherence*. This

requirement arises in the fine grain, but intermittent, nature of the educational dialogs (established as requirements **R5** and **R10**). Together with the reality check of Section 3, which states that we do not have a 24/7 on-line service, this implies the existence of local state information at both learner and educator sites, with needs for synchronization between them at frequent intervals. In essence, the learner site needs to act as cache to the educator's site, with synchronization to make them coherent.

As an example of the mechanism at work, consider the following likely scenario. Having registered for study on a distance learning course, Jazz downloads the first teaching component from the eLT provider's web site. A week passes in which Jazz works, off-line, through the first course component. During this period, Jazz works through 10 SAMs, 8 of which are answered correctly. In the mean time, two course material updates have been made by the eLT provider: one affects the first course component (which Jazz has), one the second (which Jazz does not yet have). At the end of the first week, and having finished the first course component, Jazz logs on to the eLT web site to download the second course component. Via this link, information is passing both ways: Jazz makes a request for the second course component; an updated version is downloaded to Jazz's machine; without knowing the details of the transaction, but with permission, Jazz's SAM performance profile is uploaded to the eLT site; updates to Jazz's copy of the first course component are made to reflect the course updates, and Jazz is informed that this has occurred.

Over and above the downloading of the second course component, looking at this dialog in terms of caches, *cached information at both sites has to be made coherent*: from Jazz to eLT provider - to synchronize Jazz's SAM profile; from eLT provider to Jazz - to synchronize course materials. This mechanism will, moreover, form a critical component of the dialog between student and provider that will be present within many, if not all, educational software development projects. Because of its omnipresence, an architectural solution cache coherence between sites should be thought of as a basic service of the architecture.

The EdJB architecture incorporates a cache coherence service, as is illustrated in (Fig. 1b). The client tier now contains local 'persistent' storage for 'caching' local information, as well as its own *EdJB container* that wraps
Figure 1: (a) The EJB architecture, and (b) The EdJB architecture

client business logic. This EdJB container provides cache coherence services through communication with a corresponding EdJB container in the middle-tier.

With the EdJB architecture, when off-line, the learner's interaction with the teaching materials will be through the Local Information System with the client business logic used to support it (by collecting SAM answers, for instance, etc). In off-line mode, of course, the middle and EIS tiers are not accessible for interaction. When on-line, the EdJB containers are joined so that client- and server-side data can be made coherent.

3.3. Does EdJB Satisfy the Requirements?

Requirements **R1-R10** constrain any architecture for electronic support of distance learning. We have proposed a blueprint architecture - EdJB - that we claim can provide this electronic support. The validation for the EdJB blueprint architecture against those requirements is argued in (Tab. 1)

R1, R3, R4, R6, R7	These are within the standard services provided by EJB for eCommerce
provide support for:	This is supported by the cache coherence services provided by the EdJB
R2 *provide support for the use*	architecture. EdJB does not require the user to be on-line all the time, but

of changeable teaching materials as the basis of the teaching provision **R9** *the delivery and updating of tutor notes*	ensures that both local and server information systems are made consistent as often as allowed by the end-user. This provides the mechanism for supporting changeable materials: materials delivered to the student (and so residing locally) can be updated as often as the student connects to the server.
provide support for: **R5** *provide support for periodic external study validation at a fine granularity* **R10** *provide support for fine grain interactions between tutor and course authoring team*	This is supported by the cache coherence services provided by the EdJB architecture. EdJB does not require the user to be on-line all the time, while ensuring that both local and server EJB copies are consistent as often as allowed by the end-user. This provides the mechanism for supporting fine grain study validation: student 'profiles' can be generated client-side and kept coherent with server-side copies. By making these available to the tutor, again through the caching mechanism to the tutors local cache, validation of the student 'profile' can be performed and returned to the student's local cache.
R8 *provide support for monitoring tutor performance*	This is supported by the cache coherence services provided by the EdJB architecture that provides the mechanism for supporting tutor monitoring - tutor 'profiles' can be generated client-side and kept coherent with server-side copies. Verification of the tutor's performance can be performed and returned to the tutor's local cache.

Table 1: Validation of the EdJB architecture against requirements

4. Discussion and Conclusions

In this paper, we have derived an extension of the EJB architecture that provides electronic support to the distance learning experience. We have characterized the architecture, EdJB, as *cache-coherent* EJB, in that each user has local storage (the *cache*) and supporting business logic (the *coherence*) to work with off-line. The architecture provides automatic cache coherence services whenever the user goes on-line.

We have argued that the architecture meets current high-level requirements in a distance learning setting. In this section, we will reflect briefly on a reinterpretation of the distance learning challenges that motivated cache coherence in the wider context of eCommerce.

Within an eCommerce setting, product maintenance is often also in the realm of the material world. However, there are instances where product behaviour profiles are feasible and useful. This is obviously true for software products, but could also apply to a wide range of appliances with embedded electronic components – say, the controller of a modern motor car engine or even a washing machine. We can consider the profiling of product use and performance as instances of a dialog in the EdJB sense. Working within the EdJB architecture, the development of *local* product use and performance profiles with cache coherence allowing regular updating of server-side copies is facilitated, as is the downloading of software updates, the alteration of operational parameters, *etc.*, from the server-side to the local cache.

Web-Based Training System Using Exercises in German Linked with Online Teaching Materials

Yamato HARADA, Yusuke YANAGIDA, Shinichi FUJITA, ChunChen LIN and Seinosuke NARITA
School of Science and Engineering, WASEDA University
Tokyo, Japan
harada@narita.elec.waseda.ac.jp

Abstract: In recent years, a WWW-based CAI/CAL system has been needed as the Internet spreads rapidly. We also have been engaged in developing a WWW-based multimedia CAI/CAL system that supports to learn and teach foreign language. In this paper, we present a WWW-based training system that supports to learn German. This system, which enables the learner to learn the language at a level, has the following three features: First, this system is closely linked with WWW-based teaching materials (lexical and grammar materials) which we have devised, second, the teacher can edit exercises used in this system on WEB browser, third, the form of this exercises is often used in examinations of foreign languages at universities in Japan. This system, as a pilot project, has just been used by the students at our university.

1. Introduction

For the German language teaching at the university level in Japan, focus is on teaching how to make correct sentence structure. In the most of German language classes here, however, types of "grammar translation" method are still being used to teach the language, putting German sentences into Japanese and vice verse. Moreover, to learn how to make grammatical sentences, it is not only necessary for the learner to memorize the contents of the textbook but also to compose grammatical sentences.

We have developed a system using exercises in German ("Exercise System") to teach how to compose grammatical sentences, and another system to edit these exercises ("Editing System"). The form of the exercises is often used in examinations of foreign languages at universities in Japan. Because the teacher can offer her original exercises to the learner, the learner can study how to make grammatical sentences very well, and study German language more effectively.

These systems are placed on Web Page, both the learner and the teacher can gain access to these systems through the Internet from anywhere and at any time. (We are going to open these systems in this URL: "http://www.narita.elec.waseda.ac.jp/~harada/german/index.html")

2. System Configuration

The system configuration that we have developed is shown in Fig.1. In the server the following are stored: Exercise System, Editing System, the database for exercises and the database for lexical and grammar materials. In gaining access to this server through the Internet by using on interface such as WEB browser and Shockwave Plug-in, the learner uses Exercise System. Those exercises used in Exercise System are recorded in the database for exercises, and the teacher can edit the database by using Editing System. (It is necessary for the teacher to register her ID and password.) Moreover, because Exercise System is linked to the database for the lexical and the grammar materials, the learner can use both materials freely.
Fig.1. System Configuration

3. Features of the system

3.1 Exercise System

In Exercise System, the learner can explore how to make good sentences by putting each word needed to make a sentence in the correct order by using a mouse. This system is closely linked with online teaching materials (lexical and grammar materials), the learner can study the meaning of a word, its pronunciation and grammatical features quickly at any time while learning the ways of making grammatical sentences. The learner can learn the language easily because multimedia such as movies, stationary pictures and sounds can be used within this system. We have exploited the traditional method of learning, such as translation exercises, by adding the multimedia functions to the Exercise System. Therefore, the learner can understand fully various features of the language. This system is developed by Macromedia Director 7.0J.

3.2 GRAMMATIK (Grammar Material)

GRAMMATIK is an online grammar material. By using GRAMMATIK, the learner can study the grammar with explanations and example sentences that relate to the sentence just composed by the learner in Exercise System. The learner can enhance her knowledge by using the GRAMMATIK, which is, so to speak, a textbook. The learner doesn't need any textbooks.

3.3 VERBEN (Lexical Material)

VERBEN is an online lexical material. By using the VERBEN, the learner will study the meaning of a word. At present, 100 most fundamental verbs are available, which were carefully chosen by teachers in WASEDA University. The learner can also study its inflection, its idioms and example sentences including the word. Moreover, the VERBEN gives the pronunciation of the word and the pronunciation of some example sentences for the word. The database for GRAMMATIK and VERBEN is designed by adapting Microsoft Access 2000, and the interface of these teaching materials is developed by Microsoft Visual Basic 6.0.

3.4 Editing System

Editing System enables the teacher to edit exercises used in Exercise System on WEB browser. After gain access to this system, the teacher can add, change, and delete contents of the database for the exercises stored in the server on WEB browser freely. (In the database the following are stored: question, answer, link to grammar material and lexical material, and so on.) The edited database is stored in the server again. The database for the exercises is designed by adapting Microsoft Excel 2000, and the interface of this system is developed by Perl 4.0.

4. Evaluation

At present, Exercise System has just been used on a pilot basis in an elementary German class at our university, and we take the evaluation of this system. This class is done three times a week, and about 30 students are attending each class. Their answers for the questionnaire on this system are shown in Table 1.

Effect of System	3.93 / 5.00
Operability of System	4.16 / 5.00
System Layout	4.13 / 5.00
System Speed	4.04 / 5.00
Functionability of System	4.02 / 5.00
Qualities and Number of Exercises	3.94 / 5.00

Table 1. Result of Questionnaire

5. Future Works and Conclusion

The present WWW-based training system has been introduced in this paper. This system is closely linked with the lexical and grammar materials. And, the teacher can edit the exercises on WEB browser by using this system. However, we want to improve this system based upon the above-mentioned evaluation in order to make this system easier-to-use to satisfy the needs and requests of learners and teachers. Moreover, as soon as Editing System is fully developed, we will develop a new system which can analyze the learner's errors and give feedback to her. In order to do this, we need to devise a function of recording the learner's performance. (For the development of the function to analyze the learner's errors, we are planning to use Neural Network etc.) At the same time, we want to improve the quality of the exercises (Ex. add the exercises of a new kind.) while the number of these exercises is increased.

Abstract: Teaching students to become web developers requires a hands-on approach. Incorporating live clients into student projects, instead of using case studies or mock companies, adds a dimension that exposes students to the realities of web development. This paper will describe a structured methodology used in a web development course to build complete web sites for local businesses. Based upon the written evaluations included with the final project documentation, students feel this project is the most valuable learning experience of the course. Furthermore, the positive relationship established with the clients makes this project serve as a bridge between business and academe.

Introduction

Two years ago, the US government increased its estimate on the number of unfilled IT jobs from 1 million to 1.3 million (Baldwin, 1998). Haubold reports that each year there are more than 400,000 unfilled IT positions including programmers, systems analysts and IT specialists (2000). Paul reports that the demand for IT services is growing at 25 percent per year (1999). Nowhere is this trend more apparent than in web development. In 1994, three million people used the Internet. The number of Internet users was projected to grow to approximately 320 million by 2000, and to 720 million by 2005 (Meares, 1999). There are several reasons for such an explosive growth on the WWW: ease of publishing; relatively low cost of having a Web presence; low training needs because of the simple, link-based navigational model; ease in updating and distributing information; platform independence; and the potential of reaching a wide audience (Forsythe et al., 1998).

The architecture of the World Wide Web has evolved to the point where large and small businesses will have to be prepared to compete with those who employ Web-enabled business models to offer better responsiveness and a lower cost infrastructure (Taylor, 1998). Consequently, experienced people with web technology and management skills are in high demand and command high salaries (Violino, 1998).

Purdue University's Computer Technology (CPT) Department produces graduates who can immediately assume responsibilities as systems analysts, database administrators, webmasters, and application programmers. The primary reason for this employer confidence is that the CPT curriculum provides students with practical experience applying important concepts using popular, commercial technology. In the area of web development, students learn fundamental web development concepts and gain experience designing and implementing a real web site. Since web applications are a special type of software, the web development process should closely model the software development process (Schulz, 1997).

Before teaching students traditional systems development, most curricula require students to develop programming skills. Likewise, before expecting students to build a web site, it is necessary to equip

them with fundamental web development skills. In the web development course, students are taught how to write HTML, JavaScript, VBScript, and DHTML code, and how to use Microsoft FrontPage and other tools to create web pages. Students also learn how to create image maps, form s, frames, tables, and style sheets. After discussing each of these topics, students complete weekly lab assignments to reinforce the new concepts. In addition to teaching how to use the technology, students are presented with a structured process for web site development. Throughout the presentation, there is major focus on the needs of both users and clients.

Web Development Methodology

Since the majority of students in the class are new to web development, it is important to provide them with a framework for the web development process. (See figure 1) The methodology employed in the class adapts features of traditional systems development methodologies to web site creation.
Figure 1: Web Development Methodology

The process begins with planning activities that include identifying the roles of each team member, defining who the clients and users are, and specifying the goals of the web site. Next, the proposed site needs to be sufficiently analyzed such that the developer can identify web content and organization as well as the anticipated process that the user will employ when visiting the site. Once enough details have been defined, the team should begin defining styles to be employed across the site for a consistent look and feel. This should also include designing individual pages, including graphics and multimedia. The design is frequently prototyped, so that initial user reaction can be collected.

The ease with which web novices can create a web site today and the potential value that a site can bring to the organization has resulted in an unprecedented number of sites. However, many sites have failed to realize their potential because they disregarded users' needs and requirements (Sano, 1996). For this reason, one of the most important elements of the project is the design of usability tests and analysis of the results. Students are encouraged to conduct usability testing throughout the project. In addition, they are required to include their usability tests in two separate milestones.

Based upon the results of the usability testing, there may be a need to update the design or even go back and conduct further analysis. These steps are repeated until the usability tests suggest that the site meets the user's expectations. Once that happens, the site is implemented on a production server. Usability tests should be repeated to insure that any unique aspects of the published site present no new problems. Again, the steps may be repeated as appropriate, until the client is satisfied that the site is complete. At this point, the client is educated on the maintenance activities such as registering with search engines and verifying that all links work.

Web Site Team Project

Once students have acquired fundamental web development skills through the weekly lab assignments and they know the recommended web development methodology, they embark on a team-oriented, web site development project for a real client. The project itself is divided into the following nine milestones to help the students follow the web development methodology advocated by the instructors:

1. Team profile
2. Company selection
3. Project proposal
4. Site design & resources
5. Prototype I and company feedback
6. Prototype II and usability test results
7. Web site presentation
8. Final documentation with team evaluation
9. Individual evaluation

Team Objectives

The preliminary task is to define the student teams such that each team has as close to the same background profile as possible. Students are surveyed about their related experiences and comfort level with a variety of web technologies. The instructors use the survey data to assign teams of 3-4 students with a balance of experience across all teams. For example, if only 20% of the students have substantial programming experience, each student would be placed on a different team, so every team can benefit from the programming skills of one member. Some team guidelines follow:

- Team members should have compatible schedules outside of class. To deal with this issue, each team is asked to identify three hours outside of class when they could have team meetings. Additionally, each individual team member is asked to identify three to seven hours outside of class to do work on the project.

- It would be helpful to have someone with *little to no* web development experience. It would be helpful to have someone with *some* web development experience. The instructors meet this goal by assigning students based on the results of the survey data.

- The team must designate a leader who will schedule and run all team meetings as well as serve as the team's spokesperson on communication with the instructor. The team must designate a company liaison that will be responsible for maintaining communication with the company representative. The team must designate a secretary who will record minutes from all meetings, and disseminate to all members and instructor. Teams are permitted to alternate this role, but this must be documented. The students determine their roles after their initial meeting.

- Each team member must maintain an individual log of activities related to this project. The logs may be checked each week in class and are a required part of the final project report.

Client & Web Site Objectives

Once the team has been assigned, they must identify an organization that wants to develop a presence on the Web. The organization can be a for-profit business, not-for-profit company, student club, etc. The scope of the web site should be neither too broad nor too trivial. Students are not expected to build an exhaustive web site that allows the company to conduct all of its business through the web site. Likewise, there is little value in developing a web site that documents a minute, unimportant, uninteresting aspect of the company. The teams have to find a balance that considers their schedules, the total calendar time allotted to the project (approximately 10 weeks), and their web development skills. To abet the students in this area, the instructors define minimum web site features that constitute 75% of the project requirements. The student team, in collaboration with the client, determines additional relevant features to add to the site for the remaining 25% of the project.

Minimum project requirements

The minimum project requirements are objective and fairly easy to meet. In the past three semesters that the course has been taught using a live project, only one team failed to meet all of the minimum project requirements. These requirements include:

- The complete site must include at least 10 web pages
- The home/main/start page must provide internal web site links as well as related links to external sites.
- A formal navigation standard should exist across the site (frames, buttons, menu bar, etc.).
- User information should be collected after validation assures acceptability of data.
- The site should provide company contact information (name, address, phone, fax, email).
- Any external resources used should be credited.
- The web pages must use the user's vernacular.
- The pages must be arranged in a logical fashion.
- Unnecessary or irrelevant information must be omitted.
- Images should be used, where appropriate, to convey more meaning or attract attention, but not at the expense of too much load time.
- Usability tests should be conducted throughout the project to support the point that the site continues to meet the user's needs.

Additional project features

The greatest challenge that students face is determining what additional requirements should be incorporated into their site such that they bring value to the client and target users and the challenge level warrants additional credit. To help the students with this subjective part of the project, the instructors demonstrate past student projects as well as give the students a list of possible enhancements that could qualify for the remaining 25%. The list of suggestions shared with students is below:

- Employ an image map to increase appeal and provide an alternative for linking to elements within the site.
- Incorporate security to restrict access to the entire site or to some elements within the site.
- Customize the user's experience through maintaining user data in a server database and modifying pages based on the user's profile.
- Add a floating, drop-down menu to provide access to site options without having to scroll back to the top to access the menu.
- Add relevant games (word search, hangman, tic-tac-toe, etc.) to give users a reason to return to the site.
- Add Flash movies to initially gain the new visitor's attention.

Since much of the project's success is dependent on the client, the students must identify a cooperative representative within an organization who is willing to work with them on a regular basis as a resource as well as to provide feedback throughout this project. On the second milestone, students must document this person's name, phone number, email address, role within the organization, and expected role on their project. More importantly, students must include a memo from their proposed client to the instructor accepting the role that the team has defined. If students have difficulty finding an organization, they contact the instructor to find out about any other potential clients that may be available for the project.

Project Proposal

Once the team has completed initial project planning, they must thoroughly analyze the proposed web site needs and expectations. Before they are officially allowed to develop the site, they must seek permission from the instructors by documenting their complete analysis in a project proposal. This document is written as an executive summary memo that addresses the following points:

- a 1-2 sentence statement of the proposal
- general description of the company and statement of needs for proposed web site
- outline of work to be completed, including strategy methods and criteria for collecting web site data
- development team with individual responsibilities to demonstrate that each member will be contributing equally to the project
- justification for the Web site, such as potential value of the final system
- sources of knowledge
- user profile
- benefits to all persons including the student, company, company representative, and target users
- evaluation strategy
- anticipated problems

As long as the above points are adequately addressed and all web site proposals are for different organizations, permission to pursue the proposed project is granted. However, no team member may serve as the company representative. Based on feedback from the most recent course offering, at least one student felt that no student member should be affiliated with the client organization. This is a recommendation that will be considered for subsequent semesters.

Site Design and Resources

Assuming that the proposal is accepted, students should immediately begin designing their client's site. The design must include the layout and organization of pages on the site, consistent header/footer content, and related external links. Although the design may be sketched out on paper, the majority of teams tend to use a tool such as Microsoft ® FrontPage to build a prototype.

Initial Prototype and Company Feedback

Much like any other systems development project one of the most valuable things that the teams discover is that their clients are not very helpful in specifying what the sites should look like or how they should behave; however, the clients can definitely tell them when they do not like something. This helps the students recognize the value of soliciting formal and regular feedback. Therefore, once the design has been approved, each team submits its initial site prototype along with the written feedback from the client.

Prototype II and User Test Results

As previously stated, many sites have failed because they did not consider the user's needs. To address this, the teams submit their second prototype with a status report that documents their usability tests. The report must include a description of their test strategy, include samples of the user tests, include the actual data, and their analysis of the results. Although studies have shown that the optimum number of test users is five (Nielsen, 2000), the minimum requirement is ten. This helps the students realize trends and account for different groups of users.

Team Presentations

During the semester, every team is developing a site for a different client with unique objectives. One of the most interesting milestones completed by the teams is a presentation of the site to the rest of the class. Every team member is required to actively participate in the presentation. Minimum content requirements are given to the students prior to their presentation. The presentations are timed (4-6 minutes due to limited class time) and videotaped. Finally, the presentations include a demonstration of the major elements of the site. Since the presentations are completed at least one week prior to the final submissions, many teams are able to get peer feedback and ideas for the additional features that can help improve the site for the client and target users.

Team and Individual Evaluations

Once the project has been completed, students must document their experiences in a team evaluation report and confidential individual evaluations. The team evaluation includes a discussion of each student's contribution to the project and team, individual and combined lessons learned, value added through the additional features, possible future improvements, and remaining implementation activities discussed with their client. The final set of usability tests and their analysis, along with the final client evaluation are also included. The individual evaluation allows each student to share confidential comments regarding the team interaction and contributions by teammates.

Conclusion

Based upon the written evaluations included with the final documentation package, students find this project to be the most valuable learning experience of the course. Every semester that this methodology has been employed, students have been sought after for their web development experiences, often times by the web clients from the semester project. In a few cases, the clients have recommended to others that they volunteer to serve as clients for subsequent semesters. Accordingly, this project serves as a mechanism for bridging business and academe.

Abstract Currently, the most common interaction with the Web is visual and accomplished using a keyboard or mouse. While sound files can be incorporated as part of the presentation, the user cannot interact with a Web page using speech. This orientation limits the mobility of the user and his interaction with the Web because both hands and eyes must be involved in the task. The use of speech recognition and synthesis will remove this limitation and promises to be the next wave in Web interfaces. Speech technology will promote an increased use of the Web in, as yet, untapped environments in a similar way that cell telephones have promoted an increased use of telephones. One limitation to the development of voice systems is the lack of easy-to-use tools for creating spoken dialogue systems, particularly by non-experts who have no experience with or desire to learn the low level details of speech technology. A promising emerging technology for solving this problem is VoiceXML. VoiceXML is an XML-based markup language that brings the Web and content delivery together in voice response applications in an easy-to-use manner. This paper presents an editor for creating VoiceXML documents and narrates the research behind the tool.

Introduction

Currently, the most common interaction with the Web is visual and accomplished through the use of the keyboard or mouse. While sound files can be incorporated as part of the presentation, the user cannot interact with a Web page using speech. This orientation limits the mobility of the user and his interaction with the Web because both hands and eyes must be involved in the task. In fact, most pervasive computing devices today are used in a hands and eyes busy mode. The use of speech recognition and synthesis will remove this limitation and promises to be the next wave in Web interfaces. The use of speech recognition frees the user from the windows, icons, menus and pointers (WIMP) interface. It will enable the user to interact with the Web in a hands-free or mobility required manner (e.g., while traveling in the car) with no manual intervention [1,3,7]. Speech technology will promote an increased use of the Web in, as yet, untapped environments in a similar way that cell telephones have promoted the increased use of telephones.

Currently most of the speech interfaces are similar to telephone response systems in which the user is expected to enter a preset number from a menu of choices. While these systems are commonly used today, these systems have been viewed as limited because the user must remember the mapping to keys, there may not be an appropriate option, and navigation must proceed through a prescribed set of options, even if the user knows exactly what he wishes to do [1].

A review of the recent literature indicates that researchers are working diligently to understand speech interaction and when its use is most successful. Several recent articles have reported on studies of

the voice interaction of humans with computers and how to make speech interfaces more conversational and adaptive than voice response systems [1,2,4]. In one of these articles, Schneiderman concluded that an understanding of the cognitive processes utilized in speech will aid interface designers in integrating speech in a more effective manner. Schneiderman also indicated that future uses of speech in Web environments will not be as standalone components, but as complements to visual interfaces as part of a multimodal interface [6].

One of the current limitations in developing voice systems is the lack of easy-to-use tools for creating spoken dialogue systems, particularly by non-experts who have no experience with or desire to learn the low level details of speech technology [2,3,6,7]. This lack of tools inhibits the development of applications and the portability of existing applications. It also results in a scarcity of skilled application developers and high costs of development and deployment [3].

One of the most promising emerging technologies for solving this problem is VoiceXML (Voice eXtensible Markup Language). VoiceXML is an XML-based markup language that brings the Web, content delivery and voice response applications together in an easy-to-use manner. XML is a specification for designing markup languages that are used on the Web. It is a metalanguage that is an accepted standard for providing structure to Web documents.

XML documents consist of data and markup components (e.g., element tags, processing instructions, data elements, comments, etc.) that are parsed and interpreted by an XML processor (such as a Web browser). Each component of an XML document (e.g., page, image, audio clip) is stored independently from the document. SMIL (Streaming Media Integration Language) and VoiceXML are just two of many XML vocabularies that have been developed. Currently, there are a limited number of browsers that support XML documents, but both Netscape and Internet Explorer have committed to supporting XML 1.0 [5]

VoiceXML was released in March 2000 and accepted in May 2000 by the World Wide Web Consortium (W3C) as a basis for developing a dialogue markup language for voice [8]. Basing VoiceXML on the existing standards of XML (eXtensible Markup Language) has the benefits of allowing the re-use and re-tooling of existing tools for creating, transforming and parsing XML documents. Several vendors including IBM and Motorola have implemented versions of VoiceXML 1.0 [8].

The purpose of this paper is to describe the a prototype for an easy-to-use editor for creating VoiceXML documents that is called *VoiceXML Builder*. Such an editor allows novice users, as well as experienced ones, to create or edit Web-based speech systems easily. The objectives of the project to develop *VoiceXML Builder* included (1) determining the attributes of an effective voice interaction interface, (2) identifying the components that are needed in an editor for developing VoiceXML applications, (3) designing an interface and supporting system for a VoiceXML editor that incorporates the components identified in objective two, (4) developing a prototype editor, and (5) testing the effectiveness of the editor in creating VoiceXML applications.

Voice XML Builder—the Editor

In developing *Voice XML Builder*, an editor for VoiceXML applications, the first step was to determine the attributes of an effective voice interaction interface. Current voice response system dialogues represent paths through a decision tree. An investigation of approaches to the representation of a voice dialogue in the development environment was conducted. Because the editor interface is visual, a review of the literature on the development of graphical user interfaces was also conducted in this step. Since VoiceXML

dialogues are not visual, the usual procedure used in developing graphical user interfaces by laying objects out in a window as they would appear in the interface was not deemed to be appropriate

The next step was to identify the components that were needed in an editor for voice applications using VoiceXML. During this phase of the project, a review of the VoiceXML syntax and existing language editors, were conducted to decide what support was required in an editor for creating VoiceXML applications.

Standard systems analysis and design methods and tools were used to design the interface and the software components of the editor. The design approach was object-oriented so that components could be easily modified and new features easily added to the system at a future date.

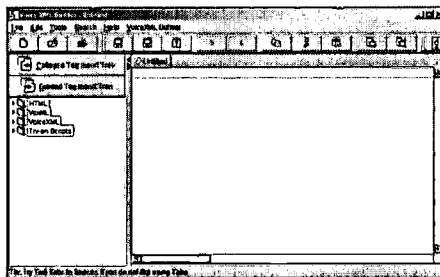
The resulting interface has some attributes that are typical of many language editors. It contains a text area for entering and displaying code as well as a toolbar for performing standard tasks such as opening and saving files, copying and pasting segments of text, and searching for text. The editor also includes a toolbar button for getting help. The basic interface is shown in Figure 1 below, and some of the editing features are illustrated in Figure 2.


Figure 1
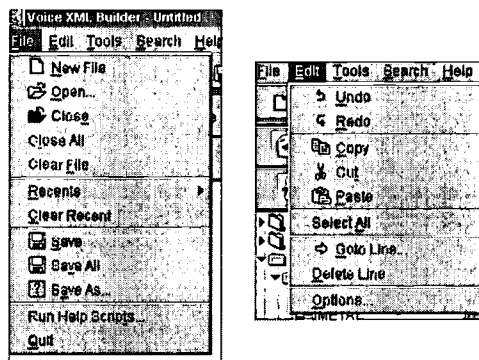
Interface


Figure 2
Editor functions

There are several unique features of the editor. First, the left side of the editor interface (see Figure 4) contains a list of elements that can be used in creating a VoiceXML application. By clicking on a selection from this list a template of that item is automatically inserted into the code in the window. A partial list of the element choices is shown in Figure 3.
Figure 3
VoiceXML element templates

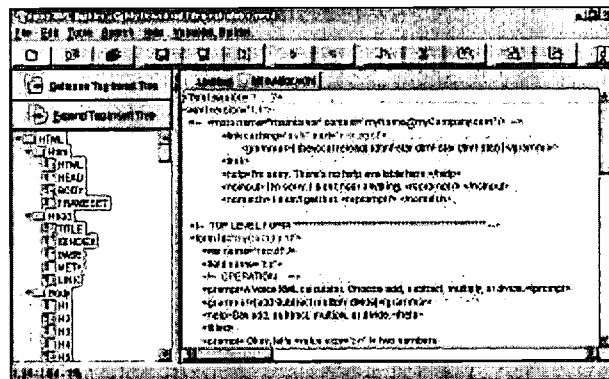
Second, the key words in the VoiceXML syntax are highlighted in different colors to illustrate what types of constructs they are. For example, tags are highlighted in blue and variable names are highlighted in red. Figure 4 illustrates this feature.


Figure 4
Editor features

The Options selection from the Edit selection on the main toolbar allows you to change the colors that are used to highlight the different code components. The Options selection contains multiple tabs for altering

general features of the editor as well as colors, filters, and styles. The muli-tabbed dialogue box is shown in Figure 5.
Figure 5
Modifying editor features

In addition to supporting the development of VoiceXML applications, *Voice XML Builder* supports the development of VoxML (Motorola's XML vocabulary) applications and HTML applications as well. VoxML is the Motorola version of a markup language for describing voice interactions.

The language used for developing the VoiceXML editor was Java since it is portable and readily supports the development of an object-oriented system. The current version of the editor is a Java application. The editor was developed and tested using a personal computer, although the code was developed using the JDK1.3 (Java Development Kit) which makes it possible to develop and execute the editor on any platform that has JDK1.3.

Several small applications were identified for development in VoiceXML and created using the editor. For each, a list of predicted behaviors and outcomes was manually generated. Since the current versions of Netscape and Internet Explorer do not support VoiceXML applications, each application was tested within a specially designed VoiceXML enabled browser. For each program, the execution behavior was matched to the predicted outcome. A sample program is shown in Figure 6.

```
<?xml version="1.0"?>
<vxml version="1.0">
        <form>
   <block>Hello World!</block>
   </form>
</vxml>
```

Figure 6
Sample Program

Summary

As Web-based voice applications become more common in our homes, offices, and vehicles, the need for tools for developing those applications will become more acute. *Voice XML Builder*, an editor for the creation and modification of VoiceXML applications that is described in this paper, was designed and developed to help meet the need for software tools to assist in the development of voice applications for the Web.

Humans are not able to cope with the exponential growth of information and the increasing speed of information and business processes fostered by information and communication technologies. Technical support not only for information storage and retrieval but also for information selection, process planning, and decision support is needed. Moreover, the use of a (desktop) computer is restricted in many ways. In this paper, it is predicted that smart and mobile computing units embedded in a variety of things, such as TV sets and cars, will bring computing power close to their users. It is also predicted that users will get closer to computing power by using natural language and by using their social skills in computer mediated communication. A holistic architecture of knowledge robots (knowbots) is described based on multi-agent platforms and distributed computational intelligence. Knowbots consist of a self-learning artificial brain, speech recognition and synthesis, direct access to other software agents and computer programs, and direct connections to networks of human users. It is pointed out that a newly defined partnership between men and machine is a possible way to keep control of the exploding 'infoverse'.

Reasoning and simulation mechanisms of currently unthinkable complexity will take over the control of process planning and information exchange. Fourth generation robots with the capability of performing more than 30 million instructions per seconds (MIPS) will be the heart of a company's knowledge base. This is the vision propagated by Hans Moravec, Principal Research Scientist at the Robotics Institute and Director of the Mobile Robot Laboratory of Carnegie Mellon University, Pittsburgh (USA).

The global economy gets accustomed to the idea of the 'new economy' where the knowledge workers' creativity and skills are the companies' most important capital and competitive advantage. If only parts of Moravec's vision come true, however, it will certainly mean that the relevance of human expertise and experience will diminish. Current developments seem to support this point of view: A supplier of computer storage systems reports that especially banks are consuming more storage space within six months than has been used during the last twenty years; the increasing speed of product innovation and life cycles depreciate technological knowledge and skills within one to three years.

The 'infoverse' stored in the worldwide Internet starts to exceed the amount of information that has been stored in more than 60,000 years of human culture before: It has been estimated that in the years 1972 to 1980 more information has been collected than in the 2000 years before. Fifty years after the publication of the first Gutenberg bible about two million books had been published; today, more than 3000 books are published per day, more than one million per year. Some authors, therefore, are discussing the advent of the 'age of knowledge'. Others, however, argue that the Internet is not more than a gigantic heap of information garbage.

Recent studies show that we are not able to remember more than one to two percent of all the information we perceive in the mass media, such as radio, TV, or newspapers. A single search engine covers not more than about twenty to thirty percent of the World Wide Web pages, meta-search services using more than one search engine comprise about fifty to sixty percent of the WWW pages. Even the best text searching and indexing techniques do not come up with more than 25 percent of relevant links or search results, that is, an optimal search process accesses a quarter of a half of the information in the Internet - and one or two percent of this information can be remembered. Thus, we have to state that we have lost control over all the information gathered in technical systems.

Exponential growth of information, information access at light speed and the increasing speed of business processes and the decreasing value of human knowledge force to re-focus the development of information and communication technologies (ICT). Information accessibility is no longer the main concern, but navigation, orientation and selection of relevant information. As computers and robots provide us with incredible capabilities to process increasing amounts of data within decreasing periods of

time, it seems clear that we can only master the self-made 'information overload' if we manage to enhance our skills by developing a real computer-man dialogue and partnership.

The key topics of this new level of CMC (computer-man communication) is a mobile, ubiquitous and selective information access enabled by smart software agents based on multi-agent platforms using distributed computational intelligence. We are now at a turning point in our cultural development where sustainable progresses can only be made if we are able to delegate information retrieval, process planning and decision support to technical systems. We have to decide whether we want to become garbage collectors within heaps of information - or the human masters of smart agent systems which we do not fully understand.

If it works, it's not AI

Up to now, the progresses of the so-called Artificial Intelligence (AI) have been disappointing. A recent study about the commercial success of AI startup companies comes to the conclusion: 'If it works, it's not AI'. This assumption has been reflected in the revenues of AI corporations during the last decades (cf. figure 1). The strong position of AI is to develop machines that are intelligent in a human way. The weak position of AI is to implement programs that can be viewed as 'partly intelligent' because they are able to perform actions that used to be dedicated to human workers. This mode of AI is now referred to as 'Computational Intelligence' (CI). Patricia Churchland pointed out that we are at a stage where the strong AI position tries to mimic human intelligence in the same way the first pioneers of flight tried to mimic the birds' way of flying. As no modern airplane or helicopter is flapping its wings, it is clear that solutions enabling flight are not relying on flapping wings but on a proper lift. So, what might be a way to lift the weak position of AI to a higher level?
Figure 1: Approximate AI revenues (Philipps, MIT, 1999).

In 1998, the non-profit association 'Institute of New Media' and Bank Academy, a non-profit educational institution of the German bank associations, formed a joint venture to implement and test new ways of autonomous software agents which could help learners and knowledge workers in information intensive industries, such as banking and finance. At the beginning of the year 2000, Knowbotic Systems Inc. Ltd. was founded by the Institute and the Bank Academy. The purpose of this company is to develop and to examine knowledge robots or 'knowbots' which help to fully exploit the knowledge capital of a company by facilitating information selection, planning and decision making. The mission of Knowbotic Systems relies on two basic assumptions: (1) As long as key concepts, such as 'learning' and 'intelligence', are not fully understood and clearly defined, computers won't be intelligent learners. Therefore, a formal learning theory has to be deduced from recent theories and empirical studies in order to set up a virtual testing environment for knowbots which helps to measure their adaptability and to extend their learning capabilities. (2) The critical lift of CI will not come if a system is intelligent in itself, but it comes from the human capability to communicate with such a system in a intelligent and social way. Thus, knowbots have to mimic intelligent communication behavior in order to transfer the results of machine learning and machine reasoning to human users (cf. figure 2).
Figure 2: Knowledge robots (knowbots) are bridging the gap between technical information and data collections (right) by using artificial brains (RNN), ears and voice (AVOICE) and connecting information (AGENT) and people (SMIS) based on the multi-agent platform FATE.

The artificial brain

Most programs which mimic intelligent behavior are based on logical oriented knowledge-based techniques which proved to be too inflexible to represent even primitive forms of learning. Moreover, they elicit a number of paradox behavior when applied to support human learning. In classical AI different forms of logical based representational schemes are used and in connectionism researchers adhere to different types of artificial neural networks (ANN). ANNs have achieved some success in non-linear forecasting, pattern matching and in artificial life paradigms. But ANNs still lack many of the vital features of biological neural networks (BNN), such as the ability of real neurons to allow self-modification with regard to short term and long term learning. The simulation of BNNs developed by neurobiologists does not seem to be promising either because recent attempts have shown that exact simulations of neuron brain cells consume a vast amount of computer resources. For instance, 18 hours of computing time on five connected Sun Sparc workstations is needed to simulate one second of the activity of a single neuron.

Knowbotic Systems combines the behavioral perspective with the physiological perspective, both embedded in concepts of learning and sign based communications (or Semiotics). We call these self learning and sign-using systems 'knowbots'. The physiological structure is the main cause for observable behavior. Thus, we have to find a model of the human brain neuron which should be empirically more sound than the classical ANNs and should also be still practically feasible on 'ordinary' PCs. Knowbotic Systems' RealNeurons® almost perfectly simulate human brain cells with respect to the height of the potentials, the timing of the processes and the concentrations of chemical substances involved. Moreover, our neural networks can model the local and global influence of hormones and psycho-pharmaceutics on brain cells. We are modeling only those properties of biological cells which are most likely underlying learning of new behavior patterns.

Only a few BNNs underlying learning, however, have been identified yet. As a first test case we have chosen a classical conditioning circuit and several candidates that might be responsible for operant conditioning. In first experiments we implemented the network which represents the eye blink reflex of a rabbit. The network matches the neuropsychological data almost perfectly (cf. figure 3): The connection of the unconditioned stimulus (US = air flow) and the conditioned stimulus (CS = sound) is learned in a few trials, if the CS is given slightly before the US. Several runs presenting the CS without the US extinguish the connection. It is re-established very quickly, if the CS and the US are displayed together

again. This means, that not only the neuro-biological structure of brain cells can be simulated on a PC, but also basic learning behavior which perfectly matches empirical data.
Figure 3: Test environment for (classical and operant) conditioning experiments with Knowbots based on artificial biological neural networks implemented with Java.

The artificial body

The artificial brain cannot communicate to humans and environments without a body. Robotics' research has shown that intelligent or adaptive behavior is based on a close interaction with the outside world. Moreover, the measure of learning or intelligence clearly depends on observable behavior corresponding to well defined learning tasks and environments. Knowbotic Systems, therefore, concentrates its technical developments on interface technologies which facilitate the access to knowbots by human users. The most important way to communication is speech. Knowbots are equipped with the speech recognition and synthesis system *AVOICE*. The speaker independent speech recognition is able to identify about fifty words in five different languages at a time. As the word recognition can be adapted according to the actual context, this small amount of words is sufficient to implement small navigational or command systems. The speech recognition unit may also be trained to understand a specific user and it is then capable to handle dictionaries of several hundreds or thousands of words. The speech synthesis can read any text, such as HTML pages, tables or documents. The user can choose between several 'speakers' with different pronunciation or intonation. In summary, AVOICE equips knowbots with a - still limited - human ear and voice. Knowbots, therefore, connect their users directly to all the information stored in the Internet, regardless whether they hook onto the Internet via a computer, a telephone, or a mobile phone.

Knowbots can also move around in the Internet, access data bases and organize their user dialogues. This is done by *AGENT*, an intelligent search agent and dialogue manager. The search agent is able to act as a search robot and a crawler in the World Wide Web. It can also get access to data bases or transform graphical information into text information. Thus, AGENT provides knowbots with a variety of ways to 'perceive' the virtual infoverse of the Internet.

The artificial environment

Up to now, there is much more talking about the irreplaceable value of the human capital and knowledge than taking actions to maintain and support the development of this capital. Most technical systems concerning the human capital of a company focus on the administration of personnel and training, such as SAP Human Resource modules, Peoplesoft or SABA - just to mention a view of them. An US-American study lists about 300 systems for training administration and delivery. But finding matches of needs and

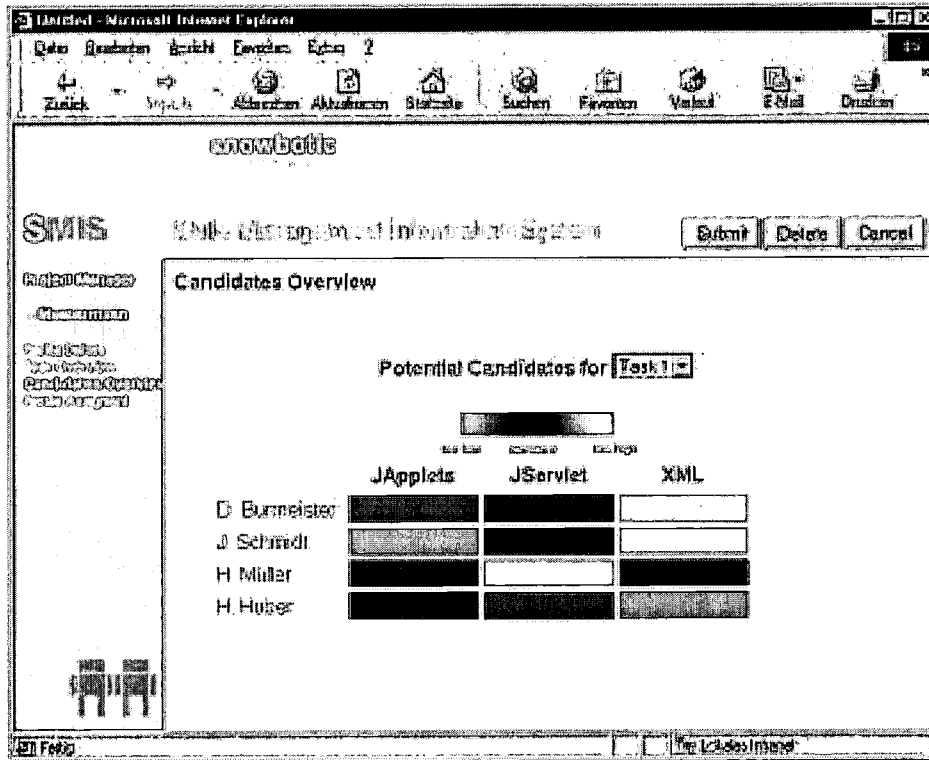
demands in the infoverse certainly means more than matching keywords to indices or user profiles to software agents. The knowledge economy is not so much about information, it is about people. Knowbotic System is, therefore, engaged in a jointly initiative of several partners to implement a Skills Management Information System called 'SMIS'.


Figure 4: Screen shot from the Skills Management Information System 'SMIS' - the candidates overview lists possible candidates for a project tasks in acolored table indicating skills below or above the standard.

Human users, the users of information systems, visitors and creators of the infoverse, are the main 'component' of a knowbot's environment. Additionally, other knowbots or standardized software agents may also enrich the knowbot environment. For this purpose, Knowbotic Systems has developed one of three worldwide available multi-agent platforms based on the FIPA standard (FIPA = Foundation of Intelligent Physical Agents). The platform *FATE* (FIPA Agent Template) comprises templates or suits which allow programmers to convert nearly any computer program into a software agent, that is, the knowbot technology provides easy-to-use ways to introduce a large variety of programs into the virtual learning environment. FATE also allows to run several platforms on different Web sites. This enables knowbots and other agents to communicate, move or replicate themselves all over the World Wide Web.

The (artificial) future
We envision future developments in networked computing and distributed computational intelligence where the users are no longer forced to adapt to the computer. The computers will adapt to the human capabilities to perceive and process data. The communication between and with computers will adapt to the human way of communication, namely natural language. And computers will be accessible at any time from any point with any device, such as handhelds, laptops, or mobile phones. Computer networks will also become people networks, taking into account specific deficits and potentials of computers and humans.

Knowbots are one of the few holistic visions of a man-machine dialogue in its actual sense, dedicated to support humans where they need help to access and select information - and to learn from

them. But knowbots are not the only development in this field. A new level of smart agents and self-learning machines will develop in the near future. Figure 5 summarizes some major developments which are expected in the near future. Among them are software agents, mobile computing, and speech control. But, most of the forecasts of technological growth and development turned out to be too conservative.

2004	2005	2006	2007	2008	2009	2010
Ubiquitous online learning in universities	Online learning in schools (K12) Interactive communities in the WWW Increasing use of eCommerce	Software agents to search and select information Interactive TV for big audiences	Increasing use of speech recognition and synthesis Central remote control station for 'intelligent buildings'	Increasing use of electronic cash Broadband access to information	Mobile computing and eCommerce	Self-learning software agents 3D virtual reality

Figure 5: Some major developments in interactive media in the next ten years according to a recent study of the Fraunhofer Gesellschaft (Institut für Systemtechnik & Innovationsforschung).

Up to now, many individuals and companies are fascinated by the potentials and the exponential growth of the Internet. We do not think that future generations will be too enthusiastic about slow networks, unstructured information heaps and poorly equipped online shopping malls. Smart computers will be part of our every-day life, will be part of houses, cars, TV sets, refrigerators, bags, and suits. As a matter of fact, many ordinary machines are based on so-called embedded systems, that is, a small specialized computer. So, the things start to become computational things - and they will be smart things in the future. Knowbots and other smart agent technologies will support work, leisure and even cultural or social entertainment. Computers in the form of smart things will make computational intelligence as ordinary as cars or TV sets. But if the computers get nearer to their users, at the same pace the humans will get nearer to the computers: Not individual human beings nor software agent platforms will be the masters of the infoverse, but partnerships of robots, knowbots, and humans.

The Use of QUEST-based Multimedia Units as a Supplemental Inservice

Ralph M. Hausman, Ph.D.
Special Education
University of Texas at Brownsville
United States
rhausman@utb1.utb.edu

Abstract: Alternatives for inservice training need to be developed to accommodate ongoing certification renewals and legislative actions requiring inservice for regular teachers new to inclusive classes. This session will demonstrate the feasibility of stand-alone multimedia that can be designed to fit a local school system's specific inservice/instructional training needs while enhancing participant's long-term learning.

In the state of Texas, all new certificates issued since 1999 require continuous inservice training for renewal. Thus far, this inservice has been provided by a combination of regional Education Service Center inservice offerings, in-house training, professional conferences, and course offerings in regional institutions of higher education (IHEs). As the number of new teachers grows and new legislation is enacted requiring additional inservice for those regular class teachers new to the inclusive environment, the current options for the inservice needed will not be sufficient.

New technology and its accompanying software now permits effective internet-based instruction using hypermedia learning environments in synchronous or asynchronous format (e.g., Fitzgerald & Semrau 1997; Spooner, et al. 1998). For the past three years, I have been developing multimedia modules combined with live videoconferencing, chat room and discussion board use within a distance training program specifically designed to develop bilingual educational diagnosticians in rural settings along the Texas/Mexico border corridor, i.e., Project DEED, Distance Education for Educational Diagnosticians (Hausman, 2000; Hausman et al. 2000). The multimedia modules have also been incorporated within my on-campus classes for the past two years, with excellent results.

Interactive, multimedia modules can provide a flexible, efficient, linear as well as nonlinear and associative learning environment useful for a wide range of learners. Current multimedia production software programs, e.g., Authorware, QUEST, Director, also permit the development of stand-alone multimedia customizable for specific systems' as well as individual learner's needs that can be provided via CD-ROMs. There is an emerging variety of formats that permit selection of approach a learner may prefer, e.g., case-analysis based, linear/directive/factual approach, etc.

Although hypermedia may not be suitable for all learners (Liu 1994), it would appear that this approach, designed for inservice rather than preservice training, may prove an excellent addition or supplement to the other approaches already in place to provide the needed inservice training required by IDEA (1990, 1997) as well as by recent state legislation. This approach would also seem to be particularly useful to Special Education Directors in that a library of multimedia CD-ROMs would be easily organized and distributed as needed. In addition, multimedia modules can be designed and constructed to cover specific topics targeted by the program directors.

A further advantage associated with a modular approach involves the record keeping system that is feasible. These modules should be made interactive in nature, hence, any and all responses by the user to the program (even the time taken between responses) may be stored in a separate file under the user's name or identification number for later print-out or forwarded to the Director's or personnel office for printing/analysis. The resulting hardcopy could then serve as documentation of the successful completion of a unit, the time taken to complete the unit, and/or an individual's need for additional training in specific areas.

The approach I have been using to produce the modules for Project DEED has been based on use of the QUEST software, a multimedia production utilities program developed by Mentergy (formerly Allen Communications) of Salt Lake City, Utah. This software program, once mastered, allows the production of multimedia modules that are far more interactive than, for example, PowerPoint. Any media can be used within QUEST, e.g., text, illustrations, graphics, graphics animation, audio/visual stimuli (still, animated, or video clips), etc. The product is limited only by one's own skill with the software and one's imagination.

My students enjoy the use of colorful, highlighted points for emphasis, with clean, clear concepts highly illustrated (where feasible), accompanied by descriptive text blocks (for those preferring visual content to auditory input), using movement to attract attention. Some prefer 'cut and dry,' factual statements, others prefer some type of hands-on activity to accompany the presentation, while there are those (myself included) who enjoy adding a story-telling approach or element to the modules, thus providing room for structure as well as individual flexibility. Through the use of extensive menus and submenus, those who enjoy a linear approach to a topic may progress through 'frame by frame,' while others may wish to jump around to subtopics of primary interest to them, and still others may wish to initiate a project of study with an orienting pre/post test. All of these types of learners can be accommodated within a well-designed QUEST based module.

The 'released' version of the completed module is a 'stand-alone' unit that can be burned on a CD-ROM for use in any IBM compatible computer, without the need for additional resident software. Module updating simply requires insertion of new information in the master copy and re-releasing the unit ... a "MUST" to accommodate all of the litigation-mandated changes in our field, i.e., special education.

Thus far, the modules have proven effective for direct, facilitated instruction (e.g., accompanied by a lecturer providing elaboration of the points made), for follow-up review by an individual or small group of an instructional unit (particularly useful when professional activities, etc., interfere with one's training attendance schedule), and for independent study/learning. The modules are particularly effective when requiring the user's interaction ... with the actual module activities and/or with small groups of other learners. The modular units may also be accompanied by a variety of "touch-feel" materials, including extensive workbooks illustrated with line drawings to be colored (i.e., using map colors) by the users as well as activities that require tactile and kinesthetic experiences. The combination of a wide variety of sensory systems permits simultaneous as well as sequential access to ever widening neural pathways, hence, should enhance acquisition of content, retention, and recall.

Abstract: This paper includes a summary of what has been learned about synchronous distance education combined with multimedia modules during a four-year, federally funded project. The project, i.e., Project DEED – Distance Education for Educational Diagnosticians, provided specialty training to bilingual students in 8 different rural sites along the Texas-Mexico border corridor.

Introduction

Documented over-representation of minority pupils in special education classes has lead to advocating for special education programming that is sensitive to the needs of children who are culturally and linguistically diverse (e.g., Baca & Cervantes, 1997). Factors that have exacerbated this problem include bilingual/bicultural differences of Hispanic children from their mainstream cohorts (e.g., Cummins, 1984), lack of bilingual and/or Hispanic educational professionals (e.g., Brown & Minke, 1986), generally high attrition rates for minorities in undergraduate and graduate education programs (Howard, Pion, Gottfresson, Flattau, Oskamp, Pfafflin, Bray, & Burstein, 1986), and lack of adequate bilingual programming for handicapped Hispanic children (Baca & Cervantes, 1997).

The situation can only worsen as the population of minority pupils in our schools continues to increase and as significant shortages of qualified personnel in all areas of special education also continue. Indeed, the classification of "diagnostic staff" has continued to rank among the highest 5 areas of greatest need in the past few years (e.g., U.S. Department of Education, 1996; Texas Education Agency, 1999).

Texas, a state with a diverse population and economy is the second largest state in the U.S. and has the second largest Hispanic population (19%) in the nation. At its southern limit, Mexico borders nearly nine hundred miles. An area extending approximately 50 to 75 miles north of the border and along its length is referred to as the "border corridor," the area targeted for service within Project DEED, Distance Education for Educational Diagnosticians. According to the Texas Education Agency, enrollment in public schools totaled 3,748,167 students; 46.4% of whom were White (not of Hispanic origin), 36.7% were Hispanic, 14.3% were

African American, 2.3% were Asian, and 0.3% were Native American. Thus, minorities comprised 53.6% of the student population in Texas public schools with Hispanics as the largest minority group. Indeed, the state's youngest and largest population is Hispanic. Of the total number of students, 12.1% have been identified as eligible for one or more special education services, most of whom are included within the regular education program. Unfortunately, only 10.2% of the educational diagnosticians are Hispanic, many of whom are essentially monolingual in English.

Along the lower "Border Corridor," few institutions of higher education (IHE) are available to the majority of school personnel in this area, particularly practicing teachers interested in obtaining graduate training. In fact, most of the rural communities along the mid- to lower Border Corridor are from 60 to 140 miles distant from any IHE offering special education courses. As this point in time, only two universities, both located within the lower Rio Grande Valley area at the tip of Texas, provide educational diagnostician/special education training thus leaving several hundred miles along the border unserved.

Recent area needs assessments have indicated a significant and long-lasting need for bilingual special education teachers as well as educational diagnosticians. In addition, there is a strong need for in-service training of regular classroom teachers focusing on dealing with children with disabilities that are included in the regular classroom setting. The same needs assessments also reveal a heavy reliance on partially-trained individuals with temporary permits in critical special education areas, permits that often prove difficult to maintain due to the paucity of geographically available IHEs. Project DEED was originally designed to help offset this lack of training programs by extending our local educational diagnostician's training program to eight distal site bases. Multimedia modules were constructed with traditional local learning styles in mind to further enhance the effectiveness of the distance learning program.

Distance learning or education, alone, can no longer be considered truly "unique" as some form of delivering university-level courses, e.g., home study, correspondence study, independent study or external studies, have been in effect for almost 300 years (Spooner, Spooner, Algozzine & Jordan, 1998). Yet, electronic distance education remains an essentially untapped resource. Due to the competitive nature of IHE funding within the state of Texas combined with local budgetary limitations, funding for this project was obtained from the U.S. Department of Education's Office of Special Education Programs (OSEP). Essentially, the purpose of the project was to demonstrate the feasibility of using currently available, relatively inexpensive resources to develop quality educational offerings targeted to the learning styles of a specific population, i.e., bilingual, primarily Hispanic graduate students along the Texas-Mexico border corridor.

Project DEED, centered at the University of Texas at Brownsville & Texas Southmost College (UTB-TSC), involves internet-based videoconferencing in combination with computer-based, multimedia learning modules, supplemented by CD-ROM based independent study units, field supervised/individually mentored practica and two campus-based summer training institutes.

The intent of this paper is to share the experiences obtained as a result of the development and implementation of our project. We are currently in our fourth, final, year of funding. The course-based portion of the project will conclude with the completion of a final field-based practicum in the summer of 2002. Also in the summer of 2002, members of the cohort, i.e., consisting of 20 bilingual, certified and practicing teachers located in 8 distal sites, will be required to successfully complete both a written comprehensive master's examination and the state required ExCET examination to obtain their educational diagnostician certificates.

Development of an Idea

This project was feasible only because of the availability of T-1 fiber optic linkages that have been extended to all the Texas school systems in recent years as well as access to the internet. Further, availability of serviceable audio/visual conferencing systems, e.g., CUSeeMe (White Pine Software) and Microsoft NetMeeting, inexpensive videocameras, e.g., QuickCam VC (Logitech) and 3ComCameras, as well as user-friendly multimedia production utilities programs, e.g., QUEST (Allen Communications, 1995, now Mentergy, Inc.), made it feasible to offer a highly interactive instructional program.

Research on learning styles (e.g., Griggs & Dunn, 1995) supported the concept that the dominant Hispanic culture have learning preference patterns that are relatively unique to their traditional culture. This seemed to strongly suggest the need to address the differential patterns, e.g., including both face-to-face instructional approach (i.e., live videoconferencing as opposed to primarily text-based instruction typical of web-based courses) as well as interactive, visually stimulating materials (i.e., multimedia modules).

The QUEST utilities program was selected as it permits nonprogrammers to combine all available media (by way of preprogrammed instructions) with minimal "computer specialty skills" and produce stand-alone, interactive multimedia modular units. These modular units can be distributed directly via the internet (with participant/student responses recorded on the sender server) when constructed in HTML format, via a campus-based File Transfer Protocol (FTP) compatible server (thus permitting students to download modules directly to their own computers as do our cohort members), and, when confidentiality is required by high-security modules focusing on the contents and use of specific diagnostic tests, via CD-ROMs delivered by mail.

When the grant proposal was originally developed, the CUSeeMe freeware was the videoconference system of choice. Unfortunately, by the time funding was obtained, it had been commercialized as White Pine's ClassPoint/MeetingPoint videoconferencing system. As it was still the least expensive and most efficient system available (of the 16 other systems investigated), we remained with the selection, purchasing a 10 site, 2 instructor site "bundle."

What we've learned thus far.

Internet Videoconferencing

The use of videoconferencing permits real-time voice communication with acceptable, though slower, video. The effects of videoconferencing have, according to the cohort members, reduced the feelings of isolation and separateness from others in the project so often reported in the literature. Provision of the professor's interactive "telepresence" also seems to appeal to the traditional conceptualization of formal instruction and respect for authority associated with traditional Hispanic students. Being able to call students by name, equally directing questions to the entire cohort and providing positive feedback and encouragement have reduced the typical effects of distance learning, e.g., a tendency to be distracted from a "talking head" or passivity.

The videoconference system in use, i.e., CUSeeMe ClassPoint/MeetingPoint, was initially difficult to implement, even with the additional support service purchased. Part of the difficulty was that ClassPoint does not work well with NAT (Network Address Translation) or firewalls. Since our 8 different distal sites are served by several different commercial internet service providers, a variety of different approaches were taken to work around the NAT incompatibility. For the firewall problem, the computers at each of the different distal sites had to be issued static IP numbers and various switches and routers were reconfigured by the internet service providers to create portals in the different firewall programs; as a result, these specific computers are allowed to connect to our server only. This arrangement has restricted some of the instructional activities, e.g., we cannot visit other URLs during class for illustrative purposes as was intended. An additional difficulty experienced early in the program focused on the fact that available equipment as well as individual computer skill varied tremendously from site to site as well as among the cohort members. All too often the equipment at the distal sites are used by a variety of other individuals (e.g., faculty, staff and students); software is often added (which takes up excessive system resources causing CUSeeMe to crash) or deleted (requiring reinstallation before that site can join the next class) and, in one case, a camera was lost. Anyone wishing to replicate this approach would be well advised to consider using the same type of equipment, ideally dedicated to this project, throughout the sites as well as provide structured training on the use of equipment and videoconferencing software for students, faculty and staff prior to the initial class.

Internet reliability remains yet another limiting factor that continues to be addressed by the UTB/TSC campus Academic Computing staff as well as the regional internet service providers and the technology staff located at each of the remote sites. Unfortunately, this will probably continue in the foreseeable future in that

the internet's complexity continues to evolve. Then, too, there are the occasional 'glitches' due to unforeseen and unavoidable environmental factors such as when a hurricane took out one of our distal site's communication tower.

Once all the connections were finally established, however, CUSeeMe's ClassPoint/MeetingPoint software offered an excellent platform of services including ongoing chat room capabilities for those students preferring to respond in writing. One of the software's major strengths was that it permitted instructor control of the communicative give and take between the students as well as with their professor. It also allowed specific inter-site communication during the 10-minute discussion periods required throughout each three-hour class session. During these topical discussions, two or three differing sites would be connected so that they could both see and hear each other; all the other sites could either mute their own stations or, if they finished the assigned task early, could listen in to the ongoing discussion. To encourage freedom of discussion, the instructor usually turns his sound off while remaining available for response to queries submitted on the chat board. Common sense rules of etiquette did have to be established early in the program so that no one 'stepped on' another's communication. Although certain types of questions did require fuller treatment at a later time via follow-up email, brief manual communication, e.g., waves, thumbs up, etc., have successfully served most of the short communication needs.

Unfortunately, we have recently been informed that the CUSeeMe ClassPoint program has been "retired" as a result of a merger. ClassPoint users have been advised to migrate to CUSeeMe Web 2.0 and CUSeeMe Conference Server 5.0. This new software is Firewall-NAT compliant, so these connection problems should not occur in future.

Eight distal sites are currently in use, all but two of which contain a cohort of 2 to 3 individuals working collaboratively as teams, separate from yet an integral part of the whole cohort of 20 students. One site contains a single cohort member; another, 4 cohort members. While these group patterns have served well, future programs will require a minimum of two and maximum of three individuals at a single site. All of the cohort members have indicated small groups of socially compatible individuals are more conducive to learning. Any opportunities for the cohort members to physically work together, e.g., summer institutes, workshops or conference attendance, should also be encouraged as these activities have strengthened the cohesiveness of our overall cohort.

Multimedia modules

According to the cohort members, the multimedia nature of the QUEST-based programs fit the traditional Hispanic students' preference for structure as well as variety. While a wide variety of structures and appearances have been and continue to be employed depending on the module's content, student responses have dictated a merging of favored styles, backgrounds, and highlight colors into a narrower range. Essentially, light backgrounds with slight 'texture' are preferred to the dark gray initially in use; similarly, consistency in highlight colors has been encouraged (i.e., highly significant concepts and words are in dark blue and red, green and dark orange indicate secondary level significance, etc.). Content organization is encouraged with natural break points occurring on a 20-minute basis; modules that can be covered over a normal three-hour class period are preferred. As interactivity is built into the modules and combined with extensive workbooks and/or hands-on activities for each unit, the reported preference for kinesthetic instructional approaches has also been increasingly addressed.

In compliance with the grant funding, the multimedia instructional modules are being designed for both synchronous and asynchronous presentation. Synchronous delivery is made during a scheduled three-hour session held once each week of a regular semester, with the instructional unit running in parallel with videoconferencing. By adding the speaker's content in audio format while developing each instructional unit and providing a button to access the audio version, each module could also be available via asynchronous presentation for independent coverage and/or later review. Although voice-overlay may be formal, we are discovering that insertion of "captured lecture" (with the instructor covering each frame during an actual class period) has a particular appeal.

The primary problem with module development using the QUEST utilities software is that it is time-consuming. Although the utilities program is basically preprogrammed, the addition of detail such as 'drag-and-drop' activities, pop-ups, animations, and selecting choices, all needed for interactivity, require an extensive time commitment. As with most activities, he process does become easier and quicker with experience, particularly as one develops their own unique modular templates. While the modules produced are easily updated, they have to be re-released or issued following any changes made to the master copy. For a truly useful and interactive module, however, one does have to have a fundamental understanding and mastery of "C" language.

Need for Team Approach

A team approach, involving a majority of our campus technology staff working closely with the project staff and other support personnel is critical to any similar project. Assistance from individuals from several departments on campus, technology staff at each distal site, and those involved in the provision of internet services was required to develop the requisite connectivity among the various computers at their respective sites, installation of new specialty equipment on campus (e.g., expanded memory, RAM as well as hard drive capacity, scanners, video capture cards, etc.), installation of software, etc. Anticipated throughout the project is continued involvement of these specialists in an advisory capacity as troubleshooters whenever the need arises. The Academic Computing department at UTB-TSC has proven extremely supportive and vital in the initiation of this project.

Academic Results

At this point in time, the cohort members are in their final year and are completing their tenth course (out of the 12 required for their master's degree in special education (i.e., educational diagnostics). Four courses (three of which were non-special education classes) out of the 12 required were covered in two summer institutes; of the eight other special education course required, five have been completed online and a sixth course is currently underway. Two additional online classes will be offered as follows: one in the Spring, 2002, semester (focusing on achievement and ability test administration/scoring/interpretation), with a final six-credit-hour practicum scheduled for the first part of the 2002 summer; this course will involve shadowing local diagnosticians under their supervision as well as that of the primary author.

All of the cohort members continue to report the maintenance of high interest levels and, in spite of a variety of personal problems (including the recent death of a spouse), have all been able to complete their course requirements successfully. The grades earned have been predominantly "A"s. With but a single exception, there have been no more than 3 "B"s earned in any single course. Interestingly, the "B"s have usually not been made by the same individuals. The exception, i.e., where grades of "C" were earned by two individuals at separate sites, involved a detail-heavy course (focusing on the visual identification of over 55 syndromes and developmental disabilities) that was taken online over an abbreviated time period, i.e., 45 clock hours over a 10 week period rather than the usual 16 week period. Although this schedule was mutually designed by students and faculty to accommodate a specific situation, it was the consensus of all that more time between was needed to learn the requisite information, particularly since each cohort member was responsible for a full time teaching load. In spite of last Spring's setback, group morale continues to be high and the interactions among the cohorts, within as well as between sites, have continued to be positive.

Conclusion

In spite of the various difficulties thus far encountered, the project has been able to meet its predicted deadlines. Site connectivity has been established to the point that few disruptions in instructional delivery occur. Those that do occur tend to involve hardware problems somewhere along the 'internet highway' or at the individual distal sites. The cohort members, previously with little or no technology skill, have become skilled troubleshooters with the issuance of a "checklist" designed and disseminated by the Project Coordinator. Of course, there is nothing we can do to forestall the occasional hardware problem, e.g. cutting a fiber cable in the state capital, the effects of hurricanes, etc., so we still have the occasional non-connects. To accommodate

same, we continue to make a conference phone connection available. Too, the availability of the multimedia modules to supplement required text reading usually cover content lost due to the occasional inability to connect via the Internet.

In addition to the basic, anticipated accomplishments of the program, three cohort members who are also certified counselors as a result of their involvement in this project have experienced unexpected gains. Specifically, all three have completed the requirements for and have received certification as Special Education Counselors. Several additional cohort members have added the generic special education teacher certification to their personal certification inventories. Still others have been reclassified from classroom instructors to "diagnostic teaching" staff, i.e., they are working in close support with their respective campus diagnosticians, administering achievement tests, scheduling IEP meetings (called ARDs or Admission, Review and Dismissal Committees in the state of Texas), and providing other types of professional assistance.

Abstract: All the data structures previously introduced by different WBT systems were "training oriented" so to speak. Learners can perceive those data structures as different training paradigms reflecting mainly different ways of accessing and working through a subset of learning material. Primitively, a "training oriented" data structure mainly prescribes reading the document "A" before the document "B" and does not reflect a possible situation that "A" may be the documentation of the software module developed in the scope of a software project "B". Nevertheless, users often need a general overview and access to all learning resources provided by a particular WBT system regardless on any training data structure where those learning resources are reused within. The WBT-Master, a novel WBT system, supports such global structure of learning resources in the form of so-called Knowledge Domains.

1. Introduction

From the functional point of view, the term "WBT" refers to systems (Andrews et al., 1995) (Helic et al., 2000) that support at least:
- Authoring and publishing of high quality multi-media courseware
- Repository of learning resources available world-wide and anytime by means of WWW (Berners-Lee et al., 1994)
- Repository containing personal info on peer helpers, on-the-fly contributions of previous users, discussions on interesting topics, etc.
- Support for personal definition of learning goals and variety of learning methods
- Synchronous and asynchronous communication and collaboration among learners and between learners and expert
- Database of previously answered questions to automatically answer similar ones
- Testing of knowledge level
- Customization of courseware to the knowledge level and the cognitive style of the learner
- IPR protection and brokerage of relevant learning services
- Progress tracking and certification as support for assessment and recognition aspects of the acquired skills.

Technically, a WBT system is a system that utilizes a large repository of multi-media (preferably HTML) documents, where information is structured according to a particular hypermedia data model (Cailliau, 1995) (Fernandez et al., 1997) (Helic et al., 2000). The first WBT systems structured information according to the most simple node-link data model utilized by the WWW. Recently, new WBT systems were introduced utilizing more powerful data modeling facilities in order to overcome well-known problems of the basic node-

link data model (Maurer et al., 1996). WBT-Master (Helic et al., 2000) is one of those systems. The WBT-Master utilizes the unified HM-Data Model (Helic et al., 1999) and data structures supported by this model. This model supports data structures, such as Learning Unit, Learning Course, Learning Goal, Discussion Forum (Helic et al., 2000), etc. Such data structures are well-defined chunks of hypermedia information that may be reused in different contexts. Moreover, they provide the satisfactory authoring interface and impose a convenient navigational structure on the top of hypermedia information encapsulated in it. All other information services in WBT systems such as information searching, synchronous and asynchronous communication, collaboration, etc. are implemented as "add on" software packages using often different protocols (Server Site Scripts, Client Site Scripts, Java Applets and Applications, etc) (Helic et al., 2000).

From the user point of view, a WBT system is a system, which supports different user roles according to basic functionality, which is required. Most common definition of user roles in WBT systems my be seen as follows (Helic et al., 2000):

- Learners utilize WBT information services in order to improve their knowledge and skills. They are motivated to use the system services by a particular Learning Goal in mind. In a simplest case, the Learning Goal may be just a wish to pass an examination and to get some credits.
- Tutors manage the learning process on some particular subject. Tutors select an appropriate learning strategy (say, Learning By-Doing, Situation-Oriented Learning, etc) to achieve better learning results. Tutor control learners' progress with the material, offer additional materials and point learners to fellow helpers if necessary, examine learners' knowledge and acquired skills, etc.
- Authors contribute to courseware repository creating and publishing documents, combining the documents into navigable structures (courseware libraries, courses, learning modules, etc.).
  Thus, one of the basic scenarios in WBT systems can be seen as follows:
- Imposing different types of data structures on top of existing collections of Learning Resources, which is done by authors, or looking from the other point of view, as reusing of Learning Resources in different contexts
- Customizing of Learning Resources by tutors to support reuse of Learning Resources in different contexts, as well as to adjust Learning Resources to different learners' preferences and needs
- Working through Learning Resources to achieve a particular Learning Goal, which is done by learners.

However, all the previously discussed data structures were "training oriented" so to speak. Thus, the previously mentioned Learning Unit, Learning Course, Learning Goal, Knowledge Card, etc., can be perceived as different training paradigms reflecting mainly different ways of accessing and working through a subset of learning material by learners. Primitively speaking, a "training oriented" data structure consisting of documents "B" and "C" mainly prescribes reading "B" before reading "C" and has nothing to do with a possible situation that "C" may be documentation on a software module implemented by the programmer "A" for a project "B". Often, users need a general overview and access to all learning resources provided by a particular server.

Let us just discuss the following situation. Suppose a software organization maintains a big repository of software technical documents. Obviously, elements of the repository are valuable Learning Resources and may be reused for training as such or as components of other Learning Resources (say, as members of Learning Units, resources for Learning Goals, contribution to discussion forums, etc.). Moreover, information on people maintaining documents and source codes is also a very valuable Learning Resource that can be reused as references to peer helpers having experience in the subject area. At the same time, localization of a particular Learning Resource (providing it was not previously reused for training) constitutes a rather difficult problem which can be solved only by structuring the repository on meta-level invariantly to any training paradigm. Using the same primitive language as above, we can say that the knowledge: "C" is a technical description of the software module implemented by the programmer "A" for the project "B"; should be kept independently of reusing "C", "B" and "A" for training purposes.

The WBT-Master supports such global structure of learning resources in the form of so-called Knowledge Domains. The rest of this paper describes the main ideas behind the concept of Knowledge Domains, as well as some of the implementation issues.

2. Knowledge Domains

Generally, a knowledge domain is a special hypermedia-structuring paradigm that is based on the concept of separating structure and content.

Each Knowledge Domain is a set of documents belonging to a number of predefined semantic categories. For the previously discussed example, we could speak about three semantic categories: "Author",

"Module" and "Project". We can also say that a document "C" is an instance of the category "Module", document "B" is an instance of the category "Project" and the document "A" is an instance of the category "Author". Speaking in general terms, we can say that each semantic category is linked to a set of learning resources that are called instances of the category.

Further, each Knowledge Domain explicitly defines a number of so-called semantic relationships between the semantic categories contained in this Knowledge Domain. Again, for the previously discussed example we could speak about the following semantic relationships: "Author Modules" is a relationship between the "Author" and "Modules" semantic categories, which denotes that a particular "Author" implemented corresponding "Modules"; "Project Modules" relationship relating the "Project" and the "Module" semantic categories and denoting that a particular "Module" is a part of a certain "Project". Applying the concept of semantic relationships to instances of semantic categories means interrelating these instances according to relationships between their corresponding categories. Now, we may say that the document "C" is related to the document "A" by means of the "Author Modules" semantic relationship. Similarly, the document "C" is related to the document "B" by the means of the "Project Modules" semantic relationship.
Figure 1: Knowledge Domain Schema

Thus, each particular knowledge domain is a collection of WBT-Master training resources (documents, learning units, individual users, etc.) that are structured using a predefined template called the knowledge domain schema.

A knowledge domain schema may be seen as a definition of all categories and all possible semantic relationships between them.

Learners may browse and search Learning Resources, reused and interrelated with other Learning Resources, as instances of semantic categories.

Thus, we may see that the concept of Knowledge Domain supports three different aspects of working with systems:

- Defining a Knowledge Domain Schema, which includes defining a number of semantic categories and a number of semantic relationships between the previously defined semantic categories
- Reusing resources as instances of different semantic categories and interrelating them with other learning resources according to a previously defined Knowledge Domain Schema
- Browsing and searching of learning resources reused as instances of previously defined semantic categories.

3. Defining a Knowledge Domain Schema

A Knowledge Domain Schema defines a data structure in the form of so-called semantic categories and semantic relationships between these categories. Any training resource added to the knowledge domain is perceived as an instance of one particular category and, thus, inherits all properties defined for the category.

The schema provides a number of attributes (data items) which should be provided for any instance of a particular category and types of relationships which should be installed between the new instance and existing instances of other categories.

Definition of a Semantic Category includes definition of a number of attributes, which are properties of instances of the Semantic Category. An attribute is a standard key-value pair. A value of an attribute is defined to be of a specified type, i.e., a value may be a string, a number or a selection from a list of possible values. For example, the "Author" may have just one associated attribute: Nam e (String). Similarly, the category "Module" may have two associated attributes - Programming Language (selection from a list of languages) and Name

(String). Looking from another point of view, we can say that each instance of the category "Author" is provided with attribute "Name".

Definition of a Semantic Relationships includes the selection of two categories that participate in the relationship. Each semantic relationship defines 1:n relationship between instances of two different categories. A category participating with a single instance in each relationship is called "Owner" of the relationship. A category participating with multiple instances in each relationship is called "Member" of the relationship. Each instance of a Member is obligatory related to a certain instance of Owner; this reference is installed whenever a new Member is created. For instance, in the example above, the relationship "Project Modules" may relate a single instance of "Project" to an arbitrary number of "Modules", or looking from another perspective, each instance of "Module" is obligatory related to a certain "Project". This relationship will be created whenever a new "Module" instance is put into the Knowledge Domain. Similarly, the relationship "Author Modules" relates a single instance of "Author" with an arbitrary number of instances of "Module".
Figure 2: Categories and Relationships in a Knowledge Domain Schema

Existing of knowledge domain schema facilitates two rather important processes: structuring of a knowledge domain and browsing a knowledge domain. Whenever a new instance of a category is created, the system may assist the user with offering special forms for providing attribute values and for selecting other instances to be related to the new one. The system may also check whether all necessary information is provided and prompt the user if necessary.

From the browsing point of view, existence of a domain schema provides very useful information on a current document position within the knowledge domain and on semantic of links emanating from or pointing to the document.

4. Instancing Semantic Categories

The knowledge domain schema defines common properties of all the category instances. Any resource may be inserted (stored) into a particular knowledge domain as an instance of predefined category. Thus, a responsible author simply selects an existing knowledge domain and a predefined category for a new resource and the system guides the author through the process of defining attributes and necessary relationship s. For example, if a new instance of the category "Module" is created, the system automatically request to select a programming language (attribute predefined for the category), and to provide references to the module author and a certain project (relation ships predefined for the category). This, of course, facilitates creating of well-structured repositories.

5. Browsing Instances of Semantic Categories

The concept of well-structured Knowledge Domains facilitates also browsing and searching the resources reused as instances of semantic categories. Thus, for example, whenever a user access the document "Module 01/01", the system automatically provides:
- Information on attributes attached to this document,
- References to instances of other semantic categories which are related to this one,
- Next/prior navigational tools, etc.

BEST COPY AVAILABLE
Figure 3: Browsing a Knowledge Domain

Thus, browsing a knowledge domain does not require any additional knowledge besides understanding of the predefined structure of the domain. Users simply select a particular knowledge domain and a certain category and all existing instances are displayed by the system. Selecting a particular instance results in the start of the actual browsing of the knowledge domain.

6. Conclusion

The concept of the Knowledge Domains facilitates many important features such as:
- Separating of the structure and the content of the resulting hypermedia database - as shown many times before (Helic et al., 1999) (Helic et al., 1999a) (Maurer et al., 1996), the crucial point for the successful maintaining of large WWW based hypermedia databases.
- Defining of new data structuring facilities through the concept of the Knowledge Domain Schema - provides a possibility to reuse learning resources in different well-defined contexts, thus, allowing learners to have new views on the learning material collected in a WBT system.
- The concept of the Knowledge Domain Schema provides means for template-based authoring - through the template-based authoring the authoring process is considerably simplified. A wizard-like authoring system is imaginable, as it is already implemented in the WBT-Master system. Such authoring system is easy to use, and a rapid production of learning material is easy to achieve.
- The result of the authoring process is a well-structured repository of learning resources - the concept of the Knowledge Domain Schema defines a database schema that is applied by authors in the authoring process to structure learning resources. Thus, the result of this authoring process is a very well structured database created in the accordance to a number of predefined database schemes.
- Searching in the system on a meta-level - attributes attached to learning resources, as defined by the Knowledge Domain Schema, may be comprised as the data on about the data, i.e., the meta-data. Such meta-data may be used to enhance searching facilities provided by the system, especially when they are predefined, as it is the case with the Knowledge Domains.
- Browsing learning resources on a meta-level - browsing of Knowledge Domains facilitates browsing of the concepts (comprised in semantic categories) and relationships between these concepts (comprised in semantic relationships between different categories) as opposed to browsing of individual documents or learning resources. Furthermore, when browsing instances of semantic categories those instances are provided with very useful additional information contained in attribute values attached to those instances.

However, we believe that the concept of Knowledge Domains, as it is implemented in the WBT-Master, requires a number of improvements. Those improvements are mainly concerned with the concept of semantic relationships:

- It should be possible to define not only relationships of 1:n character but also relationships of m:n character; often the 1:n relationships are not sufficient to describe real-life relationships between two concepts. For instance, an instance of the category "Module" (i.e., a software module) may be a part of not just one "Project", but possible two or more "Projects". This facilitates the description of the concept of reuse of software modules, which is one of the basic concepts in the software engineering field.
- It should be possible to define not only binary relationships, but also relationships of an arbitrary arity. Usually, to describe relationships between different concepts, we need to apply n-ary relations between those concepts. For instance, if we say that the category "Module" has an attribute "Name" of the type String, we may comprehend this fact as a relationship between concepts "Module" and "Name". If we now consider other relationships of the "Module" category (e.g., "Project Modules") we end up with the category "Module" that constitutes a 3-ary relationships between categories "Name", "Module" and "Project". However, this facility should be explicitly supported by the system in order to improve the expressive power of the Knowledge Domain concept.

Abstract: The basic functionality offered by WBT systems is provided through a number of tools that support different user roles in those systems: authors, tutors and learners. Usually, learners utilize WBT learners' tools in order to improve their knowledge and skills. Authors contribute to the courseware repository creating and publishing learning modules. Tutors manage the learning process on some particular subject trying to bridge the gap between the courseware and learners. Usually, the success of a particular WBT application depends on the general quality of the courseware offered by the WBT system, i.e., the success in WBT systems depends, mainly, on authors who provide the courseware. However, we believe that tutors' role, and not the authors' role, in WBT systems should become of the primary importance. It should be possible to exploit the enormous knowledge and experience that tutors posses by providing tutors with the means of more useful and powerful tools. The concept of Mentoring Sessions implemented in a novel WBT system WBTMaster provides a simple tutors' tool that improves the tutors' influence on the learning process tremendously.

1. Introduction

The enormous educational capabilities offered by the Internet, in general, and the World Wide Web (Berners-Lee et al., 1994), in particular, are very well recognized by the Internet community. In the past few years this recognition has lead to the development of a wide range of so-called Web Based Training (WBT) applications. The first developed WBT applications exploited the WWW as a perfect courseware dissemination channel to deliver the courseware to their users "anytime and anywhere". However, modern WBT systems are much more than just a simple courseware dissemination channel. Those modern WBT systems support much broader functionality providing facilities such as (Helic et al., 2000) (Andrews et al., 1996): support for different user roles (authors, learners, tutors); authoring of highly qualitative multi-media courseware; maintaining of large structured repositories of learning resources; customization of courseware to each particular learner; synchronous and asynchronous communication between different learners, as well as between learners and tutors; progress tracking, etc.

As already mentioned, one of the main concepts behind the modern WBT systems is a distinction between different user roles in the system. Thus, a standard WBT system distinguishes between the following three user roles (Helic et al., 2000):

- Learners utilize WBT information services in order to improve their knowledge and skills. They are motivated to use the system services by a particular Learning Goal in mind. In a simplest case, the Learning Goal may be just a wish to pass an examination and to get some credits.
- Tutors manage the learning process on some particular subject. Tutors select an appropriate learning strategy (say, Learning By-Doing, Situation-Oriented Learning, etc) to achieve better learning results.

Tutor control learners' progress with the material, offer additional materials and point learners to fellow helpers if necessary, examine learners' knowledge and acquired skills, etc.

- Authors contribute to courseware repository creating and publishing documents, combining the documents into navigable structures (courseware libraries, courses, learning modules, etc.).

Thus, all the previously mentioned facilities, supported by a WBT system, may be seen as different tools provided by such a system in order to support a particular user role. For instance, an HTML editor, that allows users to create highly interactive multi-media HTML documents that in turn may be interrelated into a navigable structure may be seen as a typical authoring tool in the scope of a WBT system. On the other hand, a chat tool that allows different learners to synchronously communicate with each other in order to discuss issues related to a particular courseware unit would be a typical learner tool supported by a WBT system.

The largest effort that many researchers and developers of WBT systems put in their work in the past few years, was directed toward improvements of authors' and learners' tool. Thus, all the modern WBT systems provide nowadays very powerful facilities that support authoring, structuring, providing a convenient navigational paradigms or publishing of highly qualitative multi-media courseware (e.g., Course Wizard in GENTLE (Dietinger and Maurer, 1997) (Dietinger and Maurer, 1998) or Course Scheduler in Lotus Learning Space). Further, facilities supporting learning process for learners such as: study rooms, annotations to learning material, synchronous and asynchronous communication with other learners and with tutors, course overviews, progress tracking and similar are nowadays a standard part of each WBT system.

A certain lack of good tutors' tools may be noticed in all the relevant WBT systems nowadays. Usually, tutors have just the following possibilities to influence the learning process in a typical WBT system:

- To customize the courseware prepared by authors by means of different authoring tools to the requirements and/or needs of a particular learners' group
- To communicate, synchronously and/or asynchronously, with learners, usually to answer questions related to a particular courseware unit
- To annotate particular parts of learning material that are important in the learning process
- To track the progress of a particular learner and to try to adjust, usually by means of tutors' tools already mentioned, the courseware and the learning process to a particular learner.

Even though tutors' role in a WBT system may be seen as a role of users who try to bridge the gap between the courseware on the one side and the learners on the other side (i.e., between authors and learners) they were not provided with tools powerful enough to achieve their goals. Normally, a success of a particular WBT application was based on the quality of the courseware provided by authors and the capabilities of different learners to comprehend the presented material. However, we believe that tutors should be provided with tools that will improve the significance of their role in a WBT system tremendously, even to make the tutors' role to be of the primary importance. In this way, a WBT application provided with good tutors could be a success, even if the quality of the courseware is not so high.

The WBT-Master (Helic et al., 2000), a novel WBT system, provides tutors' with much more powerful tools than it is the case with the most of today's WBT systems. For example, tutors may influence the learning process on the full extent through the concept of Learning Goals (Helic et al., 2000), or they may even author their own courseware on the fly through the concepts of unified HM-Data Model (Helic et al., 1999) (Helic et al., 1999a). In this paper we present a novel concept of so-called Mentoring Sessions, which is another useful tutors' tool supporting "live" mentoring of learners as they are working through a particular courseware unit.

2. Mentoring Session

The main idea behind the concept of so-called Mentoring Sessions tries to improve the significance of tutors' role in WBT systems. Beside authors, who prepare courseware for learners, and who are usually experts in a particular field, tutors usually have a large knowledge on a particular topic, as well as a considerable experience in working with learners. Tutors' tools in WBT systems should be designed in such a way that it is possible to take advantage over the knowledge and especially over the experience that tutors posses. In this way tutors could fulfill their main goal in WBT systems, and to do so at the full extent, namely, they could gap the bridge between the courseware prepared by authors for learners on the one side and the learners their self on the other side.

Thus, Mentoring Session is a tutors' tool that may be seen as:

- a special way of synchronous communication (online mentoring sessions) between tutors and learners
- a special method of structuring and presenting to learners existing learning resources (recorded mentoring sessions).

An online mentoring session is carried out as a data exchange between a mentor's client (so-called leading client) and a number of learners' clients (so-called led clients). Usually, a tutor operates the mentor's client, whilst learners operate their own client.

A recorded mentoring session is prepared by means of a mentor's client and can be viewed anytime by means of a learner's client.

The main idea is that the leading client is provided with a number of special tools to control the data displayed by the led clients to learners.
Figure 1: Running a Mentoring Session

Thus, a mentor initiates a mentoring session and defines restrictions for learners to join the session. Selected learners are automatically notified about the session and can join it (i.e., can activate their led clients). The mentor is informed about learners joining the session.

The mentor selects and browses learning resources by means of the leading client. The leading client may be seen as a monitor controlling other tutors' tools and sharing the resource with led clients. The leading client simply passes the selected resource to led screens.

Additionally, the mentor can provide an explanation (text, voice and/or live pointer) attached to such shared resource. The explanations can take the form of a chat session or a special transparent layer on the leading screen where a pointer and texts may be put on the top of a current picture. The explanatory layer is also automatically displayed on led screens.

The leading client allows also accepting data from led clients. Thus, the mentor can request learners to perform an action (say, to write a short article), and monitor the process from the leading client.

Learners are allowed to provide comments to a shared resource by means of special chat facilities. The same mechanism can be used to ask questions in the context of a shared resource.

3. WBT-Master Functionality: Mentoring Sessions

WBT-Master is a novel WBT system that tries to introduce new ideas and concepts that go far beyond a standard WBT system. The WBT-Master distinguishes strictly between four different user roles in a WBT system, namely learners, authors, tutors and administrators. The leading idea in the WBT-Master development was that a WBT system should be just a set (possible large set) of tools, which support the main user roles in WBT system. However, one of the main directions of the WBT-Master research and development was a quantitative and a qualitative improvement of tools for tutors. It is because; we think that the role of a tutor is of the primary importance for a successful WBT system.

Thus, WBT-Master provides a number of so-called functional panels that encourage a usage of Mentoring Sessions. Those functional panels contain a number of activation buttons used to activate different tools, such as the leading or the led client in Mentoring Sessions. Thus, we distinguish the following three Mentoring Session functional panels:

- Session selection functional panel

- Leading client (includes resource selection functional panel and resource control functional panel)
- Led client.

3.1 Session Selection Functional Panel

Mentoring Session Selection Panel is a list of all mentoring sessions (online and recorded) available on a particular WBT-Master server. A particular Mentoring Session may be selected from the list to work through it. Additionally, tutors may create a new Mentoring Session or edit an existing recorded Mentoring Session.

3.2 Leading Client

Usually, tutors use the leading client. The leading client provides:
- Information on the current session status: such information includes info on all learners working on the session and provides possibility to individually contact a particular learner by clicking on his/her name.
- Resource Selection Functional Panel; This panel provides a unified access to all training resources in a form of hierarchy of directories. In order to select a particular resource, tutors simply open a directory and click on a resource name. The resource is visualized in the working area and the leading client switches to the resource control mode.
- Resource Control Functional Panel: after a particular resource has been selected it is displayed in the working area and the tutor may work with the resource. Usually, the tutor may select to share resource with all led clients. After a resource has been shared the tutor may use pointer, write comments or install a web telephony connection, for example, with the led clients. Also, the tutor has to possibility to switch to the so-called "recording session mode" and provide learners with recorded Mentoring Sessions.
Figure 2: The Leading Client

3.3 Led Client

The led client just displays the shared documents, comments, pointer position and other explanations provided by the tutor leading the session.

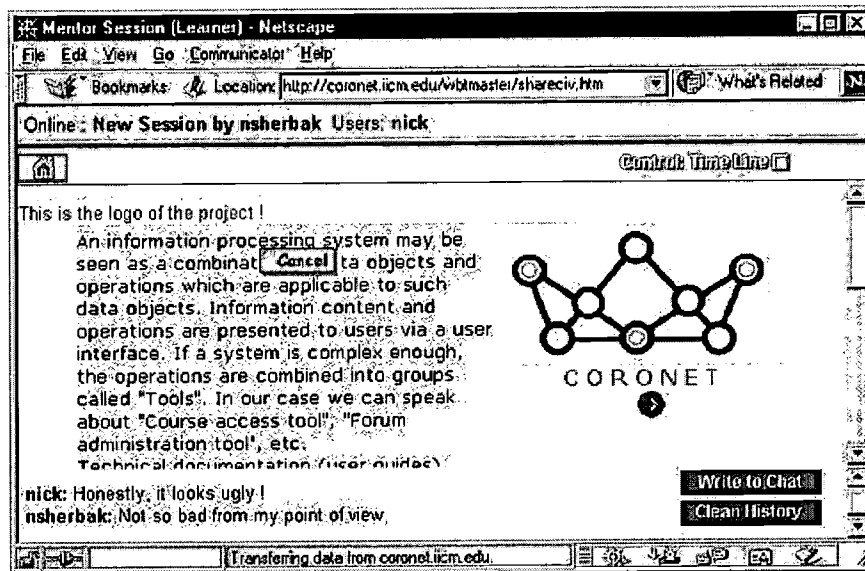
Additionally, the embedded chat mechanism may be used to communicate with the mentor or other learners.


Figure 3: The Led Client

4. Conclusion

Through the concepts of Mentoring Sessions, Learning Actions and Learning Goals, as well as through the concept of authoring on-the-fly carried out by tutors and supported by the unified HM-Data Model, the data model utilized by the WBT-Master, the significance of the tutors' role and the influence of tutors on the authoring and learning process in the WBT-Master has been considerably improved. We believe that the tutors' role and their possible influence on all the aspects of a modern WBT system is of primary importance for a WBT system to become a success. Until now, the success of a WBT application was merely based on the possibility of authors involved with a WBT application to produce qualitative multi-media courseware and the ability of learners involved in the learning process to comprehend the presented material improving in that way their knowledge level. However, through the above-mentioned concepts supported in the WBT-Master, tutors may easily gap the bridge between the courseware and its audience. Tutors are now provided with facilities to put a crucial influence to the both: the authoring as well as the learning process, leading WBT systems to achieving their basic goal, i.e., acquiring the needed knowledge by learners.

Abstract: Preparing the pre-service teacher Professional organizations have been the main thrust of the initiative to better train teachers to infuse technology into the K-12 classroom. ISTE has proposed standards for teacher preparation in technology. The National Council for the Accreditation of Teacher Education (NCATE) has developed curriculum guidelines for preparing teachers in the areas of educational computing and related technologies. Learned societies, such as the National Council for the Social Studies (NCSS) and the National Council of Teachers of English (NCTE) direct that the use of technology be incorporated into the curriculum at all educational levels. Many of today's public school teachers do not consider themselves competent in the area of technology. The principal investigators provided technology instruction and, as partner site coordinators and instructors, modeled effective use of technology in block education professional preparation classes. As an outgrowth of this project, pre-service and teachers reported much growth as measured by the new ISTE Standards A pre-test and post test were administered documenting student growth as compared with the new ISTE Standards The ISTE survey follows. In almost all cases, pre-test responses varied between 0% and 50%. Post test responses were nearly 100% on each item.

Inquiry findings from the Society for Technology in Education

(National Educational Standards for Teachers – International Society for Technology in Education)
As an education student I currently have the following knowledge, skill or ability:

31.identify the benefits of technology to maximize student learning and
facilitate higher order thinking PRE D/SD =23.5%   A/SA =52.9%//// POST D/SD =0%   A/SA =88.2%

32.differentiate between appropriate and inappropriate uses of technology for teaching and learning while using electronic resources to design and implement learning activities PRE D/SD =35.2%   A/SA53% =//// POST D/SD =0%   A/SA =100%

33.identify technology resources available in schools and analyze how accessibility to those resources affects planning for instruction PRE D/SD =41.1%   A/SA47.1% =//// POST D/SD =0%   A/SA =100%

34.identify, select, and use hardware and software technology resources specially designed for use by PK/12 students to meet specific teaching and learning PRE D/SD =47%   A/SA =47.1//// POST D/SD =0%   A/SA =100%

35.plan for the management of electronic instructional resources within

a lesson design by identifying potential problems and planning for PRE D/SD =76.5%   A/SA =23.5%//// POST D/SD =0%   A/SA =93.1%

36.identify specific technology applications and resources that maximize student learning, address learner needs, and affirm diversity PRE D/SD =58.8%   A/SA =23.5%//// POST D/SD =0%   A/SA =100%

37.design and teach technology-enriched learning activities that connect content standards with student technology standards and meet the diverse needs of students PRE D/SD =   A/SA =//// POST D/SD =   A/SA =

38.design and peer teach a lesson that meets content area standards and reflects the current best practices in teaching and learning with technology. PRE D/SD =58.8% A/SA =29.4% //// POST D/SD =6.3%   A/SA =94.7%

Abstract: The goal of this session is to provide both the novice and the digerati a systematic examination of the power and potential use of hypertext and hypermedia as Internet Resources for Multicultural instruction. The presenters will demonstrate the use of electronic Multicultural resources(both Power Point and the WWW to facilitate teaching / learning about Multicultural Issues in the pre-K through 12th grade classroom . Audience participation will be encouraged. The presenters will share their Diversity web site -- http://www.ed.wright.edu/CEHS/diversity/diversity.htm. that was designed for instructional use for pre-service and inservice teachers. This is a megasite for Diversity resources. The presenters and attendees will discuss WWW resources that may be used for Multicultural instruction. Questions will be encouraged from the audience. This session should particularly benefit those who are teaching Multicultural education, those curriculum designers who are including Multicultural education in the curriculum, those who are seeking ideas and resources for NCATE accreditation in the area of diversity

Diversity in Institutions of Higher Education: Technology Resources

The term multicultural education is understood in a number of ways by various authors, depending on their own personal perspective. James Banks, a seminal authority in multicultural education, consistently maintains that multicultural education in the United States began as a response to inequities in the areas of racism, sexism and socio-economic status. In 1981, Banks stated that multicultural education is "an educational reform movement that is concerned with increasing educational equity for a range of cultural and ethnic groups" (32).

A Multicultural Perspective for Educators

National and state education standards mandate the teaching of multicultural education at the post-secondary level. As a result, many colleges and universities require multicultural or diversity courses for all students. As those who prepare the citizens today for the world of tomorrow, it is of paramount importance that pre-service and in-service teachers receive instruction in multicultural education.

Educators are role models for their students, just as parents set an example for their children. If teachers accept students in their classroom who may have some characteristics different from their own, the students in their classrooms will be more likely to accept one another (Finegan, 1999). Gollnick and Chin (1994) in their textbook, *Multicultural Education in a Pluralistic Society*, state the often-quoted statistics that by the year 2000, one-third of the school population will be composed of students of color. The authors also reveal that nearly 25% of children in schools today are living below the established poverty level. As the nation increases in diversity, and international commerce becomes an everyday occurrence, citizens of the future will need to grow in their appreciation and understanding of others.

Electronic Multicultural Resources

Thousands of educational multicultural resources available on the internet for use with students of all ages. The authors have organized these invaluable resources into the following multicultural categories: age, belief, class, ethnicity, exceptionalities, gender, language, and sexual orientation. Websites have purposefully been selected to represent various points of view to assist the pre-service and in-service educator in the process of information gathering, introspection, and self-evaluation. Thus some of the World Wide Web (WWW) sites documented will be from an educational reform perspective or from other perspectives. An additional and primary goal of this section of the text is to assist educators in developing a multicultural perspective that can be shared with their students.

Many professional and popular journals site addresses for new web resources daily. Some very interesting web sites are available for educators and for students. In fact, it is becoming a common occurrence for students and teachers to be publishing articles and their own webpages in an electronic format (Helms, 1997). For example, at the authors' websites (http://www.ed.wright.edu/cfinegan.html) and (http://www.ed.wright.edu/~rhelms/home.html) may be found links to articles, journals, associations, syllabi and exemplars of student work as well as additional hyperlinks to general education and multicultural sites.

Creating a Collaborative Web-based Environment Through the Inclusion of Metaphorically Enhanced Graphics

Anne Henry, University of Houston at Clear Lake, USA ; Caroline M. Crawford, University of Houston at Clear Lake, USA

The inclusion of metaphors within a World Wide Web-based environment offers the users the opportunity to not only obtain a visual understanding of the information being presented but also aids the users in developing a clearer understanding of the information and builds upon their previously conceptual framework of understanding. The importance of a Web-based collaborative educational learning venture is also enhanced. Creating a collaborative Web-based environment through the inclusion of metaphorically enhanced graphics can be a difficult venture. However, through the careful and appropriate choice of a metaphor, the inclusion of metaphorically enhanced graphics will further the collaborative, creative e-learning environment that all e-learning environments strive to develop.

Project WebOracle
Developing an advanced web server security assesment tool

J.C. Hernández, E.M. Cebrián, J.M. Sierra, A. Ribagorda, B. Ramos

Abstract: In this article we present the first results of the WebOracle Project, which aim is to develop a new free and open source security assessment tool for web servers. After explaining why such a tool could be useful for improving the security of web servers, we describe its design philosophy and mention its main advantages in comparison with other security assessment tools. Finally, some improvements that are about to being implemented or will be implemented in a near future are discussed.

Introduction

A significant amount of the security incidents that are delaying the expansion of e-commerce are not a fault of the security protocols implemented, but of the lack of security in the machines involved in the transactions (mainly web, database and mail servers). There is a huge amount of web servers with a poor or null security level, which are supposed to carry out secure e-commerce transactions. The use of servers that implement high-end cryptographic solutions over a system with insufficient security is an anachronism. Unfortunately, this is a quite common situation that makes the modification of the contents of a web server or the theft of confidential data (two of the most popular attacks) relatively easy, even for newbies or script kiddies.

Why even critical web servers have, in many cases, a very poor security? There are lots of factors that explain this fact. First of all, there are not enough trained security administrators, because only large companies can afford them. Typically, security is a task accomplished by the classical system administrators that may, or may not, know much about security. In any case, they usually do not have much time to spend in learning or implementing security (usually the user that forgot his password or the printer that does not print has top priority). Web security is, also, relatively unknown to security novices. Menaces behind insecure CGI's, PHP scripts, Frontpage or Coldfusion extensions do not seem serious enough to many people, who consider them not a real threat. They even believe that a correctly configured firewall must protect their web servers from this kind of attacks or abuses. This bliss is a fatal mistake since both the search and the exploitation of vulnerabilities is done via port 80, so every firewall will allow it because it is considered ordinary http traffic between a client and a server. Finally, lack and relatively unpopularity of tools to assess the security of web servers make the discovery of weaknesses, and its fix, a little harder.

These were the foundations that prompt us to start the WebOracle Project to develop and offer a security tool that could help administrators.

Design Criteria

WebOracle is freeware. This is important because, although some well-known general security assessment tools also include web security modules, these tools are generally quite expensive and, for this reason, cannot help all the Internet community.

As expected in a project open to all the Internet community, WebOracle is open source to help others to understand how exactly it works and motivate them to cooperate with ideas, suggestions or even code to improve the tool. Open code is also a very important feature in security software, thus avoiding any suspicion of backdoors or malicious code. It is also interesting to have the source to know exactly how it works and being capable of quickly detecting possible bugs, failures or limitations.

As an example, we can cite a curious *technique* that some programmers used in the past: To verify if the answer from the web server was a *200 OK Found*, they simply checked the string returned by the server searching for a *200* sub-string. This quick, straightforward and simple technique seemed to work fine until the year 2000, when the tools that used this technique had to be changed to avoid the huge number of

false positives found because of the 2000 in the date the server returned. If this technique were applied in a non-open source tool, it would not have been so easy to detect and solve those problems.

Another good example of easier-but-not-better programming technique was used by the expensive and noted Internet Security Scanner. ISS, even when the excellent (but complex to implement) TCP/IP stack fingerprinting technique was available to determine the operating system of a remote machine, simply grabbed the easily modifiable banners of some services to do the same. In some cases, closed source code makes the use of inadequate or obsolete techniques easier.

So, apart from other advantages, security administrators must prefer open source tools for knowing which exact technique is used to do something, thus being able to completely understand the results.

WebOracle has also been developed trying to maintain as much code clarity and compactness as possible, to facilitate its understanding thus improving the learning curve by volunteers who want to collaborate in the Project.

WebOracle features

This first available version of WebOracle (v2.0) has a number of advantages, apart from being open source and free, over other similar tools. Here we will mention some of them.

1. It is an all-in-one tool for web server security. It offers all the functionality that can be expected in such kind of tools: In fact, it provides two features that no other web server security assessment tool offers simultaneously, namely security checks (named Check in the tool) and contents checks (named Explore in the tool). There are lots of security tools that can help in detecting insecure CGI's and similar dangerous scripts, but none of them are also capable of performing such a complete blind search for hidden contents in the web server. This is also an important security test, because many web developers provisionally leave contents into not directly accessible directories, these contents are usually private (user files or databases) or even dangerous (source code of new scripts in testing phase that can help others to detect bugs and exploit them later). Anyway, they commonly put these contents into not directly accessible (not reachable by clicking in links of the normal web server contents) directories, and they rely on this doubtful mechanism to maintain these contents hidden. This is a serious and extended mistake that can be easily exploited, simply doing a recursive blind attack, which consists in asking directly for common directory and file names to the web server (i.e.: /data, /publisher, /test, /mail, /cards, /pub, /public, /applications, /application, /app, /scripts, /demo, /logs, /log, /login, /search, /.htaccess, etc... or even all random combinations of less than N characters) until obtaining a positive answer from the server, and then proceeding recursively, if necessary.

2. The security checking is fast and highly configurable. This possibility of configuring what is considered a hit, and what is not, is quite relevant. For example, in some cases a *403 Forbidden* answer must be considered a relevant result that could indicate the existence of vulnerable scripts that have a (possibly simple to bypass) IP access control, and in other cases this response must be discarded as non-relevant. Classical tools usually choose one of these three main possibilities:

    a) Consider that any answer different from a *200 OK* is equivalent to a *Not Found*
    b) Consider that any answer different from a *404 Not Found* is equivalent to a *200 OK Found*
    c) Print the server answer an let the user interpret its significance

Clearly, option a) produces too much false negatives, and option b) produces too much false positives, whether option c) is more accurate but lacks flexibility and can produce mistakes or omissions when the output is large and the number of answers of a given class is small. WebOracle provides better configuration capabilities because it offers a default hit/not hit configuration that can be directly changed by the user to any on the possible combinations, thus allowing an easy and agile adaptation to different needs.

3. Update feature: The file with the data contents (vulnerabilities to check and resources to explore) can be obtained directly from within the WebOracle tool, with no need of using any other http client, although this is also a possibility. It is quite obvious that this file must be continuously updated to reflect recently discovered vulnerabilities or new default directories that new versions of web server software or applications may include. This will be one of the paramount working areas of the Project.

4. Meaningful negative server answer: In many cases, the tools that automatically check for vulnerabilities simply ask the server for a given resource, let's say /cgi-bin/phf and return its answer. In this case, it is possible that a *404 Not Found* answer is due to the non-existence of the cgi-bin directory, which could have

been renamed to /cgibin. In most web security assessment tools, this would produce a *404 Not Found* and nothing else. WebOracle has a more advanced way of managing this situations: When it is asked to look for /cgi-bin/phf, WebOracle would understand that this request is an aggregation of a location plus a resource (location=/cgi-bin/; resource=phf). If not previously checked for the location, WebOracle will firstly request the location to the web server and then the location+resource. The result of this request will be much more revealing: If the location is not found, the answer for the request of the location+resource will be another 404 Not Found but will clearly point the user to the reason of this answer. This allows him/her to change its location and, possibly, find the same resource under a new path.

In addition with all these features now included in WebOracle v2.0, for different reasons, the development team decided not to implement some other features nowadays found in web security assessment tools. As an example, he possibility of using a proxy server (commonly used to maintain anonymity while exploring or attacking other's machines) was considered and rejected, as was the use of Intrusion Detection Systems (IDS) fooling techniques implemented, for example, in Whisker and Void-Eye. We feel that our tool must not implement any technique that could ease its criminal or illegal use. This was also the main, but not unique, reason for not implementing an interesting technique found in Whisker that limits the requests for certain vulnerabilities to certain web servers. When using this technique (we can call it *intelligent request method*), after performing a request to know which exact web server we are testing, the tool only searches for vulnerabilities known to be associated with this web server software. This is a very interesting technique, but was developed mainly to reduce the number of http requests needed to detect vulnerabilities, thus decreasing the odds of being discovered by an IDS. This technique has a very important drawback, that definitely prompt us not to implement it: It can be easily abused to fool the tool to conclude that a weak web server has not any vulnerabilities. Even if the web server is buggy, simply by changing the web server identification message (something that is very simple to do in many systems), the tool will only request vulnerabilities that will not be found, thus giving a false and dangerous good security diagnostic.

Project status

WebOracle is a Project open to all the Internet community which aim is to offer a free and open source tool to assess the security of web servers that is also advanced, secure, flexible and regularly updated. This tool has been developed after careful evaluation of the characteristics and features that such a tool must offer, and has been tested by many students, whose suggestions contributed to its improvement. It is compact, and its user interface and code is simple and easy to understand to motivate others to join the Project and help in improving it. WebOracle has been developed in Delphi and nowadays runs on any Windows platform.

In the near future, we expect that, with the help of Kylix, it can be ported to Linux platforms. The actual version of WebOracle, that is WebOracle v2.0, has recently been finished and will be soon available in a large number of websites all around the world. We are now working to obtain the resources needed to get an adequate domain, web server and web site for the Project.

Future work

In the near future, apart from the obvious tasks of updating the data files with new web server vulnerabilities and resources, there are some other interesting features that are about to be implemented and will be launched in the next version of WebOracle:

-An http link will be associated with every vulnerability: this will allow any user who finds vulnerabilities in a web server to click on the results frame of the application to get information about its severity and how to solve it. In later versions, the possibility of making an automatic report of the security of a web server will be implemented.

-Every vulnerability discovered will have an associated colour that will indicate its danger. In later versions, the possibility of making an automatic user-friendly report of the security of a web server will be implemented.

-Apart from the data file with commonly found vulnerabilities and directories + resources, there will also be a special feature that will allow the use of language-specific resources. The files with these language-specific contents will be automatically generated and will be found in the web site of the Project.

-The Update function will include an integrity check of the contents of the file downloaded to verify its correctness and the success of its transfer.

-The WebOracle tool will be offered in as many webs as possible to allow its wide use and receive more feedback form its users. It will be downloadable, in a near future, apart from its own web page, from the main security sites of the web (SecuriTeam, SecurityFocus, PacketStorm, etc)

Any other new feature that any of the users of WebOracle would suggest will be seriously taken into consideration.

Conclusions

Although WebOracle is a relatively new Project, it has started offering an interesting tool that can help thousands of security administrators world wide in assessing and improving the security of its web servers.
The rest of the project is supposed to be relatively easy and straightforward, as it mainly consists of updating the data file with new vulnerabilities and resources and slightly improving the tool with new features suggested by its users.
We will try to react as soon as possible to new vulnerabilities and new trends, to evolve this Project and tool accordingly to the evolution of the security field for always offering a state-of-the-art free, open source, professional, helpful and updated security tool.

Abstract

In this article the authors want to show that search engines are excellent tools for the hackers. This is mainly due to the extremely weak security policy they implement. For that reason, the services they provide can be abused to attack machines anonymously, search for easy victims, or gather confidential data.

1 Introduction

Search engines offer an increasing number of services, and index a really huge number of pages and other resources that sometimes, inadvertently, expose the security weaknesses of companies, and even their confidential data.

In this work we present a number of techniques to show that search engines can be used, or abused, by hackers to attack anonymously, find easy victims and gain relevant knowledge that, in some cases, can be more than enough to mount a powerful and promising attack.

Anonymity is one of the main objectives of hackers, mainly to elude legal consequences of their acts but sometimes simply to avoid being thrown out by their Internet Services Providers. Some search engines services *provide* this *service* for free, because they can be abused to act as anonymous proxies, thus hiding the identity of their malicious users.

Also, many people are not really aware of the security implications of the existence of weak machines connected to the Internet. Those machines could be used to compromise the security of any other Internet machine in a variety of ways. Sometimes these machines do not store any important data but are trusted by third party networks. Consequently, a hacker could easily get access to the vulnerable machine and, from it, hack an important trusted network. In this way the attacker could also obtain anonymity, after wiping any log files or tracks in the weak machine. Another way to exploit those weak machines is to launch distributed denial of service attacks (DDoS), making them work as *zombie machines*. Unfortunately, every Search engine can be used to find easy victims almost effortlessly.

For mitigating these threats, we also present a number of countermesures that, if implemented by the search engines, would make much more difficult the task of abusing vulnerable machines.

2 Search engines can be used as a nonymous proxies

Lots of search engines, including two of the most popular (Altavista and HotBot), offer automatic web translation to its users. The working of this service is simple: the user requests an URL to the search engine translation machines, and these download this resource locally, translate it, and finally send back the result to the user.

This procedure allows any user to effectively use the translation machines as proxies, which would be quite inoffensive if it were not for the fact that both Altavista and HotBot act as anonymous proxies. This allows any of their users to navigate anonymously, hiding its real IP address behind the translation machine IP's.

Chaining translation machines from different search engines is also feasible and extremely easy, making user's identification even harder.

Although anonymous surfing could not appear as a serious security risk, this anonymity may be used to avoid the legal effects that some simple http requests could have. For example, the http request http://www.some.web.server/msadc/Samples/SELECTOR/showcode.asp?source=/msadc/Samples/../../../../boot.ini would return the contents of the boot.ini file on some web servers running Internet Informatio n Server (IIS) 3.0 and 4.0, so this feature of the main search engines can be abused to anonymously find and exploit vulnerabilities in web servers.

3 Search engines help to find easy victims

The huge number of pages indexed by the largest search engines (for example, Google announced 1,346,966,000 in June 2001) makes them excellent tools for identifying easy victims.

One extended and very simple technique is to search for recently installed or unattended web servers, because they will surely not have a very good security. This can be accomplished simply by searching for text strings, images or other contents that characterize default installations of certain web servers. For example, if the string *"Try the hyperlinks above to see some examples of the content you can publish with Microsoft Internet Information Server. To learn more about Microsoft products that you can use to create great-looking Web pages"* is found in a web server, there is a high probability that it is an out-of-the-box IIS installation.

Analogously, the string *"This page is used to test the proper operation of the Apache Web server after it has been installed. If you can read this page, it means that the Apache Web server installed at this site is working properly."* characterizes a default Apache installation.

This method for finding unattended or recent installations gives to the hacker a large list of potential easy-to-abuse victims.

Hackers can also look for default pages that correspond to old (and known to be buggy) web server versions, simply by including the copyright year into the search string (as in *"©1997 Microsoft Corporation. All rights reserved"*). They can also look for web servers with a very poor security reputation, like the Personal Web Server from Microsoft (which has a possible search string of *"This home page is hosted on Microsoft Personal Web Server (PWS) 4.0. PWS turns any computer running Windows® 95 or Windows 98 into a Web server and enables instant publication of personal Web pages"*), or the Zeus Web Server.

Obviously, the searching method explained above can be slightly improved by expanding the search string and/or restricting the search to recently indexed web pages. Some other variations are also possible, but explaining how to get better results (or weaker victims) is beyond the scope of this work.

Alternatively, many of the main search engines have a feature that allows any user to search for multimedia contents as graphics, banners or logos, including image files (jpeg, gif, etc.) that are present on default pages. This can be used to locate default installations solely or in combination with the string searching technique seen before.

4 Finding confidential files and data

We have clearly shown that some search engines are a serious security menace for the rest of the Internet because of their indexing policy and lack of defence against malicious users. If conventional search engines have those problems, the case of FTP file search engines is even more dangerous.

FTP file search engines, notably Lycos FTP Search, have thousands of entries that point to weak machines, machines which leak confidential and/or critical data, all over the net.

In spite of being encrypted, it is obvious that no sensible administrator wants to see his machine's password files linked from a search engine so that everyone can find them. Well, for thousands of machines over the net, this is exactly the case.

Obviously, FTP file search engines are not the only responsible for this information disclosure, because it would have been impossible with a proper protection of the machines.

Let's see some cases:

When using Lycos FTP file search engine to find files so confidential as /etc/passwd and /etc/shadow we got hundreds of interesting results.

But not only common files such as /etc/passwd and /etc/shadow leak important information about machines. For example the .htaccess and .htpasswd files, used respectively to control the access to some contents within a web server and to store the passwords that authenticate this access, are also relevant and easy to find with the help of Lycos FTP file search.

In many cases, the exploitation of the information leaked by search engines is much simpler and quicker, as when a hacker finds files encrypted with a weak algorithm that allows him to instantly recover a password. Passwords are frequently reused, so this could ease significantly the guess of the root's password. A typical example could be the weak encryption algorithm used by CuteFTP to store passwords in the file *SMDATA.DAT*, or the Netscape Enterprise Server password disclosure that is related with a poor encryption of the file *admpw*. A search for files as *SMDATA.DAT* or *admpw* will allow an attacker to obtain crucial information in a very simple and straightforward way.

5 Looking for auditing results

For ending this exposition of the risks of search engines, we want to remark that they can also be used to find security audits and assessments of machines, which gives crucial information to a potential attacker.

An interesting example is a file (we will not give more details to ease its finding) that can be find after a simple search with Google. This file contains audits of more than 4900 web servers, all in the *.edu domain, mo st of which are shown to have a very bad security.

6 Some countermesures

Obviously, search engines should take some actions to avoid indexing confidential information. Apart from the fact that this helps attackers, under some laws can be considered as a crime. Anyway, nowadays they do nothing at all to avoid this information leaking, which is certainly not only a fault of the web bots policy but also of the administrators of these machines.

Fortunately, there are a number of easy-to-implement ideas that can solve, or at least, minimize this abuse of services and information leaking.

Here we mention some of them:

1) The solution in which the translation machines behave like proxies is the most natural and simple and would be adequate if it were not for the fact that they act as anonymous proxies. This anonymity feature is a problem that could be easily solved if the translation machines tell the server which is the real origin of the request. This can be accomplished, for example, by using the REMOTE_ADDR, the HTTP_X_FORWARDED_FOR or the HTTP_VIA headers. If this were implemented in all the search engines, potential intruders would immediately stop using then as anonymous proxies. If, on the other hand, this is never implemented, probably there will be a rise in the number of people that use this mechanism and more and more webmasters will forbidden access to their pages from the range of IP's where translation machines are. The case of Infoseek (also known as Go) is an uncommon example of good practices: although they provide translation services trough SystranSoft, their services can not be abused because they use the REMOTE_ADDR http header to inform to the

web server of who did the original http request. They also avoid to chain translation proxies by rejecting auto-translation request.

2) There is no reason at all for indexing the default web pages that web servers offer. This indexing is only useful when trying to find easy victims, so bots should be programmed to do not retrieve default web pages or/and the search engine to do not show this kind of results. Both bots and search engines can have an easier work if the developers of web servers would include a default restrictive robots.txt (not may administrators use them) or a special META TAG such as:

<meta name="function" content="Default Web Server Page">

3) There are lots of files of different security value that must not be retrieved by any file bot. In fact, these bots probably should follow a very simple security policy: only retrieve what belongs to the /pub directories of ftp servers, no more no less. Retrieving, even partially, the contents of the /etc directory could be enough under some laws to motivate legal prosecution. The obedience to a file similar to /robots.txt could also be very useful in the case of ftp bots, if the developers of ftp daemons would include one in their distributions. Unfortunately, this is not the case and it will take some time (and many security incidents) to take us there.

7 Conclusions

As we have said, this paper is an attempt for improving the Internet security. It is clear that this is not a trivial task and also that the problems described into the above sections are only a small set of them.

Search engines have became an interesting hacking tool and, like any other new and powerful hacking tool, the security community must be aware of its use.

Obviously, all responsibility must not fall on search engine's shoulders: they are obviously not responsible of the huge number of insecure machines all over the net. Anyway, we strongly believe they must take some actions immediately to avoid their services being used to find and abuse anonymously weak machines or confidential information.

Nowadays, search engines do not take this menace seriously into consideration. The authors believe that the present situation must be improved and strongly encourage search engines administrators to take the proposed countermeasures into account.

Abstract: The World Wide Web (WWW) is a treasure of knowledge. To make good use of such web resources, we propose a method to generate a navigation script from a user's browsing log and the link structure between the pages. The system guesses the behavior of the user and generates a script. The script is described with sequential, selective and parallel controls.

Introduction

With explosive spread of the Internet, the World Wide Web (WWW) has become the most widespread electronic medium, and it's a treasure of knowledge for human beings. But it is not easy to have a good command of WWW, because each Web site is designed independently. We need some technique to search and make good use of the information on the WWW. Many people open their bookmarks to the public to share their knowledge of these resources. Many organizations are providing good lists of URLs. For example, U.S. Department of Education is systematically collecting hundreds of educational web resources supported by agencies across the U.S. Federal government at http://www.ed.gov/free/.

But, the larger the amount of information is, the harder we face when we browse Web pages one by one. To overcome the difficulty, we have developed Web Navigation System that guides viewers through the web resources in specified order and with the passage of time (S. Hirokawa et al. 2000). An organizer of a navigation course can determine how to make viewers follow a series of Web pages and how to make them choose from several courses.

In writing a navigation script, we have difficulties in
 (1) collecting many materials,
 (2) organizing materials in clusters,
 (3) arranging them in a series, and
 (4) making them for choice.

To solve (1), links and archives are effective. To solve (2), clustering or visualization of URLs is effective. But these solutions only provide static organizations of the material and cannot be used dynamically. There are some authoring tools such as Authorware (http://www.macromedia.com/jp/software/authorware/) for generating a web navigation. But only local materials can be used. The site of "tourum" (http://www.touru m.com/) supplies a web navigation. But the number of URLs is limited to 10 for one tour. In both systems, we need to generate a web tour by hand.

When we search for a web resource, we usually use search engines. We enquire a keyword to a search engine, and then get links to many pages. These pages contain information about the query that we asked, or they contain links to other pages related to the query. We would obtain a desired answer, some new keywords or links to follow. We repeat this process until we are satisfied. It differs from person to person what kind of the world he would obtain after these processes. We think that this is a process of Personal Information Organization on the WWW. In this paper, we propose a systematic method to generate a navigation script from such a process.

We generate a navigation script from a browsing log and link information. We can create a straight sequence of URLs applying a naive method for the browsing log. The method we propose in this paper guesses the behavior of a viewer of Web pages. Imagine that the viewer visited a page from which several pages are

linked. When these linked pages are listed on the log, we guess that he tried several choices among these links in the page. In such a situation, we form a navigation script with selective controls.

The relation of pages abstracted from the log is typically a directed graph. But it is not always the case that all of these pages are linked to each other. For example, when a user browsing a page recalls a new keyword, the pages obtained for the new keyword from a search engine may not connect to the pages he visited previously. We use the time stamps in the log to connect these separated directed graphs.

There are many efforts to refine site maps using log analysis (T. Joachims et al. 1997, M. Perkowitz et al. 2000). Our approach is different from them in a sense that the log we analyze in this paper is that of a client and is not that of a server of a site. There are researches of web tour systems (M. L. Huang et al. 1998, J. John et al. 1998). They are kinds of interactive authoring system. The method we propose is applicable independently from navigation system. All we need for generating a navigation script is simply to browse Web pages. There is no need for designers to generate navigation scripts since the method generates automatically from the log recorded while we are visiting interesting pages.

The rest of the paper is organized as follows. In Section 2, we explain our navigation system and the navigation scripts. In section 3, we describe the way to record a client's log via a proxy server. In section 4, we explain how we use log and link to generate a navigation script.

Navigation Script and Navigation System

In this section, we briefly describe our navigation system (S. Hirokawa et al. 2000). It organizes web resources into a web tour. The tour is described in a script which we call Navigation Script. We made an interpreter which controls the navigation of WWW automatically and interactively. The most important feature of the navigation system is to guide the user around web pages in specified order. So, we adapted sequential control to the navigation language. We can use multimedia data, e.g. audio, video, and images, together with html-files. Those multimedia data are played in parallel. To increase the variation of the navigation, we introduced selection mechanism. Thus, the language we made became a structured programming language with sequential, parallel and selective controls. The basic navigation unit is a multimedia data specified as URL. We designed the script language with XML. There are 6 kinds of elements as follows. All navigation courses can be expressed by combining these elements.

> <statement>: This tag represents the root of navigation tour. It may contain sub-tours as children. There are four kinds of tours, simple, sequential, parallel and select.
> <simple>: This is the basic unit of the navigation. It contains a message to represent a web page. It has the attributes of kind, target name, play time and delay time. Target name specifies the URL. Kind describes the kind of multimedia data. Play time is the duration time and delay time is the time to wait before play.
> <sequential>: It may contain sub-tours of simple, sequential , parallel and select. Sub-tours are followed consecutively.
> <parallel>: It may contain sub-tours of simple, sequential, parallel and select. Sub-tours are activated in parallel.
> <select>: It gives branches to a tour. It may contain sub-tours delimited by <selector> statement. Users can choose from the given sub-tours of simple, sequential, parallel and select.
> <selector>: It delimits sub-tours under <select> statement. It may contain sub-tours of simple, sequential, parallel and select.

A navigation script is interpreted by the interpreter program written in Java. In the visualization screen of the script, the current statement is highlighted and the corresponding html-file is displayed on the web browser. Users can use the control panel to move forward and backward. They can also control the web browser directly.

Proxy for Client Log

To trace the behavior of a user's browsing, we made a system, see [Figure2]. User A browses web pages via a proxy server. All requests from the browser is recorded in a log file, see [Figure1]. Each line of log file expresses the time, the size, IP-address, the URL and other information of the request. In the proxy server, a navigation script is generated from information of the log file. On the other hand, User B can obtain the same information by executing a navigation system with the navigation script generated based on User A's behavior.

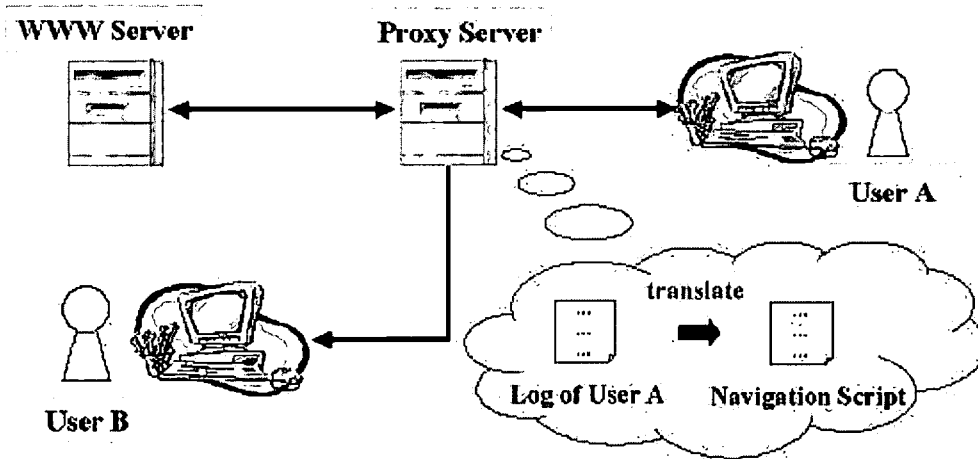
Figure1: Log file


Figure2: Proxy for Client Log

Browsing Log as Footprints on Web Graph

In this section, we explain how to generate a navigation script from a browsing log. Imagine that a user visited several pages and left the following log: a,b,e,m,n,o,f,e,b,g,b,a,c,i,j,k,l,h,p,q,t,r,u,v,w, where a,b, etc. represent URLs. And imagine that these pages are connected like [Figure 3]. The numbers on the nodes represent the time stamps when he visited the page. Note that the page "b" is visited three times and that the nodes "d" and "s" are never visited. In the [Figure3], thin arrows show links between web pages. The thick arrows "e=>m" and "h=>p" do not correspond to any link but show jumps in the browsing. We construct a navigation script as follows. Firstly we extract the URLs from the log and construct the Web Graph (D. Ikeda et al. 1999) whose nodes are URLs and whose edges are links between URLs. Note that not all of the nodes are linked. Therefore, the graph consists of separated sub-graphs. In the [Figure 3], there are three sub-trees whose roots are "a", "m" and "p". Then we try to connect separated sub-trees using time stamps. For example, we connect the node "h" to the node "p", since "p" is followed immediately after "h". We presume that the user browsed the page "p" after he visited the page "h". He might have searched for a new keyword that occurred in the page "h". Then the page "p" may correspond to the page of a search engine with the query. The page "q" and "r" may correspond to the search results. The three time stamps on the node "b" show that the user visited the page three times. There are two possibilities to interpret this log. One interpretation is to assume that he visited the page by chance. Another interpretation is to consider that he returned the page with "back button" of the

browser. We adapt the later interpretation. Secondly, we generate a navigation script from the Web Graph. We translate the nodes into <simple> statements. Then we interpret each arrow as one of the constructors of scripts, i.e., <sequential>, <select> and <parallel>. When arrows are linearly lined, as in i,j,k,l in [Figure 3], these nodes are lined as members of the same <sequential> statement. The nodes with more than two links, as b,c,p,q,u, are translated to <select> statements with their sub-trees as its members. The node "e" has two kinds of paths to "m" and to "f". The path "e->f" is a link, while the path "e=>m" is a jump. We do not distinguish these paths in translation. Thus the sub-tree that begins with "e" generates the following script [Figure 4]. Finally, we show the algorithm to translate a log into a navigation script, see [Figure 5].
Figure 3: Footprints on Web Graph

```
<sequential>
  <simple>e</simple>
  <select>
    <selector>
      <sequential>
        <simple>m</simple>
        <simple>n</simple>
        <simple>o</simple>
      </sequential>
    </selector>
    <selector>
      <simple>f</simple>
    </selector>
  </select>
</sequential>
```

Figure 4: Navigation Script generated from the sub-tree that begins with "e"

```
Input: The sequence (U_1,T_1), ...,(U_n,T_n) of URLs
       In the log with time stamp
Step 1: Generate Web Graph G=(N,E)
 N: the set of URLs
 E={(U_l, U_j) | U_l has an HREF to U_j}
Step 2: Separate G into connected components.
 G_i=(N_i,E_i) (i=1... k), N_i . N_j = ., E_i . E,
 G_i is a tree with the root U_l
 U_0 is the start point
Step 3: Make spanning trees G_i* from G_i
Step 4: Construct G* by connecting all G_i*
 for i = 1 to k{
  find the previous node U_j that proceeds U_i;
  connect U_j to U_i;
  }
Step 5:Translate G* into a Navigation Script by Tree2Script(T)

 Tree2Script(T){
 If(T is a leaf){
    output (<simple>T</simple>);
  }else{
    let T=tree(Parent, Child 1,..., Child k);
    if(k= =1){
       output (<sequential>);
       output (<simple>Parent</simple>);
         Tree2Script(Child 1);
       output (</sequential>);
    }else{
      output(<select>);
        output(<selector>);
            Tree2Script(Child 1);
        output(</selector>);

            ...
        output(<selector>);
            Tree2Script(Child k);
        output(</selector>);
      output(</select>);
    }
  }
}
```

Figure 5: Algorithm to translate a browsing log into a Navigation Script

Navigation Script as Knowledge

How to transfer and share knowledge is an important problem in information technology. When one browses web pages, he obtains much information and as a result he increases his knowledge. But it is not easy for other people to have the same experience. We can follow the pages that he saw. But we cannot understand what he was thinking and why he chose the pages. The navigation script can be an approximation of his thought and his experience. We can share his experience by following the script. The script can be a good bookmark for him as well. The script contains not only the list of the pages that he visited but also how he visited. So, he can remember what he was thinking and how he saw the pages.

In educational situation, teachers can use the script to demonstrate the process of obtaining knowledge. At the beginning, teachers keep the browsing log while they search for educational material. Then they convert the log into a navigation script. They can modify the script if necessary. The process is more important than the result. Our system can be used in another way where teachers can analyze the behavior of students.

If we focus on the logs in the same site, the system can be used for the analysis of browsing pattern of visitors to the site. The automatically generated script replays the customer's choice.

Conclusion and Further Work

We proposed a method to generate a navigation script from the user's log and the link structure of the pages. The script describes how he followed the pages and how he chose the page when there are many links from a page. The script can be used interactive tour guide of the WWW. We implemented a prototype of the system. With this prototype, we are generating many examples of navigation tour very easily. The integration of visualization and the interpreter is not completed yet. The editor for rearrangement of the script is further work.

Combining Summarization with Information Retrieval and Extraction on the Web

Beryl Hoffman
Marymount University
2807 N. Glebe Rd.
Arlington, VA 22204
bhoffman@phoenix.marymount.edu

The development of the Internet and the WWW has vastly increased the amount of information available to users. To deal with this "information overload", computer scientists are developing new tools and algorithms. Automatic summarization is becoming an important area of research (still in its infant stages) to help users deal with information overload. The ultimate goal is to have the computer "read" through a long document and automatically generate a summary of the document. However, this is a very difficult task because natural languages are so complex and full of ambiguities. This on-going research takes advantage of techniques in information retrieval and information extraction to help in the task of automatic summarization.

A summary is a brief, concise account of the key ideas in a document. To generate a summary, we must first identify the most important pieces of information from the document and then assemble them into a compact and coherent text. Our research focuses on this first task of identifying the most important information in a document; our implementation produces a summary by extracting key sentences from the document instead of concentrating on full-blown natural language generation of new sentences. Finding the most important sentences in a document is a very challenging part of summarization. Various approaches such as the frequency of words, sentence positions in the text, and the recognition of cue words have been deployed in previous research with limited success (Edmunson 1968, Kupiec et al 1995, Teufel and Moens 1997). Surprisingly, researchers have found that the cue phrase method which looks for cue phrases such as "in conclusion" was the best individual method with 55% recall and precision (Teufel and Moens 1997). Most summarization systems use a combination of many heuristics to improve their results.

Our research exploits the innovative idea of using the user's input in information retrieval and information extraction to help with the task of summarization. The implementation combines a search engine with information extraction and summarization. This allows users to search for information on the web and then see a summary constructed of extracted sentences from the documents. Search engines typically ask the user for key words in order to retrieve relevant documents. These key words can also help in the summarization task because the user will definitely want to see sentences that contain those key words in the summaries of the retrieved documents. However, the keywords are often ambiguous and do not give enough information to construct a good summary. For example, if a user types in the keyword "Washington", they may be searching for information on the person "George Washington", the city "Washington D.C.", the state "Washington", etc. To get more information from the user, the implementation asks for input typically seen in information extraction tasks.

Information extraction tools, often used for data mining, skim through documents in order to specifically look for certain information to extract. This information is then usually placed in a database. The user of these tools often specifies the exact nature of the information to extract. For example, in the information retrieval and extraction competitions sponsored by the government (MUC 1997, TIPSTER 1998), one information extraction task was to extract information about plane crashes, specifically the airline involved, the date of the crash, where the crash happened, the number of fatalities, etc., from newspaper articles online. In general, information extraction tasks seek to fill in information such as "who, what, when, and where" about a certain event. This is exactly the type of information that a summarization tool also needs.

Our enhanced search engine form asks for input keywords for the following categories from the user: Participants, Event, Date, Place, and other miscellaneous keywords. This input is used to identify the information that the user would

definitely like to see in the summaries. The software uses a typical search engine for the results; however, this separation of the keywords into different categories could really be used in the information retrieval task as well. This type of categorization can help the search engine resolve some of the ambiguities in natural language - for example, distinguishing the person "Washington" from the place "Washington".

Most information extraction tools also use pattern recognition to pick out names, places, dates, etc. This is called named-entity recognition and has been very successful. We would like to also combine named-entity recognition with information retrieval and summarization. Users should be able to enter in patterns or use patterns already stored in the named-entity recognizer to pick out any person, any place, any date, etc. This would allow users to ask questions such as "Who wrote the Catcher in the Rye?" or "When was the Declaration of Independence signed?" where patterns would be used for capitalized names or numbers that make up dates. A student researcher in our group is pursuing this area of research.

After the documents that contain the specified keywords are retrieved, they are passed into the extraction and summarization tool. The input parameters and their semantic categories (i.e. participant, event, date, place, etc.) are used to find key sentences to extract and construct the summaries. The summarization tool looks for sentences that have many of the keywords in them. This innovative approach takes advantage of the search engine input to guide the summarization and produce summaries that are custom made for the user. This agrees with the intuition that summaries are often very different depending on their intended audience and purpose.

Sometimes not all the information can be found in one or two sentences. Thus, the summarization tool also looks for sentences that just mention one or more participants and the event that the user entered. The participants and the event are the main parts of a sentence corresponding to the subject, object, and the main verb of the sentence. Additional information such as date, place, and other properties are often found in adverbial phrases attached to the main sentence or in sentences before or after the main sentence connected by pronouns. For example, if the user entered the participants "PanAm", the event "crash", and the place "Lockerbie", the following sentences may be extracted from a retrieved document:
"The PanAm crash was a horrible tragedy ... The people of Lockerbie, Scotland will never forget it."

Our research experiments with different ways to use the input parameters as well as methods such as the frequency of keywords, sentence positions in the text, the recognition of cue words for conclusion sentences, and keeping track of the subject of the sentences, to extract key sentences from documents to produce the summaries. The last method, keeping track of the subject of sentences, looks very promising. As mentioned in the example above, once the main sentence that contains the participants and the event keywords are found, additional information can usually be found in sentences that are connected to the main sentence with pronouns. These pronouns often refer to the subject of the main sentence that matches one or more of the participant or event keywords. In the example above, the pronoun "it" is used to refer to the "PanAm crash". The summarization tool recognizes pronouns and uses heuristics to resolve their antecedents in order to connect other sentences with the main sentences that contain many of the keywords. This natural language heuristic is very promising because it mimics what humans do in constructing summaries.

Our on-going research takes advantage of combining the summarization task with information retrieval and extraction tasks in order to generate custom-made summaries based on user input. The input parameters are used for natural language heuristics to aid the extraction and summarization tasks. Although summarization is a very difficult task, combining it with proven information retrieval and extraction techniques shows great potential.

Abstract: This paper describes a program of research examining ergonomic and human-computer interface issues related to on-line teaching and learning. We provide a brief description of our preliminary research where we looked at general ergonomic aspects of on-line learning (Fraser, Holt, and Mackintosh, 2000). Through a survey and focus groups with our students we investigated physical concerns, computer-related anxiety and other social and psychological impacts of computers. Several trends and contradictions emerged which we deemed worthy of further study. Students showed anxiety about several aspects of information technology: security, privacy, information overload, loss of data, cost, and keeping up with technology, which were not clearly related. Our follow-up study examined psychological and social aspects of on-line learning in greater depth, using our refined questionnaire and focus groups with nursing and computing science students. The results will be described in the presentation.

Introduction

The purpose of this paper is to describe a research program examining ergonomic and human-computer interface issues related to on-line teaching and learning. First we provide a brief description of our initial research where we looked at both physical and psychological aspects of on-line learning. The main focus of the paper will be on our follow-up research, which entailed a more in depth study of psychological and social concerns students have when they engage in on-line education.

The benefits of distance education, and particularly of on-line learning, have been widely expounded in the literature. Distance education is particularly important for many adult learners as it enables them to meet work and family commitments while pursuing their educational goals. Furthermore, computer conferencing, email and chat lines greatly enhance opportunities for collaborative learning and can help to reduce some of the isolation commonly associated with studying alone by distance education. However, whereas using technology for learning may decrease stress on one hand, on the other, it may provide added stress and discomfort for students.

Stress related to computer use can come in various forms. For example, in a review of studies of computer anxiety in the 1990s, Chua Siew Lian (1997) confirmed that computer anxiety was pervasive despite the fact that computers had been widely used for some time. There is a vast amount of literature and various studies indicating that a large number of people in the general population continue to display signs of computer anxiety as Keen (1998) and Hueser (1998) noted. There are mixed results from research on anxiety in students using computers. For instance, Taylor (1997) observed that students' anxiety decreased over time in their technology enhanced classes, and he subsequently attributed the decrease in anxiety to increased usage and familiarity with computers. It is a common myth that with more experience, people automatically become less anxious about computer use. However, Gos (1998) in his study of university students, found that 94% of the students with anxiety had prior experience, and

students without prior exp erience had no anxiety about computers. His findings led him to postulate that it may be the quality of prior experience that determines computer anxiety and not simply familiarity with computers. Hara and Kling (2000) in their ethnographic case study of students taking an asynchronous text-based, Internet-enabled course, found that students experienced a great deal of distress. Students reported pervasive feelings of frustration, anxiety and confusion due to technical difficulties and communication breakdowns, coupled with a lack of technical support

There are other concerns about computer use. Orzack (1998) and Young (1999) are among a throng of researchers who identify computer addiction as a growing issue, with a variety of negative consequences, often resulting in familial, occupational, and academic impairment. Kraut, et al (1998) in a longitudinal study of 93 families and 169 participants, found that over the first one or two years of use, greater use of the Internet was associated with declines in social involvement and psychological wellbeing. Internet users showed a decrease in communication with family members in the household, and increases in depression, loneliness and anxiety.

Ergonomics Research at Athabasca University

As faculty members in a distance education university which is offering an increasing number of courses on-line, we feel an obligation to examine potential health and quality of life issues arising from students' computer use. With that in mind, the overall objective of our program of research is to explore ergonomic/human computer interaction concerns related to on-line education, and to subsequently develop health promotion guidelines for students.

Initial research

In our preliminary research (Fraser, Holt, and Mackintosh, 2000) where we conducted a survey and follow-up focus groups with our students, we looked at aspects of computer-related anxiety and other social and psychological effects of computer use. Several trends emerged which we deemed worthy of further study. First, at least some of our students showed anxiety about several aspects of information technology: security, privacy, information overload, loss of data, cost, and keeping up with technology. Second, some aspects of computer anxiety appeared to be relatively unrelated; for instance anxiety about privacy and security issues versus anxiety about keeping up with technology. Third, heavy users appeared to have little concern about the impact that computers had upon their social lives, although there were indications that their social lives (outside of socializing on the Internet) were limited by their heavy computer use. Indeed, some had indicated that their family lives were adversely affected by their time spent on the computer. Fourth, although many users suffered moderate anxiety of one form or another, most did not see themselves as having psychological problems. This study supports other studies that have suggested that the notion of a generalized computer anxiety often cited in the literature is simplistic. Furthermore, while there are facets of computer use that make users uncomfortable, very few students seem to internalize this as a problem with themselves or with their lives. Yet the problems may be more serious than users believe: "There is an abundance of clinical and anecdotal evidence to suggest that there is something about being online that can negatively impact people in numerous ways" Greenfield (1999).

Follow-up Research on Psychological and Social Concerns.

The goals of our follow-up study were to 1) examine learners' psychological and social concerns related to on-line education and to 2) derive possible ways to prevent or alleviate these concerns. We refined our questionnaire and surveyed Athabasca University students on psychological and social aspects of computer use and tried to determine whether students are manifesting any symptoms of over-use. The survey attempted to replicate critical aspects of the previous study but concentrated on psychological/ social impacts and potential amelioration. Focus group discussions enabled us to address pertinent questions in more detail. The results of the survey and focus groups will be presented at the conference.

Teaching English Modal Verbs with Cognitive Flexibility Hypertext

Hong Lei and António Moreira
Department of Didactics and Educational Technology
University of Aveiro
Portugal
hong@dte.ua.pt
moreira@dte.ua.pt

Abstract: This paper reports an ongoing Ph.D. program conducted at Department of Didactics and Educational Technology, University of Aveiro, Portugal. The program undertakes to improve English grammar teaching and learning within the field of the English modal verbs at university level based on Cognitive Flexibility Theory (Spiro et al. 1988) employing DIDAKTOS (Didactic Instructional Design for the Acquisition of Knowledge and Transfer to Other Situations) (Moreira et al. 2001), a prototype shell designed on the basis of Cognitive Flexibility Theory.

English modal verbs have long been recognised as an area of notable difficulty for English learners at all levels of language learning (Haegeman 1983, Harris et al. 1997, Palmer 1986). The problem can be mainly attributed to their manifold meanings. The difficulties of interpreting an already complex system is compounded by the out-of-context, oversimplified, fragmentary teaching methods like providing a list of modals together with their corresponding meanings which lead to students' over-generalisation. Students may recognise or memorise the modals with their accompanying meanings but they fail to produce them in speech, a typical symptom of failure of knowledge transfer.

Within constructivist theories of instruction and learning, Cognitive Flexibility Theory (Spiro et al. 1988) provides remedy to problems associated with advanced knowledge acquisition, i.e. learning beyond the initial stage of a subject area in ill-structured and complex domains. It advocates avoiding oversimplification instruction, providing multiple representations of content, emphasising case-based instruction, context dependent knowledge, knowledge construction and not transmission, and introducing complexity at an early stage. A central metaphor associated with Cognitive Flexibility Theory is the criss-crossing of conceptual landscapes revisited from different directions in order to master the complexity and fullness of a domain, a metaphor originated from Ludwig Wittgenstein's philosophical work expounded in *Philosophical Investigations* (Wittgenstein 1997). By criss-crossing the same area from different perspectives, a web-like form of highly connected knowledge structure is created, allowing for flexibility in the application of knowledge to novel situations. A shift from single to multiple representations, from rote learning to knowledge assembly, from schema retrieval to situation-specific knowledge assembly should be realized: "information that will need to be used in a lot of different ways needs to be taught in lots of different ways" (Spiro et al. 1987)

The method most appropriate to translate the principles of Cognitive Flexibility Theory is hypertext as hypertexts provide non-linear links that allow for multiple dimensions of knowledge representation and multiple interconnections across knowledge components. These features enable learners to interact in an interconnected environment that avoids generating reductive bias which take the forms of oversimplification of complex and irregular structure, over-reliance on a single basis for mental representation, over-reliance on 'top down' processing, over-reliance on context-independent conceptual representation, over-reliance on precompiled knowledge structures, rigid compartmentalization of knowledge components and passive transmission of knowledge (Spiro et al. 1987).

Founded on the theoretical orientations of Cognitive Flexibility Theory, DIDAKTOS, a cognitive flexibility hypertext prototype, permits teachers to create hypertexts presenting any subject via different media (text, images, sound and video) when teaching ill-structured domains at the advanced knowledge acquisition stage. The instructor can create or edit cases presented in different forms, add descriptions of the cases, explain

how the themes are applied in each case, the contexts in which the cases appear, and make notes while scripting. What is more, the instructor can build special sequences to call students' attention to the connections between cases. Students can view the cases one by one, consult the descriptions of cases, themes, and contexts, look for specific themes, get special sequences, and make notes. Right now DIDAKTOS is being evaluated empirically in the present work as well as by Torres (in progress) in the area of Impressionism.

The present work strives to find out if subjects studying modal verbs in a non-linear format can achieve better levels of acquisition than subjects receiving a linear presentation of the same content and if their epistemological learning preferences influence the acquisition of this grammatical area and what the subjects' motivation and attitudes towards using this hypertext program are. English modal verbs (can, could, may, might, need, must, shall, should, will, and would) will be presented in small chunks in different contexts from distinct but complementary perspectives (normative grammar, systemic grammar, functional grammar, communicative grammar, pragmatics etc) with different levels involved (social level, socio-linguistic level, and situational level). Mini-cases of different genres (songs, video clips, newspaper articles, essays, and poems etc.) will be introduced via audio, video, graphs, and text.

Two hypertext learning environments with different structures will be created using DIDAKTOS, one in a linear, traditional way and the other in a flexible, non-linear, thematic criss-crossing way that demonstrates the conceptual interconnectedness between abstract concepts and context dependent case-specific knowledge components. Thus two groups (N=40) will be engaged. The control group will study the materials in a traditional, linear way while the experimental group will look at the hypertext with a non-linear, criss-crossed, flexible structure of content material presentation format. Pre and post tests of the subjects' factual and procedural knowledge of the modal verbs (including near transfer and far transfer) will be administered to find out whether any change will occur after the experiment. At the same time, the epistemological beliefs and preferences of subjects as regards their perception of the nature of leaning and that of knowledge before and after the experiment will be examined to determine whether there will be changes and whether it affects learning. Quantitative data obtained during the experiment will be analysed statistically. The subjects from the experimental group will be interviewed to explore their motivation throughout the experiment, opinion on the structure of the hypertext, and usability of the hypertext.

Right now, the hypertext is being scripted, themes are being delineated, and cases are being chosen. It is our belief that students will get a better understanding of this knowledge domain in terms of factual and procedural knowledge after using the program and DIDAKTOS will turn out to be an effective teaching and learning tool.

Abstract: This paper describes a Web strategic planning process at the James H. Quillen College of Medicine (COM) at East Tennessee State University (ETSU). The process began when a Web Strategic Planning Committee was charged by the Associate Dean of Academic Affairs to craft a comprehensive plan for development of the COM Website, because the existing Website did not serve the needs of students, faculty, staff, or the community. Elements of existing internal documents served as the foundation for developing the strategic plan. The resulting framework outlines guiding principles, current conditions, planning assumptions, and strategies. Strategies were aligned with the COM mission and goals. Recommendations and a framework for implementation were delineated. The resulting living document serves as a guide to help align the COM mission, goals, and values with the information technology infrastructure. It soon became evident that the original charge had broader implications affecting areas such as leadership, instruction, resources, training and support, content, quality control, and technology integration. Because these are common concerns in academia, this strategic planning process may serve as a framework for other institutions.

Introduction

Who We Are

East Tennessee State University (ETSU) is a regional comprehensive university of approximately 12,000 students and has a medical school with 250 medical students and 270 residents. The College is dedicated to excellence in medical, biomedical, and health education, research, and the improvement of health care in northeast Tennessee and the surrounding Appalachian region. The James H. Quillen College of Medicine (COM) is one of the last six medical schools established in the U.S.; the first class graduated in 1982. According to **U.S. News & World Report** (April 2001), the College tied for fourth place among the top medical schools in the nation for rural medical education.

College administrators had been aware for some time that the existing Website did not serve the needs of the students, faculty, staff, or the community. In addition, a change in administration and the departure of the sole Website administrator resulted in a chaotic state of affairs for the site. It was in this new environment that administration appointed the COM Web Strategic Planning committee and charged it with the task of producing a strategic plan. This task was to be accomplished within the timeframe of two months. The committee consisted of two representatives from the Office of Information Technology, two faculty members, one library representative and three staff members (two from the department responsible for the

COM Website). Since the committee appointees had little strategic planning experience, one of the first things to be done was to educate the members about the strategic planning process.

Strategic Planning

Strategic planning provides a means for an organization to adapt its services and activities to meet changing needs in the environment. A strategic plan is a framework that guides choices to improve and restructure programs and management, and to evaluate an institution's progress. The planning process provides direction, envisions the organization's future, and examines values, the situation, and the environment. It is a tool to align the goals developed by the planning committee with the mission and goals of the organization. A strategic plan decreases in value unless the follow-up process includes developing an implementation plan and making provisions for evaluation and continuous improvement (Fig. 1).

This document outlines a framework for creating both an academic Website strategic plan and an implementation plan. It also emphasizes the need for a formalized evaluation and continuous improvement process.

Figure 1. Strategic Planning Process

The Strategic Plan

The original interpretation of the charge was to develop a strategic plan for the COM Website. The process began by painting a vision and establishing goals for the Website, outlining guiding principles, current conditions and planning assumptions, aligning committee goals with the College mission and goals, and recommending the development of an implementation plan, as well as a process for annual evaluation and continuous improvement (Fig. 2).

Painting the Vision and Establishing Goals

The first step was to conduct a brainstorming session, during which the committee began to build a vision by articulating a desired future state of the Website and related technologies at the College. This session resulted in a vision for the Website to become a core tool to facilitate communication. The Website should enhance the ability of the College to perform its mission, reflect its image, and increase visibility by serving constituent needs. The committee goal was to create a Website that supports the COM mission.

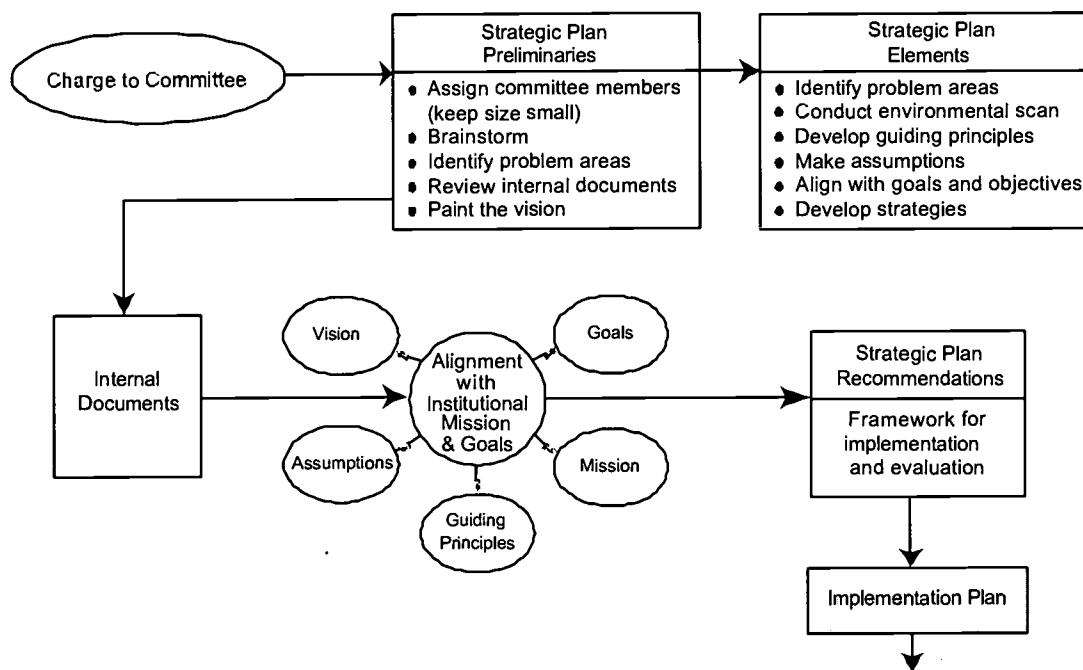
First, potential users were identified. The internal COM audience was recognized to include students, administration, faculty, and staff. The external audience was identified as prospective students and employees, the local community, business partners, government agencies, and funding sources. Second, the purpose of the Website was defined, which is to educate physicians and biomedical scientists, inform both internal and external constituents, recruit faculty, staff, students, and funding sources, and nurture constituents. Third, the purpose of the charge was discussed and problem areas were outlined. Simultaneously, a literature search was conducted. While some literature exists about strategic planning at the university and information technology levels, the search revealed that little applied to academic Websites.


Figure 2. World Wide Web Strategic Planning Process

Guiding Principles and Assumptions

Guiding principles are fundamental value statements that govern decisions and actions. These principles serve as a framework upon which infrastructure is built. At the COM, the goal is to build the framework on the acquisition and consistent use of technology throughout the College. As an example, one of the committee's guiding principles is to build and maintain a high-quality Web infrastructure that supports learning, teaching, research, community outreach, and the goals and objectives of the institution.

Planning assumptions outline the environment in which an organization exists. The committee scanned the COM environment and evaluated the state of the Website, as well as the organization of resources within the College. This environmental scan resulted in assumptions about students, administration, faculty, staff, the community culture, resources, and technology that guided decisions and recommendations.

Developing Strategies

For the Website to be an effective tool to deliver information, instruction, and other resources, strategies must be aligned with institutional planning efforts and committee goals. The committee used internal documents, including strategic plans for the University, the College, and the Office of Information Technology, to align

established goals and objectives with those developed by the committee. Strategies were developed to attain those goals (Tab. 1). Finally, prerequisites for implementing the strategies were identified.

To Enable Efficient, Effective, And Meaningful Use Of The Web To:	Web Planning Committee Strategies	Prerequisites
COM Goal #3: Promote an academic environment that nurtures research and scholarly activity **Committee Goals:** 3.1 Internal Nurturing	3.1.1 Improve access to library resources 3.1.2 Provide a searchable database for ongoing research and clinical interests 3.1.3 Provide a Web platform for collaborative consultation 3.1.4 Provide a Web reference room with appropriate links, forms, databases, and templates	? Administrative support to allocate resources ? Need standardized interface

Table 1. Strategic Plan Example

The Implementation Plan

An implementation plan is a path to the future that assesses and analyzes the needs of the institution and its constituents. The plan prioritizes core issues that are unique to the institution. The implementation plan recognizes that the Website is a critical component in the strategic planning and budgeting process.

Once the strategic plan was accepted by administration, the implementation planning process began. The committee had six months to complete the task. The implementation plan (Fig. 3) was developed by:

1. Interviewing constituents to determine their concerns
2. Analyzing information from the interviews
3. Prioritizing action items
4. Identifying resources and making recommendations
Figure 3. World Wide Web Implementation Planning Process

The traditional method for soliciting input is to develop a survey instrument. Because of time constraints, however, personal interviews were determined to be more efficient for gathering information. The interview audience was divided into two tiers. Tier one included academic and critical administrative units; tier two, special programs. Second tier interviews were postponed because first tier concerns were so consistent. When the information was analyzed, the committee discovered that problems involved more than the Website. Major concerns fell into three broad areas—user-related (delivery of instruction, collaboration, marketing, and public relations), Web-related (training and Web design), and technical-related (network infrastructure and use of databases for dynamic delivery of information). Consistent issues emerged as core topics; for example, there is a need to develop an information technology organizational infrastructure and to promote more effective internal communication. The committee prioritized core topics and made specific recommendations to help solve the identified problems.

Lessons Learned

Many lessons were learned during this process. For instance, non-experts in strategic planning are capable of creating a Website strategic plan for the institution. A little wheel spinning initially is acceptable or even desirable—working through initial struggles permits members to get to know each other and establish a productive, collaborative relationship. Other lessons learned were:

- Keep the committee small, but represent the constituents
- Stay flexible to accommodate the unexpected
- Set a timeframe
- Examine the successes and mistakes of other institutions
- Establish benchmarks prior to the evaluation process

Conclusion

The strategic plan for the ETSU College of Medicine technology infrastructure is not a rigid blueprint, but a living document to help align the mission, goals, and values with the Website strategy. The effectiveness of any strategic plan is not only implementation of the plan, but the extent to which goals are met. Therefore, an annual evaluation process, based on established benchmarks will be proposed. Following evaluation, a formalized continuous improvement process should be implemented to provide the institution with a method to analyze progress and re-evaluate goals.

Abstract: The Virtual Business Training Center (VBTC) is an integrated business resource center that provides students with access to online market research, project management, and other project-based data analysis opportunities. It also functions as a business lab and virtual training for business partners. We use this unique virtual project environment to facilitate the access of project data by students (retrieval, analysis, then evaluation), re-post as Work in Progress onto web-based environment for business partner's participation, then edit or move on to the next project phase. Our current research results indicate that the web-based environment enhances access to both volume and timeliness of data and information. This virtual training platform also speeds up analysis, and contributes to more effective project completion. The contribution to project success was measured by adherence to schedule, to agreed-upon deliverables, and to resource allocation.

Introduction

A key online business relationship exists when an organization, facilitator, and learner interact within a technology platform to develop workplace performance. These technology tools can help learners (both students and employees) target and reach their highest performance objectives quickly and with reduced trainer support. In project based classes there are exciting opportunities for problem solving to be facilitated by advanced and interactive technology interventions. New knowledge can be gained by exploring unique applications of technology platforms that facilitate project deliveries. Preliminary results indicate an increase in interaction and access (participation) of data usage, analysis of data, and facilitation work by nearly three-fold compared to traditional face-to-face project environments. Our study also reflects the number of interactions between team members and the facilitator increasing on average from 22 to 48 contacts in the web-based environment. Quality gains have been observed including an increase of at least 25% of required deliverables completed. Total project completion to schedule increased from 0% on time completion in traditional project delivery to 80% using the web-based environment. A summary of the baseline and web-based intervention environments are included in Research Design section under Background subheading of this paper. A developmental assessment effort can be used to study existing online web-based intervention platforms and their effectiveness in facilitating a project-based delivery. The focus of this paper is on the design of an assessment plan that can accurately measure the impact of using web-based deliveries to increase performance. The full discovery of this relationship requires a quick review of key trends in technology and training and then a full examination of effective assessment of online training deliveries.

Growth Trends in Technology Based Training and Instruction

There has been a tremendous explosion in the types and use of technology to deliver workplace and learning education objectives. Each technology platform has seen growth with the web-based training platforms growing fastest. Some important growth trends are highlighted by the following American Society for Training and

Development (ASTD) 1999 statistics; 30% of all training delivery types are technology deliveries, only 3% are high end interactive (EPSS) technology deliveries, the use of multimedia has risen from 12% to 22% the last two years (up to 81% with companies with progressive training strategies – designated as benchmark companies), British Open University and University of Phoenix alone has grown from 10,000 online students in 1990 to over 50,000 in 1998 (ASTD 1999), and projected growth of technology based delivery for training for 2002 is 55% an increase of 25% from 1999 (Salopek 1999).

Assessment Trends in Training and Education

There is a glaring disparity when you observe the rise of inclusion of technology in training/education while there exists a relatively low measurement of its effectiveness. The following statistics highlight some recent trends; 94% of surveyed companies assess training at Level 1 assessment which reflects no increase from 1996, 53% of surveyed companies assess training at Level 2 assessment, 29% increase from 1996, 32% of surveyed companies assess training at Level 3 assessment, 19% increase from 1996, 28% of surveyed companies assess at Level 4 assessment, 25% increase form 1996, output data collected (number of people receiving training, number of training offerings, $ spent on training, etc.) consistently lags behind input data collected (productivity, customer satisfaction, return on investment, sales, waste reduction, etc.) by 20% in almost every category, 94% of survey companies use questionnaires to assess, a low of 40% use performance records (ASTD 1997).

Assessment Challenges

The technology is used as a set of intervention tools to develop significant performance improvements. International Data Corporation's Research Manager Ellen Julian expresses the challenges as a maturation of Information Technology (IT) infrastructures that can now accommodate web based training, high interest among companies to pilot online learning systems, and an increasing pool of knowledge to implement those technologies. As an example she cites the recent acceptance and use of state of the art online chat to facilitate online training and now it is already jumped to implementing live, real time video conferencing and collaboration over the Internet (Julian 1998). The following items outline the key challenges that educators and trainers face when integrating online technologies into their delivery systems: technology developments occur faster than adoption, technology adoption occurs faster than assessment, and the most immediate evaluation challenges in business and education involve focus on expertise and commitment

New Knowledge Requirements

New Knowledge is where many training facilitators and university faculty must pause and consider their actions. Are the online interventions being used effective? Do the online interventions improve performance areas targeted? Are the online interventions more effective for the majority of the learners? Can learning using online interventions be measured? Can application of learning be measured? Other questions can and should be addressed as innovative online technology tools continue to be introduced and requirements for employee performance development increases. The burden at this point is obviously shifting from what can be done using online technology platforms to which ones work and where are they best applied. Unfortunately this is a forgotten task of trainers and faculty, we plan and do and then plan and do again without gaining key knowledge of the effectiveness of our techniques or tools. Assessment represents the set of activities that moves from doing (implementing a new online component such as video conferencing) to studying the doing action and determining whether the intervention actually made an improvement in learning or application. If we have quantitative and qualitative based knowledge in a particular online intervention that did or did not improve learning or application then we have new knowledge – assessment's ultimate goal. The process for effective gain of this new knowledge includes four steps.

Planning an online intervention – This step is not an arbitrary action guided by what technology is available or most innovative but rather a structured and focused plan. After initial defining activities selection of a subsystem to improve takes place, the improvement effort exposes identifiable skills or knowledge gaps, and then a baseline needs to be taken. What level of skills do learners possess right now? What is the level of performance exhibited currently? What is the level of satisfaction that customers of this subsystem express? What is the current training intervention used to improve these areas (classroom deliveries, CBT, etc)? This balanced measure baseline will provide data that can be used later to determine whether a new and innovative online technology training intervention has actually made an improvement in skill and knowledge application and whether that imp rovement has had an impact on exhibited performance, customer satisfaction, and competitive position. The gap between the

existing performance and desired performance is the next piece of the plan to be examined. These planning activities include identification of all the interferences between the existing performance and the desired performance. Finding the most significant interference prepares us for the next stage of a new knowledge quest.

Implementing an online intervention – Immediately after planning the training focus area that requires performance improvement selection of an appropriate online intervention is considered. The elimination of the significant interference becomes the criteria for selection of which online intervention will be best to try. At this point a match of needs, expertise and availability of technology can be maximized. A small intervention change should always be attempted first before major investments are taken and because we do not yet have knowledge of the effectiveness of the technology intervention.

Assessing the technology intervention – Quantitative and qualitative examination of the intervention as it compares to the baseline. The design, collection, analysis, and evaluation of the data results will determine whether the online technology training intervention had the desired impact, did it work?

Standardize the use of the online intervention – this step may also include the abandonment of technology interventions that do not make improvements in learning and application. Increasing retention of information that does not increase student/employee performance is not improvement and should not be used to determine technology intervention effectiveness. If an online technology intervention has been documented to improve a training output (learning and application) then the improved training intervention should be standardized. The new technology intervention should be implemented on a larger scale than the pilot. It can be used to deliver other knowledge or skills area needs (i.e. sales to software instruction) or used for all learners in a particular skill area.

Framing the Assessment

Assessment Problem Component 1 – Exhibiting Business Knowledge and Technology Skills

The project based approach is a technique, pedagogy, and delivery of business info into university and training environments and an integral piece of improving the effective training of future business leaders. Project work in general provides an environment where learners exhibit a direct, hands-on application of business skills, knowledge and attitudes. Learners have the opportunity in this environment to develop key business skills that are difficult to deliver in the traditional classroom format. The project based approach functions as a "pull" system, much like successful and innovative production control systems that require parts to be delivered only as they are needed using a Just in Time (JIT) system. Pulling the business content requirement and technical skills into the project/classroom at exactly the time learners need those enablers optimizes the benefits of experiential learning project work. It also increases the range of applications of various business skills. The question of what type of enabler (skill intervention) is needed is matched with what best enables the successful completion of the project component. The project also is the significant criteria for what should be introduced (knowledge intervention) as preparation. The timing of the required training intervention is determined by the immediate needs of the project team in resolving project problems. A comprehensive project based program will require the understanding and usage of relevant knowledge and expertise. The real time nature of projects should eliminate the expended time lag between the receipt of theoretical information and its implementation in solving problems.

Key training highlights of this Just in Time / Pull approach include; less Work In Progress – stockpiling information eliminated, quick response to problems – completion of projects require skill and knowledge gaps to be addressed immediately before progressing further, better quality – duplication of skill, knowledge, and attitudes is known and avoided by students and faculty (do it right the first time), better market response – actual business projects are as dynamic as business environment, student confidence – building cycles of success, supports practice, increases level of participation, develops levels of leadership and teamwork.

The Pull system approach - delivery and pedagogy highlights for faculty and students include; opportunities to test and refine change and improvement theories, requires exhibited knowledge, raises awareness level of business success and potential, raises awareness level of team success, raises awareness level of professional and personal success, presents challenges requiring more than one set of skills or knowledge bases, requires depth and of content and application expertise, ream centered, problem solving emp hasis, learn how to learn emphasis/self directed learning

Assessment Problem Component 2 – Making Projects Work

A comprehensive project-based approach puts tremendous pressure on the use of project management skill of both learners and facilitators. In addition, the pull system success is directly hinged to successful project completion. Unsuccessful project completion compares to covering 7 of 22 chapters in a textbook based course, the textbook range is the basis for required body of knowledge. A completed project meets the body of knowledge requirement for project-based approaches. With this in mind, executing the project effectively and efficiently is paramount to learning and success. Our recent work with technology platforms specifically focuses on more effective project management. An innovative use of online technologies is not just an alternative to be used in project based business classes, it is a better platform. An online platform in a training setting will increase participation of learners, provide more opportunities for critical thinking, enhance communication between team members, enhance communication between business sponsor/faculty facilitator/student team, increase probability of achieving required deliverables, quicker responses to faculty interventions, project closer to planned timeline schedule, more communication between team members, clearer exhibition to business skills and knowledge, more cohesive group work, project completion closer to planned specifications, earlier interaction with facilitator/faculty, earlier interaction with business sponsor, and greater number of outside experts involved with project.

Research Project Description

This applied research project will focus on examining solutions to practical problems experienced in project based classroom deliveries. This Type I Developmental Research will emphasize the study of a specific online technology platform and its use and will produce a research output that articulates lessons learned from analyzing this online technology platform in use to facilitate business projects in the workplace and college environments.

Research Questions

Can online platform improve access (increased volume – quantitative) to resources (information, data, team members, etc.)? Can online platform improve interaction (increased effectiveness – qualitative) with and among resources (team members, facilitator, sponsors, data analysis, etc.)? Can improved access and interaction through online platform improve project management success?

Are students (more?) satisfied with use of online technology to facilitate team project activities? Are students (more?) satisfied with the results of online technology toward project completion? Are students (more?) satisfied with online technology as a learning environment? Is faculty more satisfied with student participation and demonstrated expertise?

Assessment/Research Hypothesis

Can a high end and interactive online training environment enhance access and interaction of team member activities and improve project completion?

Project Statement

To improve the high end interactive online training environment as measured by frequency of access and interaction and successful project completion.

Operational Definitions for Project Statement/Hypothesis

- Access
  1. Information – schedule, work in progress, problems, questions
  2. Expertise – technical, analysis, project management
  3. Software applications – spreadsheets, scheduling, statistical analysis, etc.
  4. Planning – with sponsors, team, facilitator
- Interaction (textual or interactive multimedia using technology tools from remote locations)
  1. Synchronous – real time discussions, presentation of information or data, planning activities, consensus/decision making sessions, work sessions analyzing or stratifying data, and project status reporting.

2. Asynchronous – separate time activities that include online discussions, presentation of information or data, planning activities, consensus or decision making sessions, work sessions analyzing or stratifying data, and project status reporting.
3. Just in Time interventions – the opportunity for interventions with timely expertise. Facilitators can arrange skill based or knowledge based interventions as they observe online team activities.
- Successful project completion
  1. Deliverables – meeting agreed upon outcomes at agreed upon quality levels that become the specifications of any project.
  2. Adherence to Project Schedule

Research Design

The proposed research project will model a Type I developmental study that aligns with more traditional evaluations where the primary research focus will be on the product/program evaluation and not the development process. The development process will be described and analyzed while the online platform, as a product, will be evaluated. This research project proposes to study the impact of an existing (recently developed) online platform (product/program) on student performance with actual business projects. The product of this research will clearly be a report on lessons learned from the use of a unique online platform to facilitate and impact student teams' effective and efficient work on business projects.

Background

The evaluation of the web-based intervention will be established within a quality operations course. This Quality Principles course has 3 main learning components; review of foundation principles of quality theory, supplemental discussion issues in quality applications today (team building, organizational culture, leadership, etc.), and a business project simulation. The business simulation is an actual Continuous Improvement project completed for a Midwest organization that has been transitioned into an interactive project simulation. The project is very structure in the problem solving process as well as its required outputs, schedule, and level of accuracy. Students work in teams on the project by moving through the Plan-Do-Study-Act cycle. The cycle is broken down into a 7-phase problem solving approach with required procedures and techniques for data gathering, analysis, consensus, and decision-making. The project schedule identifies specific outputs to be completed through out the problem solving sequence including flow charts, control charts, Cause and Effect diagrams, and Pareto Diagrams. The prompt and interaction cycle is flexible but typically follows a facilitator prompt, intra team interaction, project schedule management, facilitator intervention, Work in Process outputs reviewed, team or individual interaction with the facilitator, project outputs, next prompt from facilitator.

The baseline class completes the entire project in the classroom (computer lab) with minimal outside of class interaction. A traditional business meeting format includes the team interaction as well as the facilitator/faculty participation. The meetings include work activities such as general feedback, tool development instruction, process prompts, and software application instruction.

The web-based intervention is integrated in an identical section of the quality operation course. The three main learning components remain the same with the exception being the web-based delivery and project interaction of the Continuous Improvement project. The project is facilitated entirely online including all feedback, tool development instruction, software instruction, etc. Lotus Domino and Course Info's Blackboard platforms provide threaded discussion boards, real time chat function, e-mail, file posting capability, and online work space usage.

Data to be gathered

Primary data to be gathered on frequency of access and interaction and successful project completion includes: attribute data counts on number of uses of online features (chat function, desk top video conferencing, discussion board postings, etc.), variables data on amount of time using online features as % of time on project with team and as individual contributor., attribute data on number of contacts with project data, team members, analysis features, communication, and project status information., attribute (yes/no) data on meeting project specified deliverable milestones, and attribute (yes/no) data on meeting project specified schedule milestones.

Sub study data to be gathered includes: qualitative data on student satisfaction with online platform, qualitative data on student satisfaction with project completion, qualitative data on student satisfaction with online learning environment, qualitative data on faculty satisfaction with student's demonstrated expertise and participation

Methods of Data Collection

Descriptive research method – This research method will be used to describe what is the impact on using online interventions for access, interaction, and project completion. We will summarize data (basic central tendencies – i.e. mean number of chat room intervention usage, variations – i.e. variation of measured time interacting with data posted on web site, percentages – i.e. percent of students satisfied with use of web based environment to drive business projects, and correlation between variables – i.e. measure the relationship between those students who indicate a positive attitude toward web based platform usage and number of times interacting with video conferencing feature) and review it for explanations specific to successful online interventions for effective project management. The descriptive research will also provide validation on the level of effectiveness interactive web based platforms can have on project completion.

Method of Data Analysis and Instruments

Descriptive statistic analysis – analysis will include graphics that aid in data stratification, consensus building, analysis, and decision-making. Instruments will include surveys and tally sheet/observation. This analysis will be used to represent the respondent profile, basic levels of satisfaction with online platform, baseline levels for project activity usage of online technology components (chat feature, desktop video conferencing, etc.), descriptions of use of each technology component (chat feature for brainstorming, desk top video conferencing for team data analysis, etc.), and measurement of intervention impact on team project performance. Instruments will include spreadsheet software (Excel), statistical software (SPSS), and presentation software (PowerPoint).

Cross tabulation Analysis – analysis will include graphics that aid in the interpretation of key relationships in attitudes, technology usage, and technology effectiveness. Instrument will be a survey. Software will include statistical software (SPSS) and presentation software (PowerPoint).

Variation Analysis – analysis will include attribute and variables data recording, control chart design, and control chart interpretation. The instrument will be observation/tally sheet, participant responses on checklist, and survey. This analysis will be used to represent the performance of data collected over time including counts of each tech component usage during project activity, time spent with each tech component during the project activity, determine special cause variation existence, etc.. The performance tracking will be used as baseline and as measurement to determine whether online interventions improved access, interaction, and project completion. Software will include Statistical Process Control Software (SQCPak).

Attitude Pattern Profile – analysis will include qualitative interpretation of discussions including attitude toward online technologies, use of technologies in education, use of technology in project management, team building, etc. The instruments will be interviews and focus group. This analysis will be used to verify and expand information collected and analyzed from surveys.

Abstract

This article presents the development and evaluation of a web-based lesson developed to cultivate situated learning. This research project employs the quasi-experimental method along with semi-structured interviews to investigate the effects of a web-based lesson on science learning in the senior high school level. Three classes of second-year students from two senior high schools in Taipei were selected as the participants for this study. The total participants were 110 including 49 males and 61 females. The statistic results indicated that (a) students' conceptual progress almost reached a significant level (t=1.98, p<0.051) before and after the experiment, (b) there were significant differences between male and female students on their conceptual progress before and after the experiment (F=11.48, p<0.001), and that (c) most students had positive opinions about this web-based lesson. From analysis of qualitative data indicated that some students thought that the web-based lesson, named Lesson Rainbow, provided a daily-life situation could promote their motivation on learning and help them integrate knowledge.

Keywords: Web-Based Learning, Situated Learning, Hypermedia, Science Learning

Introduction

Arising from the popularity of the WWW, education network computer applications have recently become one of the most promising education tools. The Internet provides a variety of tools for acquiring information and for thinking and allowing more students more ways to construct knowledge (Riedling, 1999). This facilitates students developing a broad, deep, and creative understanding of the available information. Based on the research reviews by Berger and others (1994), technology should be applied in fanciful and creative ways to aggrandize cognitive learning for students. These experiences provide the skills that will enable students to live productive lives in the global, digital, information-based future (Dwyer, 1994).

The merging of various types of media allows learners to select their own mode/representation during learning and make associations or links between the various representations. The digitization of media and the rapid growth of networks make the storage and retrieval of digital material, local or remote, possible. Multiple-model instructions meet individual students' needs and make learning efficient and independent. Internet technology can not only integrate the advantages of traditional CAI into instruction but also provide a variety of learning environments from self-directed learning to individual learning, one-to-one interactive learning, group learning, and situational learning (Mason, 1995). With the Internet, students are able to work with current data that are much more up-to-date, and authentic than the material in textbooks. Online resources can help students make connections between their schoolwork and the concerns of people in the real world. In these ways new technologies can make learning and curriculum more generative (Wiske, 2000). Many research have shown that the web-based instructions had positive effects on students' learning motivation, scientific attitude and learning efficiency (Hsu & Thomas, in press; Krajcik, 2000; Edelson, 2001; Hoadley & Linn, 2000). Most of these research concluded that the positive effects came from a careful design on web pages, learning

1

materials and web managements. The benefits of web-based instructions are not reaped automatically but only come as a result of careful planning.

In this study, we chose the theory of situated learning as the theoretical base for the development of a web-based lesson, named "Lesson Rainbow". It is because most of teaching contents and processes in the schooling activities do not part from real-life situations. This causes that students can not apply their learning to solve problems in their real life or in their working places. Educational reform in many countries focuses mostly on lifelong learning and transfer of what students learn to real-life situations (Ministry of Education in Taiwan, 1999; National Science Education Standards, 1996). Situated learning emphases that learning occurs in real situations and the construction of knowledge is in the continuous interaction between human and formerly situations (Brown et al., 1989; Lave & Wenger, 1991; McLellan, 1996). This leads students gain synthetic knowledge instead of inert knowledge. Three ways of realistic situations can be used in class: (1) taking students to the real workplace; (2) immersing students in an authentic or similar situation; (3) providing students an anchoring context (McLellan, 1996).

Many researchers suggested that computer hypermedia and networking technology are effective tools to simulate realistic situations when a realistic situation can not be provided in a traditional classroom (Winn, 1993; Hay,1996; McLellan, 1994; The Cognition and Technology Group at Vanderbilt, 1990, 1997; Harley, 1993). If learning activities can make a connection between the real situation and its underlying theory, it is realistic to learners (Moor et al., 1994). If computer multimedia can simulate realistic situation in a meaningful way, it can make learners to immerse in and to feel it realistic. This study attempts to develop a web-based lesson according to the theory of situated learning and to examine how the Internet supports situated learning.

Method

This research project employs the quasi-experimental method along with semi-structured interviews to investigate the effects of a web-based lesson on science learning in the senior high school level.

Participants

The participants for this study were selected from two senior high schools (called as School A and School B) in Taipei. They were second-year students and their majors were social sciences. There were four classes who enrolled in Earth Science class in School A and two of them were randomly chosen as our participants including forty-four males and forty-two females. One of two classes who enrolled in Earth Science class in school B were selected randomly as the sample including 16 males and 30 females. Totally, the participants were 132. After excluding invalid data, the number of the valid sample was 110 (49 males and 61 females).

Instrumentation

Besides the web-based lesson (called as Lesson Rainbow), there were other three instruments that were developed to collect data in students' conceptual progress and their opinions about the web-based lesson. All instruments used in this study were validated by the experts. The characters for each instrument are shown as

2

follows:

1. Lesson Rainbow (The homepage of Lesson Rainbow is shown as Figure 1): McLellan (1996) suggested there are eight key components including in situated learning: stories, reflection, cognitive apprenticeship, collaboration, coaching, multiple practices, articulation of learning skills and technology. Five of them were designed in Lesson Rainbow except for cognitive apprenticeship, coaching, and articulation of learning skills. The mapping between these components and Lesson Rainbow is shown as below (see Table 1):

Figure 1: The Homepage of Lesson Rainbow

Table 1: Mapping between the Components of Situated Learning and the Designs of Lesson Rainbow

Component	The mapping design of Lesson Rainbow
Stories	The designs of the animations display realistic situations about a story about a trip to the northeast coast in Taiwan.
Collaboration	The function of asynchronous online discussion provides students an opportunity to form a virtual learning community for collaborative learning.
Multiple practices	The formative tests following after each unit in the story provide students multiple practices.
Reflection	The electronic notebook which was designed as a learning tool helps students reflect and take notes on what they are learning.
Technology	Hypermedia and network technology display learning materials to students.

2. A Test: A test was conducted to detect students' understanding on the concepts related to rainbow, humidity, and condensation. There were 23 items in the test which was validated and was examined its reliability (The Cronbachα= 0.76) before the formal experiment.

3. A questionnaire: A questionnaire with 34 Likert-type items was used to conduct students' opinions about the design of this web-based lesson. Four dimensions in the questionnaire were the opinions on interface designs, the designs of situations, the design of learning tools and the overall design of Lesson Rainbow. The Cronbachα of the questionnaire was reported as 0.87.

4. The follow-up interviews: A semi-structured interviews were conducted to investigate students' understanding of the relative concepts and to collected their opinions about the lesson. Twenty

3

students (8 males and 12 female s) were selected for interviews based on specific purposes. Each student was interviewed for 20 -30 minutes.

Procedure

This study includes three main stages: (1) The preparation stage (01/2000~11/2000): In this stage, the major work is to develop Lesson Rainbow and instruments. After pilot study, the instruments were validated and revised for the experimental stage. (2) The experimental stage (12/2000~1/2001): The pretest of the concepts was conducted in the week before the experiment. In the experiment, students received a training session for an hour and completed Lesson Rainbow in two hours. After a week of the experiment, the posttest of the concepts and the questionnaire were administrated. Then, the selected students received the follow-up interviews few weeks later because we needed to analyze data and found typical cases for the interviews. (3) The data analysis stage (1/2001~5/2001): Data analysis and concluding remarks were the major jobs in this stage.

Data Analysis

The data were analyzed in several ways. In order to examine if there was a significant difference between before and after treatments, the paired t-test was used to compare the pretest and posttest scores on concepts. A mixed design of repeated ANOVA was used to test the hypotheses stated male students and female students had a significant difference between before and after the experiment. We used descriptive statistics for the analysis of each item in the questionnaire and used Chi square to test if there was a significant difference among the four dimensions (the opinions on the interface designs, the design of situations, the design of learning tools and the overall design of Lesson Rainbow.) in the questionnaire. The collected data was analyzed using SPSS (Statistical Package for Social Science, version 7.0). The assumptions of normal distribution and homogeneity of variance for dependent variables were tested before applying statistic methods, t test and ANOVA. If the dependent variable is not a normal distribution, the significant level is reset to 0.04 in order to reduce Type I error (Stevens, 1996). Qualitative data were coded and summarized to show a deep understanding of students' learning processes and perspectives on Lesson Rainbow.

Results and Discussion

It was hypothesized that there is a significant difference between student pre and post concept tests. For Lesson Rainbow, the mean for the pretest was 16.7 with a standard deviation of 2.32. In contrast, the posttest mean was 17.4 with a standard deviation of 2.45. The result of repeated t-test showed that there was almost a significant difference (at a 0.04 significant level because of the abnormally-distributed scores of tests) between student pretest and posttests on concepts (t= 1.98, $p<0.051$; The data is shown in Table 2).

The pretest mean was 16.6 for male students and that for female students was 17.0. In contrast, the posttest mean for male students was 16.5 and that for female was 18.1 (The data is shown in Table 4). The result of mixed design of 2X2 ANOVA showed that there was a significant different between male and female students' performances on the pretest and posttest (F=11.48, $p<0.001$; The data is shown in Table 5). Few male students said that the animations in Lesson Rainbow were not as attractive as online games in interviews. Their low

4

attention on learning materials leaded to their low performances in the posttest. Computer logs also showed that less male students participated in the online discussion than female students did. This may reduce male students' knowledge construction. Both reasons made male students could not learn better than female students.

Table 2: Summary Table for Paired-t test

N=110	Mean	S.D.	t Value	P
Pretest	16.7	2.32	1.98	0.051
Posttest	17.4	2.45		

*p<0.04

Table 3: Descriptive Statistics

	Male(N= 49)		Female(N= 61)	
	Mean	S.D.	Mean	S.D.
Pretest	16.6	2.22	17.0	2.39
Posttest	16.5	2.55	18.1	2.14

Table 4: Summary Table for Two Way ANOVA

Residual(C* S)	108	593.60	5.50		

*p<0.04; **p< 0.01

The data from interviewing the 20 students showed that most students thought the web-based lesson was more interesting than textbooks because of the animations and interactions. The online discussions made students feel more involved in the learning activities. Five of twenty students suggested that the teacher should participate in the online discussion with them because sometimes they did not know how to solve problems without the teacher's scaffolding. A student said in his interview: " *If the teacher could participate in the online discussion, it would increase the interactions and cleared confusions. I would learn better to have the teacher to involve in the online discussion.*" Different students have different needs in a web-based learning environment. Few of them need teachers' assistances because they are lack of skills on communication and reflective thinking. It is advised that the well-trained teachers involve in online communications with students in order to help weak students overcome their obstacles.

Conclusions

The focus of this study was on investigating the effect of a web-based lesson (Lesson Rainbow) developed to cultivate situated learning. The realistic situation served as a bridge to connect students' daily-life experiences and constructing knowledge. Most students had positive opinions about Lesson Rainbow. From interviews, some

5

students said that animations for the simulation of authentic situations could promote their learning motivation and immerse them in an interesting context for meaningful learning.

Networked technologies support collaborative work in which the students combine components or work together making successive drafts (Wiske, 2000). Social learning theory emphasizes the value of dialogue and collaboration in helping students develop and articulate their understanding. In order to reach effective cooperation, students need to share ideas, adventure and argue with others so that they can come to reasonable interpretations of the subjects they are studying (Blumfnfeld, et al., 1997). Students can compare the varied views of a topic and enhance cohesive understanding of science from a well-designed online asynchronous discussion In this study, Lesson Rainbow succeeded in helping students knowledge integrating by evoking discussions for searching answers of the questions after realistic situations. When students communicate with others, they retrieve their pre-knowledge and reconstruct concepts. Meaningful learning occurs when students interact with others or environments (Savery & Duffy, 1995). Therefore, online asynchronous discussion designed for a situated learning environment can promote knowledge integration.

Abstract: Increasingly, peer-to-peer collaboration is being used as an on-line instructional strategy. Unfortunately, creating an environment for collaboration over the web to occur doesn't just happen automatically. Many social and psychological barriers may present themselves. Collaboration on-line requires students to master unfamiliar technologies and ways of interacting. Furthermore, there are issues related to the lack of face-to-face contact. For example, the lack of nonverbal and social context cues (e.g., facial expressions and gestures) can hinder the development of trust. Group dynamics on-line are different, resulting in task groups taking longer to get oriented compared to face-to-face groups. Finally, a sense of social presence (for the instructor as well as students) is more difficult to establish and maintain when there is no face-to-face contact. While many papers suggest that one or more initial face-to-face meetings will improve collaboration, face-to-face meetings are not always possible or desirable. This leaves us with the need to address these issues in more creative ways. Our recent literature review provided some useful guidance on how instructors are adapting to the challenges of web-based collaboration. In an effort to gain a more complete understanding, we are posting a survey on the web that will question instructors about their collaboration facilitation strategies. Based on these results, we will develop a set of guidelines for effective use of on-line collaboration.

In the last few years, the Web has been increasingly used to not only share existing knowledge, but to create opportunities for knowledge generation through collaboration. Collaboration can occur asynchronously (for example, through e-mail) or synchronously using software packages known as "groupware." Groupware packages (e.g., Lotus Notes, Microsoft Exchange, Netscape Suite Spot, and Novell GroupWise) commonly include features such as conferencing, group decision support, meeting support, document sharing, bulletin boards, and chat that can foster direct interaction between individuals in a group. Group members can debate, engage in role-playing exercises, post questions and responses, or even compose collaborative documents in real-time.

These features have the potential to help manage and create intellectual assets by promoting the sharing and storing of ideas and expertise. Group collaboration has been used to promote learning in academia by exposing participants to alternative points of view in the context of problem solving. Conflicts between peers force them to defend their positions as well as seek additional clarifying information. In addition, the act of explaining has been shown to benefit both the more knowledgeable and the less knowledgeable peers (Webb, 1982, as cited in Hiltz, Coppola, Rotter, Turoff, & Benbunan-Fich, 2000). Not only can collaboration enhance learning, but it may also foster important social interactions, reduce the sense of alienation distance learners sometimes feel, and increase satisfaction with the learning experience (Hiltz &

Benbunan-Fich 1997; Irani, 1998; Clark, 2000). Hiltz et al. (2000) present evidence that while learning in isolation on-line is less motivating than learning in a traditional classroom, working collaboratively on-line leads to higher motivation than in a traditional classroom setting.

In contrast to cost-cutting "digital diploma mills," which require little interaction between students or between the students and the instructor, more educators are opting to create high quality on-line learning environments that embrace interaction, collaboration, and a supportive learning community (Hiltz, 1999). Unfortunately, creating an environment for collaboration to occur doesn't just happen automatically. First, considerable effort and skill on the part of the instructor is required. In addition, many social and psychological barriers may present themselves. Independent students, who may have self-selected into the distance learning format, may resist group collaboration. One hurdle is to get these students to buy into the idea. Another obstacle, which is relevant to many on-line learners, is that collaboration on-line requires them to master unfamiliar technologies and ways of interacting. Furthermore, there are issues related to the lack of face-to-face contact. For example, the lack of nonverbal and social context cues (e.g., facial expressions and gestures) can hinder the development of trust. Group dynamics on-line are different, resulting in task groups taking longer to get oriented compared to face-to-face groups. Finally, a sense of social presence (for the instructor as well as students) is more difficult to establish and maintain, when there is no face-to-face contact. While many papers suggest that one or more initial face-to-face meetings will expedite trust, familiarity, and a willingness to collaborate, one of the primary reasons why students engage in distance learning is the convenience of anytime, anyplace learning. Thus, face-to-face meetings are not always possible or desirable. This leaves us with the need to address these issues in more creative ways.

The Joint Advanced Distributed Learning (ADL) Co-lab, which supports the implementation of ADL within the military, is coordinating with the research and development and academic communities in order to identify the best practices in on-line learning. Collaborative, asynchronous learning is seen as a promising approach for training military teams, who must work collectively, despite the fact that they are often distributed geographically. A recent paper (Hughes, Wickersham, Ryan-Jones, and Smith, in press) by members of Joint ADL Co-lab reviewed the literature, finding that for on-line collaboration to be most successful, participants must: (1) see the value of expending the (considerable) effort required, (2) be comfortable with and trusting of the medium, (3) be comfortable with and trusting of their instructor (or facilitator) and their fellow collaborators, and (4) feel as though they are immersed in a rich, engaging, and rewarding social experience.

The literature review produced some good clues as to how to address these issues. Instructors working on-line have been adapting to these requirements in a variety of practical and innovative ways. For example, most instructors provide some sort of orientation training to students. The content of this training varies widely. It may include an assessment of each student's technical ability, so that the instructor gets a good idea of who will need the most technical help. Some instructors discuss "netiquette," the social conventions associated with on-line interactions. Others may include ice breaker activities such as informal social web conferences or group based on-line games. Another approach some instructors have taken is to have students introduce themselves to others in the group by posting biographical sketches of themselves.

We have a sense that many instructors teaching on-line are probably addressing the challenges of web-based collaboration in idiosyncratic and innovative ways, but not necessarily publishing their practices. Thus, a substantial amount of useful information may be slipping between the cracks. We want to gain a more complete understanding of what instructors are doing to facilitate on-line collaboration. Furthermore, we want to encourage the sharing of these practices and ideas. In order to collect more detailed information about what instructors are doing to facilitate collaboration in their on-line courses, we have developed a survey, which will be posted on http://www.jointadlcolab.org. Based on the data we collect with this survey, we will develop a set of guidelines for how to most effectively use collaboration as part of an on-line instructional strategy. This resource will be posted on the web site and will be available for civilian as well as military instructors.

The Impact of Information and Communication Technology (ICT) on Job Characteristics of South African University Academics

Andy Igonor, ICUS Pte Ltd, Singapore; Andy Igonor, University of Fort Hare, South Africa ; Yolisa Soul

A study was recently carried out on the use of Information and Communication Technology (ICT) by South African University Academics. The impact of ICT on job characteristics of academics - teaching, research and to a lesser extent, administrative duties was investigated. Academics at the University of Fort Hare, South Africa's oldest and first historically black institution (HBI) were tested in this exercise. Realizing that South Africa's HBIs exhibit a lot of commonalties in structure, operation and management, no doubt, this study strongly reflects the general situation with this country's HBIs. Academics across all disciplines and hierarchy were included in this questionnaire survey supplemented by interviews. Results indicate an established need for ICTs, a general lack of adequate computer facilities, low level of computer literacy among academics, a need for training in ICTs, high level of unreliability in networking allowing access to the use of the INTERNET, and the non-existence of ICT policies for computer equipment upgrades, hardware and software purchases and training. Albeit, it was evident from the study that academics with adequate knowledge of the use and application of ICT in their jobs did record significant improvement in the discharge of duties.

Retrieval System of On-Line Kanji Dictionary with Learning Functions

Koji IIDA, Kazuto YAMADA, Shinichi FUJITA, Seinosuke NARITA
School of Science and Engineering, WASEDA UNIVERSITY
Japan
iida@narita.elcc.waseda.ac.jp

Abstract: In this paper, the authors have attempted to develop a useful system in retrieving Kanji. It will be terribly difficult for non-Japanese people to master Kanji because Kanji characters are over 2000 and their shapes have much complexity. Especially it is hard to retrieve Kanji with a conventional dictionary. Even if the user does not know any of Reading, the total number of Strokes, Radical, this system allows people to look up Kanji characters easily by only selecting its simple peculiarity such as the number of vertical lines, a number of horizontal lines and some parameters. This system works effectively by just only mouse click when someone encounters an unfamiliar Kanji character. This system consists of the client and the server. The database of this system is updated when the user retrieves a certain Kanji. For that update, this on-line dictionary will become more useful.

1.Introduction

In this research, the author has constructed a Electronic Kanji Retrieval System which enables the user to look up Kanji characters easily only by mouse click even if the user has little knowledge about Kanji. The quantity of Kanji is over 2000 and the shapes are complicated. It is very difficult to look up Kanji characters in a conventional dictionary when people in the countries where Kanji characters are not used have met an unfamiliar Kanji on the newspaper. The author will use the term Non-Kanji-User as people in the countries where Kanji are not used. It is necessary to know any of Pronunciation, Total strokes or Radical (the special element which composes Kanji) to look up Kanji characters. However, they often cannot specify this information correctly. We know another retrieval system, which enables the user to look up Kanji characters from parts of Kanji[1]. For example, when people retrieve Kanji 春, they can retrieve it from 三, 人, and 日. This retrieval method would be effective for the Japanese. However, it is not easy for Non-Kanji-User to use this method, since foreigners will have difficulty to find an individual Kanji which composes the Kanji. Then, we have developed a quite new, epoch-making method. This method enables people to retrieve Kanji by selecting the number of vertical lines, the number of horizontal lines of Kanji, the presence of the point, etc. Furthermore, this system has the learning functions and copes with a difference of an individual sense. This system consists of the client and the server. And the database is put on the server side. The database on the server is updated in accordance with an input of the user. This system takes account of commonly selected parameters and comes to show proper Kanji characters in higher rank by updating the database.

2.System Configuration

http://www.narita.elec.waseda.ac.jp/~iida/kanji/retrieval/index.html

2-1. Advantages

Even if the user does not know any of Total Strokes, Reading and Radical, people will look up a Kanji characters easily with only mouse. The Kanji that the user wants will be displayed in the high rank even if the input parameters are different from models a little. This system is different from a conventional dictionary and it enables the user to check meanings, idioms, pronunciations, and animations that show its structure with multimedia technologies. From reason mentioned above, it is possible to use this system as the integrated study dictionary.

2-2.Procedure

The user inputs six parameters of Kanji he/she wants to look up. The definition of Parameters is given in Chapter2-3 below. These parameters are compared with models set in each Kanji. These models have been set beforehand as value the most people seem to select. Five Kanji characters that have a strong possibility are displayed in the browser. The user clicks a most pertinent Kanji. The following five Kanji characters that have strong possibility are displayed by click a NEXT button when a pertinent Kanji is not displayed. Information of the selected Kanji is

drawn out from the database, and it will be displayed in the browser. The model in the database is updated in accordance with the parameter.

2-3. Parameters

The following six parameters have been adopted. A: The number of vertical lines. B: The number of horizontal lines. C: The number of slash lines. D: The number of penetrated points. E: The existence of closed space. F: The existence of point. For instance, in the case of 村 A=2, B=2, C=2, D=2, E=0, F=1 村 does not have any closed space. So we show you another example (Fig.1). That has a closed space.
Fig. 1 parameters

2-4.Retrieval methods and Display of data

The Kanji is retrieved in accordance with the input. The following items were registered in the database. They are Kanji, Readings, Meanings, Radicals, Strokes, Examples, Animation files, Sound files and models about each of Kanji. We registered six parameters as models in advance. This system retrieves Kanji by comparing these parameters with models. This system makes proper Kanji displayed if many parameters are the same as models. The question now arises: some people may consider that there are three vertical lines and others may consider two. For instance, about 川 some people may regard a left part as a vertical line and others may regard it as slash. Using the update of the database solves such an individual difference. Concretely, the model of vertical line of 川 is three. When a user inputs a vertical line number as two, the value of the model that corresponds to two goes up gradually. When some inputs are different from models, the models in database will be updated in accordance with the each input. Five Kanji characters are displayed in order with high total point after the total point is calculated to each Kanji. When the user will choose most pertinent Kanji that is displayed in a Browser, the button of meanings, examples, Animations that show its structure is displayed in the browser. In giving the above-mentioned operation, even if the input is different from the models registered in the beginning, the total point goes up and Kanji which the user wants is displayed preferentially. That is to say, if a lot of people select a Kanji displayed as the second Kanji in the beginning, it comes to be displayed as the most pertinent Kanji. The Japanese language beginner will retrieve Kanji the user wants more easily.

3.Conclusion

In this paper, we described the Epoch-making method of Kanji-English dictionary. This system enables the user to looked up the meaning of an unfamiliar Kanji even if the user did not have detailed knowledge about Kanji. A lot of foreign students come to Japan to learn Japanese language. They need Kanji dictionary for not Japanese but them. Our system has provided foreigners with opportunities to learn Japanese by themselves. We are convinced that this system will work effectively for them.

4.Future work

After we will bring the evaluation of this system, we will improve this system in the light of advice from teachers and students. Now Shockwave Plug-in is needed to use this system. We will advance a development with Java because Java can achieve the multi platform use. We will develop PDA version of this system as soon as possible. PDA will enable the user to look up Kanji in town.

The Internet And Africa From A Sub – Saharan Perspective

Poncelet Ileleji, YMCA Computer Training Centre - The Gambia, West Africa

Owing to this my paper will try to focus on the impact of the Internet and Africa from a sub – Saharan perspective, my reason for this is based on my field of experience in this sub – continent of Africa both as a computer lecturer, educator and information technology consultant. Talking about communication in general first and fore most in Africa it is a very sorry state, either be it road communication, air communication, rail or even sea communication or telecommunication, the word communication in the whole of Africa at large has become related with the word problem. Hence it is not surprising that with the coming of the Internet in Africa which relies heavily on one form of digital communication or the other a great deal of work has to be placed for this now important aspect of communication to take place with out any loops holes.

A Web-Based Distance Learning System to Support Professional Training for Librarians

ueno@nii.ac.jp

Abstract: This paper presents a WWW-based distance learning system to support professional training for librarians and its initial evaluation. The system is taking place of a current training course that our institute offers to university libraries nationwide. The course offered by the system is about a system to support inter-library loan service, and is made up of multimedia information such as narration and animation. The course features: 1) Repetitive and clear presentation of current location of a learner 2) A simulator to learn operation of a system 3) Learning modes that support stepwise learning. The initial evaluation by questionnaire showed good acceptance of the system on the whole.

Introduction

The importance of education has been recognized anew globally. G8 Summit at Köln in June 1999 and G8 Education Ministers' Meeting at Tokyo in April 2000 were symbolic events. There the importance of lifelong learning and the importance of using information and communications technology in education were reconfirmed (G8 99)(G8 00). Research on distance learning has been active with the development and growth of information and communications technology, typically the Internet, WWW, and low-priced PCs. The circumstances are the same in Japan, but a great part has directed to elementary and secondary education. Some of the initiatives to elementary and secondary education were the 100-School Networking Project, the E square Project (Center for Educational Computing 99), and the "infomationization" of education in the millennium project(Prime Minister of Japan 99). The research and deployment of distance learning in other educational categories such as higher education and professional education are themes from now on. The higher education council organized by the Ministry of education, science, sports and culture (now the Ministry of education, culture, sports, science and technology) pointed out the importance of the provision of distance learning environment using information and communications technology (Monbusho 00). We have been conducting a research project of distance learning under those circumstances (Inoue 00).

This paper deals with a web-based distance learning system to support professional training for librarians and its initial evaluation. It is a practical research that uses an existing professional training. Also it is a project that shifts a training course in a room to a distance learning setting. Such a case will be increasing as distance learning becomes widely accepted.

The initial evaluation resulted in good acceptance of the system and the course on the whole. We could have a prospect that a use of distance learning to this type of professional training is possible through this case. Also we had many comments on our distance learning service.

An inter-library loan system and its training course are presented in the next section. Then a web-based distance learning system and its course are explained, followed by its initial evaluation.

Table 1: Table of the contents

Training Course of the Inter-Library Loan System

Our institute gathers, organizes and provides scholarly information and relevant systems nationwide. One of the tasks is catalog information service. The inter-library loan system is used to provide a part of the service. It supports to manage exchange of information that is needed when academic documents are exchanged between university libraries.

We have conducted a training course of the inter-library loan system, which offers lecture and practical training of the system to librarians. Current training course is 2-day course in a room Thus time and places for holding is limited. As a result, less than 60% of those who would like to take the course have been allowed. Booking a number of lecturers has been also a problem.

Web-Based Course of the Inter-Library Loan System

A web-based distance learning system has been developed to offer opportunity of the training widely. It is a self-paced learning system based on a commercial product. It has three-tier structure that uses a Web browser, Internet Information Server and Active Server Pages for the Web server, and SQL Server for the data base. The data base stores administration data and course structure data. The source contents are stored as HTML files, and are linked from the course structure data. The Active Server Pages script files control the system (Fig. 1).

The web-based course of the inter-library loan system succeeds the current training course in its contents. A textbook of the training course that has been revised many times so far is used as a base of the web-based course. The web-based course has the table of contents and has the structure of chapters, sections, and subsections. From the table of the contents, the chapters and the subsections are linked to the corresponding pages that enables users choose a specific topic directly. The contents are shown in (Tab. 1). Yet the course is enhanced by animation, video, and audio.

To learn the operation of the inter-library loan system is a major part of the training course. To know the whole figure of a job in advance is helpful when learning steps within. The course shows task flows and explains them before going into smaller steps. Specifically a whole figure of a job is shown and is explained in the beginning of a chapter, because typically a chapter corresponds to a job. Then a page such as (Fig. 2) is shown in the beginning of each section. Here the figure on the right is the same as presented in the beginning of a chapter. More detailed explanation for a procedure, which is a part of a job, is given in a section. In the figure, a procedure to be explained is a highlighted arrow on the right. The procedure is represented as a sequence of tasks, which are shown on the left, and is explained step by step with animation and narration. A learner is able to locate himself/herself in a way of learning because of this clear and repetitive presentation of whole figure.
Figure 2: Explanation using a task flow

Figure 3: Instruction in the lecture mode

Figure 4: Instruction in the guided mode

The course has three modes of learning, which are lecture mode, guided mode, and practice mode. In the lecture mode, the objective and outline of each chapter is explained. The operation is instructed by animation and narration. A learner learns passively in this mode. (Fig. 3) is an example. An exercise is given in the upper left. On the right is a screen of the inter-library loan system that shows the answer operation by animation. The instruction is presented on the bottom left by text and narration. The lecture mode is followed by the guided mode and the practice mode in the sections to learn operations of the system. In these modes, a learner can practice several exercises including the ones that are presented in the lecture mode by using a simulator of the inter-library loan system. The use of the simulator corresponds to a practice that uses the inter-library loan system in the current training course. (Fig. 4) is an example of the guided mode. An exercise is given in the upper left. The simulator that is on the right allows operations such as input to the blanks from a keyboard, selection of options, and putting the buttons. The screen changes to the next screen by the correct operation to the simulator. An error message window that prompts another try pops up by the wrong operation. Clicking "the operation guide" button on the bottom left calls the guidance window.This interactive environment is intended to give a learner a real learning experience. The guided mode is the same with the practice mode with the guidance window in implementation. Typically a learner begins a exercise without guidance first. When he/she is stuck on the way of the operation, he/she may call the guidance window and follows the instruction there to complete the operation. Each learning mode is intended to relate closely so a learner can progress gradually by himself/herself.

Pre test and post test are placed at the beginning and at the end of the course to assess learner's achievement by the course. The course also has exercises that are located at the end of each chapter and an comprehensive examination that is located at the end of the course. They have marking function.

Initial Evaluation

Initial evaluation of the system was conducted. Total of 34 subjects (10 men and 24 women) from 19 university libraries participated as a learner. This section describes the result as well as the improvement afterwards.

Method

The subjects filled out a web-based questionnaire after use of the system. The number of the items of the questionnaire was 15 including affiliation, name, the sections of the course you went through. Other 12 items are shown in the left side of (Tab. 2). Both structured questions that used five-point Likert-like scale and open-ended questions were applied to the questions about usability and the course.

Two thirds of the subjects went through the whole course, and most of the subjects went through more than a few chapters. The subjects were classified in terms of experience of the inter-library loan system. Majority of those had experience over a year, while rest of those were novices. Appraisal by experienced users was considered to be useful because they knew what was important for actual work and what should be learned in the course. Appraisal by novices was useful as well because they were the prospective users of the system.

Usability

"Mouse-base usability" concerns clicking operation by a mouse to move between pages. "Good" and "Neutral" were most selected. Some users would like to use short keys for buttons.

"Good" was most selected in "Narrative explanation." Repeating from the start was the only function to listen to the narration in a page. There were requests for a function to stop at and repeat from any part of the narration. A stop button was added to each page then. There was a comment that it might be a case that a course with sound like this was undesirable when used in actual work environment. We thought this was worth listening. Its situation of use should be considered when designing a course. Design of a course is not closed within the course.

"Very good" was most selected in "GUI appearance understandability." There was a comment that a repeat button of narration was not easy to find. It was a triangular icon between two arrow icons for the previous page and the next page.

"Neutral" was most selected and "Long" was also selected by several subjects in "Duration before narration." It seemed to depend much on the network conditions.

Contents of the Course

Time required

"Less than 3 hours," the shortest choice, was most selected in the "Time required for the course." It was the same as in the "Average time required for a chapter." "Less than 0.5 hours" was most selected. Wide range of choices was prepared considering that the current training course use 2 days. However more useful result might be gained if there were choices in shorter range. The relation between "inter-library loan experience" and the "time required for the course" in (Tab. 3) shows that experienced subjects tended to use shorter time than novices. Yet even novices use much shorter time than 2 days. It is known that self-paced CAI system such as this decreases learning time compared to class lecture (Yamamoto 97), although the biggest reason of the result is supposed that this use was not for actual learning but for evaluation of the system. Additionally, the net time required for the course, the time only for listening the narration once that does not take network conditions into account, is shown in (Tab. 4).

Inter-library loan system experience	None	Less than 3 months	Less than 6 months	Less than a year	More than a year
	8	1	1	2	22
Time required for the course	Less than 3 hours	Less than 6 hours	Less than 12 hours	Less than 18 hours	More than 18 hours
	23	10	1	0	0
Time required for a chapter	Less than 0.5 hours	Less than 1 hours	Less than 1.5 hours	Less than 2 hours	More than 2 hours
	25	8	1	1	0
Mouse-base usability	Very good	Good	Neutral	Poor	Very poor
	7	14	12	1	0
Narrative explanation	Very good	Good	Neutral	Poor	Very poor
	10	15	7	1	1
GUI appearance understandability	Very good	Good	Neutral	Poor	Very poor
	16	3	5	0	0
Duration before narration	Very short	Short	Neutral	Long	Very long
	0	2	18	8	6
Difficulty of the contents	Very difficult	Difficult	Neutral	Easy	Very easy
	0	1	31	2	0
Difficulty of the expression	Very difficult	Difficult	Neutral	Easy	Very easy
	0	2	32	0	0
Difficulty of pre/post test	Very difficult	Difficult	Neutral	Easy	Very easy
	1	2	31	0	0
Difficulty of exercises	Very difficult	Difficult	Neutral	Easy	Very easy
	0	1	30	3	0
Difficulty of comprehensive examination	Very difficult	Difficult	Neutral	Easy	Very easy
	0	1	31	2	0

Table 2: Result of the questionnaire

Time required for the course	Inter-library loan system experience: None	Inter-library loan system experience: More than a year
Less than 3 hours	4	16
Less than 6 hours	3	6
Less than 12 hours	1	0

Table 3: Relation between inter-library loan system experience and time required for the course

Chapter	Time (sec.)
0 (Start page)	25.4
1	585.1
2	428.0
3	670.6
4	819.6
5	229.7
6	227.9
7	315.4
8	314.5
9	160.2
10	138.7
11	665.1
12	139.2
13	228.3
14 (Appendix)	N/A
Total	4947.7

Table 4: Minimum time required

Difficulty

"Neutral" was most selected in each of "Difficulty of the contents," "Difficulty of the expression," and "Difficulty of the examination." Succession of the contents from the current training course was highly appraised. The task flows were evaluated highly as useful for understanding. In the each job of inter-library loan, a learner could be the one who send a request or the one who receive a request. We had a comment that a novice was often confused by the nature that was essential for an exchange. So we changed the background color according to the sender's side or the recipient side of a request to make the distinction clearer. It also appreciated. The examination was evaluated affirmatively on the one hand in that a learner could realize his or her own understanding. On the other hand, it was demanded to change to show explanation to the result and to show the referential part of the course.

Conclusion

Distance learning, which is getting popular, does not mean to make a big gap between conventional education in terms of the things learned. It is more likely that the contents do not change even if the form or the expression of the contents changes. This is applicable to the research presented in this paper. We explained how we had been changing our professional training course into the form of web-based learning. Development of the web-based distance learning system was carefully conducted especially in its course design. Specifically we applied a few ideas that would help learners master the contents easier. They were repetitive and clear presentation of the current location in a whole procedure, the use of a simulator of the actual system, and the application of stepwise learning modes. The course design was not totally new, but was improved substantially based on the current training course and its textbook. The course produced through such a procedure was not surprisingly fantastic, but was easy to accept for the users. It is thought to be one of the reasons that the contents of the course gained good evaluation.

From the result of the initial evaluation, we could conclude that web-based distance learning is a realistic solution to make professional training like this widely available. Besides, we could get many comments. Some of them clarified a couple of important points that should be considered when providing distance learning services. One thing was that it was currently necessary to take the network conditions into account. Those who selected "Very long" in "Duration before narration" also mentioned that point. It showed that it was important not to wait. The other was that a learner felt the course monotonous when he or she takes it continually. Long-time continuous use was often seen because the use was for evaluation this time. However it would be applicable generally. Because it is different from something that could be solved by using multimedia, it is desirable for example to give opportunities to suspend learning in the course.

Although the subject of this research is professional training of the inter-library loan system, the course elements employed in this research such as a task flow, a simulator, and a learning mode could be applied to a similar course that contains routine operations. This type of training course is presumed to be fairly common.
