ABSTRACT

Man, with his ability to develop and control his environment, and, conversely, the controlling or limiting factors of the environment that affect man's health and activities are dealt with in this prototype curriculum for grades 7-9. The basic principles related to ecology affecting man's health are given primary consideration. Specific curriculum content studies: (1) the development of ecology, (2) man's health and the physical, biological, and sociocultural environments, and (3) an individual's health as affected by reacting with his environment. Appended material includes bibliographies of multimedia resources for teachers and students. This publication is one in a series of health curriculum materials devoted to environmental and community health (Strand IV). Four other strands deal with physical and mental health, sociological health problems, and education for survival. The format consists of four columns intended to provide teachers with: (1) a basic content outline, (2) major understandings and fundamental concepts, (3) teaching aids and learning activities, and (4) information about resource materials, sources, and personnel. Because of the comprehensive nature of the total curriculum, teachers are advised to become familiar with all strands presently in print. Related documents in Strand IV are ED 037 738-9, ED 049 477-8, and SE 016 280-6. (BL)

FOREWORD

This publication contains curriculum suggestions for teaching Strand IV - Environmental and Community Health, Ecology and Health, for Grades 7, 8, and 9.

The publication format of four columns is intended to provide teachers with a basic content outline in the first column; a listing of the major understandings and fundamental concepts which children may achieve, in the second column; and information specifically designed for classroom teaching which should provide them with resource materials, teaching aids, and supplementary information, in the third and fourth columns. The comprehensive nature of the health program makes it imperative that teachers gain familiarity with all of the strands presently in print. In this way, important teaching-learning experiences may be developed by cross referring from one strand to another.

It is recommended that the health coordinator in each school system review these materials carefully and consult with teachers, administrators, and leaders of interested parent groups in order to determine the most appropriate manner in which to utilize this strand as an integral part of a locally adapted, broad and comprehensive program in health education.

The curriculum materials presented here are in tentative form and are subject to modification in content and sequence. Critiques of the format, content, and sequence are welcomed.

ECOLOGY AND HEALTH

Grades 7, 8, 9

Overview

This strand deals with man and his ability to develop and control his environment, and, conversely, the controlling or limiting factors of the environment that affect man's health and activities. The basic principles related to ecology affecting man's health are given primary consideration.

Changes in population, societal structure, purposes and activity, along with scientific development, and natural environmental phenomena, present us with challenging health implications. It has, therefore, become increasingly important for students not only to understand their environment (what it is and what it does), but also to become committed to involving themselves in bringing about its improvement. It is essential that teachers select, or create, learning experiences which will reach these ends.

Some of the concepts which students should develop through their learning experiences include:

- How to cope with health problems related to the ecological factors
- The ecological factors which affect one's behavior
- The nature of environmental variables

Pupil Objectives

Students in grades 7, 8, and 9 should:

- Develop an understanding of the nature of the ecological process.
- Understand how the ecological factors affect man and his health.
- Appreciate man's effort to improve his environment and consequently his health.
- Learn about the increased complexities dealing with disease, man, and his environment.
- Understand how geography, culture, and artificial and natural environmental factors affect man through their interactions.

MAJOR UNDERSTANDINGS AND FUNDAMENTAL CONCEPTS	SUGGESTED TEACHING AIDS AND LEARNING ACTIVITIES	SUPPLEMENTARY INFORMATION FOR TEACHERS
Numerous scientific disciplines have contributed to the science of ecology in an effort to understand, cope with, and prevent disease, defect, disability, and death. It is through the combination and application of these sciences that we can best understand health problems and, consequently, the means of attaining optimal health.	This is an appropriate time to discuss in general terms the meaning of ecology. - What is ecology? (See concept A) - Make a list of sciences which contribute to ecology. - Explain how each contributes. - How does each help us to understand the nature of disease and disability? - With what we know now about man and his environment, discuss the factors which may contribute to our further understanding, in the future, of ecology.	Ecology provides an approach to an understanding of the complex interrelationship between organisms and their environment. The study of modern man as he relates to current health problems and issues cannot be accomplished through the science of biology alone. It is only through the interrelationships and the application of the physical, biological, and behavioral sciences that we can intelligently utilize and apply scientific findings ultimately to improve the health of man in the 20th century. The prevention of disease is now becoming more of a matter of changing the habits, lifestyle, and customs of individuals and groups than of immunizing populations. It is significant that man's efforts to understand and control his environment have led to his increased health status, longevity, and efficiency. However, man's created environment continues to present serious hazard conditions to his

A. Ecological components	Human ecology is the science which studies the relationships of man interacting with his total environment (physical, biological, and socio-cultural). Man's environment is a composite of the (1) natural components, (2) man's creations, and (3) numerous combinations of the two.	Have the class give examples of how man interacts with the various parts of his environment. 1. How does each affect his behavior? Efficiency? 2. Which factor - physical, biological, or cultural - seems to have the greatest effect? Urgency? 3. What can we conclude about this from a health standpoint? 		health; air, water, and land pollution, for example. We need to reverse these artificial environmental trends and redefine our concept of progress.
Human ecology is the science which studies the relationships of man interacting with his total environment (physical, biological, and socio-cultural). Man's environment is a composite of the (1) natural components, (2) man's creations, and (3) numerous combinations of the two.	Have the class give examples of how man interacts with the various parts of his environment. 1. How does each affect his behavior? Efficiency? 2. Which factor - physical, biological, or cultural - seems to have the greatest effect? Urgency? 3. What can we conclude about this from a health standpoint?	Ecology is the science that deals with the interrelationships of organisms and their environments. In human ecology, the primary consideration is the interrelationship of man and his physical, emotional, and social environments. However, it should be noted that human ecology, at times, necessarily becomes involved with ecological relationships of other organisms. For example, intermediary hosts and vectors experience an ecological relationship in their own life cycle, and may also be implicated in the transmission of disease to humans.
Man's physical environment may favorably or unfavorably influence his health status.	Have the students list and describe ways in which the physical environment affects their health status. Include both favorable and unfavorable effects.	Various factors related to air, water, and soil are examples of the effects of the physical environment on health. . We are dependent on air to support life.

Show and discuss film *Air Pollution - Everyone's Problem* or *The First Mile Up* Refer to Strand IV - Environmental Health. Have students relate the way they feel and react when it is hot and humid.	Selected examples of effects of the physical environment upon health: . We are dependent on air to support life itself. Generally, man can live without food for 5 weeks, without water for 5 days, and without air for 5 minutes. . Air may also serve as a vehicle for transmitting infectious diseases in man. . Air also carries the pollutants of our environment that contaminate our atmosphere and produce air pollution. Our improved technology and expanding population combine to produce numerous modern day public health problems, (i. e., air and water pollution, sewage disposal, pesticides, radiation, etc.). . Man and his efficiency may be influenced by the physiological and psychological effects of the hot, humid, stagnant air that surrounds him.

The cool air becomes sealed in near the surface and the pollutants accumulate in this layer and cannot escape. (A change in the weather permits the escape of the cooler air.)	Have students do research on air pollution problems in New York City, Elmira, Buffalo, etc. How do the climate and terrain affect the air pollution problem in these areas? Refer to Strand IV, Public and Environmental Health. What are these cities doing to revise the pollution trends? What political forces are at work regarding health problems?	Los Angeles has a serious problem with air pollution because of its geographical situation on a narrow coastal strip which is rimmed by mountains and ventilated by relatively weak winds. Aggravating the problem is the large number of automobiles in the city and the weather condition called a thermal inversion which occurs approximately 100 days a year.
Pure water, as well as clean air, is an essential element of a healtful environment. Water is one of man's most pressing problems. The quality of water is of primary concern.	Question for research and discussion: What is being done in New York State to assure us of a safe water supply? The sanitary engineer or sanitarian from the county health department is a good resource. Refer to Strand IV, Environmental Health. How does water pollution affect us from a psychological viewpoint?	. Water is necessary for man's survival. . Water may serve as a vehicle of transmission for certain infectious diseases, (i.e., typhoid, dysentery, cholera, etc.) . One-fourth of the world's hospital beds are filled with people suffering from waterborne diseases. . Stagnant water combined with the proper climate, temperature, rainfall, and terrain are necessary for the perpetuation of diseases such as malaria,

		yellow fever, and encephalitis. These climatic factors create the necessary breeding environment for the survival of the mosquito.
Uncontaminated soil is necessary for growth of food.	Assign a small group of students to find out about contamination of soil by insecticides. The Farm Bureau, 4H, or other such agencies should be approached for information. You may wish to show the film: *Perspectives on Pesticides* available from the N.Y.S. Dept. of Health.	. We are dependent on the soil for plant food for our existence. . Soil erosion may lead to food shortages which produces starvation and lowered resistance to disease. . Mineral depletion in the soil may cause endemic goiter in man due to the lack of iodine in the soil. However, the use of iodized salt has alleviated the problem to a considerable extent.
Soil can harbor infectious bacteria.	Discuss the "who, how, where, when, and why" about contracting tetanus. What preventive measures can be taken?	. The soil serves as a reservoir (to a limited extent) for the spore-forming bacillus that produces tetanus. When environmental conditions become unfavorable, the tetanus bacillus assumes the spore stage. The protoplast shrivels, and changes in the cell wall occur. Spore forms of bacteria are generally re-

D. Geography and topography	Certain geographical areas of the world have higher disease rates which are due, in part, to the climatic conditions found in these areas. Geographical differences in death rates are also dependent upon variations in levels of living, composition of the population, and the availability and utilization of health services within that particular area. Characteristics of the physical terrain of a given land area may enhance the possibility that disease will occur. The physical environment appears to help in conditioning the human body to either resist or fall prey to disease.	Refer to Strand IV, World Health. Assign a student to interview a public health physician or general practitioner about the various ways of protecting individuals who plan to travel to foreign countries. Have students identify and describe the epidemiological characteristics of malaria, yaws, hookworm, tetanus, etc. Show and discuss film: *The Mosquito and Its Control*.	Tropic areas ly hav for ma yaws, Infant ity ra southe the ma diseas monia, exert in ter southe The se mosqui of the temper ence o breedi averag of 22 provid tions spread

		sistant to heat, cold, chemicals, and other unfavorable environmental conditions. When conditions become favorable, such as when introduced into a puncture wound, the spore form may return to its original state and produce disease.
Certain geographical areas of the world have higher disease rates which are due, in part, to the climatic conditions found in these areas.	Refer to Strand IV, World Health.	Tropical and subtropical areas of the world generally have higher disease rates for malaria, yellow fever, yaws, etc.
Geographical differences in death rates are also dependent upon variations in levels of living, composition of the population, and the availability and utilization of health services within that particular area.	Assign a student to interview a public health physician or general practitioner about the various ways of protecting individuals who plan to travel to foreign countries.	Infant and maternal mortality rates are higher in the southeastern states. Also, the major communicable diseases, influenza, pneumonia, and tuberculosis exert their largest toll in terms of death in the southern states.
Characteristics of the physical terrain of a given land area may enhance the possibility that disease will occur.	Have students identify and describe the epidemiological characteristics of malaria, yaws, hookworm, tetanus, etc.	The seasonal incidence of mosquitoes in many regions of the world is governed by temperature and the presence of stagnant waters of breeding. Areas that have average monthly temperatures of 22 to 25 degrees celsius provide the optimal conditions for breeding malaria-spreading anopheles
The physical environment appears to help in conditioning the human body to either resist or fall prey to disease.	Show and discuss film: *The Mosquito and Its Control*.

		mosquitoes. Adequate rainfall in the area is also essential to fill the land areas and produce the stagnant pools. Temperature and moisture conditions also play a major role in yaws. Yaws is transmitted to man by a spirochete that tends to survive best in moist, warm soils and causes infection through insect bites and scratches on the skin. Yaws is particularly common in Africa, the Philippines, Indonesia, Southeast Asia, and the South Pacific Islands. Hookworm disease is more prevalent in areas characterized by heavy rainfall, periodic flooding, sandy soil, and where disposal of human feces is inadequate.
The atmospheric environment may be favorable or unfavorable to the survival of microorganisms.	Have some students interview a public health officer in their area as to how climate influences disease. Are there some diseases that are more prevalent during certain times of the year? Are there some diseases that show a higher mortality	Geographical areas of high ultraviolet radiation, combined with low humidity and extreme cold weather, tend to be unfavorable for microorganisms. Climate can affect man and his health in many different ways. The human body has a limited ability to adjust to environmental conditions.	Discuss the various ways in which climate affects man's health. Refer to the effects of temperature and humidity. Read about health precautions taken by arctic explorers and American astronauts to prepare for their trips. Why do arthritic joints sometimes become painful in changing weather?	High temperatures, combined with high humidity and lack of ventilation, produce overheating. If a man's body temperature rises to 41 degrees celsius, heat stroke occurs and a high mortality rate ensues. Low temperatures in combination with high wind velocity cause cooling. Frostbite may be one of the first consequences. (Frostbite was one of the major causes of casualtities during the Korean conflict.) If environmental conditions cause a reduction of body temperature to 33 degrees celsius, unconsciousness occurs and death may result. Continuous exposure to cool or warm climates produces changes in man's metabolic rate. Heat production is regulated through caloric intake. The average caloric intake of servicemen stationed in a 32-degree celsius, desert environment was 2900 calories as

Ultraviolet radiation from the sun can have both positive and negative effects on health.	Research and discuss: Can too much sun be harmful? How and why? Are some people more susceptible to the effects of too much exposure to the sun? How much sun is needed to provide the daily requirement of vitamin D? How is vitamin D made by the body? (See Strand I, Nutrition.)	Overexposure to ultraviolet radiation produces sunburn, or acts as a protecting device and produces tanning of the skin. Ultraviolet radiation produces the protective provitamin D in the skin which is essential in the prevention of rickets. The most damaging effect of ultraviolet radiation is in the production of skin cancer in individuals who have been exposed for long periods of time. Ultraviolet radiation is also responsible for photochemically altering and changing man-made combustion products which cause the formation of highly irritating substances in the atmosphere. Low ultraviolet radiation, high humidity, and warm temperature appear to be conducive to the survival of microorganisms.

MAJOR UNDERSTANDINGS AND FUNDAMENTAL CONCEPTS	SUGGESTED TEACHING AIDS AND LEARNING ACTIVITIES	SUPPLEMENTARY INFORMATION FOR TEACHERS
Climate therapy has been used in the past by the medical profession for numerous health problems.	Question for discussion: For what conditions do physicians recommend that people relocate, and to where? Most physicians could respond to this question from a student.	Many patients with bronchitis and sinusitis have benefited by moving to sunny and dry climates. However, climate therapy has been largely replaced during the past several decades by chemotherapy, since chemical agents can be prescribed precisely and with reasonably foreseeable results.
Substandard housing, especially slums, is characterized by high morbidity and mortality rates.	Questions for research and discussion: What is being done in our community to eliminate substandard housing? To provide adequate housing? Who is responsible for maintaining adequate housing? (You may wish to consider the role of: lessor, lessee, homeowner, health department, and housing code enforcement agent.) What diseases and health problems exist in substandard housing areas at higher rates than in areas of adequate housing? (Health department	Although there is no proven correlation between substandard housing and disease, increased disease rates are associated with slums and blighted housing. Substandard housing is defined as crowding when 1.5 people or more per room live in a dwelling. A slum is a neighborhood in which dwellings lack inside toilet, and bath facilities, hot and cold running water, adequate heat, light, quiet, clean air, and space for the number of residents. Blighted housing is an area of no growth in which buildings are permitted to deteriorate.

If this legislation is enacted at the county level, the county becomes eligible for state aid. The code would then be enforced by the county health department. This activity could be studied by the class, or you might wish to invite the health department sanitary engineer to speak to the class on the topic.	People living in these areas experience higher morbidity rates than those people who enjoy adequate housing. Examples of some diseases and problems are: higher rates for communicable diseases, v.d., intestinal diseases, pneumonia, influenza, infective and parasitic diseases, t.b., mental illness, infant mortality rates and shorter life expectancy rates. Also, juvenile delinquency, robberies, arrests, murder, and manslaughter rates are higher.
The trend towards urban living and high population-belts is associated with certain health problems that are less evident in smaller communities.	Have the class or group read and discuss: *Health News*, October 1969. This may be obtained from the county health department, if the school library does not have a copy.	The incidence of certain diseases is considerably higher in metropolitan areas than in smaller urban and rural areas. For example, lung cancer and coronary heart disease death rates are higher in urban communities, particularly in communities of 50,000 or more compared to communities of 10,000 or less population. In the 1950's, cardiovascular disease rates in Chicago

		vs. smaller Illinois communities were: 25-34 yrs - 25% higher 35-54 yrs - 100% higher 55-64 yrs - 300% higher Air pollution, water pollution, and noise are other problems that are more severe in large cities, as well as congestion and stress.
A combination of physical components, when not maintained in a healthful state, can result in high incidence of disease.	Questions for research and discussion: How can the use of insecticides affect the quality of a water source? How does the lay-of-the-land have an effect on air pollution? In what geographical areas would the interaction of certain physical components yield a prevalence of malaria? Hepatitis? Tuberculosis? Skin cancer? What particular physical components are involved? How would you answer these questions in relation to your community?	The physical environment - consisting of air, water, soil, climate, geography, topography, communities, and housing - is dynamic and variable, - even within a given area. For example, a stream can be relatively clean at one point and polluted a short distance away; the same situation applies to air, soil, and other physical components. Many of these physical variables exist concurrently, creating conditions either favorable or unfavorable to our health. The Donora, Pa., air pollution incident is a classic example. Poverty pockets in many of our large cities are subject to substandard housing, air

		pollution, noise pollution, poor water supplies, etc. The result is high incidence of numerous diseases.
Wise use and control of the physical environment are necessary to maintain a healthful environment.	There are many agencies that are concerned with the use and control of the physical environment, such as: the health department, the conservation department, the agricultural administration, housing and urban development corporations, etc. Assign groups or individuals to interview officials of these agencies to learn how they operate to insure the optimum development and use of the various physical environmental components. This should be followed up with a class presentation of each of their findings. Refer to Strand I, Disease Prevention and Control, and Strand IV, Environmental and Public Health.	Federal, state, and local efforts are being made to assure quality control of air, land, and water. Many of these efforts are of a legislative nature to provide for regulation of the use of these natural components. Funds are also being made available for the construction of facilities and for the development of techniques to handle these products that result after they have been used. For example, building codes have been devised and regulations made for the proper treatment and disposal of waste products. Laws now exist to prevent the contamination or pollution of air and water. Construction of sanitary landfills has both the effect of eliminating vermin infested "dumps" and of providing land for other purposes such as parks, golf courses, and industrial sites. Conservation measures have assisted in

Man also lives in a biological environment surrounded by numerous plants and animals which may be either beneficial or harmful to his health.	Have the students relate and describe how the biological environment influences their health status. Be sure to discuss beneficial as well as harmful effects.	Selected examples of the effects of the biological environment on health are: 1. We are dependent upon plants and animals for the necessary quantity and quality of food growth, development, and health. In addition, man is also dependent upon his fellow man to fulfill his basic and psychosocial needs for existence. 2. Microbes may be either beneficial or harmful to man's health. . Intestinal bacteria play a role in the digestion of food and the manufacture of vitamins. . The intestine in breast-fed infants contains a certain species of bacteria (lactobacillus bifidus). This plays a role in the greater resistance to enteritis (inflammation of the intestine) of the breast-fed infant during the early period of life. . Pathogenic (disease-producing) bacteria may attack man and produce disease.

		. Poisonous plants and animals may produce illness or disease, (i.e., poison ivy, snakes, yellow jackets, poisonous mushrooms, rabies, etc.). . Microorganisms may contribute to soil enrichment by converting plant debris into humus.
Animal health influences human health directly by causing disease or indirectly by reducing the available food supply. Animals are the natural hosts for most of the zoonotic agents and man is only an incidental host; usually he becomes accidentally involved in the cycle.	Have students review the literature and report on some of the common zoonotic diseases.	Zoonotic diseases attack both animals and man. Examples of some of the zoonotic diseases are: encephalitis, rabies, tularemia, trichinosis, anthrax, leptospirosis, brucellosis, etc. A zoonotic system usually comprises a disease agent, an animal reservoir, sometimes an insect vector, and a human host. All of these are interconnected with man by climate, temperature, terrain, occupation, health, behavior, etc.
Occasionally, as in encephalitis, man becomes implicated when the mosquito transmits the virus to him.		Selected examples of zoonotic diseases include: 1. Encephalitis is an arthropodborne disease which is caused by a virus carried

Such contact generally occurs from swimming in farm ponds that have been frequented by cattle.	Invite a veterinarian to speak to the class on animal health and diseases. The discussion should include diseases common to animal and man and their protection. This discussion may be followed by a speaker from the County Health Department discussing the same basic ideas from the department's viewpoint.	

MAJOR UNDERSTANDINGS AND FUNDAMENTAL CONCEPTS	SUGGESTED TEACHING AIDS AND LEARNING ACTIVITIES	SUPPLEMENTARY INFORMATION FOR TEACHERS
	The basic transmission cycle of encephalitis is:	by mosquitoes. The virus is found in infected birds, horses, and wild animals. There appear to be many different viruses that are implicated as well as different species of mosquitoes. Sometimes permanent neurological damage occurs, particularly in infants and children.
		2. Leptospirosis is a widely distributed zoonotic disease which occurs commonly in cattle, swine, dogs, and wild animals. In some areas of the United States, estimates indicate that 20 percent of the cattle are infected. The majority of animals infected, however, do not develop any apparent signs of the disease.
Humans become infected with leptospirosis by contact with urine from the infected animals. Such contact generally occurs from swimming in farm ponds that have been frequented by cattle.	Invite a veterinarian to speak to the class on animal health and diseases. The discussion should include diseases common to animal and man and their protection. This discussion may be followed by a speaker from the County Health Department discussing the same basic ideas from the department's viewpoint.	Leptospirosis in humans is an acute infectious disease characterized by fever, chills, vomiting, muscular aches, and, infrequently, jaundice and kidney damage. The disease is generally more common in the summer months, when children sometimes use farm ponds for swimming purposes. Recently, public health officials in New York State indicated a concern over the appearance of the disease in rural

	Many beneficial effects and essential products are produced by plant life. Exposure to and abuse of some plant life and plant derivatives can have harmful effects on man's health.	Divide the class into two groups. Have one group list all the beneficial effects and uses of plant life. Have the other group list the harmful effects to man's health. Explain why. Refer to Strand II, Drugs and Narcotics. Although narcotic and drug abuse, tobacco (smoking), and alcoholism, are thoroughly covered in Strand II, it would be well to emphasize the ecological relationships involved at this time.	As with animal life, plant life provides both beneficial and harmful effects on man's health. Plant life is a source of most of man's food, and contributes much to his economy in the form of textiles, building materials, and medicines - to mention a few products. On the other hand, there are harmful effects that arise through man's coexistence with and use of plant life. The current major problem in this area is narcotic and drug abuse. Many allergies are also directly related to plant life. Tobacco use is another problem since the establishment of the causal relationship between smoking and cancer. It should also be recognized that many alcoholic beverages are made from various types of plants, e.g., fruits. In this case alcoholism is a potential danger.

The biological environment of man can affect his health status.	Discuss how the biological environment can upset the ecological balance and cause disease.	(Refer to introductory section for review of supplementary information.) The biotic environment also includes such factors as the types and amounts of food produced, food available, food toxin, and the nutrient quality of foods. Examples of biological control are seen in mosquito and rat control programs, multiphasic health screening and immunization programs, and epidemiological research - to name a few.
Historically, famines have provided a fertile breeding ground for many diseases. Most of our great plagues were brought about by drought and famine.	Conduct class discussion and research on the recent Biafra situation in view of its health implications. See Strand IV, World Health. Discuss the relationship between overpopulation. (See section I-A-3 of this strand), food shortage, and disease.	The lack of food not only produced specific deficiency diseases, but also by lessening resistance to disease made one an easy prey to infection. Historical accounts of the plague usually report that epidemics began with drought, crop failure, insect plagues, and famine. Droughts led to crop failure and the grainaries became empty. As a result, rats and other rodents moved closer to man and invaded the cities. If the rodents carried the infective flea, the chances were favorable that the

Poor standards of living and a low economy contribute both directly and indirectly to disease and illness.	Refer to the chart on p. 28. Interrelate this concept with similar concepts discussed in World Health.	The interrelationship among poverty, economics, and disease is quite complex and tends to be self-perpetuating. Each factor appears to contribute to the maintenance of other factors in the vicious cycle. Disease in a population group tends to breed poverty and poverty breeds more disease. A complicating factor is that underdeveloped nations are frequently politically unstable. The improvement of the health status of a country cannot be solved by an attack on health problems alone. Health is a major factor but higher standards of living and increased educational opportunities are also essential in interrupting the maintenance of the cycle.

		that there really is a threat involved. 2. The individual must accept the importance of the threat. He must believe that the problem is a serious one and that it is important enough for him to do something about it. 3. The individual must perceive the threat as being relevant to him. He must believe the problem is threatening to him personally. 4. The individual must feel that there is some effective action that he can take to do something about it.
The health beliefs, values, and habits of a given population are nurtured and molded by a cultural system. Culture also determines an individual's reaction to a health problem.	Discuss how culture affects man's health status. See Strand IV, World Health. Have a panel discussion involving case studies of public health programs in different cultures. Students might describe the culture, the problem that existed, and the public health program aimed at solving the problem, and then analyze the issues involved.	An individual's culture and subculture help to determine his perception of health, illness, disease, and death. In a rural village in Africa it was found that many of the inhabitants were sick with malaria. It was discovered that: Sickness was quite common but malaria was not perceived as a major health problem. The people seldom mentioned health as a problem and listed drinking water and

		irrigation needs as their major concerns. . The people thought that disease was caused by the spirits of the dead or by black magic. They had no concept of the role that microorganisms or mosquitoes played in the transmission of the disease. . Concepts of prevention were not understood by the inhabitants. . Only as a last resort would the villagers utilize the medical services provided by a health center. They felt that going to the health center meant certain death. . People relied mostly upon magic and herbs for treating their illnesses. . Mosquito abatement programs aimed at spraying the local area with DDT were met with little enthusiasm and cooperation. Such programs were perceived by them to be entirely useless. Individuals who cooperated did so not out of fear of the disease but because they feared prosecution by the authorities.

Attitudes toward disease are frequently related to the viewpoint that disease is controlled and caused by supernatural forces, demons, or black magic. Modern medicine is sometimes in direct competition with folklore and superstition. Medical measures that are curative and spectacular are sometimes more readily accepted than preventive measures or programs.	Refer to the Health Behavior model on page 34. Health attitudes and beliefs are considered predisposers to action. They would fall under the heading of both "psychological and social forces."	The reception of a health message is significantly influenced by an individual's attitudes and beliefs. Words such as "infection," "tetanus," "dysentery," "immunization," and concepts of disease agents, environmental sanitation, and disease vectors hold little meaning and signal no emergency in some cultures. The treatment of yaws by antibiotics is rapid and quite dramatic as compared to attempts to control and prevent intestinal infections. People can visually see the results of the antibiotic therapy in treating yaws but find it hard to conceive of contaminated water and food, much less environmental sanitary factors, as being responsible for the presence of intestinal infections.
At any moment behavior depends on sensory input and various kinds of environmental influences which may affect one's health.	Refer to the Health-Behavior Model on page 34.	The states of health and illness result from the interaction of numerous internal and external stimuli. Illness may be triggered or precipitated by an etiological agent, but the presence of that causative agent may not

A. Interaction of forces that may affect your health	A person's health is the result of many components interacting with each other.		
1. Social forces	Social forces are those encountered in relationships with people, for example, peer group pressure.	Have the students list examples of the various stimuli that affect their behavior.	
2. Psychological forces	Psychological forces arise in the mind as thoughts, feelings, recollections, evaluations, expectations, and emotional reactions.	Then pose a hypothetical situation or problem for the students to analyze.	
3. Biological forces	Biological forces arise in other areas of the body such as from organic functions and sensory perception.	Discuss the question: In what ways could knowledge affect one's insight regarding the stimuli that are acting and the subsequent behavior relative to the problem or situation?	
4. Environmental forces	Environmental forces emanate from objects and nonhuman events such as temperature, climate, housing, etc.

be a ugh trial e applica- elsewhere. experience ative	Internal forces: These include those forces within the individual both acquired and inherited. . Biological forces . Psychological forces	Behavior is the reaction, response, or end-product of the synthesis of internal and external forces. It may be positive or negative, constructive or destructive, acceptable or unacceptable.
eriences gination, to actual re tv, radio, films,	External forces: These forces come to affect the individual from without. . Social forces . Environmental forces The above components or forces are combined and interpreted to meet the needs of the individual in his environment with his family, peers, and others.	When confronted with a new situation or problem, an individual's behavior usually reflects a reaction to similar past experiences--both real and vicarious. This system of associations varies from person to person, according to the kinds of experiences he has been exposed to.
The orderly system of problem solving using the "causal approach" involves (1) Observe and analyze - What is the scope of the problem? (2) Plan - Design a systematic "plan of action." (3) Act - Deal with the most critical causes first.	Pose specific problems for the class to solve using the causal approach. Follow this by group or class evaluation. Suggested topics are: alcoholism and drug abuse.	When compared to students in standard classes, children taught the "causal approach" are better able to solve problems. They showed greater perseverance in the face of ambiguity and increased toleration to frustration.
