IDENTIFIERS Compulsory Education

ABSTRACT

This study reports the comparative increase in enrollments at each level of education in all 22 member countries of the Organisation for Economic Cooperation and Development between 1950 and 1965. Data are also included for Yugoslavia, an associated member country. The first two chapters deal with enrollment trend analysis -- chapter one being concerned with total enrollments and chapter two with each educational level separately; while chapter three is concentrated more particularly on the incidence of demographic factors on the rise in enrollments. In chapter four, the authors endeavor to extrapolate the trends observed during the period studied up to 1980. The main conclusions drawn from the study are presented in the final chapter. The statistical material used for determining enrollment trends, an examination of the structure of each country's system (together with the changes that have been made since 1950), and certain technical details concerning the extrapolation of the trends observed in chapter four are provided in three annexes to the document. Related documents are ED 057 470, EA 004 323, and EA 004 421-425. (Author/JH)

EDUCATIONAL EXPANSION IN THE O.E.C.D. COUNTRIES SINCE 1950Summary

Between 1950 and 1965, school and university enrolments in all Member countries combined rose from 101 million to 152 million, i.e. a 50 per cent increase, while at the same time the population aged 5 to 24 rose by only 23 per cent.

Furthermore, some 22 per cent of the total population was at school or university in 1965.

This increase in enrolments was greater in absolute figures in secondary education than in primary education for roughly half of these countries.

The structure of the educational pyramid has consequently changed; primary school enrolments have gone down relatively to the benefit of enrolments at other levels. Higher education enrolments in particular accounted for more than 4 per cent of the total for over half of the countries in 1965, whereas in 1950 only the United States exceeded this proportion.

Relatively speaking, primary school enrolments have had the slowest increase. In seven countries, secondary school enrolments went up more quickly than those in higher education (France, Iceland, Norway, Spain, Italy, Portugal and Turkey). In the other 16 countries, higher education increased more quickly. At the same time, the increase in higher education gained pace at the end of the period, while it tended rather to slow down at the other levels.

Enrolment growth indices between 1950 and 1965

(1950 = 100)

	1st level	2nd level	3rd level	Total
Common market	113	201	234	137
Other European countries	113	166	249	131
Developing countries	158	293	288	177
North America	162	206	248	176
Japan	96	152	271	121
Total	132	187	250	150

Total	72.6	95.9	24.4	45.6	3.9	9.8	101.3	152.1

* Including enrolments not divided between the various levels (e.g. special education).

Source: Table II.

The following may be observed at each of the three levels:

- (a) pre-school education enrolments increased more quickly than primary;
- (b) at the second level, technical education increased more or less quickly than general education according to the country, although there was no dominant trend;
- (c) non-university education generally developed more quickly than university education.

Within the latter, medical studies showed the lowest rise and the science disciplines increased more or less quickly than the others according to the country, although no distinct trend can be made out here either.

The percentage of girls enrolled in secondary education has risen everywhere since 1950 and was over 40 per cent in 1965 in almost all countries. However, there are fewer girls in technical than in general education and many more in teacher training.

In higher education, a preponderance of young men is still very marked in spite of an appreciable fall in this disproportion since 1950.

The increase in the age-groups concerned by education has been irregular, especially as regards the first and second levels. This was because the birthrate was very much disturbed between 1940 and 1950 in many countries. This disturbance affected primary education right at the beginning of the period studied, and secondary education towards 1955. Higher education, on the other hand, was hardly affected before 1965.

Population growth is the main explanation for the increase in primary school enrolments. It also partly explains the increase in secondary education but less than the level of enrolments already reached in 1950. In higher education, it looks as though the rise in the number of students has been independent of population growth and the level of enrolments at the beginning of the period.

Although there is not necessarily any link from cause to effect, the increase in higher education observed in many countries has been all the more rapid as that of the age-groups concerned has been slower.

If trends during the period 1950-1965 are extended into the future, complete enrolment of the 5-19 age-group should be practically achieved in several Member countries in 1980.

Note: Unless specified to the contrary, primary education, or education at the first level, should be understood to mean pre-school plus primary education stricto sensu.

EDUCATIONAL EXPANSION IN THE O.E.C.D. COUNTRIES SINCE 1950

INTRODUCTION

1. The following report is a study on the comparative increase in enrolments at each level of education in all 22 Member countries and Yugoslavia, an associated Member country, between 1950 and 1965.
2. The first Chapter briefly analyses the trend in total enrolments. Chapter II analyses each level of education separately and Chapter III concentrates more particularly on the incidence of demographic factors on the rise in enrolments. Chapter IV endeavours to extrapolate the trends observed during the period studied up to 1980. The last Chapter draws the main conclusions from the study.
3. The internal analysis of each level of education in Chapters II and III has been reduced to a minimum since it has been gone into in greater detail in other Secretariat publications (1).
4. The statistical material used is assembled in Annex I. Annex II examines the structure of each country's system, together with the changes that have been made since 1950. It is recommended that these Annexes be read first for complete understanding of the figures given in the tables that follow.
5. Annex III gives certain technical details concerning the extrapolation of the trends observed in Chapter IV.

(1) See Development of Secondary Education, Trends and Implications, O.E.C.D., 1969. A study on higher education is at present being carried out in the context of the "Statistical survey on the quantitative development of higher education".

CHAPTER ITREND OF TOTAL ENROLMENTS BETWEEN 1950 and 1965

6. Between 1950 and 1965, the school and university population in all 22 Member countries plus Yugoslavia rose from 104 million to 152 million (1), i.e. a 50 per cent increase (an average of 2.7 per cent per year) (see Table I). However, this increase varied a great deal from one country to another, since on the basis of 100 in 1950 the index ranged 15 years later between 106 for Germany and 266 for Turkey (see Graph I).

7. This rise in enrolments is first explained by demographic changes. Member countries' total population rose by only 1.2 per cent per year, from 571 million in 1950 to 686 million in 1965. At that time, therefore, some 22 per cent of the total population was at school or university, as opposed to 18 per cent 15 years earlier.

8. Taking only the population aged between 5 and 24, which are approximately the age-limits of formal schooling, it would seem that two-thirds of this population attended school or university in 1965 as against a little over half at the beginning of the period. The school population therefore increased more quickly than the population of school age, although the correlation between the growth indices of each is quite high as Graph II shows ($r = + 0.68$).

9. This same graph also shows, however, that population growth cannot alone explain the rise in enrolments, since for an increase of less than 10 per cent in the 5-24 age-group there are 9 countries where the rise in enrolments is between 6 per cent (Germany) and 74 per cent (Yugoslavia).

It is to be assumed that enrolments increased all the more quickly as the level of school attendance already achieved in 1950 was lower. The y-axis in Graph III takes the growth index of enrolments from the preceding graph; the enrolment ratio in 1950 on the x-axis is the percentage ratio between the school population and the population aged 5 to 24. On this assumption, the liaison between the two indices is slightly negative ($r = - 0.48$).

10. The increase in enrolments is therefore not only linked with population growth but also with the previous level of enrolments. This intuitively quite obvious conclusion has no great significance in itself, but it is nonetheless interesting to note that the combined effect of these two variables considerably raises the correlation with the index of increase in enrolments ($R = 0.91$).

(1) These figures do not in principle include part-time secondary school pupils (except for Germany and Austria). Higher education, on the other hand, includes part-time students. For further details, see Annexes I and II.

Source : D'après le tableau I - Table I.

Another way of presenting the matter is to assume that the previous level of enrolments is constant, so that the correlation between the index of increase in enrolments and the index of population growth rises from + 0.68 to + 0.82 (1).

11. This brief review has brought us incidentally in sight of some of the topics expounded later in the present study:

- (a) Does the preponderant influence of demographic factors persist when passing on from an overall study of the rise in enrolments to the study of the increase at each level? One might suspect on the face of it that this is not so since primary education - which carries great weight in total enrolments - depends almost exclusively on demographic factors because of compulsory school attendance, while this is no longer the case for secondary education and still less for higher education.
- (b) In addition, the exact measurement of the progress in enrolments assumes a precise assessment of the effect of population growth and this raises one or two delicate problems. Returning for a moment to Table I, one can see that in the case of Germany, for example, the proportion of the population attending school or university between 1950 and 1965 falls as compared with total population but rises as compared with the population aged 5 to 24. In Switzerland, on the other hand, the results are reversed. No hasty conclusions should therefore be drawn, and we shall consider these problems in greater detail in Chapter III.

(1) This is so because the liaison between the index of population growth and the ratio of enrolments in 1950 is not very strong ($r = + 0.17$). Each variable then combines with the other, almost independently. Thus, on the basis of a known formula, we have:

$$r^2 = \frac{(-0.48)^2 + (0.68)^2 - (2)(-0.48)(0.68)(0.17)}{1 - (0.17)^2} = 0.8277 = (0.91)^2$$

and again:

$$\frac{[0.68 - (-0.48)(0.17)]^2}{[1 - (-0.48)^2][1 - (0.17)^2]} = 0.7761 = (0.88)^2$$

CHAPTER II

COMPARATIVE TREND OF ENROLMENTS AT EACH LEVEL OF EDUCATION

A. Absolute rise in enrolments

12. Table II shows the trend of enrolments between 1950 and 1965 by level of education. In primary education, enrolments fell in Germany, Austria and Japan; they rose in all other countries. At the same time, enrolments at the second and third levels increased everywhere.

13. Apart from Germany, Austria and Japan, there are eight other countries where the absolute rise in enrolments was greater in secondary than in primary education (see Table III): the Netherlands, Switzerland, Finland, Ireland, Norway, the United Kingdom, Greece and Italy. On the other hand, the rise in enrolments in higher education was everywhere, except in Greece, very much lower than the rise at the other levels. In short, the overall rise in enrolments between 1950 and 1965 was very irregularly distributed among the different levels of education from one country to another. In Italy, for example, over 80 per cent of the increase was due to secondary education, while in Turkey it was due for a slightly lower percentage to primary education.

14. The structure of the educational pyramid in each Member country has therefore changed during the 15 years of the period under study (see Table IV). There were relatively fewer pupils in 1965 than in 1950 at the first level and more in secondary and higher education. In 1950, no country had more than 4 per cent of its enrolments in higher education (apart from the United States: 7.2 per cent). In 1965 over half of the countries were above that percentage, while the United States was still in the lead with 10 per cent (1).

B. Relative rise in enrolments

15. Table V shows the rate of increase in enrolments at each level of education between 1950 and 1965. The rate of first-level enrolments is always lower than at subsequent levels. Secondary education always increased more quickly than higher education in France, Iceland, Norway and four Mediterranean countries (Spain, Italy, Portugal and Turkey). But higher education rose more rapidly in the remaining 16 countries.

16. However, the rise in enrolments at each level of study was not uniform during the 15 years of the period. In order to examine this point, we calculated the growth indices as compared with

(1) The figures in Tables IV and V should be used with caution as the period of study is not the same at each level in all countries. At the same time, the reforms introduced in some countries during the period under study distort comparison to some extent (e.g. in Denmark). See Annex II in this respect.

12 to 12,9			Luxembourg (12,7)	

Source : based on Table II.

average enrolments in each five-year period from 1951 to 1955, 1956 to 1960 and 1961 to 1965. The results are given in Table VI (1). The average indices are as follows:

	1951-55 to 1956-60	1956-60 to 1961-65	1951-55 to 1961-65
1st Level	111	106	118
2nd Level	134	132	180
3rd Level	139	154	215

The rise in higher education enrolments speeded up at the end of the period, while primary and secondary education enrolments tended to slow down.

17. Graphs IV, V and VI demonstrate this conclusion. The x-axis shows the index for the second period as compared with the first and the y-axis the third period as compared with the second. At first level (Graph IV), most countries are below the line bisecting the angle formed by the axes of the graph, which means that the increase at the end of the period is lower than that at the beginning. In higher education (Graph VI), the opposite may be observed, while in secondary education (Graph V) the countries are more or less equally divided on either side of the bisecting line. Furthermore, the correlation between the indices is higher in secondary education ($r = + 0.68$) than in primary ($r = + 0.51$) and higher education ($r = + 0.38$).

18. We have endeavoured to group countries with more or less similar growth characteristics and proceeded as follows for this purpose. The increase in each level of education between the second period (1956-60) and the third (1961-65) may be higher (+) or lower than or equal (-) to the increase between the first period (1950-55) and the second. A succession of signs such as (+++) for example means that the rise for the country concerned was higher in primary education, lower in secondary education, and higher in higher education. As there are three levels of study, $2 \times 2 \times 2 = 8$ groups of signs are therefore theoretically possible. In fact, 14 of the 17 countries for which data exist concerning the three levels are divided into two groups (---) and (---), with a slower increase in primary education and a faster increase in higher education, while the difference appears in secondary education, where the rise was more rapid in 8 countries (Belgium, France,

(1) The indices calculated for the whole period over an average of ten years are not therefore directly comparable with those in Table II, which are calculated for 15 years. The results are nonetheless coherent from one table to the other, except that in Table VI the rise at first level in Germany seems to be slightly higher than at second level.

Spain, Italy, Yugoslavia, Canada, the United States and Japan) and less rapid in the 6 others (the Netherlands, Denmark, Finland, the United Kingdom, Sweden and Portugal).

Three groups represent one country only (++-) for Germany, (+--) for Austria and (+--) for Japan. The last three possible groups (+++), (-+-) and (---) are not represented.

C. Trend within each level of study

19. As we have said in the Introduction, we shall confine ourselves here to a few remarks directly concerned with the statistical material in Annex I, while referring the reader to the Secretariat's specialised work for an exhaustive study.

20. Tables VII to X show the growth indices for the main types of study within each of the three levels of education (1); these tables lead to certain significant conclusions:

- (i) Pre-school education has increased more rapidly, almost everywhere than primary education proper, although its relative importance is still small in several countries (see Table VII).
- (ii) No very marked trend appears when comparing the respective rises in general education and technical education (see Table VIII). Of the 15 countries appearing in this table, 8 have a higher growth index for technical education than for general education. At the same time, in most countries teacher training has increased less quickly than total secondary school enrolments but more rapidly than primary school enrolments.
- (iii) Non-university education has generally increased more quickly than university education (especially in Turkey and Yugoslavia), but it still varies a great deal in importance (see Table IX); it is practically non-existent in Austria, but on the other hand concerns over half of the enrolments in the United Kingdom.
- (iv) Table X only concerns university enrolments due to the lack of sufficiently complete figures on non-university education. It shows that, apart from Germany, enrolments in medicine have risen less quickly than in the other branches. On the other hand, the science disciplines have on the whole developed more rapidly.

(1) The indices are calculated in relation to average enrolments from 1951 to 1955 and from 1961 to 1965. The percentages are calculated on enrolments in the latter period.

TABLE VII - Increase in enrolments in pre-school and primary education between 1951-55 and 1961-65

D. Enrolment differences between boys and girls

21. In primary education, equality between boys and girls exists in practically all Member countries except Turkey (37 per cent girls in 1950 and 40 per cent in 1965).

22. In secondary education (see Table XI), equality was very nearly achieved in 1965 except in the Mediterranean countries in spite of an appreciable improvement since 1950. However, the differences between types of study are quite marked. Girls are relatively more numerous in general education than in technical and are almost everywhere very much in the majority in teacher training.

23. Lastly, in higher education (see Table XII), we are still quite a long way off equality since the highest proportion of girls in 1965 was not quite 40 per cent (the United States, France and Sweden), apart from Finland where this proportion was 48 per cent. Nonetheless, the progress made since 1950 was generally very marked.

CHAPTER III

POPULATION GROWTH AND THE INCREASE IN ENROLMENTS

24. In this Chapter, we shall consider the effect of demographic factors on the rise in enrolments at each level of education, and the way we shall go about this is dictated by a difficulty of method which should first be pointed out.

25. If we know the age distribution of enrolments, we can calculate an enrolment rate for each age or for any age-group. These rates combined would certainly be the best possible tool for our present purposes. Unfortunately, apart from a few countries, few exist for the period under study so that they cannot be used for any comparison, no matter how general.

26. We shall therefore begin by analysing the trend of the population belonging to the age-groups which are roughly speaking likely to enrol at each level of education; we shall then compare this trend with the trend of enrolments (section A) and this will lead us to a brief review of the birthrate during the last few decades (section B). Next, as we have done in Chapter I, we shall consider the effect on the rise in enrolments of population growth and of the level of enrolments at the beginning of the period (section C). Lastly, we shall make a direct study of enrolment ratios (1) (section D) and conclude with a study of the enrolment rates available (section E).

A. The increase in enrolments and in the corresponding age-groups

27. As a first approximation, we shall take the age of enrolment at each level as being between the following limits:

- for the 1st level: 5 to 14 years of age;
- for the 2nd level: 10 to 19 years of age;
- for the 3rd level: 20 to 24 years of age.

The real limits will of course vary from one country to another with the theoretical length of study and the extent to which classes are repeated. As we shall see later, however, the combination of different age-groups in any case introduces a new slant, so that any additional refinement is pointless. At the

(1) By enrolment ratio we mean the ratio between the population enrolled at a level of education (e.g. 1st level) and the total population in the age-group approximately corresponding to this (e.g. the population aged 5 to 14).

These ratios are often wrongly called enrolment rates but we consider it essential to keep this title for one case only where a ratio is established between enrolments at a specific age (or for a specific age-group) and the total population belonging to the corresponding age or age-group.

TABLE XIII - Increase in the numbers of the 5-14, 10-19 and 20-24 age-groups between 1951-55, 1956-60 and 1961-65

Source : Annex I, Table I.

same time, we first study the increase from one period to the next and the conclusions on this point would undoubtedly not have changed very much if we had taken other limits (1).

28. Table VIII therefore shows the increase during the period under study in the numbers in each of the three age-groups. This table should be compared with Table VI concerning enrolments; the comparative rise for all countries combined was as follows:

	1951-55 to 1956-60	1956-60 to 1961-65	1951-55 to 1961-65
(1st level (5-14 age-group)	111 110	106 105	118 115
(2nd level (10-19 age-group)	134 110	132 110	180 120
(3rd level (20-24 age-group)	139 98	154 105	215 103

In principle, the rise in primary education is largely explained by population growth. It is not surprising therefore that the ratios are very similar. On the other hand, they differ considerably in secondary education and still more in higher education: the rise in enrolments was one and half times faster than the rise in the corresponding age-groups in secondary education and twice as fast in higher education.

29. Population growth was not uniform during the 15 years of this period. However, it varied approximately in the same direction as the rise in enrolments. In order to show this, we have grouped the Member countries on the basis of the three age-groups exactly in the same way as we did above on the basis of levels of education. By crossing the two classifications, we obtain Table XIV. The countries on the diagonal line descending from left to right, i.e. ten out of seventeen for which the two classifications are available, belong to identical groups in each category.

(1) Moreover, the age-groups used coincide with the five-year groups usually found in the demographic yearbooks, while age-groups adapted to each country would have necessitated additional calculations with all their concomitant approximations.

Lastly, comparisons between countries would in this case have been a problem because of the lack of homogeneity between the enrolment ratios calculated.

TABLE XIV - Characteristics of the increases in enrolments at each level of education and of the corresponding age-groups

		Enrolments							Not available	
		+++	++-	+ - +	+ - -	- + +	- + -	- - +	- - -	
Age-Groups	+++									Luxembourg
	++-									Greece
	+++			Austria						
	++-	Germany				Italy				
	-++					Belgium France Spain Canada				Iceland
	-+-				Turkey	Yugoslavia		Portugal		
	---+					U.S.A. Japan		Netherl. Denmark Finland U.K. Sweden		Switz. Ireland Norway

When the classifications differ, the reason is usually that the categories chosen are not fine enough and in particular overlook approximate stability in the increase from one period to the next (as is the case for example for Germany and the United States).

30. If on the basis of the figures in Table XIV we draw up a classification allowing for this stability (1), then $3 \times 3 \times 3 = 27$ groups are possible this time. All of the 23 O.E.C.D. countries are distributed among 11 groups only, as follows (the symbols refer successively to the 5-14, 10-19 and 20-24 age-groups):

- +++ : Spain, Italy
- ++- : Portugal
- +- : Greece, Turkey, Yugoslavia
- +++ : Luxembourg
- : Austria
- +- : Germany
- ++ : Canada, Japan
- ++ : the United States
- ++ : Belgium, France
- ++ : Iceland
- : the Netherlands, Switzerland, Denmark, Finland, Ireland, Norway, the United Kingdom and Sweden.

This shows that all of the Mediterranean countries are characterised by relative demographic stability, especially in the age-group corresponding to primary education. At the same time, the Northern European countries, apart from Iceland, are all in the last group. The Western European countries are dispersed in several groups.

31. As the increase in the age-groups largely reflects the trend of births, we shall now examine the latter.

(1) We have arbitrarily assumed that the increase was stable when the ratio of the second period did not differ by more than 3 points above or below the ratio of the first period. We indicate this stability by the symbol ±.

B. Trend of births

32. Graph VII shows the trend of births since 1925 in each Member country except Turkey, for which the figures are not available. On the whole, the countries grouped in the last section have very similar curves. The birthrate in many Member countries was very much disturbed between 1940 and 1950, as Tables XV and XVI demonstrate. The number of births often increased considerably, the most spectacular case being provided by France, where the age-groups rose suddenly from under 600,000 to over 850,000. These changes affected primary education right at the start of the period under study, and secondary education towards 1955. Higher education, on the other hand, was only affected towards 1965, at the end of the period.

33. Many Member countries therefore had to face considerable difficulties and it may well be asked whether postwar generation enrolments have not been affected to a certain extent. The matter will be dealt with later.

C. The increase in enrolments, population growth and previous enrolments

34. We return here to the question asked at the end of Chapter I: is the influence of demographic factors identical for each level of education? The correlation between the growth index of enrolments and the growth index of the corresponding age-group is as follows (these correlations have been calculated on the basis of Tables VI and VIII for the entire period):

1st level: + 0.82
 2nd level: + 0.36
 3rd level: + 0.13.

This shows that the demographic factor is very important in primary education but loses much of its significance in secondary and higher education.

35. The correlation between the same growth ratio of enrolments and an ratio of enrolments at the beginning of the period (1) is equal to:

1st level: - 0.31
 2nd level: - 0.76
 3rd level: - 0.17.

In primary education, maximum enrolment was practically achieved as early at 1950 in most Member countries and could make little further progress. In secondary education, on the other

(1) Ratio between average enrolments between 1951 and 1955 and the average size of the corresponding age-group for the same period.

Source : based on Table XV.

Note : (a) excluding Germany and Yugoslavia.

hand, some countries advanced relatively little because they already had a high rate of enrolments, while others made considerable progress, which would appear to indicate that at this level the inequalities between Member countries tended rather to diminish. These observations are really quite straightforward. On the other hand, it is less evident that higher education has developed independently of the level of enrolments at the beginning of the period.

36. If we now combine the population growth index with the level of enrolments at the beginning of the period, the multiple correlation with the growth index of enrolments becomes (1):

1st level : 0.93
2nd level : 0.87
3rd level : 0.25.

If we now eliminate the effect due to the variation in the level of enrolments, we find the following partial correlation between the growth indices:

1st level : + 0.92
2nd level : + 0.64
3rd level : + 0.19.

37. To sum up, we can conclude that population growth and the level of enrolments at the beginning of the period largely explain the rise in primary and secondary school enrolments, the first variable being preponderant in primary and the second in secondary education. On the other hand, neither of these two variables can significantly explain the increase in higher education (2).

38. It will be noted that in order to interpret these results correctly we have endeavoured to explain the variation in enrolments from one period to the next and not their size at any particular date. In the latter case, it would obviously be absurd to conclude that the size of the age-group has no influence. Furthermore, all our calculations concern variations in the stock of enrolments; it would certainly have been more significant to allow for variations in flow (new entries, repeaters, dropouts, graduates). The statistics are very fragmentary on all of these points and their comparability also raises problems which are difficult to overcome in the present state of available documentation.

(1) The correlation between the population growth index and the level of enrolments at the beginning of the period is:
1st level: + 0.16; 2nd level: + 0.06; 3rd level: + 0.25.

(2) It might be assumed that in this case the influence of the previous rise in secondary education is overriding. However, the correlation between the growth index at third level from 1956-60 to 1961-65 and the growth index at second level from 1951-55 to 1956-60 is only +0.34, but this calculation is not very conclusive.

D. Trend of enrolment ratios

39. Having studied the trend of enrolments and the trend of the corresponding age-group we shall now analyse the ratio between these two which we call the enrolment ratio.

40. These ratios are assembled for each country and for the entire period in Tables IX to XIII in Annex I. Table XVII below simply shows the average (1) of these ratios for 1951-55, 1956-60 and 1961-65, while Table XVIII shows the increase in these averages from one five-year period to the next. However, a few remarks are called for in order to interpret the data in Table XVII correctly.

41. Since the length of study varies for each level of education from one country to another, comparisons between countries must be treated with caution, especially as regards primary and secondary education. On the other hand, the total length of these first two levels is approximately identical and we have therefore calculated an enrolment ratio covering the first and second levels (as compared with the population aged 5 to 19).

However, even when the length of study is approximately identical, the age structure of the school population biases comparison between countries and also, although to a smaller extent, comparison from one year to the next in the same country. This is especially the case for the enrolment ratio calculated on the basis of primary and secondary school enrolments and for the enrolment ratio calculated on the basis of total enrolments. It is in fact obvious that, all other things being equal, the ratio will be all the higher when the relative size of the age-groups corresponding to compulsory school attendance is greater. The deviation between the ratios does not therefore only reflect real differences in enrolments.

Thus, instead of making any direct comparison of the ratios in Table XVII, we shall examine their rise over the course of time (Table XVIII), since the difficulties we have just mentioned are then reduced.

42. The comparisons between 1951-55 and 1961-65 are summed up in Graph VIII (1st level), IX (2nd level) and X (3rd level). The y-axis of each graph shows the rise in enrolments and the x-axis the rise in the corresponding age-group. The ratio between these two increases gives the rise in the enrolment ratio, which may be read approximately along the group of dotted straight lines. In addition, the lines parallel to the axes of the graph after the 100 reference mark divide the countries into four groups according to whether both enrolments and the size of the age-group

(1) This is the average of the ratios for each of the five years of the period concerned and not the ratio of average enrolments to the average number in the corresponding age-group. The two calculations in fact give practically identical results.

TABLE XVII - Enrollment ratios at each level of education (1951-55, 1956-60 and 1961-65 averages)

*/% of the corresponding age-group

Source: based on Table XVII.

diminished or increased (lower left and upper right quarters) or moved in the opposite direction (upper left and lower right quarters). In short, these graphs sum up the information in Tables VI, XIII and XVIII for the three groups considered and call for the following remarks:

- (a) In all three graphs, most countries are in the upper right quarter, i.e. enrolments have risen at the same time as the age-group; but higher education enrolments have risen in nine countries out of seventeen in line with a fall in the 20-24 age-group.
- (b) In primary education, countries are generally grouped around the bisecting line of the axes, which is logical since enrolments increase with the size of the age-group and the enrolment ratio therefore remains constant (1).
- (c) In secondary education, it will be observed that all the Mediterranean countries are grouped in the upper part of Graph IX, which therefore implies a higher rise in the enrolment ratio than in other countries.
- (d) In higher education, the enrolment ratios have risen faster than in secondary education since (apart from Switzerland) this increase is above 50 per cent for eleven countries out of twenty.

43. It has often been claimed that the "educational explosion" of the sixties was the consequence of the postwar "demographic explosion". We shall examine this assumption a little more closely. Earlier sections, in any case, already contain certain considerations on this point.

44. If we take S as enrolments at a particular level of study, P as the size of the corresponding age-group and W as the enrolment ratio we have by definition for each academic year:

$$W = \frac{S}{P}$$

If ΔS , ΔP and ΔW indicate the increase in these figures between any two academic years, we then have:

$$S + \Delta S = (W + \Delta W)(P + \Delta P)$$

or:

$$S = W \cdot \Delta P + P \cdot \Delta W + \Delta P \cdot \Delta W \quad \square$$

- (1) The ratios for Turkey and Yugoslavia have risen. In the case of Turkey, compulsory school attendance was not operating in 1950. As regards Yugoslavia, it includes in the eight years of primary schooling enrolments which in other countries are included with secondary education. For Denmark and Sweden, the deviation from the bisecting line is probably due to the incidence of educational reforms made during the period.

The absolute increase in numbers is thus divided into three parts:

- $W \cdot \Delta P$ is the increase due to demographic changes;
- $P \cdot \Delta W$ is the increase due to changes in the enrolment ratio;
- $\Delta P \cdot \Delta W$ is the increase due to the combined effect of demographic changes and changes in the enrolment ratio.

If we now take s , p , and w as the annual rate of increase of S , P and W , expression $\boxed{1}$ may be read:

$$s = p + w + pw \quad \boxed{2}$$

In this latter expression, the combined effect pw is practically negligible, which is not necessarily the case for $\Delta P \cdot \Delta W$ (1). We have finally made two series of calculations using each formula:

(a) The first series of calculations according to expression $\boxed{1}$ is presented in Tables XIX (second level) and XX (third level). It concerns the rise in enrolments between 1950 and 1965. Table XXI shows the absolute percentage increase in enrolments which is attributable to the rise in the enrolment ratio. Some percentages are above 100, which simply means that the size of the age-group has diminished. Except in Germany and Austria, the effect due to the enrolment ratio is everywhere greater in higher education than in secondary education; it is also greater in higher education and in all countries (except Switzerland) than the demographic effect. On the other hand, it is greater in secondary education in 14 countries out of 23.

(b) The annual rates of increase in S , P and P are shown in Table XXII. They have been calculated on the basis of periods 1951-55 and 1961-65 in order as far as possible to avoid fluctuations due to the choice of a single base year. As can be seen, the result is practically that $s \approx w + p$. (2)

The conclusions which may be drawn from this table supplement those of the three preceding tables. The rates of increase w in primary education are very small apart from four countries to which we have already drawn attention in connection with Graph VIII. The rates w in higher education are greater than in secondary education

(1) Various methods have been suggested for distributing combined effects $\Delta P \cdot \Delta W$ between the two pure effects. They all have the disadvantage of being arbitrary and of leading to results which are sometimes very different. The reader is referred in this connection to Annex Q of Volume II in Education, Human Resources and Development in Argentina, O.E.C.D., 1968.

(2) The deviation between s and $w + p$ is due not only to the combined effect but also to errors in rounding off the figures, since the rates have been calculated directly from the ratios in Tables VI, XIII and XVIII.

except in three Mediterranean countries (Spain, Italy and Portugal). They are also, apart from a few exceptions (Switzerland for higher education; and Luxembourg, the Netherlands and Denmark for secondary education), always greater than the rate of increase in the age-group.

(c) It may be assumed, lastly, that a relatively small population growth encourages a relatively high increase in enrolments. The correlation **between** w and p should therefore be negative in this case. This assumption may be examined in Graphs XI (secondary education) and XII (higher education). In secondary education, the correlation is almost nil ($r = - 0.12$); if we discount the Mediterranean countries, which are quite isolated in the upper part of the graph, the correlation becomes positive ($r = 0.46$). It is plausible that this result is due to the fact that some pupils covered by compulsory school attendance are in secondary education, and that the legal extension of compulsory school attendance could also tend in many countries to cover a good portion of the period of study at second level. In higher education, on the other hand, the correlation falls in line with the assumption ($r = - 0.53$ or $- 0.63$, according to whether the Mediterranean countries are included or not).

45. As the rise in the postwar birthrate reaches higher education towards the end of the period analysed in this study, it may well be asked whether the rise in the enrolment ratio will not now tend to fall in the '70s.

E. Enrolment ratios and enrolment rates

46. We have defined the enrolment ratio as being the ratio between S enrolments at a level of study and the population P of the corresponding age-group:

$$w = \frac{S}{P}$$

If we take as numerator enrolment S' corresponding exactly to the age limits of population P (whatever the level of study of these enrolments), we obtain the enrolment rate w' of the age-group concerned:

$$w' = \frac{S'}{P}$$

For the same academic year, we have:

$$\frac{w'}{w} = \frac{S'}{S}$$

and for two academic years separated in time (indexed 1 and 0 below on the right of the symbols):

$$\frac{w'_1/w'_0}{w_1/w_0} = \frac{S'_1/S'_0}{S_1/S_0} = \frac{S'_1/S_1}{S'_0/S_0}$$

" and W' may therefore be very different and their increase over the course of time may also be very different.

In order to illustrate this analysis, we shall compare the ratios and rates for the countries where the two calculations are possible; we shall therefore begin by considering the data available.

47. In point of fact, the enrolment rates are only sufficiently detailed for the whole of the period in the United States and the Netherlands. They may be calculated on the basis of 1957 in the case of Belgium and 1958 in the case of France. Some rates are scattered over the course of time for other countries and for others again only incomplete data exist which leave out higher education enrolments, for example. In short, a comparative study based only on enrolment rates and their trend is practically impossible.

48. Table XXIII gives for 1960 (or the nearest year) the enrolment rates for a few age-groups and the enrolment ratios. These rates and ratios are taken up in Graphs XIII to XVII; if there were equality between the two, the points would be grouped on the line bisecting the axes. In secondary education (Graph XIV), the ratio is always lower than the rate since the latter includes some enrolments at first level (1). In higher education, the ratio is higher than the rate (2) since enrolments are greater than the 20-24 age-group. On the other hand, the ratios for primary and secondary education combined (Graph XV) and for total enrolments (Graph XVII), as well as to a smaller extent the ratio for primary education (Graph XIII) are nearer the corresponding rates. Thus in these last cases the grading of countries in relation to each other is better respected, as demonstrated by the coefficient of correlation of ranks between the grading resulting from the ratio and that resulting from the rate:

1st level	: 0.63
2nd level	: 0.51
1st and 2nd levels	: 0.92
3rd level	: 0.53
Total enrolments	: 0.86

-
- (1) If the ratio for secondary education had been calculated in relation to the 15-19 age-group, the ratio would have been higher than the rate; we have verified that the deviation would have been as wide.
 - (2) Except in Portugal. The rate in this country for the 20-24 age-group shown in Table XXIII seems high. This figure is due to the 1960 census, which gives an enrolment of 33,600 for the 20-24 age-group, whereas higher education enrolments for the same year 1960 are 25,200. In any event, the rates resulting from population censuses are generally higher than those obtained from education censuses.

(2) For ratios : see Annex I, Tables IX to XIII.

49. We shall now compare the respective increases in the ratio and rate of enrolments. These increases are calculated in Table XXIV, to which Graphs XVIII to XXII correspond. Here, too, the points should be situated on the bisecting line of each graph if the increases were equal, which is only approximately the case for the same ratios and rates as in the preceding graphs. The correlation of ranks is as follows:

1st level	: 0.47
2nd level	: 0.46
1st and 2nd levels	: 0.74
3rd level	: 0.55
Total enrolments	: 0.96

These correlations seem to be even poorer than the preceding, but there are really too few countries for any definite conclusion to be drawn.

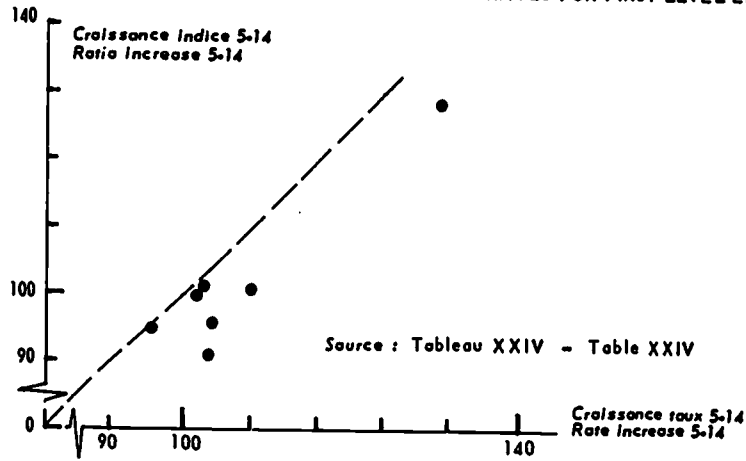

50. In short, enrolment rates and their increase cannot be estimated precisely enough from the enrolment ratios. The least erroneous are those calculated for very aggregate age-groups (5-19 and 5-24). Unfortunately, an additional source of error here is introduced by the change over the course of time in the population structure.

51. In Table XXV, we have, as an illustration, calculated the enrolment rates by 5-year age-groups in France for 1961 and 1964. This shows that all the partial rates increase while the 5-24 rate falls. Similarly, Table XXIV shows that the enrolment rate in secondary education fell in France between 1958 and 1965 (from 66.9 per cent to 66.2 per cent), whereas in fact there was an overall increase in the rates for single years of age, sometimes considerable, during the same period (see Table XXVI). This is explained by the fact that the postwar disturbance in the birth-rate produced a larger age-group in 1965 than in 1958.

52. This difficulty in handling the aggregate rates, which is very familiar to the demographers, may be partially overcome by calculating fictitious rates on the basis of a population whose structure does not vary. For example, by applying the 1965 enrolment rates to the 1958 population, we find (see Table XXVI) a fictitious 10-19 rate in 1965 of 71.5 per cent (therefore an increase - instead of a fall - of 6.9 per cent over the real rate for 1958 of 66.9 per cent). However, it is just as feasible to apply the 1958 rates to the 1965 population and to find for 1958 a fictitious rate of 60.8 per cent, i.e. this time a higher increase of 8.9 per cent over the real rate of 66.2 per cent in 1965.

The conclusions may therefore be different according to the population sample chosen. Moreover, the risk of reaching an arbitrary conclusion is still greater when comparing countries with each other instead of confining the comparisons to the country itself.

CHAPTER IVTHE INCREASE IN ENROLMENTS BETWEEN 1965 AND 1980

53. We endeavour in the present Chapter to estimate enrolments up to 1980 on the assumption that the educational system will develop until then in accordance with certain trends prevailing between 1950 and 1965.

54. The method of extrapolation used is based on a strictly deductive methodological approach and not on the probability nor even necessarily the possibility of maintaining past trends in the future. On the contrary, this assumption is even doubtful for several countries. In this sense, it must be clear that the estimates which follow are not forecasts. Nor of course do they constitute any attempt to define a desirable trend.

55. We have not taken account of the national forecasts made in several Member countries nor even of the projected reforms now known, especially as regards the extension of compulsory school attendance. These forecasts and projects generally imply the desire to change past trends, which is by assumption not one of our own preoccupations. Our results therefore certainly differ from national work, although no value judgement, whether favourable or unfavourable, can be deduced from these results concerning such work.

56. Our estimates are not therefore necessarily probable, necessarily possible or necessarily desirable; of what interest can they be in these circumstances? They are simply intended to amplify (possibly even over-exaggerating) the consequences of the analyses in preceding Chapters with a view to highlighting certain important points. We also hope in this way to provide some sort of answer to the question which is often asked: is it possible to continue in the future the considerable efforts made in the past?(1)

57. From the point of view of methods, the ideal would be to build up stocks of enrolments on the basis of the trend in the successive cycles of study of the annual mass of new entries, allowing for repeaters and dropouts. Since this method is inapplicable for lack of sufficient data, we are obliged to choose a few parameters which are assumed to be representative. The choice is partly arbitrary and the trends selected do not necessarily coincide with those which would result from another choice.

(1) Similar estimates, also for 1980, concern teachers and financial resources; they are given in the Background Studies prepared for the Conference.

58. We first extrapolated the enrolment ratio for the first level:

$$\left(\frac{\text{First level enrolments}}{\text{Population aged 5 to 14}} \right)$$

which in the light of the population forecasts also available permits an estimate of primary school enrolments. We then extrapolated the ratio between second level enrolments and first level enrolments five years earlier and also the ratio between third level enrolments and second level enrolments five years earlier. Secondary education and higher education enrolments are based on these calculations, allowing for the primary school enrolments previously extrapolated. Adjustments were made by means of the least squares method on the basis of enrolment series from 1950 to 1965.

The technical details of these calculations as well as the detailed results are given in Annex III. For the present, we shall simply give the principal estimates obtained.

59. Table XXVII shows the increase in a few age-groups between 1965 and 1980 as compared with their increase during the preceding 15 years (1).

In the 5-14 age-group corresponding to primary education, the increase is lower after 1965 in roughly half of the countries. However, the falls are generally greater than the rises, e.g. Belgium, France and Canada. On the other hand, in 15 countries out of 21, the 5-19 age-group should increase less rapidly. As opposed to this, the 5-14 age-group shows a faster and sometimes considerable rise in most countries (e.g. Ireland, Turkey, Yugoslavia and Canada).

60. Enrolments in 1980 by level of education are given in Table XXVIII, while Table XXIX shows the distribution between the three levels of the absolute rise in enrolments between 1965 and 1980. This table is the equivalent to Table III covering the period 1950-1965. Table XXVIII only gives the estimate resulting directly from the extrapolation of trends, but Annex III also contains a minimum estimate and a maximum estimate. That is why we have included a margin of variation in the growth index in the last column on the right of the table. This margin is all the greater when the level of study is higher since the uncertainty inherent to each level combines with the uncertainty due to preceding levels of study; it is also greater when the quality of the statistical adjustment is poorer. For some countries, the limits of the index are very high, so that the enrolments given for 1980 are only indicative in value (e.g. higher education in Greece, Turkey and Yugoslavia). The following remarks sum up the results obtained:

- (1) These increases are the result of national demographic projections mentioned in Annex III. These projections are extraneous data for us; they are based on methods which are evidently different from those we have ourselves used since they indicate a probable trajectory.

Source : Annex III

Notes : (a) The method used to calculate these figures is different from that used for the other countries. Total enrolments for each country do not include "other types of education"

51(10)6

- (a) total enrolments should rise more quickly between 1965 and 1980 than between 1950 and 1965 in the following seven countries: Germany, Austria, Ireland, the United Kingdom, Sweden, Greece and Italy;
- (b) primary school enrolments should also rise more quickly in the same countries (except Greece) and in the Netherlands. They should fall in absolute value between 1965 and 1980 in five countries: Belgium, France, Finland, Greece and Japan;
- (c) in four countries only (Germany, Austria, Luxembourg and the United Kingdom), secondary school enrolments should rise at a higher rate;
- (d) the same should apply to higher education enrolments in seven countries: Germany, Austria, Canada, Spain, Greece, Italy and Yugoslavia;
- (e) lastly, the increase in higher education should remain greater than that of secondary school enrolments, except in Portugal and Turkey; it should not differ a great deal in the Netherlands.

For some countries, the increases calculated are very high, especially in higher education: 505 in Greece (i.e. 11.4 per cent per annum) and 409 in Yugoslavia (i.e. 9.9 per cent per annum). However, the calculation is very uncertain for these two countries.

61. Lastly, Table XXI gives the enrolment ratios for the 5-19 and 5-24 age-groups. Some ratios are above 100, which is not strictly impossible if it is accepted that quite a large number of children may be sent to school before the age of five (which is incidentally the case in Belgium, where the ratio should be 110 for the 5-19 age-group). It is possible to conclude from these indices that the extension of compulsory school attendance until the end of secondary education is the natural result of the extrapolation of the trends for the majority of Member countries.

In some cases, the ratio diminishes between 1965 and 1980. This does not necessarily mean a fall in enrolments, as we have shown in the last Chapter. In Japan, in particular, the drop in the ratio is largely attributable to considerable changes in the population structure.

CONCLUSIONS

62. We should like in conclusion to refer to a few essential points which we feel result from this work.

63. In the first place, it is certain that the pertinence and depth of the preceding analyses are limited by the quality of the statistics available and also by the absence of certain essential figures.

64. There can be no doubt that the average quality of the statistical material is rather poor. Proof of this may be obtained simply by trying to find the enrolments for a particular level of study, for a particular country, in a particular year: it will very often be found that the existing sources, including the most official ones, give figures that are sometimes very different although the divergence cannot always be explained. Even though matters have considerably improved in this respect over the last few years, much still remains to be done in order to make the national data comparable.

65. The inadequacy of the available statistics is particularly clear for forms of education which are more or less marginal to the traditional system, such as part-time and adult education. The statistics haphazardly included enrolments for all ages and all levels counted very differently from one country to another and which could not finally be used, so that the enrolment effort made by certain countries (1) was certainly underestimated.

66. Besides being inadequate in quality, the statistics are also inadequate in quantity, especially as regards the flow within the system (new entries, repeaters, departures with or without a diploma or degree). In particular, the absence of an age distribution of enrolments whereby enrolment rates could be calculated is as we have seen extremely regrettable; one of the most urgent tasks of responsible national services is now no doubt to collect such statistics.

67. Notwithstanding these limitations, certain conclusions are still sufficiently justified and we shall mention some of them.

68. The sudden increase in births after the war does not seem to have permanently held up the advance in enrolments. Without going into details for each Member country, we can at least mention the case of France, where the "demographic explosion" was the greatest of all the O.E.C.D. countries. Whereas the number of births was 626,000 in 1945 (maximum figure since 1937), it rose to 844,000 the following year (i.e. 25 per cent up) and stayed above 800,000 up to 1965. In spite of this, the enrolment rate

(1) In Denmark, for example, total enrolments at 1st, 2nd and 3rd levels were 901,000 in 1965. In the same year, adult education enrolments were 470,000.

at 14 years of age when compulsory school attendance ended at that time fell only slightly in 1960 and the rate at 15 years of age fell even more slightly in 1961. On the other hand, the enrolment rates at 16 and 17 years of age were constantly rising, as the following table shows (as a percentage of the age-group).

	14	15	16	17
1959	69.3	53.9	45.0	29.1
1960	68.2	53.4	45.3	30.4
1961	68.8	53.3	46.4	32.4
1962	71.3	56.6	47.6	33.7
1963	71.8	56.8	49.0	34.9

69. In all countries, an increasingly large fraction of each age-group stays in the educational system longer and longer to pursue their studies further and further. The two phenomena are certainly not inextricably linked since the period of study may be extended by a rise in the number of repeaters, but there is no doubt about the trends. (1) This rise in the average level of education is reflected in what we have observed in the majority of countries: the second level has increased more quickly than the first level and the third level more quickly than the second. Four Mediterranean countries out of six (2) nonetheless form an exception: the increase in secondary education was much greater than in higher education and secondary school enrolments grew even at a faster rate than in most other countries.

70. The rise in enrolments between 1965 and 1980 will probably be less than that observed between 1950 and 1965, the main reason for this conjecture being that for many countries complete enrolment of the 5-19 age-group, which is already far advanced, will combine with a smaller demographic increase in this age-group than occurred in the past. It will be recalled, however, that this lower increase does not necessarily mean that the efforts made so far should be curtailed, since as enrolment gradually reaches its maximum it concerns pupils whose problems will perhaps be more difficult to solve than those of other pupils who are already inside the educational system.

(1) Although inequalities between social classes may still be considerable, the reader is referred in this connection to Background Study No. 4 of the Conference on Policies for Educational Growth "Group Disparities in Educational Participation".

(2) The two others are Yugoslavia and perhaps Greece (the restriction made in regard to this latter country is due to the inadequacy of the basic statistics).

71. All of this obviously raises the problem of available resources up to 1980. Two Conference Studies deal more closely with teacher requirements and financial resources. They show that even though the pupil/teacher ratio improves, teacher requirements should generally grow in primary and secondary education at a slower rate than during the period 1950-1965. On the other hand the rate should be greater in higher education for a few countries (the Mediterranean countries in particular).

72. At the same time, the extrapolation of trends as regards financial resources does not on the whole reveal any evident limits, although it is possible that the rise in educational expenditure is slowing down in roughly half of the countries.

73. To sum up, the less developed countries will still have to face problems as a result of the quantitative expansion of their educational systems. On the other hand, it is probable that the more developed countries' priority problems during the period 1965-1980 will be qualitative rather than quantitative.

ANNEX I

Statistical series

The tables that follow present three categories of statistical series:

- demographic statistics;
- enrolment statistics;
- enrolment ratios.

Member countries have been grouped in the following order:

- Western Europe: Germany, Austria, Belgium, France, Luxembourg, Netherlands, Switzerland;
- Northern Europe: Denmark, Finland, Ireland, Iceland, Norway, United Kingdom, Sweden;
- Mediterranean countries: Spain, Greece, Italy, Portugal, Turkey, Yugoslavia;
- North America: Canada, United States;
- Japan.

The figures in brackets quoted in any of these tables are Secretariat estimates.

Totals may differ slightly from the sum of their components owing to rounding.

1. Demographic statistics

Table I shows the breakdown by five-year age groups of the population aged from 5 to 24 years between 1950 and 1965.

The figures in this table have been taken from successive editions of the United Nations Demographic Yearbook. The 1960 edition, in particular, quotes year by year all the series for the period 1940-1960.

Estimates in place of missing data were made as follows:

In cases where one or two years were missing from a series, population numbers were estimated from the survival rates deriving from the statistics for the nearest available years.

Where several successive years were missing yet full birth statistics were available, the first step taken was to calculate the ratio between the number of persons in the different age groups and that of corresponding births, for the years where this was feasible. Generally speaking this ratio followed a fairly pronounced trend which was used to complete the series. This was the method used in the case of Portugal, Ireland, Iceland, Italy, Luxembourg and Spain. However, the same procedure could not be followed in the case of Turkey, where no birth statistics are available, and Yugoslavia, where there are no birth statistics for the period 1940-1946. In both instances, the proportion of each age group was simply interpolated into the total population.

By and large, the estimates are for mid-year. In the few countries for which this was not so (Ireland for April, Spain for December, Turkey and Japan for October), no adjustment was made.

The sources for Tables II (Total Population) and III (Births) were the League of Nations and United Nations Yearbooks.

2. Enrolment statistics

(a) Enrolments were divided into three levels of studies:

1st level: pre-primary and primary education (Table IV);

2nd level: secondary education - general, technical and vocational, and teacher training (Table V);

3rd level: higher education, university and non-university (Tables VI and VII).

Table VIII gives the combined figures for the three levels and includes a heading entitled "Miscellaneous" which essentially covers special education (1).

(b) The figures given in these tables represent aggregate enrolments in public and private educational establishments. They do not, insofar as it was possible to make the distinction, include part-time enrolments other than in higher education. An exception was made, however, in the case of the Austrian and German Berufsschulen.

The year specified is that of the beginning of the academic year (e.g. 1960 for 1960-1961).

(1) In the case of Great Britain this heading also covers a proportion of independent schools whose enrolments cannot be divided into 1st and 2nd levels.

- (c) The absence of a specific heading does not necessarily mean that a given type of education does not exist. This is the case, in particular, with teacher training and special education, which it was not always possible to isolate.
- (d) An endeavour was made to include terminal primary education in 2nd level education, wherever this was justified (1). On the other hand, where secondary education was concerned, it was not possible to distinguish for a sufficient number of countries between short- and long-course education, nor even, as the Secretariat's manual suggested, between studies that normally lead to higher education (type a) and those that do not (type b). This would imply that it is possible to convert national classifications into a uniform international classification, but the Secretariat's work on the "conversion key" is not yet sufficiently advanced.

For the same reasons, the distinction between general education and technical education (Table V) is probably not uniform in all countries (certain forms of commercial education, in particular, can be classified under either heading).

- (e) The statistics for higher education are, in this respect, much more uniform. They represent the findings of a special survey made by the Secretariat (2).
- (f) Additional information on organisation of studies in primary and secondary education may be found in Annex II and in Development of Secondary Education, Trends and Implications, O.E.C.D. 1969.
- (g) The statistical series were compiled from national publications supplemented, where necessary, by earlier Secretariat publications (Mediterranean Regional Project reports, reports on the programme for Educational Investment and Planning) or UNESCO publications (Statistical Yearbook, World Survey of Education). All the statistics on higher education were taken from the survey mentioned under (e). (3)

-
- (1) This was not always possible. In Yugoslavia, for instance, 1st level enrolments include those in the upper primary cycle, which it would have been more accurate to classify under the 2nd level.
 - (2) Statistical survey on the quantitative development of higher education. A separate paper was prepared for each Member country which may be referred to for further details.
 - (3) There may be a few slight differences between the figures quoted here and those of the survey, in the case of Finland, the United Kingdom, Luxembourg and Germany. This is due to subsequent revision of the documents concerned.

The main national publications used were the following (in many cases they are annual, and the most recent editions were therefore consulted);

- Germany : - Statistisches Jahrbuch für die Bundesrepublik Deutschland.
- Austria : - Statistisches Jahrbuch für die Republik Österreich.
Österreichische Schulstatistik
Zahlenmäßige Darstellung des Schulwesens in Österreich.

3. Enrolment ratios

These ratios have been defined as follows:

1st level (Table IX)

$$1000 \frac{\text{1st level enrolments}}{\text{Population aged 5 to 14 years}}$$

2nd level (Table X)

$$1000 \frac{\text{2nd level enrolments}}{\text{Population aged 10 to 19 years}}$$

1st and 2nd levels (Table XI)

	1st and 2nd level enrolments
1000	<hr/>
	Population aged 5 to 19 years

3rd level (Table X)

	3rd level enrolments
1000	<hr/>
	Population aged 20 to 24 years

Total enrolments (Table XI)

	Total enrolments
1000	<hr/>
	Population aged 5 to 24 years

TABLE I - Five-year age-groups of the population aged 5 to 24 (1950-1965)

ANNEX II

STRUCTURE AND DEVELOPMENT OF SCHOOL SYSTEMS
IN O.E.C.D. COUNTRIES

Comparative analysis of the expansion of education on the basis of the statistics used in this study calls for as accurate a knowledge as possible of school systems in Member countries, and more particularly the structural changes that have occurred in these systems during the period concerned (1950-1965).

In interpreting the growth of enrolments it is necessary to take account of the relative prominence of each level and type of education in the various national systems, especially in regard to the duration of studies and the corresponding age-groups. Also, it is important to allow for the fact that the uniformity of statistical series is liable to be affected by changes introduced as a result of educational reforms in one country or another.

The present Annex starts with an analysis of compulsory schooling, after which the different levels of education from pre-primary to secondary are considered. Since higher education is the subject of a special study by the Secretariat, it will not be dealt with here.

1. Compulsory schooling

The existence of legislation making it compulsory for children to acquire a basic education through attending school over a given period means that everyone in certain age-groups should be enrolled at an educational establishment. Within these age limits, therefore, the growth of enrolments in theory depends solely on demographic factors. However, apart from the fact that total participation has not yet been achieved in practice in a number of countries, the education received is not always the same, given that there may be some diversification of studies before the end of compulsory schooling.

In 1950 the period of compulsory school attendance in O.E.C.D. Member countries ranged from a maximum of ten years to a minimum of three. In most countries it was eight years: namely in Belgium, Finland, France, Germany (1), Iceland, Ireland, Italy, Luxembourg, Netherlands, United States and

-
- (1) In Germany, apart from eight to nine years' compulsory attendance at a full-time educational establishment, pupils are subsequently required to take part-time courses in a vocational school (Berufsschule) until the age of 18 unless enrolled at some other type of school.

in parts of Norway and Sweden. It was ten years in the United Kingdom; nine years in Japan and in certain states, provinces and cantons of the United States, Canada and Switzerland; seven years in other parts of Canada and Switzerland and in Denmark, Norway, Sweden and Yugoslavia; six years in Greece and Spain, five years in Turkey and three years in Portugal.

Age of entry was six or seven years (1), several countries admitting children at either age. Since the school-leaving age has been set at 14 years in the vast majority of developed European countries and at 15 years in a small number of others, it can be seen that for a proportion of students at any rate compulsory schooling extended into the secondary stage. However, for other students compulsory schooling ended at primary level, which meant that there was already some measure of discrimination. Lastly, in the less developed countries, like the Mediterranean nations, compulsory schooling coincided exactly with the period of primary education. The normal school-leaving age was still 11 years (Greece and Spain) and even 10 or 9 years (Turkey and Portugal), although in cases where pupils had schooling to make up, compulsory attendance could be extended for a few years (up to the age of 12 in Portugal and 13 in Turkey).

During the period covered by the study some changes took place in a number of countries, especially from 1960 onwards. Other reforms, either in preparation or already approved, had yet to be put into effect. In most Member countries, however, no significant changes occurred, which explains the uniformity of the statistical series for the educational levels covered by compulsory schooling in each country.

There is seen to have been an increase in compulsory education in all the Mediterranean countries. In Spain the school-leaving age was raised from 11 to 13 years in 1964, making the period of compulsory schooling eight years in all. In Greece the school-leaving age was raised to 14 years also in 1964, thus increasing compulsory school attendance from six to nine years. In Turkey a reform is under way which will gradually increase the period of compulsory attendance to eight years. In Portugal compulsory education was increased to four years in 1956, with the introduction on an experimental basis of fifth and sixth year primary classes as from 1968/69. In Yugoslavia, the period of compulsory schooling has been increased from seven to eight years, so that the school-leaving age is now 14 years.

(1) Except in the United Kingdom, where the age of entry is five years.

This raising of the school-leaving age has meant by and large that compulsory schooling extends into secondary education. In some cases, in fact, pupils completing their basic primary education are offered a choice between a further primary course and the lower secondary course. Thus, in Spain, a pupil who has completed his enseñanza elemental may either go on to enseñanza media or continue in primary school until the age of 13. In Greece provision has been made for pupils to move on from the elementary school to the gymnasium. In Yugoslavia, on the other hand, the entire eight-year compulsory course is primary, secondary education beginning in theory at the age of 15 (although in fact the second cycle of primary education - from 11 to 14 years of age - may be equated with the lower secondary cycle).

The most significant reform to have taken place in Member countries, namely in Sweden, has been the introduction of a comprehensive school (Grundskola), providing nine years of complete compulsory education. This reform, which had been progressively implemented since 1962, became fully operative as from 1968/69. The school covers three levels of education ranging from the erstwhile primary course to the lower cycle of secondary education.

In the other countries, the most notable extension of compulsory schooling took place in certain states of the U.S.A., where it now lasts 12 years, while in other states it still only lasts eight. In the European countries the changes have been minor ones: in Austria the period of compulsory education was increased from eight to nine years, as it also was in Luxembourg. However, plans to prolong compulsory attendance have been put in hand in certain countries, notably France, where the period was set at 10 years as from 1967.

It would be a mistake to regard legally compulsory schooling as synonymous with 100 per cent attendance: in a number of countries it is more a question of a trend than of a reality. As already pointed out in the study of the development of secondary education (1), there are noticeable instances, especially in the Mediterranean countries, in which compulsory schooling legislation is not fully implemented, the main causes being absenteeism and drop-outs (permanent or temporary) in rural areas where school-age labour continues to be frequently used.

2. Pre-primary education

Pre-primary education, which in its various forms exists in all Member countries of the O.E.C.D., is playing an increasingly important part in preparing children for school

(1) See Development of Secondary Education: Trends and Implications, O.E.C.D., 1969, Chapter II.

life. It is tending to become more and more widespread, although in some countries there are still not enough schools to meet the growing social demand. Furthermore, the function fulfilled by pre-primary schools is not always an initiation to school life; much of the time the schools serve simply as nurseries. Yet even allowing for cases where this is so, the expansion of pre-primary education helps to promote the implementation of compulsory school attendance, in that there is less tendency than before to keep school-age children at home, sometimes for the purpose of looking after other children (an important cause of absenteeism in the less developed countries). At the same time, mothers are free to go out to work and the active population is thereby increased.

But it is basically from the teaching standpoint that these schools are of special interest; the introduction of new methods is more common there, and this at the same time encourages their use in primary education.

Pre-primary education in the various Member countries lasts from two to four years, depending on the age of entry, which ranges from two to five, and the lower age limit for compulsory schooling, which as has been seen is set at six or seven years (except in the United Kingdom, where it is five). In eleven countries (1), pre-primary education extends over three years, whereas in seven others (2) it lasts four years and in five (3) only two years.

Some countries authorise different ages of entry and transfer to primary education depending on the maturity of pupils. In the Netherlands, for example, children may stay on at a pre-primary school until the age of eight, provided that a certificate is issued stating that at the age of seven the child is not yet ready to enter a primary class.

Pre-primary schooling may in some cases be spread over more than one type of establishment. Thus, in Canada the child moves on from the nursery schools (three and four year olds) to kindergartens (five and six year olds). In Spain there are escuelas maternas (two and three year olds) and escuelas de parvulos (four and five year olds). In Turkey the nursery schools cater for children of two and three years of age and the kindergartens for four and five year olds.

-
- (1) Austria, Belgium, Canada, Finland, Germany, Italy, Japan, Netherlands, United Kingdom, United States, Switzerland.
 - (2) Denmark, France, Norway, Spain, Sweden, Turkey, Yugoslavia.
 - (3) Greece, Iceland, Ireland, Luxembourg, Portugal.

The types of establishment in question may differ very considerably depending on whether they are nurseries or real pre-primary schools. In some cases too, they use different teaching methods or are organised by different authorities. In nearly all countries, these authorities are both public (the state or local authorities) and private (trade associations, religious denominations or merely private persons). In some cases the state subsidises the private establishments, their operation being almost invariably subject to official authorisation and supervision. Also, in view of the fact that these establishments are performing a real social service they are responsible, in some countries, not only to the Ministry of Education but also to the Ministry of Social Affairs (Denmark, Finland, Norway and Sweden).

The structure, duration and age limits of pre-primary education underwent no significant changes during the period covered by the study.

3. Primary education

Primary education's place in the school systems of Member countries differs appreciably, which makes inter-country comparisons difficult. For one thing, its duration varies considerably, and for another, the age limits and especially the age at which pupils move on to secondary education are not the same everywhere. Lastly, specifically national schemes have been developed for the internal organisation of study cycles, particularly the terminal cycle, which underwent some changes during the period in question.

(a) Duration of primary education

In 1950 the duration of primary education ranged from four to eight years, virtually the same difference remaining at the end of the period covered by the study. However, a distinction must be made between the duration of elementary education, which represents the primary course in the true sense, and that of the continuation course, which is usually intended for pupils completing their compulsory education but not taking secondary studies. In the statistics given in Annex I, enrolments in continuation courses have, wherever possible, been assimilated with enrolments in secondary education.

(b) Study cycles in primary education

Primary education is not always a single study cycle representing one portion of the educational system. In many countries it comprises several cycles, with not only a break between the elementary and continuation courses but in some cases within the elementary course itself.

In this regard, Member countries can be divided into three main groups:

- those in which primary education comprises a single course;
- those in which it comprises an elementary course and a continuation course; and
- those in which the elementary course is divided into more than one cycle with, if need be, a continuation course as well.

The first of these groups comprises Japan, Greece, Scotland and Northern Ireland. There the studies are continuous and form the common course of the primary schools, entry to secondary schools taking place when the pupil has completed his full primary education.

The next group consists of 10 Member countries: Austria, Denmark, France, Finland, Germany, Ireland, Netherlands, Norway, Spain and Yugoslavia. In all those countries elementary education is supplemented by an upper primary or continuation course, as the case may be, for pupils who at the end of the lower primary course do not go on to a secondary school. This, as we have already seen, introduces a dichotomy into the educational system even before the end of primary education, the result of which is that pupils are trained to different standards during the period of compulsory schooling.

The third group, which in some cases may bear a similarity to the previous one, depending on whether or not the primary system provides for a continuation course, comprises those countries in which there is a sequence of primary education cycles. The countries belonging to this group are Belgium, Luxembourg and certain states of the U.S.A. with three cycles, and Iceland, Italy, Portugal, Sweden, England and Wales, and Canada with two. Each cycle lasts either two or three years.

(c) Adult primary education

In some Member countries where there is still a relatively high rate of illiteracy, efforts are being made to check this trend by means of primary education for adults. Thus, in the Mediterranean countries one finds in addition to the normal primary schools educational centres where adults are taught to read and write. These centres may be either public or private establishments, and classes generally take place in the evening. There are also schools for the armed forces (Portugal and Turkey), where recruits are given basic training during the period of their

compulsory military service. Adult primary education is sometimes supplemented by vocational training. This type of education should not be confused with the complementary education for adults provided in a number of countries. The statistical tables in Annex I do not cover these courses for adults.

4. Secondary education

In nearly all Member countries the transition to secondary education brings the first diversification of study courses. Secondary schooling offers a wide variety of courses, which may be grouped in three main categories:

- general education;
- technical and vocational education; and
- teacher training.

The first two types can be further divided into the long secondary course leading to higher education (called type a in the O.E.C.D. classification) and the short secondary course (type b) for pupils proposing to acquire a general or vocational education at intermediate level, usually with a diploma at the end of the course that will serve as direct qualification for a job.

In the initial stages of compiling the figures that form the statistics used in the present study, allowance was made wherever possible for this diversity of types of secondary education. The distinction between the three main categories (general, technical and vocational, teacher training) was relatively easy to establish. Between the long and short courses it is much more vague, however, since the channels of transition from one to the other are not always clearly defined. This is a question which turns on the relative rigidity of the various school systems and will be discussed later on.

It is proposed first of all to consider access to secondary education and then to analyse each type of course.

(a) Access to secondary education

The normal age of entry to secondary schools ranges from 10 to 14 years (1), depending on how long the common elementary cycle of primary education lasts. From a comparative standpoint, it may therefore be said that the distinction between primary and secondary education in the 10 to 14 age group is only very relative,

-
- (1) Following the 1962 reform, the Swedish comprehensive school provides education up to the age of 15 years, after which the pupils may go on to secondary schools. However, the upper cycle of the comprehensive school, for 13 to 15 year olds, may be regarded as equivalent to the first cycle of secondary education.

especially as in every country where pupils may start on the first cycle of secondary education at an earlier age alternative provision is made, as we have seen earlier, for a continuation course at primary level.

In most Member countries, pupils start their secondary education at 11 or 12 years of age. The exceptions among the European countries are Austria, Germany and Spain, where the changeover normally takes place at the age of 10, and Norway, part of Switzerland and Denmark, where it occurs at 13 or 14. Sweden has already been noted as a special case in that the comprehensive school caters for children up to the age of 15. In some parts of Canada children may go over to secondary education at the age of 13, while in some states of the U.S.A. the age of entry is 14 years.

No major reforms were introduced in this area between 1950 and 1965, other than in some of the Scandinavian countries (Sweden and Denmark) where there was a tendency to raise the age of entry to secondary schools.

(b) General secondary education - long course (type a)

The training given on this type of course corresponds to what is commonly called a general education (literary and scientific), the diploma awarded on completion of the course being the prerequisite for entry to an establishment of higher education. Conventionally, therefore, these courses form the backbone of secondary education, linked as they are to the national traditions of each country. Hence the diversity of schools offering these courses in Member countries. This diversity relates to the duration of studies as well as the nature of the establishments concerned and curriculum structure. It is now proposed to consider each of these differing aspects in turn.

As already noted, the standard age of entry to secondary schools ranges from 10 to 14 years but in most countries is set at 11 or 12 years. The normal school-leaving age is 17 or 18 years in nearly every country, with the exception of Spain (15 years), Turkey (16 years) and Iceland (20 years). Within these age limits the duration of studies not only varies but relates to different age-groups, which makes inter-country comparisons difficult.

The most usual duration of studies is either six or seven years, not only in most European countries but also in the United States, Canada and Japan. Some of these countries allow a shorter duration of studies, however: in the Netherlands and Canada secondary education may be reduced to 5 years. In other countries

the studies last longer: eight years in Finland and Italy and up to nine years in Austria and Germany.

There are cases in which the formal distinction between primary and secondary education does not coincide with the actual place occupied by the relevant establishments in the educational system. In Yugoslavia, according to the national classification, general secondary education does not begin until the age of 15, with the result that its duration is limited to four years; but in fact the upper primary cycle (11-14 years) may be regarded as a lower secondary cycle. For purposes of inter-country comparison, therefore, enrolments in the latter category should be aggregated with total enrolments in secondary education. Unfortunately, with the statistics that were available it was not possible to do this here.

In Sweden, following the introduction of the comprehensive school the upper-level course of the Grundskola (13-15 year olds) corresponds to the first cycle of secondary education. Thus, what counts is not the official nomenclature of establishments but the type and content of the education they provide.

Some countries provide a uniform type of long secondary course, others do not: in some cases diversification occurs in the terminal cycle when, after an initial common course, pupils begin to specialise in preparation for higher education. In most Member countries secondary education is divided into two cycles, the first of these sometimes being an orientation course. However, some Member countries introduced reforms during the period under consideration, and these have to be taken into account in order to understand how the system functions during the transition phase when old and new structures exist side by side and to interpret the relevant statistics.

The most radical reforms were those introduced in Denmark (1958), Norway (1959) and Sweden (1962).

In Denmark the mellemskola (intermediate lower secondary school) was abolished; this brought the age of transfer to secondary education up to 14, thereby reducing the length of the general secondary course by two years.

In Norway, on the other hand, the age of admission to secondary education was lowered from 14 to 13 years through the introduction of a first cycle, the duration of secondary education being increased from 5 to 6 years.

The Swedish reform replaced the realskola (intermediate lower secondary school) with the upper course of the comprehensive school, the second cycle being covered by the gymnasium. The duration of general secondary education is still unchanged, therefore, but its structure is different.

It should also be noted that in Italy the scuola media (intermediate lower secondary school) was opened up in 1963 to all children in the 11-13 age-group as the first cycle of secondary education.

In all the other Member countries there was no appreciable change in the structure of general secondary education. Consequently, the statistical series used in order to study the development of secondary education are largely uniform over time.

Although the diversity of establishments and training precludes pertinent and significant country-to-country comparisons in some cases, a common function can at least be discerned: namely preparation for higher education substantiated by a certificate of general secondary studies.

It should be remembered, however, that in some countries this certificate is but one of the prerequisites for admission to a university, an entrance examination being prescribed as well. Also, for admission to a non-university establishment of higher education other diplomas, attesting to technical or vocational training, are sometimes required.

(c) General secondary education - short course (type b)

In addition to secondary education leading to university entrance, there are courses for pupils whose formal education will end either at the end of the compulsory schooling period or at secondary level. As noted earlier, there is the upper primary course (or primary continuation course), which can in fact be regarded as the first cycle of secondary education. Then there are establishments where the courses lead to a diploma giving access to jobs for which a general qualification above primary level is required. Normally, these types of establishment also offer courses that lead to further education in that they give privileged access to technical and vocational training, but in addition some of them enable their pupils to go on to the second cycle of general education, thereby making the distinction between long- and short-course education difficult: this is in fact only one of the forms which the first cycle of secondary education may take. For the purposes of this study, only the education provided by

short-course establishments will be considered, as opposed to that which forms the first cycle of the long course. It should be pointed out, however, that a diploma is very often awarded at the end of the first cycle.

The duration of studies in short-course establishments is in many cases the same as that of the first cycle of the long course, especially when there are parallel long-course schools to which pupils may transfer. But it can differ, notably in the case of upper primary schools. The most usual period is three or four years but it may be as long as six years (United Kingdom and Germany) or as short as two years or even one.

There are a few countries in which no differentiation is made between the long and short courses. For instance, in some Mediterranean countries (Spain, Greece, Portugal and Yugoslavia) the educational system does not include general secondary schools for pupils not intending to go on to higher education, while in the United States and Canada the various types of educational establishment are not differentiated in the same way as they are in Europe.

As regards the outlets of the general short course, several possibilities exist. In a number of countries pupils have the choice of either transferring to the long general course (upper cycle) or going on to technical and vocational establishments. In other countries technical and vocational training is the only outlet, although this may lead to higher education (generally non-university).

(d) Technical and vocational education

The organisation of technical education everywhere is more complex than that of general education, which makes inter-country comparisons even more difficult. The primary cause of this complexity is the highly varied content of technical and vocational education, which by its very nature necessitates many different branches of study. Another factor is the existence of several organisational authorities: in addition to the ministry of education, other administrative bodies are often involved, given that they are more directly concerned with vocational training in one or other sector of the economy.

The first distinction to be made here should be between establishments of technical education and establishments of vocational education. Not only do they teach different subjects but they teach them to a different standard: there is little in common, for instance,

between courses for skilled workers and training of middle-level technical executives. But quite apart from the fact that hybrid establishments exist in some cases, the line of demarcation is not always easy to draw.

The differentiation between secondary and higher education also raises particular difficulties. Certain establishments considered to be of secondary or intermediate level by the national authorities in fact come within the framework of non-university higher education, according to the O.E.C.D. classification.

It is also possible to distinguish between long- and short-course education, according to probability of access to higher education.

Lastly, there are a large number of part-time technical and vocational establishments.

Because this branch of education is so diverse, it did not seem possible to make a detailed study of it here. In some countries students may take up technical and vocational courses immediately after completing their lower primary education; in others the changeover takes place at a more advanced stage of the curriculum.

In most school systems it is possible for students to transfer from a general secondary course to technical and vocational training, especially at the break between the first and second cycles. In some countries there is even a preparatory cycle common to both types of education; in others, however, the early partitioning of studies into parallel courses is more constraining and rigid.

For the purposes of the present survey, enrolments in technical and vocational education were grouped in a single category after as detailed a study as possible of the establishments concerned. Because of the foregoing considerations, particular care must be taken to avoid any outright comparison of trends in this type of education in Member countries.

5. Teacher training

Training of primary and pre-primary teachers is given by specialised teaching establishments whose status, length of curriculum and organisation differ according to the countries concerned.

Although most teacher training establishments belong to the secondary school system, there are some countries in which the same studies form part of higher education e.g. in Germany,

Japan, the United Kingdom and the United States. Generally speaking, teacher training follows on from the upper secondary cycle, a school-leaving certificate being required in many cases. But teacher training schools may themselves also provide general education for their pupils. Thus, in some countries, two possibilities exist: either the student already holds a secondary school-leaving certificate and simply takes a teacher training course, or he has first of all to complete his general studies before receiving his specialised training. In some countries, pre-primary teachers are trained in special establishments. In others, they receive their training along with primary teachers.

The length of the teacher training course in most countries is three or four years (including general education in the majority of cases). In a few countries it is only two years (Portugal and Luxembourg), while in certain others it is as much as five (Netherlands, Switzerland and Ireland). Care must be taken, however, to avoid any hasty comparison of training durations owing to the abovementioned disparity of structures.

The age-groups covered by teacher training are not the same in every country. In some the course coincides with the upper secondary cycle, while in others it corresponds to the first few years of higher education.

Training of secondary school teachers is not dealt with here, since this comes under the heading of higher education.

6. Complementary education

In a number of north European countries one finds, alongside the ordinary schools, establishments providing continuation courses either for young people or for adults who have not taken their studies beyond the period of compulsory schooling.

Cases in point are the Folkehøjskoler (colleges for adults) and Andre ungdomskoler (schools for young people) in Denmark; the Kansanopistot (people's university) and the Työväenopistot (civic institute for workers) in Finland; the Folkehøgskoler (schools for adults and young persons) in Norway; the Folkhögskolor (adult colleges) in Sweden; and the Skole za dopunsko obrazovanje (schools of further education) in Yugoslavia.

Enrolments in these establishments are not included in the tables in Annex I.

7. Special education

In all Member countries special education is provided for maladjusted, backward or handicapped children. Wherever

possible, the relevant statistics have been isolated.

This type of education may be given in separate establishments or in special classes provided by ordinary schools. In some countries both procedures are used. Generally speaking, schools or classes are differentiated according to the type of disability suffered by the child. The structure and curriculum of the courses are in some cases patterned on those of the ordinary school system, but may be adjusted to a greater or lesser degree. The duration of attendance, in particular, does not always coincide with that of compulsory education, since in a number of cases the upper age limit is exceeded: thus, in the United Kingdom attendance may continue until the age of 17 or 18 and in Finland up to 16 in some schools.

These special courses are not solely confined to primary education, moreover. In some countries they extend to secondary level also. They may be both general and vocational, manual work even being a preferred means of rehabilitation. Consequently, some special schools are independent of the educational system, being responsible to institutions of social rehabilitation.

ANNEX IIIEXTRAPOLATION OF ENROLMENTS UP TO 1980

The following extrapolations concern enrolments at each of the three levels of education up to 1980. They cover all 23 O.E.C.D. countries apart from Iceland and Switzerland whose basic data were too incomplete.

1. Stages of the calculation

The successive stages of the calculation are as follows:

E1- Extrapolation of the enrolment ratio at 1st level, W , defined as follows:

$$W(t) = 1000 \times \frac{\text{1st level enrolments in year } t}{\text{population aged 5 to 14 in year } t}$$

E2- Extrapolation of ratio R_{21} defined as follows:

$$R_{21}(t) = 1000 \times \frac{\text{2nd level enrolments in year } t}{\text{1st level enrolments in year } t-5}$$

E3- Extrapolation of ratio R_{32} defined as follows:

$$R_{32}(t) = \frac{\text{3rd level enrolments in year } t}{\text{2nd level enrolments in year } t-5}$$

E4- Calculation of 1st level enrolments by multiplying the numbers in the 5-14 age-group, which are also known through ratio W , extrapolated in E1;

E5- Calculation of 2nd level enrolments by multiplying 1st level enrolments extrapolated in E4 by ratio R_{21} extrapolated in E2;

E6- Calculation of 3rd level enrolments by multiplying 2nd level enrolments extrapolated in E5 by ratio R_{32} extrapolated in E3;

E7- Calculation of total enrolments.

In short, the sequence of calculations is as follows:

Ratio $W(t)$ is given in Table IX of Annex I and ratios $R_{21}(t)$ and $R_{32}(t)$ are in Tables I and II which follow; these data are also used in country Graphs I to XX.

2. Adjustments of W , R_{21} and R_{32}

When extrapolating a trend by the least squares method, it is essential that the adjusted curve follow the data observed as closely as possible otherwise the extrapolation loses all significance. But a glance at Graphs I to XX shows that in many cases an adjustment covering the entire period would have necessitated choosing a complicated function. Unfortunately, such functions are usually unsuitable for extrapolation as they lead, if the horizon is too distant, to such great confidence intervals that they lose nearly all practical meaning. Moreover, these functions do not always lend themselves to simple theoretical interpretation.

We have therefore confined ourselves in all cases to a linear adjustment in the form:

$$W(t) = a_0 + a_1 t$$

$$R_{21}(t) = b_0 + b_1 t$$

$$R_{32}(t) = c_0 + c_1 t$$

t being the time in years ($t = 1$ for the 1st observation used in the adjustment).

However, it was necessary to check that the linear model adopted fell in line with the observations. Thus, in this case the sequence of residuals between values observed and theoretical values has to be distributed haphazardly around the trend. This assumption may be tested by calculating Von Neumann's ratio:

$$\frac{n}{n-1} \frac{\sum [\bar{u}(t+1) - u(t)]^2}{\sum [u(t)]^2}$$

where n is the number of observations and $u(t)$ the residual. This ratio has been tabulated by Hart for confidence levels of 95 per cent and 99 per cent.

We have finally selected for each ratio the maximum number of successive observations compatible with a haphazard distribution of residuals (at the level of 99 percent), where necessary discarding the oldest observations. The period of adjustment retained is shown in Table III as well as the parameters of the equations, the standard deviation of residuals σ_u , as well as this same standard deviation as a percentage of the average value of the adjusted variable. This latter quantity enables the accuracy of the various adjustments to be compared rapidly.

3. Extrapolations of W , R_{21} and R_{32}

For year T , the extrapolated trend of W (for example) is given by:

$$W(T) = a_0 + a_1 T$$

and this estimate falls between a maximum value and a minimum value given by the expression:

$$W = (a_0 + a_1 T) \pm k \sigma_u \sqrt{\frac{1}{n} + \frac{(T - \bar{T})^2}{\sum (t - \bar{t})^2}}$$

k being a factor read in Student's table for a particular number of observations and confidence levels (we have chosen 98 per cent).

The confidence interval is therefore all the greater and the estimate of the trend is therefore all the less precise when:

- the standard deviation of residuals σ_u is greater;
- the number of observations n is smaller.

This explains the very wide intervals which may be observed on certain country graphs (Greece, Japan, the United Kingdom and Yugoslavia).

The value found for the trend and the interval on either side are shown in Table IV.

4. Demographic projections

The demographic prospects for 1970, 1975 and 1980 will be found in Table V. The sources used and indicated at the end of the table often gave different figures for 1965 from our own, but we have retained the latter for the sake of coherence in our own calculations. This explains why for certain countries the difference between the numbers in a particular age-group in 1965 and the numbers in the same age-group five years later in 1970 is a little too great. However, this has little importance for 1980.

Table VI shows the increase in a few age-groups between 1950 and 1965 and between 1965 and 1980.

5. Enrolments in 1980

Enrolments are calculated on the basis of the extrapolation of ratios and demographic prospects. A calculation example concerning the Netherlands is given in Table VII and the results for each country in Table VIII (1).

Table IX shows the deviation between the minimum and maximum estimates expressed as a percentage of the minimum estimate. The deviation increases from primary education to higher education since the deviation for each level of study combines with that for the preceding levels of study. These deviations are all the wider when the number of observations used for the adjustment is smaller and when the standard deviation of residuals is greater. For some countries, they are very great and the following remarks are called for in this connection:

- (a) In primary education, it would no doubt be possible to obtain more precise estimates by taking the age-groups corresponding to compulsory school attendance. However, it will be recalled that our calculations do not allow for the uncertainty inherent in demographic projections, which is fairly great precisely for the age-group concerned.
- (b) From the strict point of view of statistical accuracy, there is no justification in extrapolating 15 years ahead, series as short as those in our possession. However, considering the existing data, no other method appears to be better and greater detail would certainly have been misleading.

Lastly, Table X shows the enrolment ratios in 1950, 1965 and 1980.

- (1) These figures do not include various types of education not classified by level which account for a negligible proportion of the total.

For Denmark, changes in the educational structure prevent E_{10} and E_{21} from being calculated separately. We have therefore directly extrapolated the primary plus secondary education index, whose value is:- 1970 : 750 ± 13 ; 1975 : 766 ± 18 and 1980 : 782 ± 24 . We have also extrapolated the ratio between higher education enrolments and primary plus secondary education five years previously, i.e.: 1970 : 170 ± 4 ; 1975 : 202 ± 5 and 1980 : 234 ± 7 .

For Norway, we have assumed that non-university higher education enrolments accounted for 50 per cent of university enrolments, i.e. the proportion observed in the last few years for which figures are available.
